Abstract

Background: The integration of digital technologies is becoming increasingly essential in cancer care. However, limited digital health literacy among clinical and nonclinical cancer health care professionals poses significant challenges to effective implementation and sustainability over time. To address this, the European Union is prioritizing the development of targeted digital skills training programs for cancer care providers, the TRANSiTION project among them. A crucial initial step in this effort is conducting a comprehensive gap analysis to identify specific training needs.

Objective: The aim of this work is to identify training gaps and prioritize the digital skill development needs in the oncology health care workforce.

Methods: An importance-performance analysis (IPA) was conducted following a survey that assessed the performance and importance of 7 digital skills: information, communication, content creation, safety, eHealth problem-solving, ethics, and patient empowerment.

Results: A total of 67 participants from 11 European countries completed the study: 38 clinical professionals (CP), 16 nonclinical professionals (NCP), and 13 patients or caregivers (PC). CP acknowledged the need for a comprehensive training program that includes all 7 digital skills. Digital patient empowerment and safety skills emerge as the highest priorities for both CP and NCP. Conversely, NCP assigned a lower priority to digital content creation skills, and PC assigned a lower priority to digital information and ethical skills. The IPA also revealed discrepancies in digital communication skills across groups (H=6.50; P=.04).

Conclusions: The study showcased the pressing need for comprehensive digital skill training for cancer health care professionals across diverse backgrounds and health care systems in Europe, tailored to their occupation and care setting. Incorporating PC

perspectives ensures a balanced approach to addressing these training gaps. These findings provide a valuable knowledge base for designing digital skills training programs, promoting a holistic approach that integrates the perspectives of the various stakeholders involved in digital cancer care.

KEYWORDS

health literacy; professional competence; health personnel; telemedicine; oncology nursing

Introduction

Background

Cancer is the second leading cause of premature mortality and morbidity worldwide [1]. In the European Union, nearly 4.7 million new cases of cancer and 2.1 million cancer-related deaths occur each year [2]. According to the European Commission, the urgency to address cancer control and outcomes is a significant political challenge, as reflected in Europe's Beating Cancer Plan [3], with cancer being one of the 5 missions included in the Horizon Europe program.

Health literacy (HL), defined as the individual capacity to access, understand, evaluate, and apply health information to make informed health decisions [4]**,** is widely recognized as a critical factor in effective cancer care [5,6]. With the increasing integration of digital technologies, such as symptom monitoring platforms, treatment adherence tools, telehealth, and mobile apps, in oncology, HL has evolved to encompass the digital environment, giving rise to the concept of digital health literacy (DHL) [7-11]. DHL has been defined in various ways, reflecting the evolving nature of health information environments. Broadly, DHL refers to the ability to seek, find, understand, and appraise health information from electronic sources and to apply this knowledge to solve a health problem [12,13]. However, there is ongoing debate about its key attributes, particularly the relative weight of technical skills, critical thinking, health knowledge, and digital engagement, in shaping a comprehensive definition [14,15]. In response, recent studies have focused on 4 major areas: (1) conceptualizing and measuring DHL; (2) identifying and addressing the digital divide; (3) exploring the factors that influence DHL development; and (4) examining the health outcomes associated with DHL levels [16]. Regarding the latter, DHL enhances access to and quality of health care to the extent of being considered a "super determinant" of health, a factor with a profound impact across various health outcomes [17,18].

In cancer care, DHL is particularly relevant, enabling health care professionals and patients to benefit from digital innovations such as electronic health records, patient portals, symptom tracking tools, and remote care services [19]. Low levels of DHL have been associated with poorer clinical outcomes, including reduced overall survival among patients with cancer [20-22]. Limited DHL not only hinders patients and caregivers (PC) but also poses challenges for health care professionals, potentially impeding the effective adoption of digital health solutions in clinical practice [23]. The Towards European Health Data Space (TEHDAS) project highlights significant disparities in the health system infrastructures across European countries, with not all of them being adequately equipped to ensure effective management of digital health [24]. Still, the main barriers to implementing digital health strategies in health care organizations are not technical issues (such as infrastructure or connectivity). Instead, they are rooted in gaps in digital skills among professionals and patients, concerns about data security and confidentiality in digital environments, and limited time availability [25-28].

As a result of these challenges, experts in the field emphasize the need to develop flexible and easily accessible training programs, such as online modules and hands-on learning approaches, supported by appropriate incentives to engage and retain the oncology workforce [29]. Nevertheless, the results of DigiCanTRain, a European-cofunded project under the EU4Health Programme (2021-2027) of approximately €1.98 million (US $2.32 million), highlight significant challenges in the implementation of digital skills training programs for cancer professionals across 25 EU countries. These challenges include a lack of coordination between national and international organizations in promoting training initiatives, as well as limited access to continuous accreditation mechanisms that ensure the quality and consistency of educational content [30]. In response to these gaps, DigiCanTRain aims to design, pilot, and evaluate a comprehensive digital skills training curriculum for both clinical and nonclinical oncology professionals, with the goal of enhancing the adoption of eHealth technologies and fostering more person-centered, efficient, and resilient cancer care.

Despite these initiatives, international continuing education programs fail to identify the specific digital skills required by health care professionals [31]. Even if DigComp 2.2: The Digital Competence Framework for Citizens provides a reference framework for the global population on existing digital competencies [32], it does not include specific competencies oriented to health care professionals in cancer care, such as ethical or patient empowerment skills [33,34]. Moreover, there are no validated and widely used measurement tools available to assess eHealth competencies [35,36]. Therefore, the review by Tinmaz et al [37] highlighted the need to create updated digital frameworks for different work settings, professional categories, and contexts. In the context of cancer care, the study by Leena et al [34] revealed that the digital skills of health care professionals are multifaceted. Consequently, the authors indicated that it is imperative that these skills be subjected to a process of assessment to facilitate the provision of training that is based on the actual learning needs of the professionals in question.

In view of this, the TRANSiTION project [38] was cofunded at 80% by the European Union with a total budget of €2,299,541.28 (US $2,690,371). The project aims to design an advanced training program for both clinical professionals (CP)

and nonclinical professionals (NCP) involved in cancer care, equipping them with essential digital skills to enhance the efficiency and effectiveness of information exchange with patients and other health care providers. TRANSiTION brings together an interdisciplinary consortium of 24 partners from 14 member states, all with extensive experience in the development, evaluation, and successful implementation of continuing professional development and training programs in oncology.

Theoretical Framework

According to the European Commission, the development of a digital skills training program should be preceded by a thorough analysis of training needs and existing gaps [39]. A needs analysis is a systematic process used to identify discrepancies between the current and ideal states of an organization or service [40].

One widely adopted and intuitive method for conducting such an analysis is importance-performance analysis (IPA). Originally developed by Martilla and James [41], IPA provides a visual and analytical framework to support strategic decision-making by comparing the importance of specific attributes to their perceived performance. It has been extensively applied across diverse sectors, including IT services, marketing, banking, tourism, and sports [42]. More recently, IPA has been used in the assessment of training needs [43,44], process improvement [45], and evaluation of health care services [46].

IPA is based on a 2D grid that plots attributes according to their mean scores on 2 axes: (1) importance, which is the value or relevance assigned to the attribute by users, and (2) performance, which is the perceived effectiveness or quality of that attribute.

The axes of the IPA grid are determined by the overall mean scores of importance and performance across all attributes assessed. The position of each attribute within the grid reflects its scores on these 2 dimensions. This allows for a relative comparison, enabling the identification of attributes that deviate from the general trend.

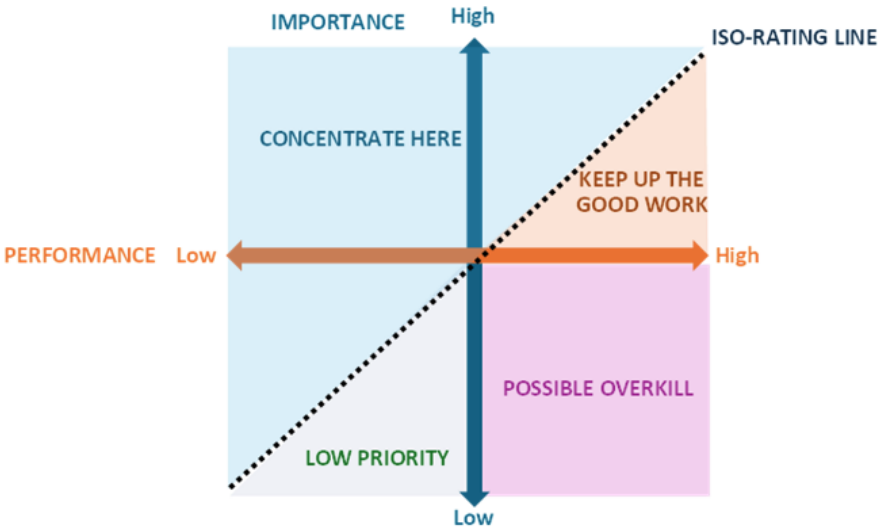
The resulting matrix is divided into 4 quadrants, each linked to distinct action strategies [47]: Quadrant I—Focus here: high importance, low performance; these are critical areas in need of immediate improvement. Quadrant II—Keep up the good work: high importance, high performance; these are strengths to be preserved. Quadrant III—Low priority: low importance, low performance; these areas require minimal attention as they are not strategically significant. Quadrant IV—Possible overkill: low importance, high performance; these attributes may be receiving more resources than necessary.

To enhance the discriminative power of the analysis, this study used a modified version of the IPA proposed by Abalo et al [48]. This adaptation addresses the common issue of attribute saturation, whereby attributes tend to receive uniformly high ratings, limiting the ability to differentiate among them. The modified approach uses ordinal rankings instead of mean scores, improving the identification of priority areas, particularly relevant in health care settings [49] and training needs assessments [50].

Based on this approach, an IPA chart was generated using discrepancy scores from 3 key stakeholder groups: CP, NCP, and PC. CP were defined as members of health care organizations providing direct cancer care (eg, oncologists, radiotherapists, oncology nurses, family physicians, and community nurses). NCP included individuals performing administrative or managerial tasks related to cancer care, regardless of professional category. Caregivers were defined as those who provide physical, emotional, practical, and, in some cases, medical support to individuals diagnosed with cancer. These may be family members, close friends, or other persons designated by the patient who play a critical role across all stages of treatment and recovery. A patient with cancer was defined as any individual at any stage of the disease, including those undergoing active treatment, in remission (with favorable progression and no ongoing treatment), considered cured but undergoing regular follow-up, cured without active medical surveillance, or experiencing a relapse.

The position of each attribute was analyzed in relation to the diagonal and the corresponding quadrants of the IPA grid (see Figure 1).

Figure 1. Representation of the alternative version of the importance-performance analysis (IPA) grid.



The current literature highlights a significant gap in digital skills among health care professionals [51]. Furthermore, although it is widely recognized that digital skills in health care are inherently multifaceted, a standardized framework to delineate and prioritize the most essential skills remains absent. Furthermore, we expected not only training gaps but also differences between the health professionals included in the study.

Consequently, the aim of this study was to identify training gaps and prioritize the digital skill development needs in the oncology health care workforce through the application of IPA.

Methods

Study Design

A selective methodology was used. It involved conducting an online survey among a group of experts selected within the consortium of the European project. Given the exploratory nature of the study and the specific expertise required from participants, a convenience sampling approach was used to facilitate recruitment across diverse stakeholder groups and countries. This strategy was deemed appropriate due to the practical constraints of accessing individuals with relevant professional or lived experience in cancer care across several member states, all within a limited time frame.

The inclusion criteria required participants to be CP, NCP, or PC from member states of the TRANSiTION consortium, with the ability to comprehend and respond in English. Moreover, participants were required to have the capacity to provide informed consent. Recruitment was supported by consortium partners who identified and invited suitable individuals based on their direct involvement in cancer care or their experience as patients or caregivers. This pragmatic sampling approach enabled the collection of meaningful insights while ensuring feasibility in a multinational context.

Instrument

An ad hoc online questionnaire, available exclusively in English, was developed by the research team. Although several validated instruments exist in the fields of DHL and eHealth for the general population [12,15], they did not adequately address the specific objectives or context of our study. The TRANSiTION project aimed to design a training course tailored to professionals involved in cancer care. Therefore, beyond assessing general skills, it was crucial to identify the specific learning needs, expectations, and contextual factors affecting this particular group. Given these requirements, the development of a customized instrument was deemed necessary to ensure the relevance, specificity, and practical utility of the collected data for informing the design of the training intervention.

The structure and items of the questionnaire were based on *DigComp 2.2: The Digital Competence Framework for Citizens* [32] and *Measuring What Matters: The Patient-Reported Indicator Surveys* [52]. For the development of the items, the contents of the *Core Curriculum in eHealth* from the EU×US initiatives were reviewed [53], as well as the document *Mapping Health Data Management Systems through Country Visits: Development, Needs, and Expectations of the EHDS* by TEHDAS [24].

The final selection of questionnaire items was reached by consensus in an online focus group conducted in May 2023. During this session, it was decided to include 2 additional and independent sections (ie, patient empowerment and ethics) informed by the prior work and practical experience of project partners who had previously identified core digital health skills as applied in professional practice [54].

The questionnaire was organized into 3 thematic sections. The first section included the information sheet and the consent form for participants. The second section addressed sociodemographic variables. The third section focused on assessing the need for training of 7 key digital skills: information, communication, content creation, safety, problem-solving, ethics, and patient empowerment. Moreover, 7-point Likert scale items were used to evaluate performance (with 1 representing “Very bad” and 7 representing “Very good”) and importance (with 1 representing “Not important” and 7 representing “Highly important”). The questionnaire items for CP and NCP were identical. Additionally, to make the results more representative, the third section asked about the performance of their colleagues within their organization from the respondent’s perspective, aiming to shift the focus away from self-assessment of personal skills. Similarly, the items on the importance of digital skills referred to how crucial these skills are for cancer care. In contrast, patients were asked about their perception of the digital skills shown by the cancer professionals attending to them and about the importance of these skills for their cancer care—or, in the case of caregivers, for the care of the patient. The information letters and questionnaires can be found in Multimedia Appendix 1.

Procedure

The questionnaire was administered as a closed, invitation-only survey, accessible exclusively to individuals invited by TRANSiTION consortium partners. It was fully compatible with mobile phones, tablets, and computers across all major operating systems. To prevent multiple entries from the same individual, participants were authenticated through their email address prior to receiving single-use access to the survey platform.

Recruitment was facilitated by the TRANSiTION consortium, which disseminated information about the study to eligible participants. The consortium consisted of 24 European reference partners in the field of cancer care, including research institutes, universities, hospitals, oncology centers, and patient organizations [38].

The survey was piloted by 8 members of the Spanish partners of the TRANSiTION consortium during June 2023 and July 2023. Based on the pilot, minor adjustments were made to improve the wording of certain items. On average, it was estimated that participants required approximately 15 minutes to complete the online questionnaire. Additionally, it was suggested to include the item “Have you received prior training in digital competencies/skills?” with a dichotomous response option of “Yes” or “No.”

Participants were recruited during July 2023 and August 2023. Data were collected and stored using an online questionnaire implemented through the eDelphi website [55] in September 2023. To ensure procedural standardization, daily monitoring of the data collection process was conducted, allowing for the immediate resolution of any questions or technical issues that arose.

Data Analysis

Data analysis included descriptive statistics, reported as mean and SD. Internal consistency of the items assessing digital skill domains was evaluated using Cronbach α. Normality was assessed using the Shapiro-Wilk test. In cases where the assumption of normality was not met, nonparametric tests were applied. Specifically, group comparisons of importance and performance scores across CP, NCP, and PC were conducted using 1-way ANOVA or, when appropriate, the Kruskal-Wallis test. All analyses were performed using SPSS version 25.0 (IBM Corp).

Ethical Considerations

The study was reviewed and approved by the Pontevedra-Vigo-Ourense Research Ethics Committee (reference: 2023/309).

Before the survey, they were informed about the study's objectives, reminded of the voluntary nature of their participation, and asked to provide informed consent.

The online questionnaire platform provides a confidential, single-use access system to the questionnaire for each participant, ensuring the confidentiality and anonymity of responses. No financial compensation was provided to the participants.

Results

Demographics

Initially, 152 participants expressed interest in taking part in the study. Of these, 33 were excluded for not meeting the inclusion criteria. Specifically, 24 participants who had registered as CP or NCP were in fact students without professional experience, and 9 PC were excluded due to insufficient English proficiency. Additionally, 28 participants (12 CP, 10 NCP, 3 patients, and 3 caregivers) accepted the informed consent but did not begin the questionnaire. A further 24 participants (8 CP, 10 NCP, 3 patients, and 3 caregivers) declined to provide informed consent.

A total of 67 participants completed the study: 38 CP, 16 NCP, and 13 PC. All participants who completed the survey responded to all questionnaire items. Of the total, 50 participants were women (50/67, 75%), participants were primarily aged between 31 years and 45 years (27/67, 40%), and most resided in municipalities with populations greater than 100,000 (44/67, 66%). Table 1 presents the main sociodemographic characteristics of the sample, stratified by group.

Table 1. Sociodemographic data of the participants, by group.

Characteristic	CP[a] (n=38)	NCP[b] (n=16)	PC[c] (n=13)
Gender (female), n (%)	29 (76)	12 (75)	9 (69)
Age (years), n (%)			
18-30	10 (26)	5 (31)	0 (0)
31-45	14 (37)	7 (44)	6 (46)
46-60	11 (29)	3 (19)	5 (39)
≥61	3 (8)	1 (6)	2 (15)
Population of the resident municipality, n (%)			
<50,000	7 (18)	2 (13)	5 (39)
50,000-100,000	6 (16)	1 (6)	2 (15)
>100,000	25 (66)	13 (81)	6 (46)

[a]CP: clinical professionals.

[b]NCP: nonclinical professionals.

[c]PC: patients and caregivers.

The participants were from 11 European countries: Belgium (3 CP, 5 NCP, and 2 PC), Bulgaria (10 CP and 2 NCP), Croatia (4 CP, 1 NCP, and 3 PC), Cyprus (6 CP), Greece (1 CP, 1 NCP, and 1 PC), Italy (1 CP, 1 NCP, and 2 PC), Lithuania (1 CP and 1 NCP), Poland (1 PC), Portugal (3 CP, 1 NCP, and 2 PC), Slovenia (1 CP, 1 NCP, and 1 PC), and Spain (8 CP, 3 NCP, and 1 PC).

The professions of the health care professionals were diverse. Among CP (n=38), 16 (42%) were oncologists, 12 (32%) were oncology nurses, 6 (16%) were clinical researchers, and 4 (11%) worked in other clinical professions related to cancer care. Additionally, 19 (50%) worked in public organizations, 12 (32%) worked in subsidized private organizations, 4 (11%) worked in nonsubsidized private organizations, and 3 (8%) preferred not to specify. Among NCP (n=16), 5 (31%) were clinical data managers, 4 (25%) were part of the administrative staff related to cancer care, 3 (19%) worked in health care service management, and 4 (25%) were in other nonclinical professions related to cancer care. Furthermore, 8 (50%) worked in public organizations, 7 (44%) worked in subsidized private

organizations, and 1 (6%) preferred not to specify. All PC (n=13) were users of public health care services.

Internal Consistency

As shown in Table 2, the internal consistency of the digital skills questionnaire was high across all domains (items B1 through B7 in Multimedia Appendix 1) and participant groups. At the global level, Cronbach α values ranged from 0.92 (information) to 0.97 (ethics), indicating excellent reliability. When analyzed by subgroup, responses from CP and PC consistently showed very high internal consistency, with α values greater than 0.85 in all domains. Responses from NCP also showed acceptable to excellent consistency, though slightly lower in the domains of eHealth problem-solving (α=0.86) and ethics (α=0.90). These results support the internal reliability of the instrument across different respondent profiles.

Table 2. Internal consistency of the digital skill domains.

Digital skills	Global, Cronbach α	Clinical professionals, Cronbach α	Nonclinical professionals, Cronbach α	Patients and caregivers, Cronbach α
Information	0.92	0.95	0.91	0.85
Communication	0.93	0.95	0.89	0.90
Content creation	0.95	0.95	0.92	0.95
Safety	0.96	0.96	0.95	0.97
eHealth problem-solving	0.94	0.97	0.86	0.92
Ethics	0.97	0.97	0.90	0.97
Patient empowerment	0.96	0.96	0.90	0.98

Performance and Importance Scores

This section presents the results from the third part of the questionnaire, which focused on 7 core digital competencies relevant to cancer care professionals. Additional findings related to perceived training needs are available in Multimedia Appendix 2. The 7 competencies assessed were information, communication, content creation, safety, eHealth problem-solving, ethics, and patient empowerment.

Information is defined as the ability to search, evaluate, and manage digital health information effectively. Communication refers to the capacity to interact, share, and collaborate using digital tools in health care contexts. Content creation is understood as the skill to produce, edit, and adapt digital content appropriately for clinical use. Safety encompasses data protection, privacy, and cybersecurity practices. Problem-solving is the ability to identify and resolve technical or digital challenges in the care process. Ethics is related to the understanding and application of ethical principles such as confidentiality, consent, and digital equity. Patient empowerment is defined as the ability to support patients with using digital tools to actively participate in their care.

Table 3 shows the importance and performance results for CP, NCP, and PC. As can be seen, all performance and importance scores reached notably high values, reflecting that oncology health care professionals perceive themselves as having strong digital skills, and, at the same time, that digital literacy is considered important in cancer care. Moreover, 22 of 38 CP (58%) reported having received prior training in digital skills, a figure that reached 11 of 16 NCP (69%).

Table 3. Importance and performance for clinical professionals (CP; n=38), nonclinical professionals (NCP; n=16), and patients and caregivers (PC; n=13).

Digital skills by group	Performance, mean (SD)[a]	Importance, mean (SD)[b]
Information		
CP	6.18 (0.98)	6.34 (1.34)
NCP	5.88 (0.96)	5.94 (1.23)
PC	5.85 (2.07)	5.23 (1.59)
Communication		
CP	6.03 (0.97)	6.45 (1.29)
NCP	5.94 (0.85)	5.69 (1.08)
PC	5.23 (1.78)	5.31 (1.32)
Content creation		
CP	5.37 (1.58)	5.79 (1.36)
NCP	5.56 (1.03)	5.44 (1.03)
PC	4.15 (2.03)	4.15 (2.03)
Safety		
CP	5.21 (1.49)	6.08 (1.56)
NCP	5.25 (1.06)	5.81 (1.05)
PC	4.69 (1.84)	4.62 (2.10)
eHealth problem-solving		
CP	5.53 (1.31)	6.18 (1.37)
NCP	5.56 (1.09)	5.81 (1.17)
PC	4.38 (1.80)	4.38 (1.55)
Ethics		
CP	5.61 (1.28)	6.03 (1.50)
NCP	5.50 (1.15)	5.75 (1.06)
PC	4.92 (2.10)	4.38 (1.85)
Patient empowerment		
CP	5.50 (1.45)	6.32 (1.36)
NCP	5.56 (1.09)	6.00 (1.15)
PC	5.08 (2.11)	5.23 (1.36)

[a]Overall mean (SD): 5.38 (1.47).

[b]Overall mean (SD): 5.57 (1.40).

The digital skills that showed the highest performance among CP were information (mean 6.18, SD 0.98) and communication (mean 6.03, SD 0.97). Similarly, these same digital skills, but in reverse order, were considered the most important for cancer care (mean 6.45, SD 1.29; mean 6.34, SD 1.34, respectively). Additionally, patient empowerment digital skills achieved a similar level of importance (mean 6.32, SD 1.36). In contrast, the digital skill with the lowest performance and importance scores was content creation (mean 5.37, SD 1.58).

Digital communication (mean 5.94, SD 0.85) and information (mean 5.88, SD 0.96) skills exhibited the highest performance scores among NCP. In contrast, the skills considered most important for cancer care were those related to patient empowerment (mean 6.00, SD 1.15). In comparison, the digital skills of content creation and eHealth problem-solving demonstrated the lowest performance scores (mean 5.56, SD 1.03; mean 5.56, SD 1.09, respectively), with the former also showing the lowest importance score (mean 5.44, SD 1.03).

For PC, the digital skills in which they thought oncology health care professionals perform best were communication (mean 5.23) and information (mean 5.85). The digital skills considered most important were communication (mean 5.31, SD 1.32) and patient empowerment (mean 5.23, SD 1.36). In contrast, the lowest performance and importance scores were observed for the digital skills related to content creation (both: mean 4.15, SD 2.03).

Discrepancy Analysis

Table 4 presents the results of the discrepancy analysis, defined as the mean difference between performance and importance for each of the digital skills. As shown, for CP, information digital skills exhibited the most positive discrepancy (mean difference 0.62). Conversely, safety (mean difference –0.87) and patient empowerment (mean difference –0.82) digital skills showed the most negative results. Regarding NCP, communication digital skills displayed the most positive discrepancy (mean difference 0.25), while safety digital skills had the most negative discrepancy (mean difference –0.56). For PC, the highest positive discrepancy was observed for information digital skills (mean difference 0.62), whereas the most negative discrepancy pertained to patient empowerment digital skills (mean difference –0.15).

Table 4. Discrepancy for clinical professionals (CP; n=38), nonclinical professionals (NCP; n=16), and patients and caregivers (PC; n=13).

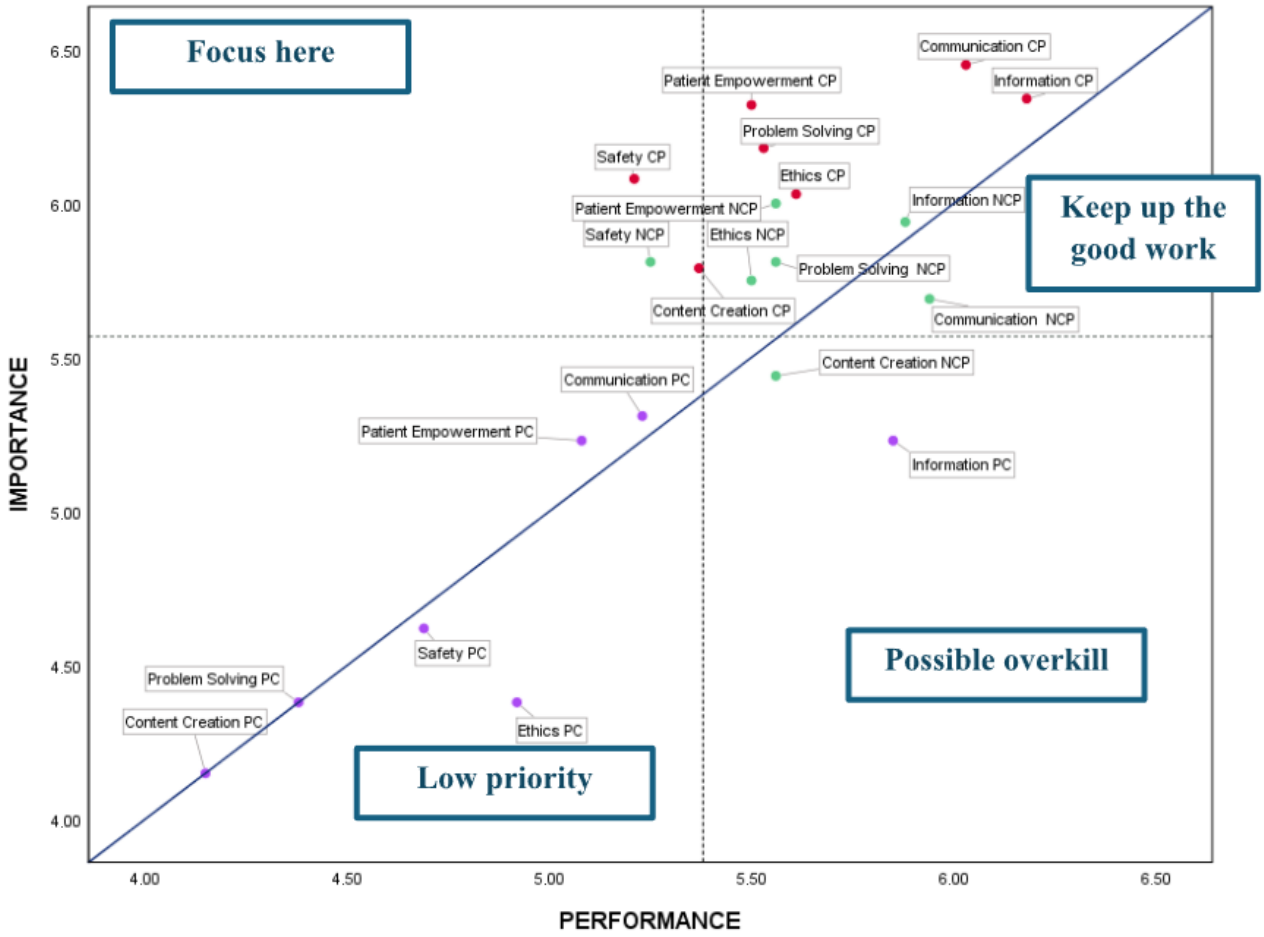
Digital skills, by group	Discrepancy, mean difference	*F* (*df*)	*H*
Information		1.13 (2)	3.58
CP	–0.16		
NCP	–0.06		
PC	0.62		
Communication		1.25 (2)	6.50*
CP	–0.42		
NCP	0.25		
PC	–0.08		
Content creation		0.65 (2)	1.26
CP	–0.42		
NCP	0.12		
PC	0		
Safety		1.10 (2)	2.89
CP	–0.87		
NCP	–0.56		
PC	0.07		
eHealth problem-solving		0.85 (2)	1.86
CP	–0.65		
NCP	–0.25		
PC	0		
Ethics		1.24 (2)	2.19
CP	–0.42		
NCP	–0.25		
PC	0.54		
Patient empowerment		0.70 (2)	2.76
CP	–0.82		
NCP	–0.44		
PC	–0.15		

Notably, despite the small sample size, statistically significant differences were identified in the discrepancies associated with communication digital skills. Specifically, the discrepancy was positive for CP, negative for NCP, and nearly neutral for PC (–0.42 vs 0.25 vs –0.08; H= 6.50, P=.04.

IPA Chart and Key Findings

As a result of these discrepancies, the IPA chart was developed (Figure 2). The axes of the graph were formed using the mean scores of performance (mean 5.38) and importance (mean 5.57), as shown in Table 2. Results were segmented for CP (in red), NCP (in green), and PC (in purple). This segmentation allowed for the identification of high-priority training needs, as well as areas where training is of low priority or may even represent a misallocation of resources. Two key findings emerged from the overall analysis.

Figure 2. Importance-performance analysis (IPA) graph comparing clinical professionals (CP), nonclinical professionals (NCP), and patients and caregivers (PC).



First, both CP and NCP perceived a greater need for training compared with the skills PC attributed to them. This is evident, as most elements related to health care professionals are positioned above the diagonal, with some at a significant distance. In contrast, digital skills for PC are located on or near the diagonal, with a few even below it.

Second, all digital skills for CP fell within the "Focus here" quadrant, indicating that, although their prioritization may vary, all these skills require targeted training for this group. When evaluating each element individually, the IPA chart confirmed that patient empowerment and, particularly, security skills are the furthest from the diagonal and within the "Focus here" quadrant for both CP and NCP. Consequently, these represent the most critical digital skills requiring training.

For NCP, security and patient empowerment skills were similarly the top training priorities. Notably, communication skills met the expected importance levels (located in the "Keep up the good work" quadrant), whereas content creation skills were deemed redundant (falling into the "Possible overkill" quadrant).

In the case of PC, ethical skills fell into the "Low priority" quadrant, while information skills are in the "Possible overkill" quadrant. The remaining digital skills clustered near the diagonal, indicating a moderate level of alignment between their perceived importance and performance.

Discussion

Principal Findings

This study identified key training gaps and digital skill development priorities within the oncology health care workforce by applying IPA to a diverse panel of experts. The panel included 3 stakeholder profiles: CP, such as physicians and nurses; NCP, including managers, educators, and researchers; and PC.

A major finding was the assessment of 7 digital skills (information, communication, content creation, safety, eHealth problem-solving, ethical, and patient empowerment) and the specific training needs associated with each stakeholder group.

Notably, the prioritization of these competences differed across groups. For CP, the analysis revealed that all digital skills require further training, with safety and patient empowerment emerging as the highest priorities. NCP showed a comparable pattern, although they assigned less importance to content creation. None of the competencies was considered a low priority in this group.

In contrast, PC viewed information digital skills as having high performance but relatively low importance. The remaining competencies were positioned in the low performance–low importance quadrant, though communication and patient

empowerment were perceived as the most important among them.

These findings underscore the need for tailored digital training strategies that reflect the differing perceptions and priorities of each stakeholder group.

Comparison With Other Studies

Several previous studies have highlighted the widespread lack of digital literacy among health care professionals [56], which has led to the development of initiatives aimed at addressing this issue, particularly in the oncology field [38,57]. As Foadi and Varghese [58] suggested, although CP demonstrate a high level of proficiency with using specialized software for their daily tasks, they do not receive sufficient training on the basic principles of digital systems, which are essential for thriving in an ever-evolving digital health care environment [59]. In fact, Ramachandran et al [60] emphasized that, although health care professionals should demonstrate a general orientation toward digital skills, opportunities are created for specialized digital skills, particularly for the safe and equitable use of new technologies. Regarding cancer care, the study by Barbosa et al [61] identified digital safety skills as one of the 6 key domains for therapeutic radiographers and radiation therapists. Concerning patient empowerment, Navarro Martínez et al [62] emphasized a worrisome trend: Nurses, especially younger ones, exhibit limited or negligible use of technology to empower patients.

Incorporating the experience of health care service users is a central principle for the transition to digital health care with a patient-centered approach [63], making it essential to understand what PC expect regarding the digital skills of their oncology professionals. eHealth policies should be designed to consider the diverse perspectives of health professionals, patients, and caregivers. Furthermore, it is essential to bridge the digital divide for patients with cancer who have low digital literacy, enabling them to effectively use digital platforms designed by professionals [64]. In this regard, it is noteworthy that this study highlights that NCP perceived training in digital content creation skills as a potential misallocation of resources. Therefore, although these digital skills are important for enhancing cancer care, they should not be prioritized in training programs for this professional profile. The results suggest that enhancing digital information skills training within the oncology workforce may not be a pressing priority, as indicated by feedback from PC. However, this does not imply that patients with cancer are uninterested in receiving information on all aspects of the disease [65] nor that they are unwilling to embrace the potential of telecommunications to access relevant information [66]. In fact, the most necessary digital health function among patients with cancer and caregivers is information and education on symptom management following cancer treatment [67], and the use of digital health technology can be experienced as a person guiding them during their cancer treatment [68]. However, as previous studies noted, the interest of patients with chronic diseases in receiving health information through digital modalities is often hindered by educational and age-related gaps. In many cases, this must be preceded by social and instrumental support from health promoters [69].

This study has also yielded a significant finding when comparing results across different groups: CP, NCP, and PC. Digital communication skills were rated as highly important by all 3 groups. This is consistent with the fact that social support through digital tools provides significant benefits for both patients and caregivers during cancer treatment [70]. However, when analyzing discrepancies between CP, NCP, and PC, we found that the discrepancies between performance and importance were statistically significant. The results indicate that digital communication skills training is a priority for CP, somewhat unnecessary for NCP, and considered almost neutral by PC. First, NCP have limited direct interactions with patients, as their primary responsibilities center on the management and administration of services, which may account for the observed differences between CP and NCP. Accordingly, communication skills training for cancer care professionals who interact directly with patients has become a critical focus, using structured checklists to systematically assess oncologists' behaviors during specialized doctor-patient consultations [71]. Second, the review by Henry et al [72] emphasized that digital communication skills are essential for CP to perform telehealth tasks, which may explain the priorities for training in this group. Third, although patients with cancer consider online platforms a preferred option for cancer follow-up consultations and delivering good news, they are not seen as suitable for initial visits or discussing bad news [73]. Therefore, PC may demonstrate a less favorable stance toward digital communication skills than CP. For instance, when oncology nurses and surgeons do not mention electronic patient-reported outcome measures, patients also refrain from discussing them [74].

Finally, it is worth mentioning that, in comparison, both CP and NCP are more critical of their digital skills training needs than PC. Overall, health care professionals recognize that they are not achieving a level of performance that aligns with the importance of these skills for cancer care. This finding, in which service providers perceive a worse outcome than users, has been observed in other studies using IPA [47]. This apparent "halo effect," where PC may rate professionals' digital skills more positively than professionals rate themselves, could reflect a high level of trust in health care providers. This is particularly relevant in the context of implementing new technologies and addressing the urgent need for digital skills training, as it suggests that end users may be more receptive to digital innovation than expected, potentially easing the path for adoption and integration of new tools in cancer care.

Strengths and Limitations

This study has several strengths. It sought input from a sample of experts purposely selected by the TRANSiTION project consortium [38]. The partners belong to 14 countries from different geographic regions, with different types of organizations and occupational profiles. The partners have the personal email addresses of their members. Therefore, this ensured variability in the professional profiles of the participants, as well as different geogeographical backgrounds; additionally, patient involvement in the long-term improvement of HL is an essential requirement [25], making the inclusion of their perspective in this gap analysis a notable strength. Furthermore,

although the use of the IPA method is well-documented in the literature, to the best of our knowledge, it has not been applied to evaluate training needs in digital skills for health care professionals, specifically in cancer care. Therefore, this study represents an innovative approach that could serve as a methodological foundation for future research. In addition, the survey probes aspects of cancer care that are not included in more general questionnaires. Moreover, the internal reliability of the instrument across different respondent profiles supports the incorporation of these skills in training design or scale development.

This study also has several limitations. First, the questionnaire did not rely on previously validated scales to assess digital skills. However, there is currently no gold standard for measuring digital skills among health care professionals, and the instrument was developed based on established digital competence frameworks to ensure alignment with the study's specific objectives. Moreover, the aim of the project was not to validate a scale but to collect meaningful data to inform the design of a massive open online course (MOOC) [38]. Although participants from several EU countries were included, the use of a nonprobabilistic, purposive sampling strategy through consortium partners limits the representativeness of the sample and the generalizability of the findings beyond the context of the TRANSiTION network. Additionally, as the survey was available only in English, 9 potential participants were excluded due to insufficient language proficiency, which may have introduced selection bias. The administration of the survey during the summer months also contributed to a relatively low response rate within a limited population. Moreover, the use of self-reported data introduces the possibility of response bias; although prior research supports the validity of self-report measures [75], the results should be interpreted with appropriate caution. Finally, although IPA is a widely used tool to guide priority setting in training and service improvement [43,44,46,76], it has certain methodological limitations [77]. The technique relies heavily on mean values to allocate items to quadrants, which may not fully capture the distributional characteristics of the data. In addition, the cut-off points, typically overall means, are somewhat arbitrary, which can affect the robustness and interpretability of the results. This study did not include a sensitivity analysis to explore the impact of alternative quadrant definitions, which could have helped mitigate this limitation. This decision was primarily influenced by the exploratory nature of the research and the limited sample size. Future research should address these aspects to improve the reliability of IPA-based prioritization.

Impact on Organizations and Health

There is a growing body of literature that demonstrates the pivotal role of HL for achieving better health outcomes and higher quality of care [78]. Crucially, HL is modifiable, and improving HL is increasingly recognized as a way of improving outcomes, including in Europe's Beating Cancer Plan. Therefore, the concept has rapidly gained an emerging strategic role in several governing bodies and cancer organizations, although more comprehensive implementation of interventions and strategies is still needed.

The information that cancer patients need to know for their diagnosis and treatment is indeed complicated. It includes a new language of health terminology, understanding consents for complex treatments and procedures, attending appointments at the right time and place, and seeking help appropriately and in a timely manner. Equally, citizens should have the necessary skills to interpret information and make appropriate decisions for cancer screening (eg, high-risk group of citizens) and prevention (eg, lifestyle behaviors). Competencies in HL and communication can significantly contribute to reducing barriers related to HL and to improving the quality of health care and health outcomes for patients [78]. However, studies have shown that health professionals tend to overestimate the HL of patients and citizens and lack adequate competence to compensate for it. Therefore, preparing staff to respond to patients' HL is seen as a responsibility of health care organizations, which should be incorporated into their training programs.

Cancer care systems need to adapt to technological advancements by providing online health materials that are evidence-based, quality-controlled, reliable, and both culturally and linguistically appropriate. Therefore, the incorporation and management of digital technologies that facilitate interactions between health care professionals and patients seem essential in current and future training programs. It should be noted that the digital skills of CP involved in cancer care are multifaceted, and all of them are essential for providing high-quality cancer care [34]. Therefore, the findings of this study support the need to implement comprehensive training programs for CP that address the main digital skills cited in the literature [37].

It is worth mentioning that, although patient empowerment is a vague concept, it has been increasingly applied in cancer care over the past decade [33]. The accumulated evidence suggests that shared decision-making and the use of interactive digital tools lead to positive outcomes for cancer patients [79,80].

In addition, the future European Health Data Space, which aims to provide a coherent, reliable, and efficient system for the exchange and reuse of health data in research, innovation, policy-making, and regulation, will require a greater mastery of digital security skills for both CP and NCP [81].

The importance given by the European Union to digital skills training has already been outlined. Based on expert input, our consortium believes it is essential that countries incorporate DHL training at the earliest stages of education for health professionals and health managers and develop programs focusing on digital skills in oncology [29]—not only in the university setting but also in continuing education—including hands-on training through internships, clinical rotations, and simulation exercises and promoting interdisciplinary collaboration.

The extension and adaptation of competencies to the health environment represent an example to follow. The involvement so far of 60 countries worldwide and 1300 participants will facilitate this impact, supported by multiple meetings with European stakeholders [38] and diffusion through scientific societies and partners' universities and national health services.

Finally, it points to research gaps for new scientific projects in the fields of social sciences and citizen science.

Conclusions

This study conducted a gap analysis using the IPA to assess the digital skills of health care professionals in oncology and identified areas where further training is needed. The results highlight the necessity of developing comprehensive training programs for CP. Additionally, it underscores the critical importance of digital safety and patient empowerment skills for both PC and NCP. The study incorporates the perspectives of PC, who prioritize different training needs for health care professionals, placing comparatively less emphasis on digital information and ethical skills. These findings provide a knowledge base for designing training programs and eHealth policies, promoting a holistic approach that integrates the perspectives of the various stakeholders involved in digital cancer care.

Policy Summary

Health care professionals acknowledge that their digital skills require enhancement across all areas. Specifically, doctors and nurses need additional training in digital problem-solving, communication, and, above all, skills linked to patient safety and empowerment. These priorities align with the perspectives of PC, who emphasize the critical need for health care providers to strengthen their digital communication and patient empowerment capabilities.

Abstract

Background: Learner autonomy—the ability to self-direct and regulate learning—is a key determinant of success in online education, yet its quantifiable impact in voluntary noncredit courses remains unclear. Understanding how autonomy translates into measurable behaviors and outcomes in clinical skills training may inform more effective online learning design and learning outcomes.

Objective: This study aims to quantify the association between behavioral indicators of learner autonomy and performance in a voluntary noncredit online cardiac auscultation course.

Methods: We conducted a prospective, self-controlled, single-center study. A total of 199 registrants (n=122 physicians and n=77 medical students) were recruited via WeChat and attended four weekly 2-hour synchronous sessions using authentic patient heart sound recordings with imaging-based explanations. The primary outcome was the final posttraining quiz score (0-100); training effectiveness was assessed by the pre- to posttraining score change. The autonomy indicators were full participation (attendance at all four sessions), in-class engagement (number of responses to brief content-aligned prompts posed approximately every 10-15 minutes; responses recorded for participation monitoring only), and postclass review (frequency/duration of reviewing recordings and materials). Analyses included Wilcoxon signed rank tests, χ^2 tests, multivariable linear regression, and receiver operating characteristic profiling of “excellent learners” (top 10% improvement).

Results: Of the 199 registrants, 146 (73.4%) attended ≥1 session and 46 (23.1%) completed all sessions. Median test scores improved from 40 (IQR 20-50) to 70 (IQR 50-83; P<.001). Intrinsic motivation was associated with full participation (χ^2_1=4.03; P=.045). In multivariable models, full participation (unstandardized B=41.55, 95% CI 24.43-58.67; standardized β=0.60; P<.001) and in-class engagement (B=4.79 per additional response, 95% CI 3.05-6.45; β=0.70; P<.001) independently predicted higher final scores (adjusted R^2=0.48). Receiver operating characteristic profiling indicated that greater postclass review (recordings/materials) led to learners achieving excellent performance.

Conclusions: In this voluntary online clinical skills course, showing up consistently, engaging during class, and reviewing after class—practical expressions of learner autonomy—were key correlates of short-term performance. These behaviors may be encouraged through simple, feasible course designs such as clear expectation setting, periodic interactive prompts, and structured review opportunities, which warrant prospective evaluation in future studies.

KEYWORDS

learner autonomy; online learning; clinical skills; medical education; student engagement

Introduction

Online education has become an essential component of health professional learning and continuing professional development, especially since the COVID-19 pandemic [1-3]. Among factors determining online learning success, learner autonomy—the capacity to self-direct and regulate one's learning—has been recognized as fundamental in distance education theory [4,5] and self-determination theory [6-8]. Autonomous learners set personal goals, regulate study behaviors, and reflect on their progress, achieving deeper and more durable learning [9]. However, despite extensive theoretical discussion, quantitative evidence linking measurable expressions of autonomy—such as participation, attention, and review behaviors—to concrete learning outcomes in clinical skills training remains scarce [10,11]. Understanding this relationship may help learners and educators make more strategic use of limited study time and improve learning efficiency.

For medical professionals, online education generally follows two distinct patterns. The first consists of institution-driven structured courses provided by medical schools or training organizations through online platforms, often with mandatory participation and formal assessments [12,13]. The second is learner-driven and self-directed, where participants independently choose courses aligned with their interests or professional needs, often without credit or compulsory evaluation [7,14]. Such voluntary online courses place high demands on learners' autonomy, time management, and self-discipline. Capturing behavioral indicators of autonomy in freely accessible nonmandatory settings and examining their relationship with learning outcomes can yield insights into continuing medical education.

Cardiac auscultation remains a crucial yet challenging diagnostic skill in clinical practice [15-17]. Traditional bedside teaching is limited by the scarcity of authentic cardiac sounds and the difficulty of linking acoustic findings to underlying pathophysiology. These challenges make auscultation training well suited to online formats that can provide repeated exposure to verified recordings and integrated visual explanations. In line with this rationale, recent studies have shown that carefully designed digital modules can complement traditional instruction and improve diagnostic competence [18].

Based on these premises, we developed a voluntary noncredit online cardiac auscultation course that used authentic patient recordings, multimodal imaging, and interactive components. To examine the learner side of online success, we quantified autonomy through observable behaviors—full participation, active in-class engagement, and postclass review frequency—and evaluated how these dimensions predicted learning outcomes. This study aimed to provide quantitative evidence on how learner autonomy influences achievement in voluntary online clinical skills training.

A preliminary version of this study was shared as a preprint on Research Square [19].

Methods

Learner Recruitment

This was a prospective, self-controlled, single-center study that recruited doctors and medical students interested in free cardiac auscultation training through multiple channels within our hospital and affiliated medical school. The recruitment campaign was coordinated by the hospital's Department of Medical Education and disseminated via several official WeChat groups, including those for undergraduate medical students, staff physicians, and visiting trainees. In addition, printed recruitment posters containing a QR code for registration were displayed in various teaching and clinical areas of the hospital and medical school.

Interested individuals could scan the QR code to access an online registration form. The form collected basic demographic information, participants' prior experience with cardiac auscultation, and their motivation for enrolling in the course. Enrollment was open until the maximum capacity of the online classroom was reached, resulting in a total of 199 registrants on a first-come, first-served basis.

Ethical Considerations

This study was approved by the Institutional Review Board of Peking Union Medical College Hospital (I-23PJ1679). During registration, all prospective participants were presented with an electronic informed consent form that described the study purpose and procedures, explained that the online teaching sessions would be recorded, and noted that anonymized data might be used for research analysis. Only those who read and electronically signed the consent form were able to complete registration and participate in the course. Participation was entirely voluntary, and no financial or material compensation was provided.

Teaching Process

Teaching Contents

The cardiac sounds used in this training were authentic recordings collected from real patients over the past decade. When patients presented with abnormal heart sounds, simultaneous phonocardiographic recordings were obtained using an electronic stethoscope, and echocardiographic videos were captured to ensure precise correlation between auscultatory findings and underlying pathophysiology. Each recording was processed using acoustic analysis software to remove distortion and verify signal integrity, and all recordings were independently reviewed and validated by experienced cardiologists to confirm diagnostic accuracy.

Through this long-term systematic collection, we established a curated library of several hundred authentic cardiac sound recordings representing a broad spectrum of pathological findings. A total of 80 representative sounds were selected from this database, together with more than 30 clinical cases, 5 animations, and 100 echocardiographic clips, to form the course materials and cover the essential elements of cardiac auscultation relevant to internal medicine and clinical diagnostics.

Teaching Setting

All training sessions were conducted on an online teaching platform (Plaso, PLASO Network Technologies Co, Ltd) and consisted of four 2-hour live-streamed sessions held weekly. The platform supported real-time teacher-student interaction, and participants used in-ear headphones to ensure optimal sound quality.

Participants completed a 10-item cardiac sound identification test both before and after the course. Each correct answer was awarded 10 points (maximum score of 100 per test). The pre- and posttests used different sets of heart sounds that together covered all essential auscultatory findings.

During each live session, the instructor posed brief content-aligned questions approximately every 10-15 minutes. Items were randomly drawn from a preestablished question bank covering clinically relevant cardiac sounds and key conceptual checkpoints. Typical examples included "Which of the following four murmurs best represents a patent ductus arteriosus?" and "Which of the following murmurs is the most common systolic murmur?" Learners submitted responses through the platform; answers were recorded only to confirm participation and attention, not to evaluate correctness or to influence grading.

After each class, video recordings and supplementary review materials were made available on the platform for 1 month to facilitate voluntary review.

Definition of Key Variables

Motivation Classification

Learning motivation was categorized as intrinsic or extrinsic according to self-determination theory, in which intrinsic motivation refers to engaging in an activity for inherent interest or enjoyment, whereas extrinsic motivation involves participating to obtain external rewards or avoid negative consequences [20]. Motivation type was determined using a single self-report item included on the WeChat recruitment page. For physicians, the question read "Are you attending this training simply because you want to master cardiac auscultation, rather than for work or promotion needs?" This wording was chosen because, in current clinical practice, cardiac auscultation is no longer indispensable for diagnosis—most structural cardiac abnormalities can be identified by echocardiography. Therefore, physicians who voluntarily return to study auscultation, often years after graduation, generally do so out of strong personal interest and professional self-expectation rather than institutional or promotion requirements. Selecting this option was classified as intrinsic motivation, whereas choosing "because it is required for work or promotion requirements" represented extrinsic motivation. For medical students, the item was simplified to two options on the registration page: "interested in learning about heart sounds" (intrinsic motivation) or "because it is needed for work or exams" (extrinsic motivation).

Participation in training was defined as attending at least one session or reviewing the provided postclass materials at least once. Full participation was defined as attending all four sessions.

Other Variables

Participant engagement during sessions was measured by the duration of attendance recorded by the online system and the frequency of responses to randomly posed questions.

Postclass review activities were assessed based on the frequency and duration of video reviews and the number of supplementary materials reviewed.

Total learning time included cumulative time spent attending live classes and reviewing class materials.

Training effectiveness was determined by comparing pre- and posttraining quiz scores. Learning outcomes were indicated by the final quiz scores. Participants whose score improvement exceeded the 90th percentile of all participants were classified as excellent learners.

Statistical Analysis

Continuous variables were assessed for normality using the Shapiro-Wilk test. Normally distributed data were presented as means (SDs), while nonnormally distributed data were expressed as medians (IQRs) or median (minimum, maximum). Categorical variables were presented as frequencies and percentages. Nonnormally distributed data were analyzed using the Wilcoxon signed rank test. Differences in categorical variables were analyzed using either the χ^2 test or Fisher exact test, as appropriate.

Spearman correlation coefficients and multivariate linear regression analyses were used to identify factors influencing final quiz scores. Variables with Spearman correlation coefficients (P<.05) were included in the multivariate regression model. Collinearity diagnostics were performed, and variables inducing collinearity were excluded. Factors associated with excellent learners were evaluated using receiver operating characteristic (ROC) curve analysis.

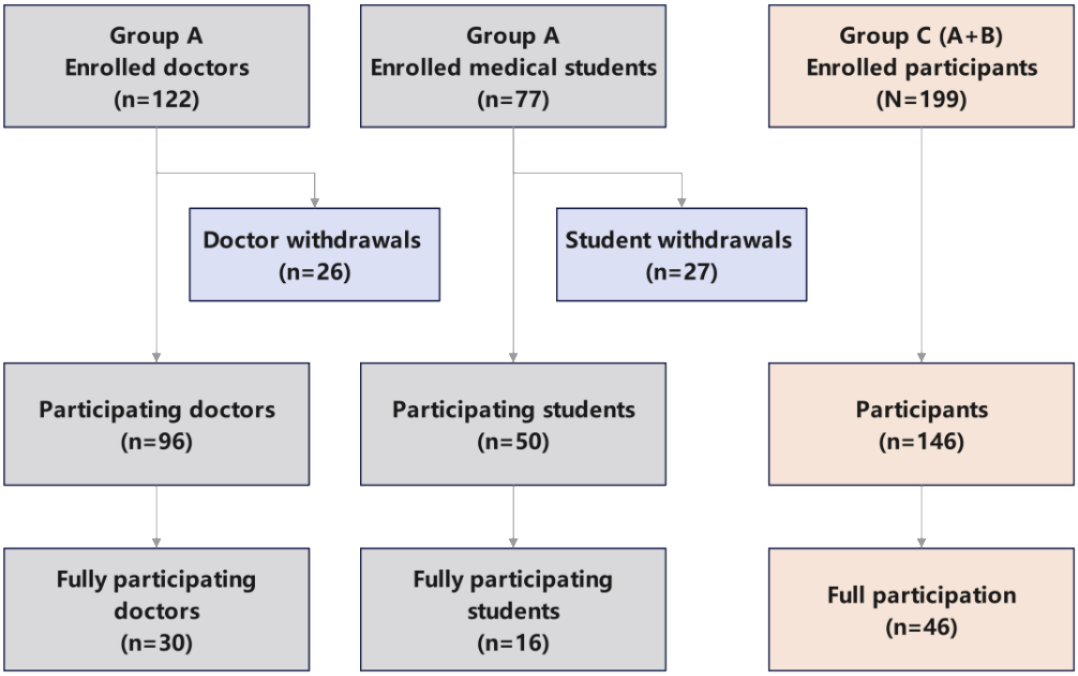
All statistical analyses were performed using SPSS Statistics for Windows, Version 23 (IBM Corp) and GraphPad Prism, Version 10.1.2 (GraphPad Software). Statistical significance was defined as P<.05.

Results

Overview

A total of 199 individuals voluntarily registered for the training, including 122 doctors and 77 medical students. The recruitment of doctors was completed within 2 days, whereas student recruitment required about a month. All registrants indicated that they had not yet mastered the skill of cardiac auscultation. The doctors were significantly older than the students and had substantially more years of prior exposure to auscultation learning. From registration to actual participation, a higher proportion of doctors attended the training compared with medical students (96/122, 78.7% vs 50/77, 64.9%; χ^2_1=4.57; P=.03). Overall, 73.4% (146/199) of registrants participated in the training, corresponding to a 26.6% (53/199) dropout rate. However, only 23.1% (46/199) of all registrants attended all four sessions (Figure 1), with no significant difference in full participation between doctors and students.

Figure 1. Participant flow diagram from registration to full course completion.



For participation motivation, doctors were more driven by intrinsic motivation than medical students (89/122, 73.0% vs 15/77, 19.5%; χ^2_1=54.10; *P*<.001). Intrinsic motivation was significantly correlated with age (*r*=0.394; *P*=.004) and total study time (*r*=0.145; *P*=.04), but not with the number of in-class random questions answered (*r*=0.153; *P*=.11). A χ^2 test further indicated that intrinsic motivation was associated with full participation (χ^2_1=4.03; *P*=.045). A significant increase in posttraining scores suggested that the program was effective (Table 1).

Table 1. Characteristics of participants in online heart auscultation training.

Variable[a]	Total (N=199)	Doctors (n=122)	Medical students (n=77)	*P* value
Age (years), median (IQR)	26 (23-31)	29 (26-35)	22 (20-25)	<.001
Female sex, n (%)	136 (68.3)	91 (74.6)	49 (63.6)	.26
Years of learning heart sound auscultation, median (IQR)	5 (3-8)	7 (5-11)	2 (1-4)	<.001
Training participants, n (%)[b]	146 (73.4)	96 (78.7)	50 (64.9)	.03
Participants who attended all 4 sessions, n (%)	46 (23.1)	30 (24.6)	16 (20.8)	.61
Motivation				<.001
Intrinsic motivation, n (%)	104 (52.3)	89 (73.0)	15 (19.5)	
Extrinsic motivation, n (%)	95 (47.7)	33 (27.0)	62 (80.5)	
Pretraining score, median (IQR)	40 (20-50)	40 (20-50)	30 (20-50)	.47
Posttraining score, median (IQR)	70 (50-83)	70 (50-90)	50 (50-75)	.29
Individual score change, median (IQR)	30 (10-45)	35 (10-50)	30 (0-40)	.66

[a]Continuous variables compared using the Mann-Whitney *U* test; categorical variables compared using the χ^2 test or Fisher exact test, as appropriate. Two-sided *P*<.05 indicates statistical significance.

[b]Defined as participants attending ≥1 session or reviewing postclass materials at least once.

During the four sessions, a total of 16 random questions were posed, and 11 sets of review materials were distributed online after each class. The system automatically recorded the number of in-class responses and the frequency of postclass access to review materials. Of the 146 training participants, 49 (33.6%) participants watched the lecture videos after class; however, only 10 (6.8%) viewed all four full recordings. The lecture material was reviewed by 111 (76.0%) participants, but only 20 (13.7%) accessed all available materials.

The duration of postclass video viewing varied substantially among participants. Age was significantly and positively correlated with total study time (*r*=0.366; *P*<.001), time spent reviewing recorded videos (*r*=0.330; *P*<.001), and the number of review materials accessed (*r*=0.355; *P*<.001; Table 2).

Table 2. Assessment results for classroom attendance and postclass review. Data are limited to training attendees only.

Variable[a]	Total	Doctors	Medical students	*P* value
Live class participations (n), median (IQR)	2 (1-4)	2 (1-4)	2.5 (1-4)	.41
Total duration of live class participation (min), median (IQR)	191 (84-384)	183 (79-375)	210 (84-404)	.77
Random questions in class (n), median (IQR)	5 (1-16)	5 (1-14)	5 (3-16)	.23
Course materials reviewed after class (n), median (IQR)	1 (0-3)	1 (0-5)	0 (0-1)	.01
Duration of watching lecture videos (min), median (IQR)	0 (0-578)	0 (0-578)	0 (0-169)	.01
Total study time (min), median (IQR)	202 (86-422)	192 (86-424)	210 (88-416)	.89

[a]Continuous variables compared using the Mann-Whitney *U* test. Two-sided *P*<.05 indicates statistical significance.

Analysis of Factors Affecting Training Scores

We performed univariate correlation analyses to examine the relationships between multiple factors—including learning motivation, overall participation, number of class attendances, duration of class participation, frequency of in-class responses to random questions, number of postclass material reviews, number of times watching lecture videos, and total study time—and the final scores. Significant correlations were observed between the final scores and full participation (r=0.351; P=.02), frequency of in-class responses (r=0.431; P=.004), and number of postclass material reviews (r=0.345; P=.03).

Age, participant type (doctor or student), years of prior auscultation study, motivation for participation, and time spent attending live sessions were not significantly correlated with final scores. Further multivariable linear regression analysis showed that only full participation and frequency of in-class responses remained independently associated with final scores, whereas postclass material review frequency did not significantly affect performance (Table 3).

Table 3. Multivariate linear regression results for factors associated with final auscultation scores (adjusted R^2=0.483).

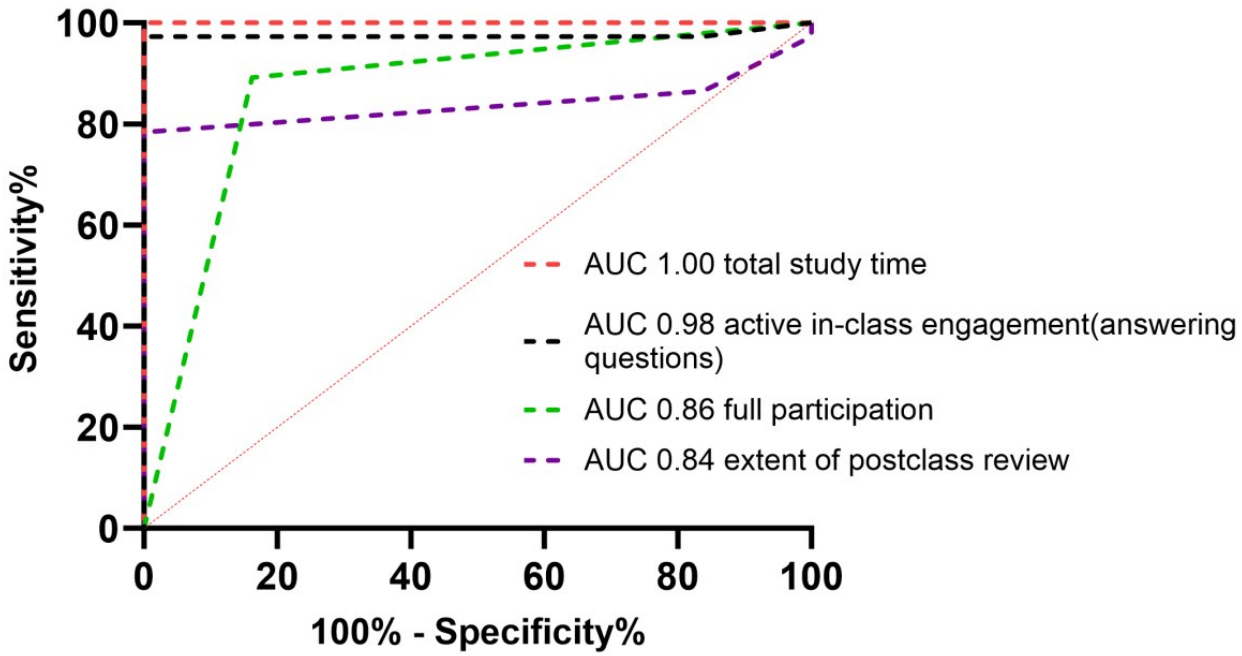
Regression variables	B (95% CI)	β	*P* value
Constant	–21.789 (–50.855 to 7.277)	—[a]	.13
Full participation	41.547 (24.426 to 58.667)	0.602	<.001
Times of answering random questions in classes	4.794 (3.054 to 6.445)	0.695	<.001

[a]Not applicable.

Factors Influencing Becoming an Excellent Learner

Six participants increased their scores by more than 60 points after the training, placing them in the top 10% of all participants and defining them as excellent learners. ROC curve analysis suggests that total study time, actively answering questions in class, full participation, and the extent of postclass review were all significantly related to achieving excellent learner status (Figure 2).

Figure 2. Receiver operating characteristic curve analysis of factors related to excellent performance. AUC: area under the curve.



Discussion

Principal Findings

In this voluntary noncredit online cardiac auscultation course, cohort-level test scores improved from pre- to posttraining, indicating overall instructional effectiveness. Nevertheless, only 23% of registrants completed all four sessions, underscoring the difficulty of sustaining participation in voluntary settings. Within the cohort, intrinsic motivation was positively associated with full participation, and both full participation and more frequent content-aligned in-class responses were independently associated with higher final scores. Postclass review was not an independent predictor in multivariable models, yet it consistently characterized learners who achieved excellent performance in ROC analyses.

Interpretation and Comparison With Prior Work

Taken together, the data suggest a plausible pathway for success in voluntary online learning: autonomous motivation→sustained participation→active content-aligned engagement→higher performance. This pathway is consistent with the self-determination theory and with contemporary applications of autonomy-supportive design in health professional education, which emphasize persistence and self-regulation in learning tasks [20,21]. Methodologically, our study contributes by operationalizing autonomy through objective behavioral traces—attendance, periodic in-class responses, and review—rather than relying solely on self-report, which aligns with recent work mapping measurable dimensions of student engagement in health professional education [22].

Low completion in our cohort mirrors patterns reported in large-scale voluntary online courses, where completion is often modest; for example, completion of massive open online courses frequently clusters around 10% in some contexts. A recent systematic review concluded that dropout is multifactorial and more closely related to course attributes, learner behaviors, and motivation/self-regulation than to content alone, reinforcing the need for proactive planning to sustain participation in voluntary courses [11]. In practical terms, clear expectation setting before enrollment—regarding time commitment, learning objectives, and assessment schedule—and simple scheduling reminders have been reported to improve learner persistence in online education [11] and may help participants maintain full engagement in voluntary courses.

Beyond attendance, maintaining focused attention during sessions appears salient. Empirical work shows that off-task device use is more frequent online than face-to-face and is associated with perceived distraction, which can erode engagement [23]. In medical education contexts, survey evidence and expert opinion further suggest that attention tends to decline after approximately 10-15 minutes unless refreshed through interactive elements. Accordingly, periodic content-aligned checks (brief questions or polls), as implemented in our study, are advisable in synchronous sessions [24].

Finally, postclass review may play a selective role in mastery. Although postclass review was not an independent predictor in our adjusted model, high performers engaged in postclass review more often. This pattern is consonant with meta-analytic evidence that spaced or retrieval-based reviews improve long-term retention and, in some cases, clinical behavior change relative to massed learning [25]. In health professional education, spaced e-learning has been shown to enhance knowledge retention in basic life support compared with single-session learning [26]. Future implementations could explore embedding simple, low-burden review structures—such as a 48-hour recap and a 1-week revisit—and providing automated reminders to prompt learners to consolidate key material.

Notably in our cohort, the associations between participation/engagement and performance were not explained by measured demographic characteristics (age, years of exposure to auscultation, workplace), suggesting that the behavioral pathway outlined above could be applicable across subgroups in similar settings.

Limitations

This study has several limitations. It was conducted at a single center with voluntary participation, which may limit generalizability and introduce self-selection bias. The primary outcome was a short-term test score, and long-term retention was not assessed. Although the pre- and posttests followed the same blueprint, using different item sets may have introduced measurement variability. Motivation was assessed by a single unvalidated item, and the voluntary single-center sample entails self-selection; hence, residual confounding and limited generalizability remain.

Conclusions and Broader Implications

Learners who consistently attended all sessions, stayed focused during class, and reviewed material after class achieved the best results in this voluntary online clinical skills course. These behaviors represent practical expressions of learner autonomy and can be strengthened through simple habits—committing to scheduled sessions, engaging actively with class tasks, and revisiting key materials on a spaced schedule. For busy health professionals, such disciplined learning routines may transform limited study time into durable competence.

Beyond this specific course, these findings highlight the importance of quantifying and supporting learner autonomy as a measurable construct in online medical education. Incorporating behavioral analytics to monitor participation, engagement, and review patterns may provide educators with actionable insights to design more autonomy-supportive learning environments. Future research should investigate how these learner-driven behaviors can be further supported through course design and motivation-enhancing strategies to sustain long-term engagement and performance across diverse educational settings.

Abstract

Background: Social media platforms are increasingly integrated into higher education, enabling collaborative, student-centered learning. Yet, few instruments specifically measure students' satisfaction with these activities across platforms. A brief, valid tool is needed to evaluate perceived quality and guide instructional design in social media–based learning environments.

Objective: This study investigated the use of social media as educational tools in the university environment, with the aim of designing and validating the CuSAERS (Questionnaire of Satisfaction With Educational Activities Performed on Social Media).

Methods: Using a mixed and sequential methodology, we explored the perceptions of bachelor's and master's degree students in physiotherapy who participated in teaching activities through X (formerly Twitter) and Instagram. The first phase of the project identified key dimensions of satisfaction from the literature, expert interviews, and cognitive interviews. The second phase assessed the psychometric properties of the CuSAERS in a sample of 150 students, addressing construct validity, internal reliability, concurrent validity, and discriminant validity.

Results: Exploratory factor analysis supported a 3-factor structure—perception of learning, task satisfaction/environment, and self-realization—explaining 61.9% of the variance, with acceptable overall reliability. Concurrent validity was supported by moderate correlations with the Academic Satisfaction Scale. Master's students reported higher scores than bachelor's students.

Conclusions: CuSAERS provides preliminary evidence as a promising measure of student satisfaction with social media–based learning activities; its use should remain formative and cautious until confirmatory and invariance analyses are completed.

Trial Registration: No applicable.

KEYWORDS

academic engagement; collaborative learning; digital learning; educational technology; learning environments; psychometric validation; social media; student satisfaction

Introduction

Social media refers to online resources designed to facilitate interaction and engagement among individuals [1]. Over the last decade, these platforms have transformed the way people communicate, learn, and collaborate, extending far beyond personal and social contexts into education [2-4]. Tools such as X (formerly Twitter), Instagram, Facebook, and YouTube now support innovative pedagogical strategies aligned with digitalization and global collaboration, promoting learning experiences that transcend geographic and temporal boundaries [5-7].

In health professions education, social media can promote collaborative learning, reflective discussion, and peer interaction, enhancing students' engagement and motivation [8-10]. Platforms like X facilitate professional dialogue and access to scientific information, while Instagram and YouTube enable visual learning and dissemination of clinical content [11,12]. However, drawbacks include information overload, variable content quality, and risks related to privacy or professionalism [13,14]. These limitations underscore the need for structured pedagogical design and critical evaluation of their educational use.

Despite the rapid adoption of social media in educational settings, systematic approaches to evaluate their educational impact remain limited. Existing measures often emphasize usability, frequency of use, or performance metrics while neglecting students' affective responses and satisfaction with learning experiences [15-18]. Yet satisfaction is closely linked to engagement, retention, and perceived learning quality, making it a key outcome for educational quality assurance [19-21].

Assessing satisfaction requires specific, psychometrically sound instruments that capture the attitudinal evaluation of students toward learning activities conducted on social media, beyond usability or behavioral engagement [22,23]. Such measurement tools can inform educators and institutions about the perceived quality and effectiveness of teaching innovations in digital environments and guide continuous improvement in educational design [24].

This study aimed to develop and provide an initial psychometric evaluation of the CuSAERS (Questionnaire of Satisfaction With Educational Activities Performed on Social Media), a tool designed to assess students' satisfaction with learning experiences delivered through social media. Specifically, we examined its internal consistency, factorial structure, and construct, concurrent, and discriminant validity across subgroups using different social media platforms.

Methods

Ethical Considerations

The university's ethics committee of La Salle Higher Center for University Studies determined that, given the design of the study, formal ethics committee review and approval were not required and therefore granted an exemption, authorizing the study to be conducted without ethics committee approval. All students signed an informed consent document before participating, which explained the objectives of the study, the confidentiality of the data, and the voluntary nature of their participation. The database was encoded using an alphanumeric code, and no personal data was recorded. No compensation was provided to the participants.

Study Design

This study used an exploratory sequential mixed design, combining qualitative and quantitative methods for the development, construction, and validation of the CuSAERS. The first qualitative phase, which included a literature review, semistructured interviews, expert content validation, cognitive interviews, and a pilot test, has been previously published [25]. This first phase had been aimed at identifying the dimensions of satisfaction perceived by students with regard to educational activities carried out on social media, such as interaction with the teacher, the quality of the content, and collaboration between colleagues.

The second phase focused on the psychometric evaluation of the CuSAERS. During this stage, the questionnaire was administered to a representative sample of bachelor's and master's students to assess its psychometric properties, including validity and reliability.

Participants

The sample selected on a nonprobabilistic basis consisted of 160 bachelor's and master's degree students in physiotherapy from a Spanish university. Of these, 110 were bachelor's students and 50 were master's students. All participants were aged 18 years or older and enrolled in official academic programs. As an inclusion criterion, participants had to have previously participated in educational activities developed on social media, specifically on X or Instagram.

Teaching Innovation Activities

The master's students participated in an academic activity designed on Instagram. This activity consisted of the critical analysis of therapeutic exercises published in video format on this platform. Students watched the videos, identified technical errors, proposed modifications, and justified their proposals based on scientific evidence. This task not only fostered autonomous and critical learning but also promoted the use of social media as a professional learning tool. The students'

responses and observations were subsequently discussed in a digital forum supervised by the teacher, who acted as moderator and interlocutor, offering specific and targeted feedback.

The bachelor's students participated in an activity developed on X. This activity included a virtual debate on aspects related to chronic pain. Each student had to perform prior research on the assigned topic and present their position in the form of X threads, using technical but accessible language. The debates were enriched with bibliographical references and the integration of specific hashtags to facilitate the monitoring of the discussions. The teacher's involvement focused on moderating the debate, posing critical questions to deepen the arguments, and providing direct feedback on the content and quality of the interactions.

Both activities were designed to maximize students' active participation, integrating the use of social media as an innovative pedagogical resource. The strategies used sought to foster critical, technical, and communicative skills in digital contexts, thus contributing to more dynamic and meaningful learning.

Procedure

Phase 1: Development of CuSAERS

The first phase was described in a previous study and consisted of a literature review and interviews with experts in educational methodology, social media, and rehabilitation, as well as with physiotherapy students [25].

Phase 2: Psychometric Evaluation

In the second phase, the CuSAERS questionnaire was administered to a sample of 150 students, of whom 90 were bachelor's and 60 were master's students. The students completed the questionnaire online, and a cross-sectional design was used to assess the psychometric properties of the instrument.

Data Analysis

Descriptive Statistics

The data analysis was performed exclusively using JAMOVI (version 2.6; The Jamovi Project) software, which allowed all statistical evaluations of the study to be performed. Descriptive statistics were used to summarize the categorical variables, expressed in absolute and relative frequencies, and the continuous variables, which were reported in terms of means, SDs, and 95% CIs.

Normality Assessment

The normality of the data was comprehensively assessed, using both statistical tests and graphical methods.

The Kolmogorov–Smirnov test was applied to determine whether the distributions of the variables differed significantly from a normal distribution. This test was complemented by a visual analysis using quantile–quantile (Q–Q) plots and histograms, which allowed the alignment of the data with the theoretical normal curve to be assessed.

In addition, skewness and kurtosis coefficients were calculated to assess the shape of the distributions. Skewness values close to 0 indicate symmetric distributions, whereas positive or negative values indicate skewing to the right or left, respectively. As for kurtosis, values close to 3 indicate mesokurtic distributions, whereas higher or lower values suggest leptokurtic or platykurtic distributions, respectively. These metrics provided a quantitative framework for interpreting the normality of the data distributions.

Lastly, additional analyses were performed to assess the influence of outliers on the distributions. They were identified and visually examined using boxplots, which allowed us to determine whether these outliers had a significant impact on the structure of the data.

Construct Validity

We conducted an exploratory factor analysis (EFA) using the minimum residual extraction method with oblimin rotation. Sampling adequacy was evaluated with the Kaiser-Meyer-Olkin (KMO) index and Bartlett's test of sphericity. The number of factors was determined using multiple criteria: Kaiser's rule (eigenvalue ≥1), scree plot, parallel analysis, and exploratory graph analysis. Factors were retained when they had ≥2 items with minimal cross-loadings.

The root-mean-square error of approximation (RMSEA) was calculated with a 90% CI. RMSEA values up to 0.08 are considered indicative of a reasonable fit to the data, with values closer to 0.05 or lower suggesting a good fit. In addition, the Tucker-Lewis Index (TLI) was calculated, with values close to or above 0.95 indicating an excellent fit. The Bayesian information criterion (BIC) was also assessed, in which lower (more negative) values are preferred, suggesting a model that better explains the data with fewer parameters. Lastly, the model fit was confirmed using the chi-square test. A nonsignificant chi-square value indicates that the observed and expected covariances of the model do not differ significantly, supporting an adequate model fit.

Item retention followed a priori thresholds to preserve content validity and parsimony: only items with primary loadings ≥0.40 on a single factor were kept; items with cross-loadings within 0.20 of the primary loading or with communality/uniqueness values indicating poor common variance were considered for removal [26]. The final solution and retained items were based on these empirical criteria in conjunction with theoretical interpretability.

Internal Consistency (Reliability)

Internal consistency was assessed using Cronbach α coefficient, with values above 0.70 considered adequate, and McDonald omega (ω) coefficient, which provides a complementary estimate of internal consistency. This approach allowed a robust assessment of the homogeneity of the items that make up the dimensions of the CuSAERS.

Concurrent Validity

Concurrent validity was assessed by calculating Pearson correlations between CuSAERS scores and the Academic Satisfaction Scale (ASS), used as a reference instrument. The ASS defines academic satisfaction as "the well-being and

enjoyment that students perceive in their experiences within the academic role" [27].

This instrument, composed of 7 items organized into a single factor, uses a 7-point Likert scale and has demonstrated high reliability (ordinal α=.92) and structural validity in Chilean university contexts [28].

In addition, previous experience in using social media, measured in months, was included as an additional variable to explore its relationship with CuSAERS scores. This information allowed us to assess whether the length of time spent using social media significantly influences the perception of academic satisfaction in activities performed in these environments.

The values of the correlations between the CuSAERS, ASS, and social media experience were interpreted according to the criteria of Schober et al [29]. The correlations were classified as follows: insignificant (0.00-0.10), weak (0.10-0.39), moderate (0.40-0.69), strong (0.70-0.89), and very strong (0.90-1.00).

Floor and Ceiling Effect

The presence of floor and ceiling effects was assessed by calculating the percentage of participants who obtained the lowest or highest possible scores on the questionnaire. An effect was considered significant if more than 15% of participants were at these extremes.

Discriminant Validity

The discriminant validity of the CuSAERS was explored by comparing groups of students with various levels of engagement in educational activities on social media platforms. Specifically, analyses were conducted to compare students who participated in activities on X versus those who used Instagram, examining differences in their satisfaction scores.

Additionally, students with prior experience using social media were compared with those without such experience to determine the impact of this variable on perceptions of educational satisfaction. A comparative analysis was also performed between physiotherapy master's students and bachelor's students to evaluate potential differences based on academic level.

The comparisons were conducted using the Mann–Whitney U test as a nonparametric method for independent samples, and effect sizes were calculated using rank-biserial correlation. Effect sizes were interpreted as small (r=0.10), moderate (r=0.30), and large (r=0.50). These analyses identified significant differences that support the ability of the CuSAERS to distinguish between groups with diverse educational characteristics and contexts.

Discriminant comparisons (eg, bachelor's vs master's degree; prior social media experience) are reported as exploratory contrasts with effect sizes and are not adjusted for covariates. In subsequent work we will conduct confirmatory factor analysis (CFA), multigroup measurement invariance (by degree level, gender, and age), cross-validation in an independent multisite sample, and covariate-adjusted models (eg, regression or standard error of means) to strengthen causal interpretability of group differences.

Results

Normality Analysis

The normality of the data was assessed through a comprehensive analysis that included both statistical tests and graphical methods, providing an in-depth understanding of the distribution of the items in the CuSAERS. The results of the Kolmogorov–Smirnov test indicated that the data significantly deviated from a normal distribution (P<.001), confirming that the variables did not meet the assumption of normality. This finding was consistent with skewness and kurtosis values, which suggested deviations from perfect symmetry and distributions far from the ideal mesokurtic shape. Most of the items showed negative skewness, indicating a tendency for participants to give higher scores on the satisfaction scale, while predominantly platykurtic kurtosis reflected lower concentration at the scale's extremes.

The visual analysis complemented these statistical evaluations. Q–Q plots and histograms demonstrated that the data did not align with the theoretical normal curve, confirming the presence of biases and lighter tails in the distribution of scores. Additionally, the influence of outliers was explored using boxplots, which revealed greater dispersion in specific items, such as Item 8 and Item 12. These items, which had the highest SDs, reflected the heterogeneity in the participants' perceptions regarding these specific aspects of the questionnaire.

Descriptive Analysis

The descriptive analysis of the items showed means and medians centered around values close to 3, reflecting a tendency toward neutral or moderately positive responses. SDs ranged between 0.752 and 1.046, demonstrating differences in the dispersion of responses. Items with the highest dispersion were Item 8 and Item 12, whereas Item 16 presented the lowest variability.

Regarding distribution, most items exhibited negative skewness, suggesting a slight tendency toward higher scores, except for Item 8, which showed skewness close to 0. Platykurtic kurtosis predominated, indicating lower concentration of responses at the extremes, except for some items, such as Item 3 and Item 4, which displayed more leptokurtic distributions.

In terms of internal consistency, the item-total correlations were heterogeneous, ranging from −0.001 (Item 16) to 0.539 (Item 10). Items 11 and 16 stood out for having near-zero or negative item-total correlations, suggesting a lower contribution to the instrument's consistency. Cronbach α and McDonald ω coefficients ranged between 0.645 and 0.716, and between 0.674 and 0.755, respectively, indicating moderate reliability overall. The highest reliability values were observed for Items 11 and 16, although these items had low item-total correlations, which might imply atypical behavior for these items (Table 1).

Table 1. Descriptive statistics and reliability coefficients upon item removals.

Item	Mean (SD)	Median (IQR)	Skewness	Kurtosis	Item 1: all correlation	Cronbach α	McDonald ω
Item 3	2.98 (0.797)	3.0 (3-3)	−0.948	1.01	0.481	0.653	0.683
Item 4	3.12 (0.764)	3.0 (3-4)	−0.977	1.31	0.455	0.657	0.685
Item 6	2.92 (0.821)	3.0 (3-3)	−0.897	0.7	0.296	0.679	0.729
Item 7	3.02 (0.846)	3.0 (3-4)	−0.552	−0.323	0.490	0.650	0.684
Item 8	2.49 (1.046)	3.0 (2-3)	−0.05	−1.18	0.287	0.683	0.732
Item 9	2.98 (0.831)	3.0 (2-4)	−0.352	−0.618	0.432	0.659	0.695
Item 10	3.19 (0.773)	3.0 (3-4)	−0.929	0.887	0.539	0.645	0.674
Item 11	3.18 (0.831)	3.0 (2-4)	−0.351	−1.47	0.029	0.715	0.752
Item 12	2.63 (1.05)	3.0 (2-3)	−0.204	−1.14	0.382	0.666	0.721
Item 13	3.04 (0.846)	3.0 (2-4)	−0.387	−0.78	0.274	0.682	0.731
Item 16	3.01 (0.752)	3.0 (2-4)	−0.021	−1.22	−0.001	0.716	0.755
Item 17	3.02 (0.935)	3.0 (3-4)	−0.786	−0.164	0.311	0.674	0.723

Factor Analysis (Construct Validity)

The data were suitable for factor analysis (KMO=0.754; Bartlett's χ^2_{45}=685; P<.001). An exploratory factor analysis with oblimin rotation supported a 3-factor solution explaining 61.9% of the variance (sum of squared loadings: 3.07, 1.56, 1.56; 30.7%, 15.6%, 15.6%). Interfactor correlations were small (r=0.06-0.20).

Factor 1 (perception of learning) showed high primary loadings for Item 10 (0.821), Item 4 (0.820), Item 3 (0.803), Item 7 (0.748), and Item 9 (0.695), with uniqueness ranging from 0.318 to 0.518 (Table 2).

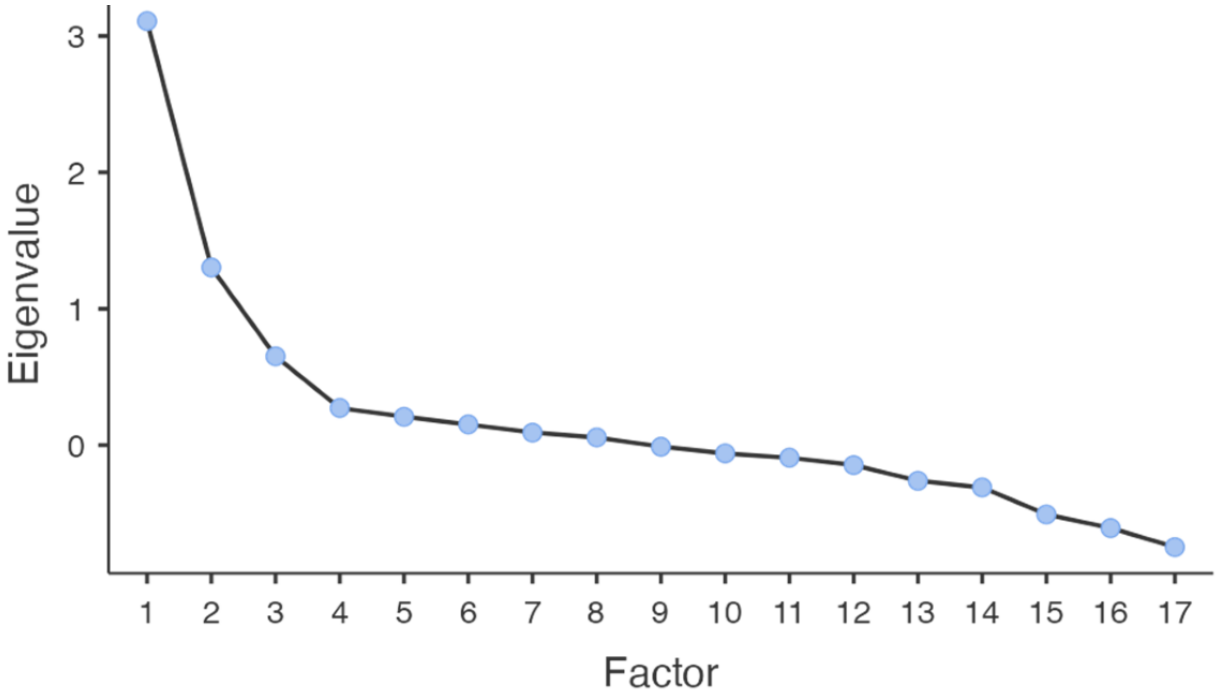
Table 2. Factor loadings of the items in relation to the factor solution. Extraction was performed using the minimum residuals method with oblimin rotation. Only primary loadings ≥0.40 are displayed. Factor labels follow the retained 3-factor solution. Factor 3 should be interpreted with caution because of a boundary estimate for Item 8. Factor 2, representing task satisfaction/environment, was defined by Item 13 (0.763), Item 6 (0.745), and Item 17 (0.626), with higher uniqueness for Item 17 (0.593). Factor 3, representing self-realization, was defined by Item 8 (1.002; boundary estimate) and Item 12 (0.722).

Item	Statement	Factor 1 (perception of learning)	Factor 2 (task satisfaction)	Factor 3 (self-realization)	Uniqueness
Item 10	Training activities on social media foster my reflection, synthesis, and reasoning. [Las actividades formativas en redes sociales fomentaron mi reflexión, síntesis y razonamiento.]	0.821	—[a]	—	0.318
Item 4	Educational activities on social media motivate me to ask questions and participate in discussions. [Las actividades educativas en redes sociales me motivan a hacer preguntas y participar en discusiones.]	0.820	—	—	0.330
Item 3	Educational activities on social media promote my participation. [Las actividades educativas en redes sociales promueven mi participación.]	0.803	—	—	0.334
Item 7	The use of social media in education has increased my interest in the course content. [El uso de redes sociales en la educación aumentó mi interés en los contenidos de la asignatura.]	0.748	—	—	0.431
Item 9	Using social media as a learning tool is beneficial. [Es positivo usar redes sociales como herramienta de aprendizaje.]	0.695	—	—	0.518
Item 13	The time spent on training activities on social media is well utilized. [El tiempo dedicado a actividades formativas en redes sociales está bien aprovechado.]	—	0.763	—	0.419
Item 6	My educational experience on social media makes me feel that it is a suitable environment to express my ideas. [Mi experiencia educativa en redes sociales me hace sentir que es un entorno adecuado para expresar mis ideas.]	—	0.745	—	0.427
Item 17	My experience indicates that social media is suitable for acquiring knowledge related to my field of study. [Mi experiencia indica que las redes sociales son adecuadas para adquirir conocimientos relacionados con mi carrera.]	—	0.626	—	0.593
Item 8	I am satisfied with my participation in educational activities conducted through social media. [Estoy satisfecho con mi participación en las actividades educativas desarrolladas con redes sociales.]	—	—	1.002	0.001
Item 12	I am satisfied with what I have learned in educational activities on social media. [Estoy satisfecho con lo que he aprendido en las actividades educativas en redes sociales.]	—	—	0.722	0.441

[a]Empty cells indicate loadings <0.40 on that factor.

Overall model fit was acceptable (RMSEA=0.058; 90% CI 0.00-0.100; TLI=0.961; χ^2_{18}=27.9; BIC=–63.4; *P*=.06). All retained items met the a priori loading threshold (≥0.40), and cross-loadings were minimal (Table 2). The scree plot and parallel analysis supported the retention of three factors: the first 2 observed eigenvalues were clearly above the simulated distribution, the third was approximately at the simulated threshold, and from the fourth onward, the observed eigenvalues fell below the simulated ones (Figure 1). We note that Item 8 presented a boundary (Heywood) estimate—an occurrence that can arise in small samples and oblique solutions—so this third factor should be considered provisional pending confirmatory testing and item redevelopment in an independent, larger sample.

Figure 1. Scree plot of the exploratory factor analysis of the CuSAERS (Questionnaire of Satisfaction With Educational Activities Performed on Social Media), showing the eigenvalues of the extracted factors; the "elbow" in the curve suggests retaining 4 factors, which explain the majority of the total variance.



Consistent with the scree plot and parallel analysis (Figure 1), we retained the 3-factor solution as the primary model (Table 3). The 2-factor alternative, although parsimonious, collapses conceptually distinct domains and does not map cleanly onto the theorized constructs (Table S1 in Multimedia Appendix 1). The 4-factor alternative introduces a psychometrically weak structure: after applying the a priori retention rule (primary loading ≥0.40), one factor is left with a single indicator (Table S2 in Multimedia Appendix 1), which is not recommended for latent constructs. Taken together, the 3-factor model offers the best balance between empirical support and theoretical interpretability.

Table 3. Fit measures for the comparison between the 3 models. The 3-factor solution is the primary model; the 2- and 4-factor solutions are provided for comparison.

Model factors	Variance (%)	RMSEA[a] (90% CI)	TLI[b]	BIC[c]	Chi-square (*df*)	*P* value
2	57.5	0.064 (<0.001 to 0.111)	0.963	−44.4	21.6 (13)	.06
3	61.9	0.058 (<0.001 to 0.1)	0.961	−63.4	27.9 (18)	.06
4	58.4	0.055 (<0.001 to 0.092)	0.948	−86	35.8 (24)	.06

[a]RMSEA: root-mean-square error of approximation.

[b]TLI: Tucker-Lewis Index.

[c]BIC: Bayesian information criterion.

Internal Consistency

Table 4 presents the descriptive statistics and reliability coefficients for the evaluated scales. The overall mean for the CuSAERS was 2.93 (SD 0.503), with moderate internal consistency coefficients for both Cronbach α=0.743 and McDonald ω=0.787. Among the subscales, perception of learning showed the highest internal consistency (α=0.882; ω=0.884) and a mean of 3.06 (SD 0.662), indicating a positive perception of learning.

Table 4. Descriptive statistics and reliability of the CuSAERS (Questionnaire of Satisfaction With Educational Activities Performed on Social Media) questionnaire and its subscales.

Scale	Mean (SD)	Cronbach α	McDonald ω
CuSAERS total	2.93 (0.503)	0.743	0.787
Perception of learning	3.06 (0.662)	0.882	0.884
Task satisfaction	2.99 (0.709)	0.749	0.756
Self-realization	2.56 (0.977)	0.849	0.849

Concurrent Validity

Concurrent validity was assessed using Spearman correlations between the CuSAERS scores and the ASS, as well as prior experience with social media (Table 5). The results showed that the total CuSAERS score had a moderate positive correlation with the ASS (ρ=0.59; *P*<.001), supporting its validity as an instrument to evaluate the perception of educational activities on social media. Additionally, significant positive correlations were observed between the ASS and the subscales perception of learning (ρ=0.44; *P*<.001), task satisfaction (ρ=0.31; *P*<.001), and self-realization (ρ=0.29; *P*<.01), indicating a consistent relationship between academic satisfaction and the dimensions evaluated by the CuSAERS.

Table 5. Correlation matrix.

Variable	ASS[a]	Social media experience	CuSAERS[b] total	Perception of learning	Task satisfaction	Self-realization
ASS	—[c]					
Social media experience	0.17[d]	—				
CuSAERS total	0.59[e]	0.27[e]	—			
Perception of learning	0.44[e]	0.20[f]	0.72[e]	—		
Task satisfaction	0.31[e]	0.14	0.54[e]	0.09	—	
Self-realization	0.29[f]	0.23[f]	0.56[f]	0.10	0.19[d]	—

[a]ASS: Academic Satisfaction Scale.

[b]CuSAERS: Questionnaire of Satisfaction With Educational Activities Performed on Social Media.

[c]Not applicable.

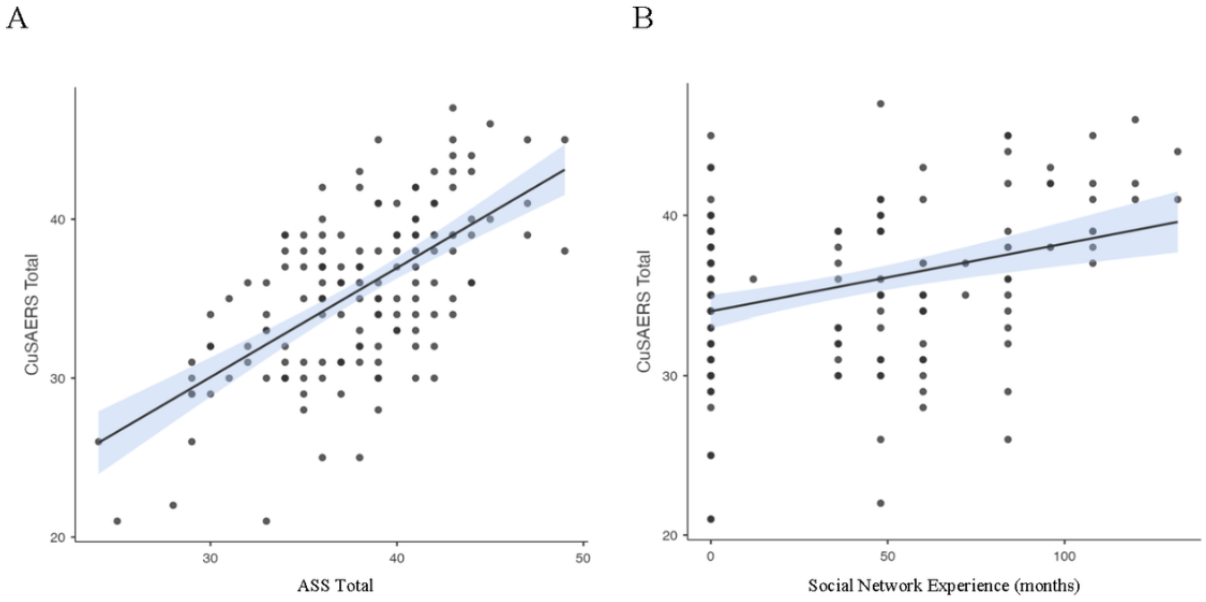
[d]*P*<.05.

[e]*P*<.001.

[f]*P*<.01.

On the other hand, prior experience with social media showed a weak positive correlation with the CuSAERS total score (ρ=0.27, *P*<.001), as well as with perception of learning (ρ=0.20; *P*<.01) and self-realization (ρ=0.23; *P*<.01). However, no significant correlations were observed with the task satisfaction subscale (ρ=0.14; *P*>.05). These results suggest that, although prior experience with social media has a positive relationship with overall perception and some specific aspects evaluated by the CuSAERS, its influence on dimensions such as motivation is limited (Figure 2).

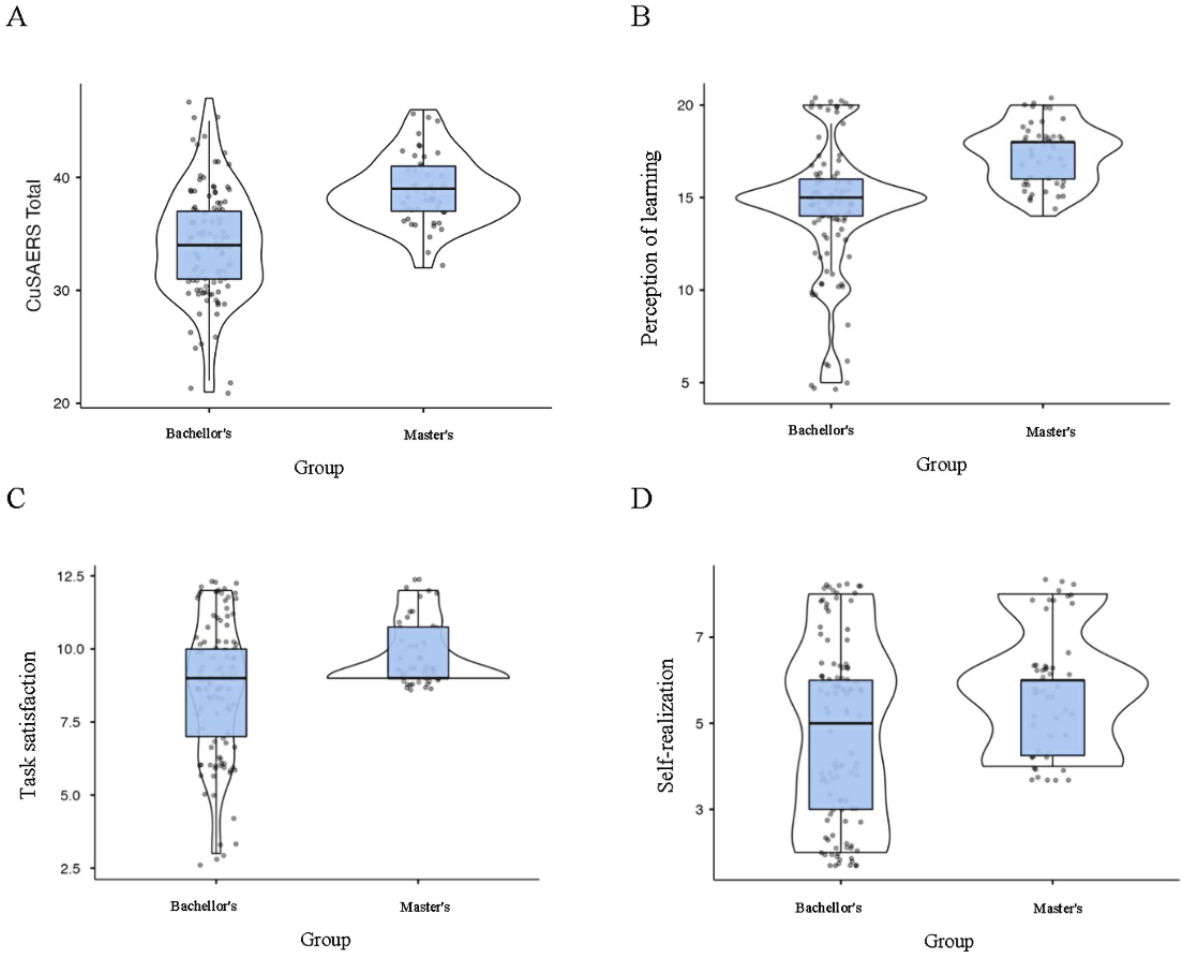
Figure 2. Correlations between the total CuSAERS (Questionnaire of Satisfaction With Educational Activities Performed on Social Media) score and external variables, showing (A) the relationship with Academic Satisfaction Scale (ASS) and (B) the relationship with experience with social media (measured in months).



Discriminant Validity

The discriminant validity of the CuSAERS was evaluated by comparing groups of students based on their academic level (bachelor's or master's). These comparisons were conducted using the nonparametric Mann-Whitney *U* test, and the effect size was calculated using rank-biserial correlation. The statistical results and graphical inspection through box and violin plots reveal clear differences between the 2 groups, supporting the CuSAERS's ability to discriminate between students with different educational levels (Figure 3).

Figure 3. Comparative box and violin plots between bachelor's and master's groups in the CuSAERS (Questionnaire of Satisfaction With Educational Activities Performed on Social Media) subscales and total score, showing (A) total CuSAERS scores, (B) the perception of learning subscale, (C) the task satisfaction subscale, and (D) comparison of the self-realization subscale.



For the total CuSAERS score (Figure 3A), master's students had significantly higher scores (U=1113; P<.001), with a median of 39 (IQR 37-41), compared with the bachelor's group, whose median was 34 (IQR 31-37). Box and violin plots showed greater dispersion in the bachelor's group, whereas scores for the master's group were more compact and centered on higher values.

The perception of learning subscale (Figure 3B) also showed significant differences (U=1064; r=0.613; P<.001), with higher scores and less dispersed distributions in the master's group (median 18, IQR 16-18). The plots reveal greater variability in the bachelor's group, with individual cases at considerably low levels.

For the task satisfaction (Figure 3C) and self-realization (Figure 3D) subscales, significant differences were found (U=2006; r=0.271; P=.005). For task satisfaction, the master's group showed higher scores with less dispersion (median 9, IQR 9-10.8), whereas for self-realization, the master's group's scores were also higher (median 6, IQR 4.25-6), in contrast to the greater dispersion and lower values observed in the bachelor's group (Table 6).

Table 6. Comparison of CuSAERS scores by academic level.

Variable	Bachelor's degree (physiotherapy; n=110)			Master's degree (physiotherapy; n=50)			Mann-Whitney *U* test	*P* value	Effect size
	Mean (SD)	Median (IQR)	SEM[a]	Mean (SD)	Median (IQR)	SEM			
CuSAERS Total	34.10 (4.96)	34 (31-37)	0.47	38.96 (3)	39 (37-41)	0.42	1113	<.001	0.595
Perception of learning	14.86 (3.46)	15 (14-16)	0.33	17.34 (1.62)	18 (16-18)	0.23	1064	<.001	0.613
Task satisfaction	8.62 (2.37)	9 (7-10)	0.22	9.78 (0.15)	9 (9-10.8)	0.15	2006	.005	0.271
Self-realization	4.81 (2.08)	5 (3-6)	0.19	5.80 (1.44)	6 (4.25-6)	0.20	2006	.005	0.271

[a]SEM: standard error of means.

The results also indicated differences between students with and without prior experience in social media. The group with experience obtained higher scores across all subscales and in the total CuSAERS score, although the differences were only significant for the total score (U=2514; r=0.2045; P=.03). For the perception of learning and self-realization, although statistical significance was not reached (P>.05), trends toward higher scores were observed in the group with experience (Table 7).

Table 7. Comparison of CuSAERS (Questionnaire of Satisfaction With Educational Activities Performed on Social Media) scores by participants' experience with social media.

Variable	Experience with social media (n=89)			No experience with social media (n=71)			Mann-Whitney *U* test	*P* value	Effect size
	Mean (SD)	Median (IQR)	SEM[a]	Mean (SD)	Median (IQR)	SEM			
CuSAERS Total	36.42 (4.96)	37 (33-39)	0.53	34.55 (4.77)	35 (31-38)	0.57	2514	.03	0.205
Perception of learning	15.65 (2.97)	15 (15-17)	0.31	14.85 (3.67)	15 (14-17.5)	0.44	2794	.20	0.116
Task satisfaction	9.06 (2.31)	9 (8-11)	0.25	8.89 (1.89)	9 (8-10)	0.22	2920	.40	0.076
Self-realization	5.35 (2.09)	6 (4-7)	0.22	4.83 (1.74)	4 (4-6)	0.21	2639	.07	0.165

[a]SEM: standard error of means.

Results for the motivation facet—considered at the content-validation stage but not retained by the final EFA—are provided in Table S3 in Multimedia Appendix 1 for completeness. These results suggest that familiarity with the use of social media might positively influence overall perceptions of educational activities, although its impact on specific subdimensions is more limited.

Discussion

Overview

The present findings support CuSAERS as a preliminary instrument for assessing student satisfaction in social media–mediated learning environments. In its 3-factor configuration—perception of learning, task satisfaction/environment, and self-realization—the scale shows acceptable reliability at the total-score level and coherent relations with external criteria, while some facets remain candidates for refinement. Construct validity, analyzed through EFA, supported a 3-factor solution that aligns with prior conceptualizations of satisfaction in digital educational settings [18,19] and with the multidimensional notion of academic satisfaction [30-32].

Among the 3 identified factors, perception of learning and self-realization showed the strongest relations with external criteria, consistent with previous findings highlighting the importance of acquiring new skills and the sense of achievement in digital learning experiences [5,7]. These components moderately correlated with the ASS, supporting the concurrent validity of the CuSAERS. In line with research linking satisfaction to performance and retention, students who perceived greater learning and personal growth also tended to report higher overall academic satisfaction [33,34]. Socioemotional elements and social support are key in online contexts; recent work shows that emotional support and effective communication through social media increase student satisfaction and motivation [35].

Psychometrically, internal consistency was acceptable overall. The perception of learning dimension exhibited the highest internal consistency, reflecting its stability. Although motivation emerged at the content-validation stage as a relevant facet, the present exploratory analyses did not retain a stable motivation factor. This facet remains a target for item redevelopment and confirmatory evaluation in future studies. Notably, recent studies suggest that visually rich platforms (eg, Instagram) can enhance motivation, whereas text-centric platforms (eg, X) may require higher digital literacy for comparable satisfaction [36,37]. These

considerations are congruent with standard scale-development practice, where less stable content is refined after initial validation [26].

Discriminant analyses revealed significant differences between bachelor's and master's students, with higher scores among the latter on most subscales. Explanations may include greater academic and professional experience and stronger self-management skills among master's students [3,23].

By contrast, bachelor's students engaged in an X-based debate on chronic pain, a context in which lower academic maturity and less experience with educational uses of social media may temper satisfaction [2,9,15,38-41]. Importantly, the bachelor group's scores were moderately positive, indicating overall acceptance of social media–based activities, while calling for replication in other health disciplines.

Regarding platform differences (X vs Instagram), platform use was not randomized and tasks differed in nature; therefore, any platform contrasts are descriptive and noncausal. Prior literature suggests that Instagram's audiovisual format may favor motivation and participation [8,42,43], whereas X is powerful for debate but may demand greater digital literacy [11,16].

The moderate correlation between CuSAERS scores and ASS scores further supports the instrument's concurrent validity, indicating that satisfaction with social media activities is related to overall academic satisfaction [27,28]. Prior experience with social media showed weak-to-moderate associations with satisfaction, suggesting that technological familiarity helps but does not solely determine satisfaction; interaction quality, content relevance, social presence, and the teacher's facilitating role also matter [13,14,19,21,36,44].

Taken together, the findings support CuSAERS as a preliminary instrument with acceptable reliability at the total-scale level and a provisional self-realization subscale. The scale can inform formative pedagogical reflections, whereas policy or high-stakes decisions should await confirmatory replication and measurement-invariance testing.

Limitations and Future Perspectives

This study used a nonprobabilistic, single-institution sample, which limits generalizability [45]. Future work should include larger, multisite samples spanning diverse programs and contexts [46,47]. Platform use was not randomized: students in the master's degree used Instagram and students in the bachelor's degree used X, and activities differed, so platform effects are confounded by academic level and task; future studies will randomize platform assignment or use within-subject counterbalanced designs with covariate-adjusted models.

Next steps will subject the 3-factor structure to CFA, test configural, metric, and scalar measurement invariance (degree level, gender, age), and conduct cross-validation in an independent, multi-institutional sample [48]. The motivation facet will undergo item redevelopment prior to confirmatory testing. Beyond psychometrics, it will be useful to relate CuSAERS to outcomes such as academic performance, motivation types, peer and teacher interaction, and participation in learning communities [49].

Conclusions

This study provides initial evidence that the CuSAERS is a promising, early-stage instrument for assessing student satisfaction with learning activities delivered over social media. In its 3-factor configuration—perception of learning, task satisfaction/environment, and self-realization—the scale showed acceptable reliability at the total-score level and coherent associations with an established academic satisfaction measure. Group contrasts by academic level were observed, but platform-related differences should be interpreted cautiously given the nonrandomized design.

CuSAERS should be regarded as an early-stage measure with promising properties. Its routine use will benefit from CFA, measurement-invariance testing, and multisite replication, alongside ongoing item refinement. Within the broader trend toward digitization in higher education, tools such as CuSAERS can inform formative pedagogical decisions and help tailor social media–based activities to student needs, while definitive applications should await confirmatory evidence.

Abstract

Background: Palestinian higher education institutions face limitations in providing interactive practical training for medical education. Extended reality (XR), which encompasses virtual reality and augmented reality, is increasingly recognized for addressing these challenges by offering immersive learning experiences.

Objective: This study investigates the factors influencing the acceptance and adoption of XR in health care education within Palestinian universities, exploring its potential to transform traditional teaching methods.

Methods: A qualitative approach was used in this study to collect data through semistructured interviews and artifacts from the participants. The participants of the study were 25 faculty members from 2 large Palestinian universities who teach in the field of medical sciences.

Results: Three primary categories—external, internal, and design-related factors—emerged as pivotal in influencing XR adoption. Professional development, technical support, and infrastructure were key external enablers. Internally, prior experience with digital tools and positive attitudes had a significant impact on the adoption of XR. Design factors, including ease of use and interactivity, played a crucial role but also posed challenges for less tech-savvy educators. Despite barriers such as cost and technical issues, XR demonstrated notable benefits, including enhanced learning outcomes, improved knowledge retention, and the ability to simulate complex medical scenarios.

Conclusions: XR technologies offer transformative potential for health care education in Palestine. By addressing challenges and leveraging XR's strengths, educational institutions can foster innovation and improve student engagement and skill acquisition. The study contributes to the theoretical understanding of technology acceptance in education by identifying the interplay of external, internal, and design factors. Practically, it emphasizes strategic investments in infrastructure, professional training, and institutional policies to optimize XR integration.

KEYWORDS

extended reality (XR); health care education; educational technology; Sustainable Development Goals (SDGs); Palestine

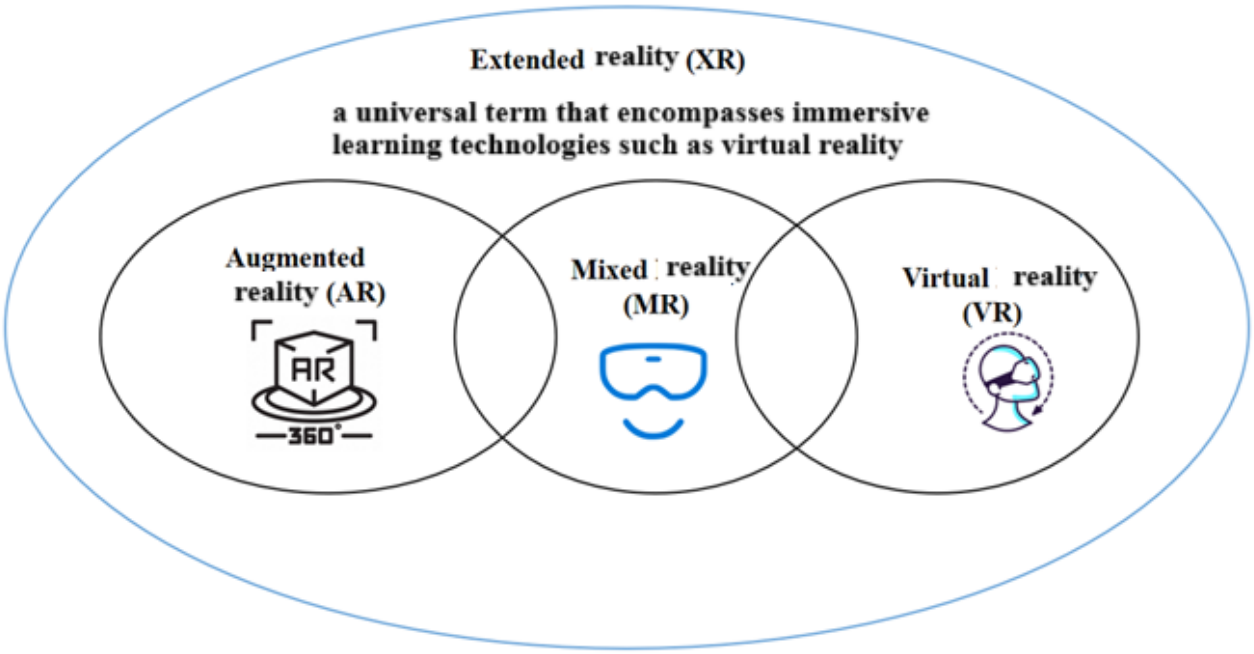
Introduction

Background

The integration of emerging technologies such as artificial intelligence and XR has significantly enhanced learners' engagement and interaction with educational environments [1]. XR, an umbrella term encompassing virtual reality (VR), augmented reality (AR), and mixed reality (MR), facilitates human-machine interaction through computer-generated content [2]. VR provides a fully immersive digital environment, AR overlays virtual objects onto real-world settings, and MR blends physical and digital elements into a seamless interactive

experience [2]. By incorporating visual, auditory, and interactive elements, XR enhances real-world learning by immersing students in digital environments that facilitate deeper engagement with educational content [3]. As shown in Figure 1, XR encompasses AR, MR, and VR, creating a spectrum of immersive experiences. Figure 1, developed by the authors, shows how XR encompasses AR, MR, and VR.

Figure 1. Illustration showing how extended reality (XR) encompasses augmented reality (AR), mixed reality (MR), and virtual reality (VR), as developed by the authors.



XR technologies are transforming medical education, particularly in resource-constrained settings, by providing cost-effective, risk-free learning environments. Head-mounted devices enable students to practice medical skills repeatedly without compromising patient safety. A review of 27 studies found XR-based training to be highly effective in surgery and anatomy, although more large-scale research is needed to fully assess its impact [4]. While some studies, such as Behmadi et al [5], found no statistically significant improvements in knowledge retention when comparing XR-based learning with traditional methods, they reported enhanced student engagement and satisfaction. This suggests that XR should be integrated alongside conventional teaching methods to cater to diverse learning styles and develop critical decision-making skills. Additionally, XR reduces dependence on costly medical equipment and provides students with virtual laboratories to conduct experiments, mitigating financial and logistical barriers [3,6]. By enabling hands-on practice in safe, controlled environments, XR improves learning accessibility and instructional quality [6].

In Palestinian higher education, XR adoption remains in its early stages, particularly in health care disciplines such as medicine and nursing. Its integration is closely tied to broader digital transformation policies, which aim to modernize educational practices and align with global trends in technology-enhanced learning. However, the transition faces barriers such as limited resources, inadequate infrastructure, and the need for faculty capacity-building. Despite these challenges, Palestinian universities are increasingly prioritizing XR within their strategic frameworks, reflecting a commitment to leveraging emerging technologies to enhance learning outcomes.

This study contributes to the growing research on XR adoption by examining Palestinian higher education institutions, a unique and underrepresented context. Unlike studies from technologically advanced regions, where XR adoption is often supported by substantial funding and infrastructure, this research highlights the policy-related, infrastructural, and faculty-specific challenges of implementing XR in resource-limited settings. While previous studies in Latin America and Southeast Asia have explored XR's role in medical education, they have often overlooked institutional policies, faculty readiness, and regional constraints. By addressing these factors, this study provides a comparative perspective on XR adoption in Palestinian universities and offers global insights into key determinants for sustainable technology integration in medical education.

Literature Review

The Unified Theory of Acceptance and Use of Technology Model in XR Adoption for Health Care Education

Overview

VR and AR are highly adaptable technologies that use various systems, setups, and content types, ranging from immersive and dynamic to nonimmersive and static environments. These technologies are characterized by 3 key elements: immersion, presence, and interaction [7,8]. Immersion depends on the

technological medium, such as head-mounted displays, concave or 3D projections, or interactive videos where users engage as protagonists. Presence and interaction, by contrast, relate to an individual's perception of connectedness within the virtual environment and their ability to act upon it and receive feedback [7,8]. These elements are crucial in defining the effectiveness and adoption of XR technologies, particularly in educational contexts such as health care training.

The Unified Theory of Acceptance and Use of Technology (UTAUT), developed by Venkatesh et al [9], serves as the theoretical framework for examining the adoption of XR in health care education. Over time, various theories and models have been proposed to understand the factors influencing the acceptance of new technologies. One of the foundational models in this field is the Technology Acceptance Model (TAM), developed by Davis [10] and based on the Theory of Reasoned Action. The TAM has been widely used to investigate the adoption of emerging technologies, including XR in surgical training, artificial intelligence adoption, and mobile learning [11-13]. However, the TAM has been critiqued for its limited predictive accuracy, as it fails to account for technology acceptance in nearly 40% of cases [14].

To address these limitations, Venkatesh et al [9] developed the UTAUT, which integrates multiple previous models, including the Theory of Reasoned Action, to provide a more comprehensive framework for understanding technology adoption. The UTAUT identifies 4 key constructs that shape an individual's intention to use, as well as their actual usage behavior of a new technology: Performance Expectancy, Effort Expectancy, Social Influence, and Facilitating Conditions.

Performance Expectancy

In the context of XR adoption in health care education, performance expectancy refers to the extent to which faculty members perceive XR as beneficial for both educators and students. XR facilitates immersive learning, enhances knowledge retention, and allows for realistic simulations of medical procedures without risks to patients. Faculty members recognize its potential to improve teaching effectiveness, help achieve learning objectives, and develop students' practical skills in a safe environment.

Effort Expectancy

Effort expectancy concerns the perceived ease of use of XR technology in teaching and learning environments. Faculty members' willingness to integrate XR depends on how intuitive and user-friendly the technology is. Instructors with prior experience using digital tools often find XR more accessible, while others may require training and technical support to overcome usability challenges.

Social Influence

The role of social influence in XR adoption is significant, as faculty members' decisions are shaped by the expectations of colleagues, mentors, and students. In this study, social influence extends beyond professional networks to include university policies, peer recommendations, and online technology communities that encourage XR integration.

Facilitating Conditions

The successful adoption of XR technology in health care education depends heavily on facilitating conditions, including institutional support, infrastructure, and technical assistance. Universities must provide adequate resources, professional development programs, and robust digital infrastructure to support faculty members' continued use of XR. Without sufficient technical support and access to XR-compatible hardware, faculty adoption may be hindered.

Virtual Reality in Health Care

VR technology has revolutionized health care education by offering immersive, interactive learning experiences. It creates realistic simulations that allow students to practice procedures and decision-making without risks [15]. For instance, the Stanford Virtual Heart Project uses VR to help students understand cardiac anatomy through 3D models. Furthermore, VR allows for detailed exploration of the human body, aiding in the comprehension of anatomical structures. The HoloAnatomy program at Case Western Reserve University uses Microsoft HoloLens for holographic dissections, enhancing anatomy learning and critical thinking [15].

VR provides simulation-based training for medical procedures, enhancing skills and confidence before actual patient care. Apps such as Surgical Theater aid in understanding and practicing surgical procedures [16]. VR also enables collaborative learning through merged MR and mixed XR platforms, enhancing teamwork and communication skills by combining the virtual and physical worlds [15]. VR makes learning more engaging and accessible by bringing medical simulations to remote or underresourced areas, ensuring that high-quality medical education is available to a broader audience [17].

XR Adoption in Education

Researchers have reported that XR is the future of learning and teaching in higher education institutions worldwide [6]. XR promotes teamwork through collaboration in VR environments [6]. Moreover, using XR in education transforms the learning process from traditional methods to active learning, where learners engage directly in learning activities [18]. In addition, XR enhances personalized learning by creating a customized learning environment tailored to the learner's needs and abilities [19]. Educators can design digital content to simulate immersive and interactive environments, making XR particularly suitable for teaching high-risk procedures, using expensive equipment, and conducting practical training activities that require additional resources, such as those in medicine or medical sciences [20].

Other studies have confirmed that using XR in learning fosters creativity, innovation, and design among learners [21,22]. Aguayo and Eames [23] reported that virtual agents in XR facilitated language learning and teaching by making complex knowledge more accessible. Moreover, these technologies offer immersive and interactive simulations that replicate complex real-world scenarios [24]. Consequently, using XR in education enhances the real-world experience by incorporating sounds, videos, and graphics into the learning environment, enabling learners to interact more effectively [3].

Benefits and Challenges

VR and AR offer numerous benefits over conventional therapy, including cost reduction, fewer hospital visits for immobile patients, user-friendly experiences, and improved patient safety. They also facilitate data collection in research settings and reduce surgical errors in training [25,26]. However, many studies indicate that determining the benefits of VR and AR in health care is challenging due to their small sample sizes, heterogeneous nature, and lack of proper controls. Pain relief mechanisms remain debated, and implementation is technically complex and expensive, with lower acceptance among older adults [7,27].

One of the main advantages of using XR is its ability to provide practical training without the need for expensive physical equipment [28]. For example, medical students can practice surgical procedures in a virtual environment, reducing the need for costly medical equipment and minimizing the risks associated with real-life practice on patients [29]. The implementation of virtual laboratories through XR not only makes education more accessible but also enhances the learning experience by offering hands-on practice in a safe and controlled environment [6].

Factors That Influence the Continued Intention to Use XR in Health Care Sciences

A previous study explored the potential of VR and AR technologies, particularly XR, in enhancing patient care, medical education, and presurgical planning [30]. It highlights the potential of integrating XR into medical education to provide immersive, interactive experiences.

Burian et al [31] highlighted that XR technologies provide more effective training compared with traditional methods, particularly for novices. Chuah [32] conducted a study involving 45 relevant studies to assess and analyze user acceptance of XR technology from multiple theories, disciplines, and perspectives. Wearable XR technology is influenced by various factors, including cost, technical and performance issues, hardware size, sensory inputs, content quality, cognitive impacts, user satisfaction, attitudes, intentions to visit tourism sites, expectation confirmation, personality traits, knowledge transfer, support needs, presence, boundary considerations, consumer characteristics, spatial awareness, control, participation, effectiveness, familiarity, innovativeness, value perceptions, decision comfort, spatial understanding, cognitive load, virtual embodiment perception, sense of presence, health and privacy concerns, and psychological and physical risks. Curran et al [33] stated that XR technologies offer portability, standardization, replicability, accessibility, and the ability to function without heavy manikin parts. They can be widely distributed without the need for a live instructor, thereby increasing learner engagement and enhancing spatial representation.

Kluge et al [34] noted that despite limited experience with XR technology, staff and students at the University of Newcastle view it as a standard tool for teaching. They aim to develop a sustainable implementation framework within 5 years. VR, AR, and MR technologies are disrupting medical education by offering immersive experiences and alleviating traditional learning constraints. XR technologies, particularly in emergency medicine, enable remote clinical skill development, even amidst the challenges posed by COVID-19 [33]. Li and Keskitalo [35] emphasized that XR technology is commonly used in health care education for safe treatments, communication, and decision-making. It supports 5 cognitive-processing dimensions: remembering, understanding, applying, analyzing, and evaluating. AR, VR, and MR can positively impact medical education. To effectively implement XR, it is important to consider existing resources and Bloom's taxonomy, and select the most suitable technology. Optimizing and expanding XR utilization are crucial for promoting deeper learning in health care. There is a significant gap in research regarding the factors influencing the continued use of XR in medical science, emphasizing the need for further studies in this area.

Methods

Study Design

We used a qualitative approach to explore faculty members' lived experiences with using XR in medical education at 2 Palestinian universities. This approach allows researchers to gain insights into the phenomena from practitioners who are using XR in teaching [36]. We gave participants the opportunity to share their experiences with using XR in their courses. The 2 universities involved are The Arab American University-Palestine and An-Najah National University. Both universities have established digital transformation centers focused on immersive technologies to enhance teaching and learning. The Arab American University-Palestine has developed a VR laboratory within its nursing and medicine departments, using cutting-edge technology to improve educational experiences. Similarly, An-Najah National University has created VR laboratories for its Departments of Dental Medicine and Medicine, along with a general XR center that serves both the university and the surrounding community. These laboratories provide training in XR technologies for faculty and students, supporting the integration of immersive tools into the curriculum.

Participants

This study involved 25 faculty members (18 males and 7 females) from diverse disciplines within medical sciences, representing 2 universities in the West Bank of Palestine. All participants had a minimum of 1 year of experience using XR in their teaching of undergraduate medical sciences courses, ensuring their expertise and relevance to the study's focus. Participants contributed by engaging in semistructured interviews and providing examples of their own work and that of their students. Table 1 presents the demographic characteristics of the participants, highlighting their diversity and alignment with the study's objectives.

Table 1. Demographic information about the participants in the study.

Variable and category	Frequency, n
Gender	
Male	18
Female	7
Education level	
Doctorate	19
Master's degree	6
Teaching experience	
5 years or less	5
6-10 years	12
11 years or more	8
Medical sciences field	
Nursing	7
Human medicine	8
Pharmacy	4
Dentistry	6

Recruitment of Participants and Justification of Sample Size

This study used purposive sampling, a qualitative method that selects participants based on predefined criteria relevant to the research objectives [37]. Faculty members, aligned with the study's focus on XR adoption in medical education, were recruited through official invitations sent by the deans of the 2 Palestinian universities.

Eligible participants were required to meet several inclusion criteria: at least one year of experience using XR in teaching, an academic position within the Faculty of Medical Sciences, and a minimum of 3 years of higher education teaching experience. Their expertise was further validated through prior research or publications on XR, active involvement in curriculum development, and proficiency with XR tools, demonstrated through certifications, training, or workshops. Additionally, student evaluations and feedback on XR-based teaching were considered.

To enhance transferability, the study included faculty from the fields of nursing, human medicine, pharmacy, and dentistry, ensuring representation across disciplines with varying levels of reliance on XR-based learning. Participants ranged from early-career faculty with 5 or fewer years of teaching experience to senior faculty with over 10 years, providing a range of professional perspectives. The sample also encompassed both experienced and novice XR users, drawn from universities at different stages of XR adoption—one with an established XR laboratory and structured training programs, and the other in an early adoption phase—offering a comprehensive view of institutional challenges and implementation strategies.

The sample size of 25 faculty members was determined based on data saturation, a key principle in qualitative research. Saturation is reached when further data collection no longer generates new themes or insights [38]. In this study, saturation was achieved by the 22nd interview, as recurring patterns related to institutional barriers, faculty perceptions, and XR adoption challenges emerged. The remaining interviews were conducted to reinforce the robustness of these themes. Prior research [9,36] on technology adoption in higher education suggests that qualitative studies with 15-30 participants provide sufficient depth to capture rich, context-specific insights. Given the exploratory nature of this study, the selected sample size was deemed appropriate for gathering in-depth faculty perspectives on XR integration in medical education.

We acknowledge that the small sample size may limit the generalizability of the findings. However, this study was designed to explore educators' lived experiences and provide deep insights into XR adoption in medical education, rather than aiming for broad generalizability. The qualitative methodology, supported by data triangulation through interviews and artifacts, enhances the trustworthiness and validity of the findings despite the limited sample size. To mitigate this limitation, participants were purposively selected from diverse medical disciplines and institutions to ensure a variety of perspectives. Rigorous thematic analysis techniques were used, validated by multiple coders with high interrater reliability. Additionally, the findings were cross-referenced with existing literature to contextualize and strengthen the conclusions.

While future studies with larger samples are necessary to further validate these findings, this study provides valuable foundational insights into XR adoption in medical education. These findings can serve as a reference for similar educational contexts, aiding institutions and educators in navigating the complexities of XR implementation.

Study Context

The context of this study involved faculty members from the Faculty of Healthcare Sciences at 2 major universities in the West Bank of Palestine. Both universities have a clear vision and policy to integrate emerging technologies, such as XR, into medical education and research. To facilitate the adoption of XR in teaching, 4 training workshops were organized at each university to equip faculty members with the knowledge and skills necessary to understand and apply XR in their practices. The length of each training session varied depending on the topic, generally ranging from 2 to 7 days. These sessions provided teachers with the opportunity to create and develop learning objects using XR. Various topics were covered, including an introduction to VR, AR, and XR; designing lessons using objects on the platform; and creating avatars for lessons, among others.

Research Instrument

A semistructured interview was the primary research instrument for data collection. We developed an interview protocol to guide the process. The protocol (Multimedia Appendix 1) consisted of 2 sections. The first section introduced the study to the participants and confirmed the confidentiality of their responses. Participants were informed that the interview would be recorded, provided they agreed, and that they could withdraw at any time. They were also asked to sign a consent form before the interview was recorded. The second section contained interview questions developed from a literature review, aligned with the research questions. Another data source consisted of artifacts provided by the participants during the interviews or submitted via email, illustrating how XR was used in medical education.

Data Collection

The researchers sent invitations to the nominated participants to schedule semistructured interviews at their convenience. Participants were given the flexibility to choose the time and location of the interviews. Each interview, lasting 30-45 minutes, was conducted individually and recorded. The interview protocol began by asking participants to discuss their general experiences with technology, followed by specific inquiries about their experiences with XR, allowing them to share their stories and journeys. Follow-up questions were asked to delve deeper into their experiences, especially regarding student collaboration on projects. For example, when one participant mentioned that students learn more through exploration, a follow-up question was, “Can you provide more details about what exploring entails and the role of XR in facilitating that exploration?” The interviews were designed to capture as much detailed information as possible from the participants’ experiences. In addition to the interviews, participants provided various artifacts, including samples of student work and activities implemented using XR. These artifacts served as valuable secondary data sources.

Trustworthiness

To ensure trustworthiness and methodological rigor, this study followed established qualitative research principles, emphasizing credibility, confirmability, dependability, and transferability. Credibility was enhanced through the use of multiple data collection methods, including semistructured interviews, participant-submitted artifacts, and institutional policy documents. Member checking was conducted by sharing transcribed interviews and preliminary themes with participants, enabling them to verify the accuracy of interpretations and provide clarifications where necessary. Additionally, peer debriefing was used, where external researchers reviewed the coding process and emerging themes to refine definitions, minimize bias, and ensure analytical coherence.

Conformability was maintained by carefully documenting the research process and prioritizing participants’ statements to minimize researcher bias. The interview protocol was developed based on the research questions, a pilot study, and expert reviews, ensuring its relevance and alignment with the study’s objectives. Dependability was reinforced through rigorous coding procedures, with data being independently coded 3 times, achieving 92% interrater reliability. This process ensured consistency in theme identification and analysis. Transferability was supported by purposive sampling, which selected participants from diverse academic disciplines and career stages to capture a broad range of perspectives on XR adoption. Additionally, data triangulation—incorporating interviews, observational notes, and artifacts from faculty members—provided a comprehensive understanding of the factors influencing XR integration in medical education. By incorporating these robust qualitative validation strategies, the study strengthens its credibility, validity, and applicability, ensuring that the findings accurately reflect participants’ experiences while addressing potential biases in sample selection and data interpretation.

Ethical Considerations

This research was approved by the institutional review board committee at An-Najah National University under reference Med. April.2024/18. The study adhered to strict ethical guidelines to ensure participant confidentiality, informed consent, and data protection. Before participation, all participants were provided with detailed information about the study’s objectives, procedures, and their rights as participants. Participants were explicitly informed that their participation was entirely voluntary, and they could withdraw from the study at any time without facing any consequences or needing to provide an explanation. To document consent, participants signed an informed consent form that outlined the scope of the study, the types of data to be collected, and how the data would be used solely for research purposes. The consent form also detailed the measures taken to protect their identities and ensure the confidentiality of their responses.

In terms of data protection, stringent protocols were followed to safeguard participant information. Personal data, including contact details, were securely stored on a password-protected and encrypted computer. Both physical and digital access to these data was restricted to authorized researchers only. Furthermore, any identifying information was anonymized during the data analysis process to further protect participants’ privacy. Interview data were stored in encrypted files, and backup copies were securely maintained to prevent data loss.

Additionally, the researchers communicated the steps taken to comply with ethical research standards, including adherence to the principles outlined by Ngozwana [39]. These procedures ensured that participants felt confident their contributions were protected and respected throughout the research process. By incorporating these comprehensive protocols, the study's transparency and ethical rigor were enhanced.

Data Analysis

To address the research questions, inductive thematic analysis was used, following the 6-step methodology proposed by Braun and Clarke [38]. The research process involved conducting 10.5 hours of recorded interviews. Before data analysis, the researchers transcribed the audio recordings and shared the text files with participants for validation. Participants were given the opportunity to amend, rewrite, or supplement the content as needed. Once the files were returned, no further modifications were expected. The thematic analysis was carried out in 6 phases, as outlined by Braun and Clarke [38], and these phases guided the data analysis process in this study.

The researchers began their analysis by organizing the individual transcript files, labeling them as F1, F2, and so on up to F25. The initial phase involved familiarizing themselves with the data. The researchers, who had conducted the interviews, carefully read through each transcript while simultaneously listening to the corresponding audio files. This process of immersion allowed the researchers to take detailed notes in the margins of the transcripts, ensuring a thorough understanding of the data. In the second phase, coding, the researchers developed labels for significant features of the data that were relevant to the research questions. As they meticulously read through the transcripts line-by-line, they created a coding book to document these labels. This phase focused on identifying key concepts or ideas that were central to the research, such as how faculty members experience XR in teaching medical concepts and in transferring medical knowledge and skills to their students. Next, the researchers moved to the theme development phase, where they identified patterns related to the research questions. They grouped similar and contrasting codes into coherent themes, resulting in a structured coding book (Table 2 and Multimedia Appendix 2). In the fourth phase, reviewing themes, the researchers examined these themes across all data, using inductive analysis to refine and combine them as needed. This iterative process of theme development was essential for generating meaningful insights from the data.

The fifth phase involved defining and naming themes based on the research questions, literature review, and theoretical framework. This phase integrated both inductive and deductive approaches, which are common in qualitative data analysis. Finally, in the reporting phase, the researchers documented and presented the analysis results, supporting the findings with direct quotations from the participants' interviews. This approach helped provide concrete evidence and context for the identified themes.

The data analysis process began with a thorough review of each transcript to familiarize the researchers with the material. During this phase, ideas and concepts were identified as units of analysis, and a coding process was developed. A coding book was created to assist with data coding. Ideas and concepts sharing similar characteristics were organized into emerging subthemes, which were then grouped under primary themes, informed by prior research findings. The research questions guided the analysis process. Table 2 illustrates the inductive thematic analysis approach used to develop the coding book for each research question.

Table 2. An overview of the themes and data sources (interviews and artifacts).

Major themes and sub-themes	Findings from interviews	Findings from artifacts
External Factors		
Professional Development	Faculty attended training sessions on XR[a], viewed as beneficial for skill-building and knowledge sharing.	Training materials and lesson plans demonstrated faculty engagement with XR-based teaching.
Technical Support	Faculty emphasized the need for technical support, linking it to continued XR use.	Technical support records showed assistance provided for troubleshooting XR-related issues.
Infrastructure	Challenges related to limited XR devices, weak Wi-Fi, and lack of educational resources.	Limited XR-enabled classrooms and laboratories were documented in institutional reports.
Social Influence	Positive influence from colleagues, social media, and university policies encouraged XR adoption.	Shared lesson plans and peer-reviewed materials indicated knowledge exchange among faculty.
XR Features		
Ease of Use	Some faculty found XR easy to use, while others struggled with the complexity of designing activities.	User guides and simplified XR tools were developed to address faculty concerns about complexity.
Interactivity	Interactivity was valued for facilitating learning objectives and engagement.	Lesson artifacts included interactive 3D models and gamified simulations.
Imagination and Immersion	Imagination linked to visualization capabilities, enhancing the learning experience.	Students' assignments showed creative applications of XR for visualization.
Internal Factors		
Previous Experience With ICTs[b]	Prior experience with ICTs contributed to smoother XR adoption.	Faculty-created resources mirrored existing ICT teaching practices, aiding XR integration.
Digital Competencies	Digital literacy skills were essential for the effective use of XR in teaching.	Assessment rubrics reflected the need for digital competencies in grading XR-based tasks.
Attitudes Toward XR	Most faculty had positive attitudes, seeing XR as engaging; a minority found it too complex.	Students' reflections indicated excitement about XR use; some reported difficulty in self-directed learning.
Design Factors		
Design Challenges	Time constraints and lack of technical expertise made designing XR activities difficult.	Course syllabi showed attempts to integrate XR but highlighted gaps in structured activity design.

[a]XR: extended reality.

[b]ICT: information and communication technology.

Results

Key Factors

Participants identified key factors based on their experiences with XR in health care education. Faculty workload and responsibility were recognized as significant factors influencing the integration of XR into teaching practices. Additionally, experience with medical technology was found to be linked to the use of XR. Data analysis revealed various influencing factors, which were grouped into 3 categories: internal factors, design factors, and external factors, which include XR features (Table 2). Each category encompasses several specific factors, as detailed in the following sections. Table 2 provides an overview of the themes and data sources.

External Factors

Institutional Drivers of XR Adoption in Teaching

External factors related to higher education institution policies and readiness, such as professional development, technical support, infrastructure, social influence, and XR features, were identified as factors that could positively influence the acceptance and continued use of XR in teaching practices.

Professional Development

All participants confirmed their attendance at training sessions on using XR in their teaching. These sessions covered a range of topics, from recognizing the value of XR as an advanced technology to creating lessons and activities using existing platform assets. For example, one faculty member mentioned, "The training was helpful in various aspects, such as understanding the value of XR and learning how to use it in my class activities" [D1]. Additionally, some faculty members viewed the training sessions as opportunities to share their knowledge and receive feedback, enhancing their practices in medical education. One participant noted, "I shared the activities I designed from scratch to get feedback from my colleagues. It was a good chance to share experiences and learn from others" [P5].

Integrating VR into medical education, particularly in fields such as nursing, offers students the chance to learn in authentic, immersive environments and practice practical tasks through simulations. However, some participants raised concerns that

VR might not substantially enhance student learning, as they believed students could already visualize real-life situations without the need for VR. This underscores the importance of professional development programs in equipping educators with the strategies needed to design VR experiences that extend beyond imagination, offering unique, hands-on, and interactive learning opportunities that traditional methods cannot replicate.

Technical Support

Most participants emphasized the importance of technical support in ensuring the continued use of XR, as it helps minimize technical difficulties faced by faculty members in medical sciences. Technical support encompassed a range of services, from creating platform accounts to troubleshooting issues with platform assets and student access. One faculty member stated, "Technical support is essential to continue using XR as it's a new technology, and I had no previous experience with it" [D25]. Some faculty members associated the availability of technical support with saving time and being able to focus more on the quality of activities and assessments. However, a few reported a lack of technical support due to insufficient staffing at the XR center. Providing technical support also positively impacted students' timely completion of assignments and tasks using XR.

Infrastructure

Infrastructure plays a crucial role in the use and continued adoption of XR in medical education. Participants defined infrastructure in terms of the availability of suitable VR devices, strong Wi-Fi, and educational resources. One faculty member mentioned, "I confront challenges to find assets related to Nursing relevant to my teaching topic" [D24]. A few participants cited the lack of infrastructure as a significant challenge. For instance, one faculty member said, "I have 45 students in Human Medicine, and it's difficult to take them all to the computer lab to use the VR devices because there is only one device" [D5].

One of the novel findings of this study is its emphasis on the intersection of institutional policies, faculty readiness, and infrastructural limitations in shaping XR adoption in medical education. While faculty members acknowledged the pedagogical benefits of XR, they also highlighted significant challenges related to institutional support and funding constraints. Unlike institutions in high-income regions, where government and private sector investments facilitate the widespread adoption of XR, Palestinian universities rely primarily on limited internal budgets and external grants. Consequently, the lack of funding for VR-compatible hardware, insufficient training opportunities for faculty, and inadequate technical support staff emerged as critical barriers to adoption. This study underscores the importance of targeted policy interventions, including faculty incentives, resource-sharing initiatives, and digital transformation strategies, to address these systemic barriers and promote sustainable XR integration.

Social Influence

Positive Influence of Colleagues

When asked about the impact of colleagues on their use of XR, most participants reported a positive influence from both within and outside the university. This influence included sharing expertise, providing technical and instructional support, and exchanging lessons and learning objects on the XR platform. One participant stated, "It was challenging to design lessons using the XR platform, so I asked a colleague for help" [D20].

The Power of Social Media

Some participants reported being members of social media groups focused on advanced technology in engineering, such as Twitter groups. These communities helped them exchange ideas about designing VR activities and share lessons using 3D and 360-degree techniques. One participant shared a lesson about the human body on Facebook and received feedback to improve the lesson using advanced VR features. Another participant said, "I share my lessons and activities in the group and exchange ideas on using XR in teaching various topics" [D6].

XR Features

Impact of XR Features on Adoption in Medical Education

The XR features reported by the majority of participants included ease of use, imagination, interaction, and immersion, all of which could influence the use of XR in medical education.

Ease of Use

Most participants highlighted the importance of XR's ease of use in lesson activities and content presentation. Some linked the simplicity of designing activities and lessons on the platform to their intention to continue using it. One faculty member stated, "I liked using XR because it was easy to design activities to show hidden parts of the human body" [D4]. However, a few participants found XR complicated and challenging for designing lesson activities, which led them to stop using it, although they continued assigning XR-related tasks to students.

Interaction Feature

Many participants emphasized the role of interactive features in facilitating and achieving lesson objectives. One participant said, "interactivity is important for me and my students because it enables activities that are otherwise impossible" [D11]. They also highlighted the importance of designing interaction types between students and learning activities, as well as interactions among students.

Imagination and Immersion

All participants confirmed the significance of imagination in medical sciences education, which could lead to greater immersion in class activities. One faculty member reported, "My students used XR to virtually perform a surgery" [D3]. Many participants linked imagination to visualization features that attract faculty members to use XR in assignments and activities.

Internal Factors

Role of Digital Competencies and Experience in XR Adoption

Internal factors included previous experience with information and communication technologies and digital competencies.

Previous Experience With Information and Communication Technologies

The majority of respondents indicated that previous experience with information and communication technologies and mobile technology was crucial for accepting and using XR in medical education. Experience with smartphones also facilitated their use of mobile VR for course instruction and activities.

Digital Competencies

In this study, digital competencies refer to the knowledge, skills, and attitudes related to XR. Most interviewees reported that their digital competencies were crucial for continuing to use XR. One faculty member stated, "My experience and knowledge are important for using XR in medical education." [D9].

Design Factors

Design factors refer specifically to the pedagogical and instructional aspects of XR integration, particularly in creating activities, materials, and assessments in health care. This process often requires the application of instructional design principles. Most participants indicated that their primary difficulty was designing course-related activities. Many felt they lacked the technological expertise required, and some reported insufficient time due to commitments at private hospitals and clinics.

Attitudes Toward Using XR in Medical Education

Positive Attitudes

Many participants expressed positive attitudes toward using XR in medical education, attributing these attitudes to features such as interaction, visualization, and immersion. Some mentioned that the simplicity of XR saved both time and effort. For instance, one faculty member noted, "My students were excited to use XR." [D4].

Negative Attitudes

A minority of participants, fewer than one-third, reported obstacles that negatively influenced their attitudes toward using XR. These challenges were related to the complexity of XR usage.

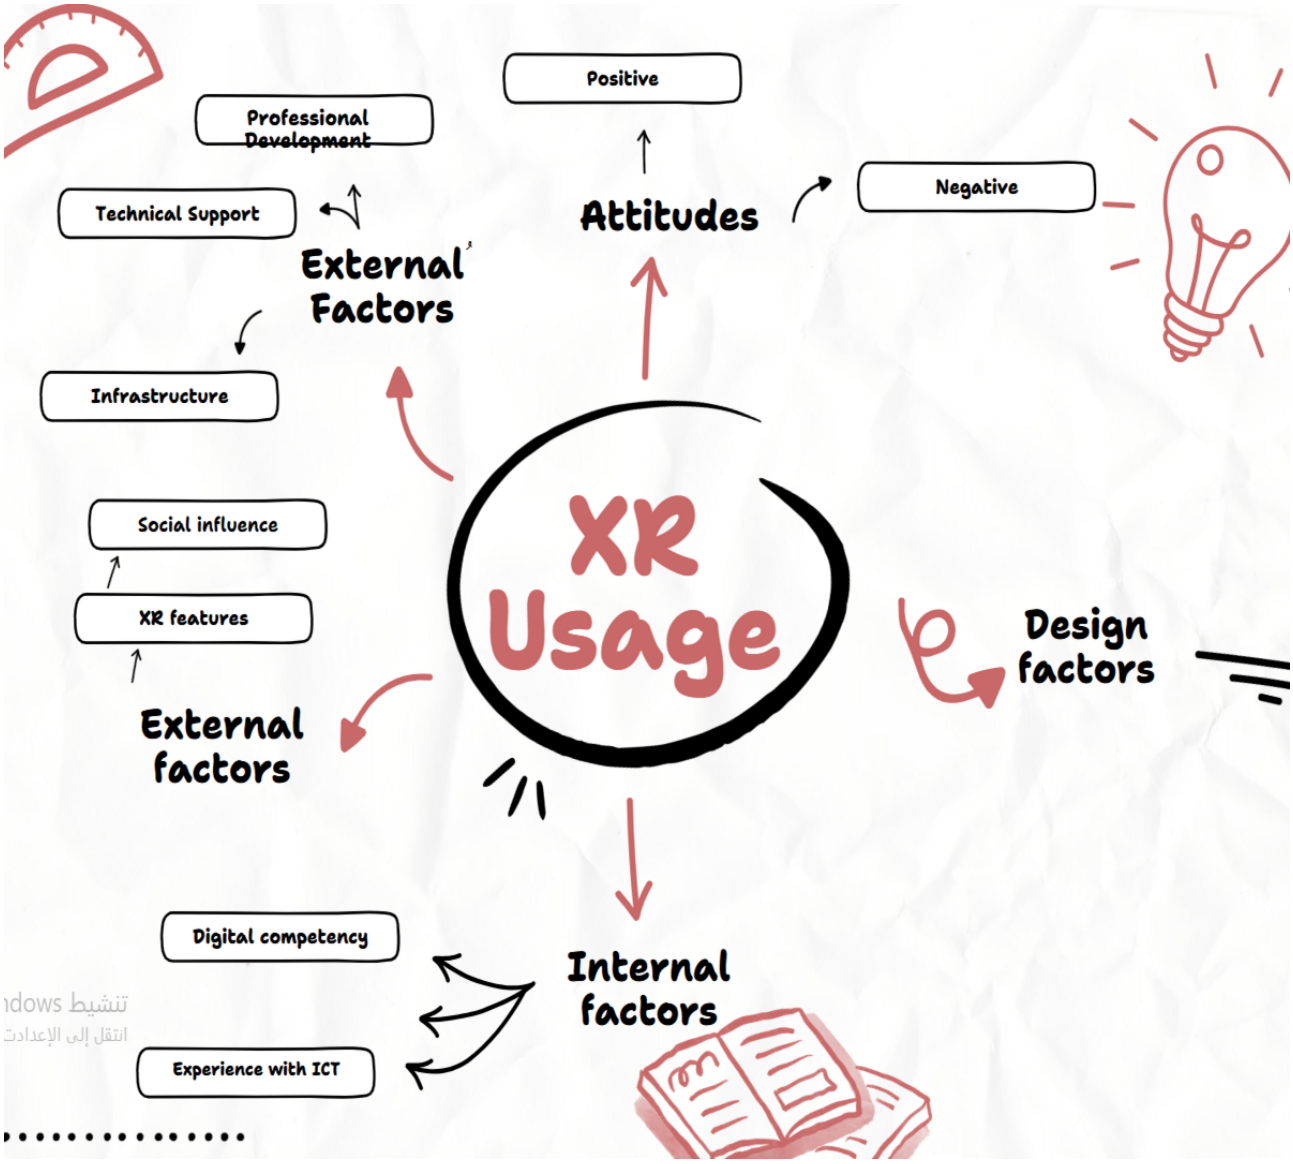
Socioeconomic Factors and XR Adoption

Socioeconomic factors significantly influence XR adoption in Palestinian higher education, particularly in infrastructure investment, faculty training, and institutional support. The high costs of XR hardware, software, and maintenance, coupled with limited government funding and restricted access to grants, present a major challenge. Many universities struggle to scale XR beyond pilot initiatives, limiting widespread faculty adoption. A key barrier is faculty training and professional development. While some institutions offer workshops, many educators lack consistent training and technical support, resulting in uneven adoption across disciplines. Comparisons with developing regions, such as Latin America and Southeast Asia, reveal similar constraints, while well-funded institutions in South Korea and Germany address these challenges through government investment, faculty incentives, and public-private partnerships.

To bridge this digital divide, Palestinian universities must increase funding, establish training programs, and explore resource-sharing models across institutions. Addressing these socioeconomic barriers will ensure sustainable XR integration, enabling faculty to effectively utilize immersive technologies in medical education. Future research should explore scalable funding models and institutional collaborations to support long-term XR adoption. In conclusion, we visualize the factors influencing faculty members' use of XR in medical education.

Figure 2 visualizes the factors influencing faculty members' use of XR in medical education.

Figure 2. Visualization of the factors influencing faculty members to use extended reality (XR) in medical education.



Discussion

Principal Findings

The findings of this study highlight the complex factors influencing XR adoption in medical education, categorized into external, internal, and design-related elements. Professional development emerged as a key enabler, with faculty members who participated in XR training reporting increased confidence and capability in integrating the technology into their teaching. These sessions provided both technical knowledge and collaborative learning environments, aligning with prior research emphasizing the role of continuous professional development in technology adoption [40]. However, technical support and infrastructure remain critical challenges. While access to reliable support enhances faculty engagement with XR, inconsistent availability of assistance and limited institutional investment in technical staff hinder seamless integration. Similarly, infrastructure gaps—such as limited access to XR devices, inadequate internet connectivity, and insufficient educational resources—remain substantial barriers, especially in resource-constrained settings [41]. These findings align with studies in other developing regions, where high costs and inadequate infrastructure are primary obstacles to XR adoption [42].

Although this study applies the UTAUT model to analyze XR adoption, the findings suggest that policy and institutional support are crucial facilitating conditions not explicitly accounted for in the framework. Additionally, socioeconomic constraints, including funding limitations and digital infrastructure challenges, significantly influence adoption behaviors [43]. To extend the theoretical framework, we propose a modified model that integrates 2 additional dimensions: Pedagogical Readiness, encompassing faculty training, instructional design capabilities, and institutional encouragement for XR use, and Technical and Logistical Support, emphasizing the role of digital infrastructure, maintenance, and technical assistance. These modifications offer a more contextualized perspective on XR adoption in developing regions, reinforcing the need for localized implementation strategies [44].

The role of social influence in XR adoption extends beyond institutional policies and peer encouragement. This study found

that faculty skepticism, generational differences in adoption, and student perceptions significantly influence XR use. While peer influence and institutional endorsement encourage adoption, some senior faculty members expressed skepticism about XR, fearing that it might disrupt traditional pedagogical methods rather than complement them. These concerns align with prior research on faculty resistance to emerging technologies [32]. By contrast, younger faculty members demonstrated greater openness, reflecting trends observed in broader educational technology adoption studies [30]. Additionally, students' positive engagement with XR significantly influenced faculty willingness to integrate the technology, reinforcing prior findings that student enthusiasm can drive faculty adoption [33]. However, some educators expressed concerns that XR might encourage passive rather than active learning, highlighting the need for interactive and problem-solving–oriented XR applications to maximize its educational impact [33].

To overcome financial barriers to XR adoption in Palestinian universities, alternative and sustainable funding models are essential. While current efforts often rely on short-term external grants, more resilient approaches—such as public-private partnerships, collaborations with technology firms, and the use of open-source XR platforms—could help support long-term implementation and scalability [45]. Although the return on investment in XR may not be immediately measurable in financial terms, it can be demonstrated through improvements in student performance, engagement, and retention. These outcomes contribute to institutional sustainability by reducing dropout rates and enhancing overall learning effectiveness [41].

Lastly, design-related challenges, particularly the complexity of XR tools and time constraints for faculty, emerged as barriers to effective integration. While many faculty members appreciated the interactive and immersive capabilities of XR, others found content creation and instructional design challenging, highlighting the need for user-friendly design tools and targeted training [46]. Digital competencies were also found to be a critical factor, with faculty members possessing stronger digital skills demonstrating greater ease in XR adoption. This underscores the importance of developing digital literacy as a core competency in medical education [47].

Overall, this study emphasizes the need for a holistic approach to XR adoption, integrating technical, economic, and pedagogical strategies. In comparison to universities in Latin America and Southeast Asia, where national digital education strategies and structured funding initiatives have facilitated XR adoption, Palestinian institutions require policy-driven interventions and regional partnerships to develop scalable, sustainable funding models [48]. Addressing these economic and infrastructural constraints will be essential to ensure that XR can be effectively integrated into medical education in underresourced contexts.

Theoretical and Practical Implications

The study on integrating XR in Palestinian health care education highlights key theoretical and practical implications. Theoretically, it advances technology acceptance models by identifying factors influencing XR adoption, including institutional policies, social influences, digital competencies, and attitudes. It also emphasizes the need for robust infrastructure and professional development to support technology integration.

Practically, effectively implementing XR in medical education requires a well-structured, phased approach to fully realize its transformative potential. The first priority for institutions should be establishing robust foundational infrastructure, including high-quality hardware and software solutions that are scalable and adaptable to evolving needs. This requires substantial initial investments, not only in technology but also in developing technical support systems to address challenges such as high costs, operational complexities, and the demands of maintaining cutting-edge solutions. Along with infrastructure development, it is essential to provide comprehensive training for educators and students, focusing on the digital literacy skills needed to use XR effectively. Clear guidelines should also be developed to ensure consistent, meaningful integration of XR into the curriculum.

Higher education institutions should also consider designing and adopting performance indicators specifically tailored to measure the success and impact of XR implementation. These indicators could include metrics such as student engagement levels, improvements in skill acquisition, and the cost-effectiveness of XR solutions. By establishing these benchmarks, institutions can monitor progress and identify areas for improvement, ensuring a data-driven approach to XR adoption.

Early adoption strategies should emphasize piloting risk-free, immersive simulations that allow educators and students to explore XR's capabilities in a controlled environment. These pilot programs serve to demonstrate the tangible value of XR, helping to build confidence among stakeholders and secure their buy-in for broader implementation. However, institutions should be cautious of potential pitfalls. For instance, underestimating the need for ongoing technical support can lead to system failures and diminished user satisfaction. Similarly, neglecting to align XR initiatives with specific, well-defined learning outcomes can result in unfocused or ineffective use of the technology. Finally, failing to allocate adequate resources for regular maintenance and updates may jeopardize the long-term sustainability of XR programs.

Addressing Technical and Economic Barriers to XR Adoption

Sustainable integration of XR in medical education requires a strategic focus on viable funding models, cost-effectiveness, and long-term impact. In resource-constrained settings, such as Palestinian universities, advancing XR implementation depends less on reiterating existing challenges and more on identifying innovative, context-sensitive solutions. Strategic partnerships—with private technology firms, medical institutions, and international funding bodies—can facilitate access to sponsored XR hardware, software, and training. These collaborations support the co-development of immersive learning programs and enable cost-sharing arrangements that reduce the financial burden on institutions.

Adopting open-source XR platforms also presents a promising avenue for sustainable integration. These tools offer flexibility in content creation and deployment without the high costs associated with proprietary systems, making them particularly suitable for universities with limited budgets. Beyond initial implementation, institutions must assess XR's return on investment through educational outcomes rather than direct financial metrics. Improvements in student engagement, knowledge retention, and academic performance are strong indicators of XR's value and can contribute to institutional sustainability by reducing dropout rates and enhancing graduate readiness.

To ensure scalability and impact, universities should adopt data-informed strategies, including cost-benefit analyses, pilot programs, and scalable deployment models. Aligning financial planning with pedagogical goals ensures that XR technologies are integrated not only as innovative teaching tools but also as sustainable investments in the future of medical education. A methodical, forward-looking approach enables institutions to transform economic limitations into opportunities for creative problem-solving and long-term growth.

Limitations

The study acknowledges several limitations. First, the research was conducted during the initial stages of XR adoption in Palestinian higher education, which may limit the generalizability of the findings. The small sample size and the focus on specific institutions further constrain the applicability of the results to other contexts. Additionally, the high upfront costs and technical challenges associated with XR technologies may pose barriers that were not fully explored due to the limited scope of the study. Finally, the study relies on self-reported data from participants, which could introduce bias or inaccuracies in the findings.

Future Research

Future research should focus on scaling the study to larger populations across multiple universities to provide a more comprehensive understanding of XR's applicability and effectiveness in diverse educational contexts. Expanding research across different institutions, disciplines, and settings will offer broader insights into how XR can be integrated into various pedagogical frameworks.

Additionally, longitudinal studies are essential to track XR adoption over time. These studies would assess the long-term impact of XR on educational outcomes, skill retention, learner engagement, instructor effectiveness, and curriculum integration. Examining how faculty and students interact with XR technologies over extended periods will help identify patterns of adoption, sustained challenges, and evolving best practices. This approach will also contribute to understanding the long-term sustainability of XR implementation in higher education.

Further research should also investigate the technical and pedagogical challenges associated with XR adoption. Identifying these challenges could lead to detailed, actionable guidelines that institutions can use to optimize XR deployment strategies. Beyond health care education, exploring XR's potential in fields such as engineering, humanities, and business would provide insights into its broader applicability. Moreover, examining how XR interacts with emerging technologies such as artificial intelligence, machine learning, and data analytics may reveal innovative ways to enhance teaching and learning experiences.

Another critical area for future research is the development of performance indicators to measure the success of XR adoption. These indicators should assess learning outcomes, user satisfaction, cost-effectiveness, and scalability, providing institutions with data-driven benchmarks to evaluate and refine their XR initiatives.

Finally, addressing the digital divide in XR adoption is crucial, particularly in developing regions. Investigating how educational institutions can ensure equitable access to XR technologies for students from varied socioeconomic backgrounds will help create inclusive and accessible learning environments. This research will be instrumental in bridging technological disparities and promoting digital equity in higher education.

Conclusion

XR technologies have the potential to revolutionize health care education by providing immersive learning experiences that enhance practical skills and knowledge retention. This study highlights several key factors for the successful adoption of XR in medical education, including professional development, adequate infrastructure, robust technical support, positive social influence, and user-friendly design. Strategic investments in these areas are vital to overcoming initial barriers and aligning XR adoption with the Sustainable Development Goals of quality education and good health. By addressing these complex factors, educational institutions can create an environment conducive to the successful integration of XR technology, ultimately improving teaching practices and student learning outcomes in medical and nursing programs, particularly in Palestine.

The findings of this study emphasize that successful XR adoption in medical education requires more than just technological availability—it demands strong institutional policies, sustained funding mechanisms, and structured faculty development programs. Higher education institutions must move beyond pilot initiatives and develop long-term strategies for integrating XR into curricula, supported by clear guidelines, resource-sharing models, and institutional incentives. Additionally, regional collaborations among universities in developing contexts could facilitate knowledge exchange and infrastructure sharing, reducing the financial burden on individual institutions. Future research should further explore **scalable policy interventions** that enable sustainable XR adoption, particularly in resource-constrained environments where technology-enhanced learning can play a crucial role in addressing educational inequalities.

Abstract

Background: Standardized patients (SPs) have been crucial in medical education, offering realistic patient interactions to students. Despite their benefits, SP training is resource-intensive and access can be limited. Advances in artificial intelligence (AI), particularly with large language models such as ChatGPT, present new opportunities for virtual SPs, potentially addressing these limitations.

Objectives: This study aims to assess medical students' perceptions and experiences of using ChatGPT as an SP and to evaluate ChatGPT's effectiveness in performing as a virtual SP in a medical school setting.

Methods: This qualitative study, approved by the American University of Antigua Institutional Review Board, involved 9 students (5 females and 4 males, aged 22 - 48 years) from the American University of Antigua College of Medicine. Students were observed during a live role-play, interacting with ChatGPT as an SP using a predetermined prompt. A structured 15-question survey was administered before and after the interaction. Thematic analysis was conducted on the transcribed and coded responses, with inductive category formation.

Results: Thematic analysis identified key themes preinteraction including technology limitations (eg, prompt engineering difficulties), learning efficacy (eg, potential for personalized learning and reduced interview stress), verisimilitude (eg, absence of visual cues), and trust (eg, concerns about AI accuracy). Postinteraction, students noted improvements in prompt engineering, some alignment issues (eg, limited responses on sensitive topics), maintained learning efficacy (eg, convenience and repetition), and continued verisimilitude challenges (eg, lack of empathy and nonverbal cues). No significant trust issues were reported postinteraction. Despite some limitations, students found ChatGPT as a valuable supplement to traditional SPs, enhancing practice flexibility and diagnostic skills.

Conclusions: ChatGPT can effectively augment traditional SPs in medical education, offering accessible, flexible practice opportunities. However, it cannot fully replace human SPs due to limitations in verisimilitude and prompt engineering challenges. Integrating prompt engineering into medical curricula and continuous advancements in AI are recommended to enhance the use of virtual SPs.

KEYWORDS

medical education; standardized patient; AI; ChatGPT; virtual patient; assessment; standardized patients; LLM; effectiveness; medical school; qualitative; flexibility; diagnostic

Introduction

Standardized patients (SPs) have been a cornerstone of medical education since the 1960s, offering students an immersive, real-world experience in a controlled environment. Studies have demonstrated that SP programs are superior for teaching consultation skills compared with traditional methods, with medical students trained using SPs showing increased confidence and competency compared with those trained through other modalities [1,2].

While SPs provide valuable opportunities for students to practice diagnostic and interpersonal skills under standardized conditions, several inherent challenges exist. The resource-intensive nature of SP programs has been a persistent issue, with significant costs associated with recruitment, training, and maintenance of an SP bank [1,3]. Additionally, questions have emerged about SPs' ability to adequately represent the nuances of real patient presentations.

These challenges are particularly pronounced in specific contexts. For instance, Caribbean medical schools face unique obstacles due to limited local health care infrastructure and varying access to clinical training resources. Many offshore institutions in countries such as Aruba and Antigua and Barbuda must rely on partnerships with local health care providers, often resulting in inconsistent access across student cohorts [4,5]. The COVID-19 pandemic exposed additional vulnerabilities in traditional SP programs. The discontinuation of the USMLE Step 2 Clinical Skills examination in 2022, for instance, highlighted the risks of relying solely on in-person SP encounters for assessment [5].

In the 21st century, virtual SPs have emerged. These are computer programs that simulate specific illnesses and respond to learner inputs [6]. They have become invaluable tools in both teaching and assessment. However, their development also requires significant resources, making it challenging for institutions without robust educational technology support departments [7].

As the field of artificial intelligence (AI) has advanced, the potential for its application in medical education has expanded. Large language models (LLMs), such as ChatGPT (OpenAI), have revolutionized natural language processing. These sophisticated neural networks, trained on vast amounts of web-based data, are adept at predicting subsequent words in a sequence [8]. ChatGPT, a chatbot based on the GPT-3.5 model, has an enormous 175 billion parameters and displays a remarkable capacity for understanding and reasoning, bordering on human-like proficiency [9]. Since its introduction in November 2022, sectors spanning from history to entertainment have rapidly adopted the LLM [10].

This advancement in AI has led to the development of virtual SP chatbots. A number of major educational material suppliers and specialized companies are offering chatbot SPs, based on LLMs capable of natural language interactions, for students to practice clinical skills. One example is Oscer, which can present more than 200 virtual patient conditions and boasts above 90% accuracy in symptomology [11]. Similarly, the University of Texas Medical Branch makes use of an AI agent termed Virti, which they use to conduct virtual Observed Structured Clinical Examinations with medical students [12]. Other publicly accessible sites offering virtual patients include Soma Lab [13] and Body Interact [14]. However, for this new generation of virtual patients there is again considerable time and resources required for the company or the institution to develop the program and train the LLM on specific datasets and student access can be limited by cost and locality [7].

The debut of ChatGPT sparked inquiries into its potential as an SP. Liu et. al [15] crafted 10 medical histories with ChatGPT, which were then vetted by experienced physicians. Their results highlighted ChatGPT's promise in clinical education, although some responses came across as robotic [15]. Suarez et.al [16] gathered dental student's feedback after interacting with an AI chatbot. The majority found the experience valuable, especially those who made a correct diagnosis. This underscores the potential of integrating AI into health sciences training [16].

Weidener and Fischer [17] emphasized the growing consensus on incorporating AI into medical education. Their study indicated the importance of both practical and technological skills for leveraging AI in medicine [17]. Similarly, Jowsey et. al [18] have recommended adoption of AI into medical education as a way of preparing future physicians for the reality of modern practice.

We were aware that SPs at our school, American University of Antigua (AUA), were in limited supply and had received feedback indicating that while SPs are effective, students would like greater access to them. In fact, some students had no access during their course, depending on their cohort.

One of our study's aims was to assess medical students' perceptions and experiences regarding the use of AI in medicine—specifically by examining their views before and after interacting with ChatGPT as an SP. A second aim was to evaluate whether ChatGPT can perform adequately as a virtual SP in a medical school setting. Guided by these aims, our investigation focused on the following research questions: (1) How do students perceive the effectiveness of ChatGPT compared with traditional SPs in medical training scenarios? (2) To what extent can ChatGPT function effectively as a virtual SP in medical education?

By addressing these questions, our study seeks to inform the potential integration of AI-driven virtual SPs into medical curricula, particularly in settings where access to traditional SPs is limited.

Methods

Ethical Considerations

This study was given expedited approval by the AUA Research committee (no. AUAIRBa23011). Eleven medical student volunteers enrolled in the MD course at AUA were recruited via a campus-wide email. Two participants were lost to follow-up, leaving a total of 9 participants. Students were 5 females and 4 males, aged 22-48 years, comprising students from both first and second years of the basic sciences course

section of the MD program. Participants were explicitly informed that their involvement in the research was completely voluntary. They were also assured that their responses would remain confidential and anonymous, and all participants signed informed consent agreements. All data were anonymized and no compensation was provided to participants.

Study Design

Students were given access to ChatGPT version 4.0 accounts, the most recent available at the time of the study. Students were observed during a live role-play, in which a student inputted a predetermined prompt, provided by the study authors, into ChatGPT. The prompt directed the LLM to present as a patient with a neurological condition (Figure 1).

The student, in the role of physician, then interviewed the ChatGPT and attempted to make a differential diagnosis (Figure 2).

Figure 1. Prompt used in ChatGPT role-play.

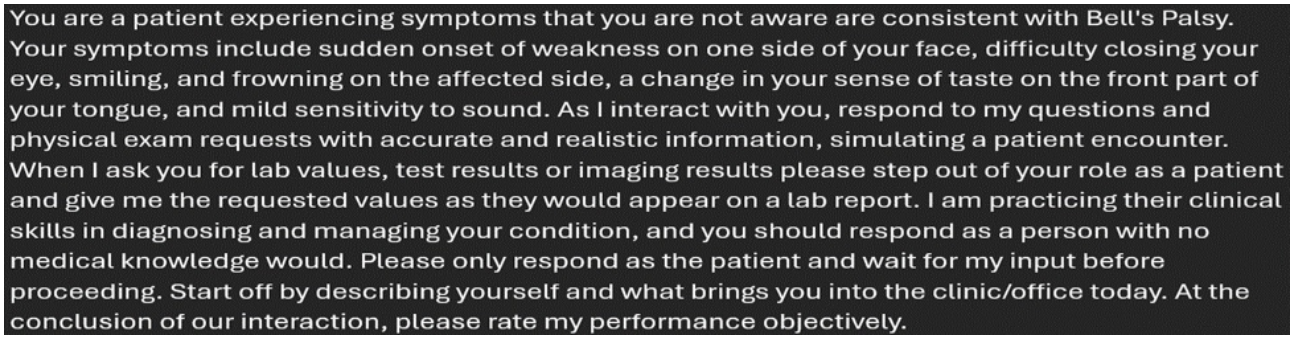

Figure 2. Screenshot example of ChatGPT standardized patient interaction.

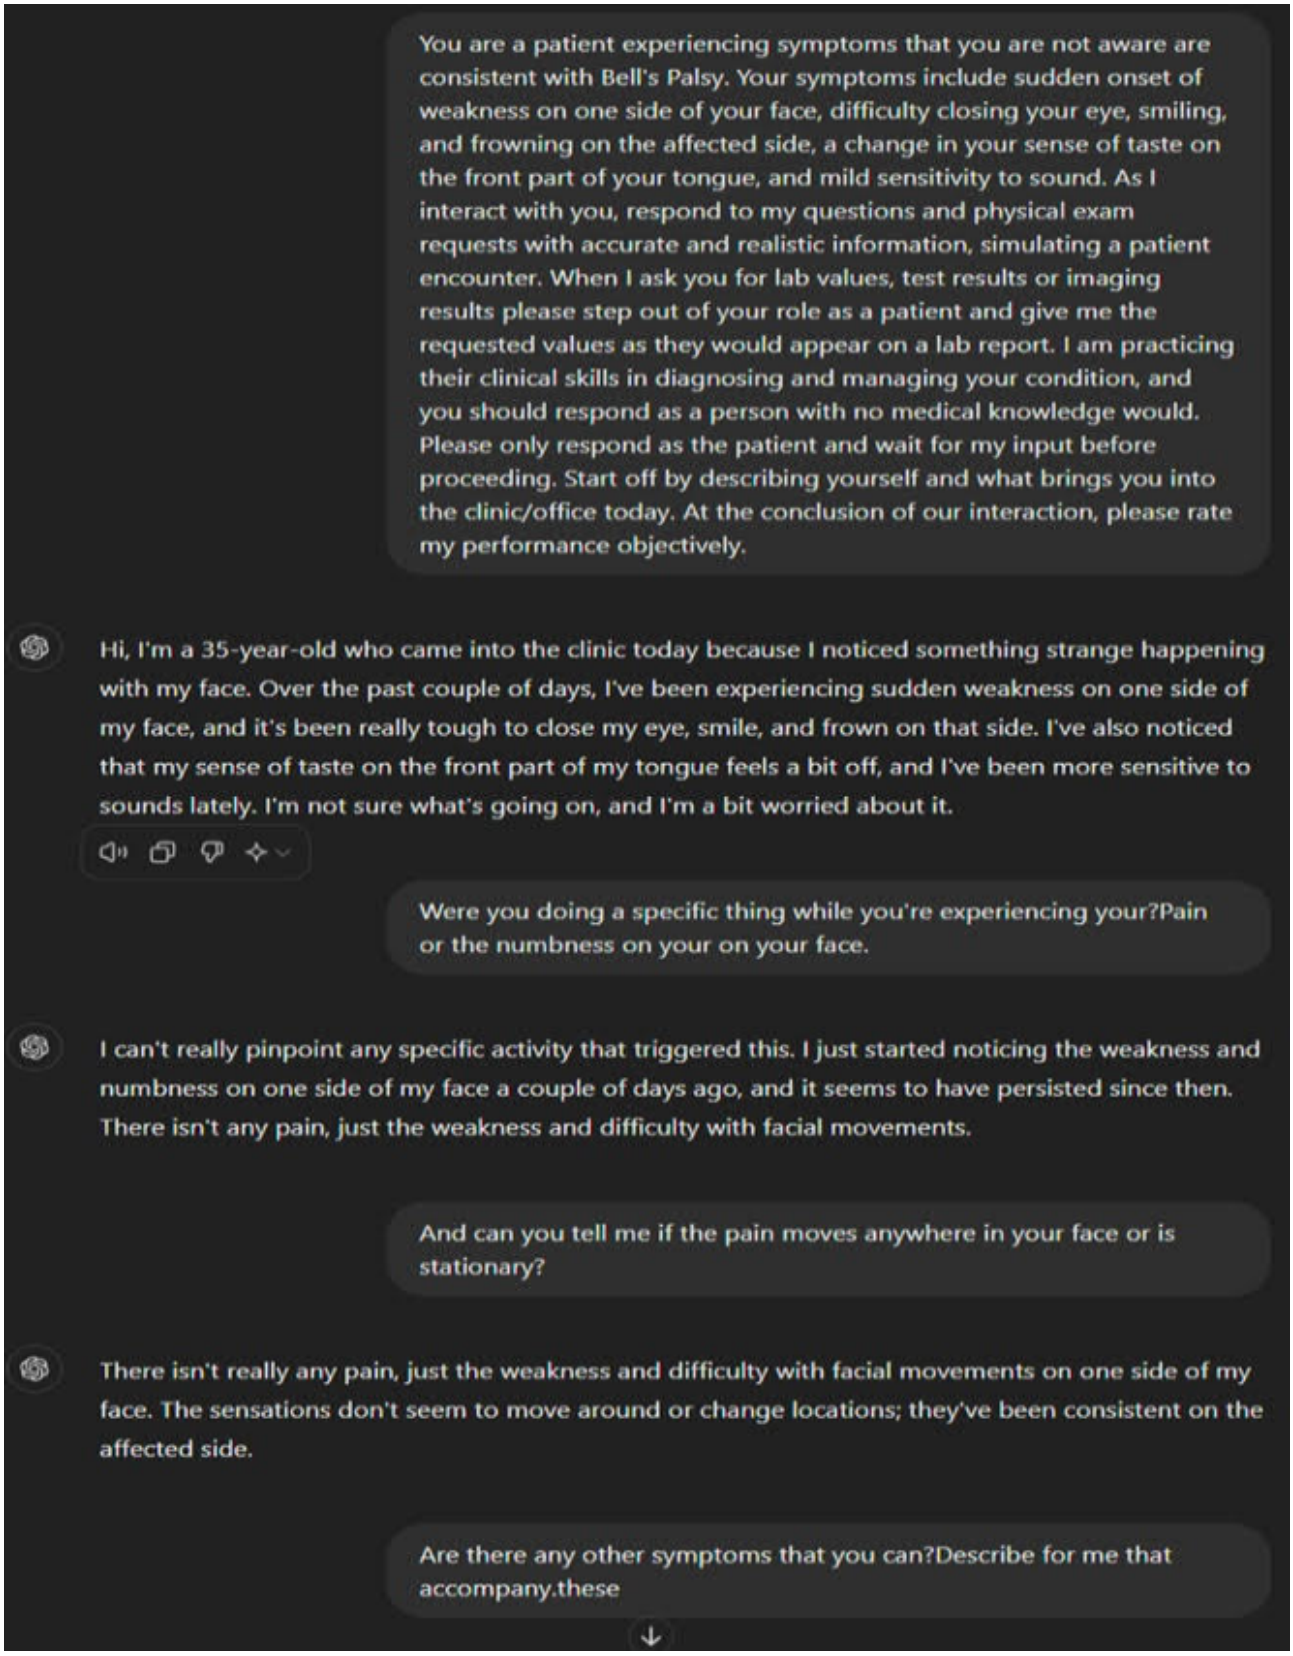

Prompt Development

The development of the prompt for ChatGPT's simulated patient interaction underwent an iterative process prior to its use by students. This process involved a 6-member faculty team comprising both clinical and nonclinical faculty, ensuring a diverse range of perspectives and expertise. The faculty were tasked with using the prompt in simulated interactions with ChatGPT, assessing the following factors:

1. Consistency: ensuring the chatbot consistently adhered to the patient role and provided responses aligned with the illness script.
2. Accuracy: evaluating whether the responses were medically plausible and aligned with the provided case information.
3. Likelihood of misleading the SP: assessing whether the chatbot responses could inadvertently lead users to incorrect assumptions or conclusions.
4. Quality of output: reviewing the depth and appropriateness of responses to ensure a realistic and effective simulation experience.
5. Adherence to prompt instructions: verifying that ChatGPT's responses followed the specific behavioral and informational instructions embedded in the prompt.

Faculty provided detailed feedback based on their observations, leading to refinements in the prompt. Suggestions included adjustments to phrasing, additional clarifications to the illness script, and enhancements to behavioral instructions to minimize the potential for ChatGPT to deviate from the assigned patient role. This iterative process was instrumental in optimizing the prompt's effectiveness before deployment in the study.

Rationale for Clinical Case Selection

Bell palsy was chosen as the clinical condition for the simulation due to its relevance to the material being taught at the time. This alignment ensured that the scenario was both clinically pertinent and integrated with the participants' ongoing coursework in both basic sciences and clinical disciplines. The familiarity of the students with the foundational aspects of Bell palsy was intended to facilitate meaningful engagement with the simulated patient, allowing them to focus on the interaction and diagnostic questioning rather than struggling with unfamiliar content.

Purpose of the Evaluation

It is important to note that the primary goal of this study was not to evaluate the students' diagnostic accuracy. Instead, the focus was on assessing their perceptions of ChatGPT's performance as a simulated patient. This distinction was critical to the study design, as it allowed for an emphasis on the usability, realism, and educational value of AI-driven SP interactions without conflating these aspects with the participants' clinical competencies.

The role-play was conducted verbally, as a voice control extension added to the ChatGPT accounts allowed natural language conversation between the student and the LLM [19]. A structured questionnaire consisting of 15 open-ended questions was administered before and after interaction with ChatGPT in the role of an SP. Students were asked about specific elements of their interaction and interviews were conducted in person by faculty team members (Multimedia Appendix 1).

Participating students were introduced to the ethical considerations of using LLMs such as ChatGPT. This included training on the importance of deidentifying patient data, recognizing the limitations of AI, and understanding the potential biases inherent in AI responses, such as those related to gender or ethnicity. This ethical orientation aimed to ensure that students approached the interactions responsibly and with an awareness of the technology's constraints.

Thematic Analysis

The results of the students' group work were recorded, transcribed, and coded by 3 different authors (JC, TK, and RER). Following discussions in regular meetings, findings were summarized, and a category system consisting of main and subcategories, according to Mayring's [20] qualitative content analysis, was agreed upon. Selected text passages were used as quotations to illustrate each category. Inductive category formation, a qualitative research method used to analyze data by identifying patterns, themes, or categories that emerge directly from the data itself, without predefined hypotheses or coding frameworks, was used to analyze open-ended survey responses and interview transcripts.

To explore differences in prompt engineering techniques across academic levels, we asked students to describe how they approached questioning and refining their prompts during the postsession interviews. First-year students, who had less clinical exposure, were expected to rely more on general inquiry methods, while second-year students might leverage slightly more clinical insight. Recording these observations allowed us to compare prompt engineering strategies between these groups and understand how curriculum familiarity influenced interactions with the AI-driven simulated patient interactions.

Results

A total of 9 students participated (5 females and 4 males, aged 22 - 48 years) (Table 1). All students had had some prior experience with traditional SPs, with more senior students having had a greater number of encounters. This contextualizes their perceptions of ChatGPT as a supplement and provides a baseline for understanding the comparative effectiveness of the AI-based approach.

Table . Demographic data.

Characteristics	Participants (n=9), n
Age (years)[a]	
22 - 30	4
31 - 40	4
41+	1
Sex	
Male	4
Female	5
Semester	
1	0
2	7
3	1
4	1
5	0
Prior experience with SPs[b]	
Yes	9
No	0
Prior experience with AI[c]/ChatGPT	
Yes	6
No	3

[a]Mean age: 31.22 (SD 6.8) years

[b]SPs: standardized patients.

[c]AI: artificial intelligence.

The thematic analysis of student feedback prior to interaction with ChatGPT as an SP identified several key themes and subthemes (Table 2). Under the theme of technology limitations, students noted challenges with prompt engineering, such as difficulty in asking effective questions, because the AI could not role-play a physical examination. In terms of learning efficacy, students mentioned the potential for personalized learning materials, grammatical assistance, and the ability for repeated practice without the constraints of limited SP availability. Additionally, some students highlighted the potential for increased convenience, as they could practice as often and whenever they wanted. A potential reduction in SP interview stress was also seen as a benefit of increasing virtual practice. However, under the theme of verisimilitude (ie, the degree to which a simulation mirrors real-life scenarios, including the subtle behaviors and interactions that contribute to a convincing experience), students expressed concerns about the absence of visual cues and rapport, which are important in real patient interactions. Finally, trust issues were raised regarding the accuracy of the LLMs output.

Table . Thematic analysis of student feedback preinteraction with ChatGPT standardized patient.

Themes and subthemes	Representative quotations
Theme 1. Technology limitations	
Prompt engineering	"The challenges might be just asking the right questions, because it's an AI, you can't ask them to do physical examinations."
Theme 2. Learning efficacy	
Personalized learning materials	"Triple checking work and not only getting the right answer, but getting explanations for the right answer and then why the wrong answer is wrong."
Grammatical assistance	"It would be helpful because English is not my first language."
Repetition	"There's usually 10 medical students to one patient, and sometimes you're fighting over each other to get the interview, so this allows us to get more repetitions."
Depth of medical knowledge	"The sky's the limit with regards to what we can practice."
Interview stress or anxiety	"It will kind of be a bit more stress free because you know you're talking to a computer rather than an actual patient."
Convenience	"Be able to practice it as much as I want, as often as I want and any time I want."
Theme 3. Verisimilitude	
Absence of visual cues	"You have to figure out ways to ask the question without the visual cues."
Absence of rapport or empathy	"Building the communication and the relationship with your patient is important."
Theme 4. Trust	
Inaccurate output	"One incident was in the small group activity, where it gave us the wrong answer."

Following interaction with ChatGPT, the thematic analysis of student feedback revealed some changes in perceptions (Table 3). While technology limitations were still noted, students mentioned that they had learnt to improve the output from ChatGPT by tailoring prompts. They also reported alignment issues, such as ChatGPT not providing information on sensitive topics such as patient sexual history. Learning efficacy remained a significant theme, with students appreciating the convenience and repetition benefits. They found the ability to practice history taking without stress and receive feedback useful for skill development. However, verisimilitude issues persisted as a theme, with students noting the absence of visual and tonal cues, and the lack of rapport and empathy, all of which impacted the effectiveness of the patient interview and the ability to make a diagnosis. Some students experienced information overload, feeling that ChatGPT provided more information than a real patient would.

Table . Thematic analysis of student feedback postinteraction with ChatGPT standardized patient.

Themes and subthemes	Representative quotations
Theme 1. Technology limitations	
Prompt engineering	"You could put in the prompt that you want to tailor the responses you want to get back."
Alignment	"When I asked like about sexual history, they were not able to give information."
Theme 2. Learning efficacy	
Convenience	"Having ChatGPT to practice history whenever we want, I think that's the improvement."
Repetition	"You are able to have a lot more repetitions than you are in lab."
Interview stress or anxiety	"Since it's a computer, it's not real. I had less anxiety."
Feedback	"I can ask 'hey, how did you think I did?'"
Skills development	"It highlighted the importance of on-the-spot thinking and memory recall in a medical scenario."
Overall enhanced learning	"It's going to make you sharper. You know, you're probably going to be ahead of your peers, you're going to be able to answer a patient in a better, more detailed manner. Give them a better treatment or care plan."
Theme 3. Verisimilitude	
Absence of visual cues	"For the standardized patient you physically see them. You can see if they're in pain, they don't have to explain where they are in pain."
Absence of tonal cues	"ChatGPT had the same tone, even if it was saying something sad."
Absence of rapport or empathy	"It takes away the personal connection between the doctor and the patient."
Information overload	"It felt like it was offering more information than a regular patient would."

To provide broader context, we compared ChatGPT with some other virtual SP platforms or platforms that could provide this function (Table 4). The comparison highlights the unique strengths and weaknesses of ChatGPT identified in this study in comparison with other platforms, including Claude AI (another chatbot often ranking near the top of benchmarking tables), Body Interact, Oscer AI, and Soma Lab [13,14,21-23]. Both ChatGPT and Claude AI offer flexibility and unlimited practice but are limited by uncurated outputs and reliance on prompt engineering. Oscer AI and Som Lab provide curated clinical cases with tailored feedback, yet their visual representation and interactivity vary, with Soma Lab integrating natural conversational voice modes. Body Interact enhances verisimilitude through patient avatars and curated cases but lacks voice interaction. Cost structures range from free access for basic use to subscription-based models for advanced features.

Table . Comparison of various platforms able to function as standardized patients.

Platform	Technology limitations	Learning efficacy	Verisimilitude	Model cost
ChatGPT	Requires effective prompt engineering; uncurated outputs	Offers flexibility and unlimited practice	Limited visual and tonal cues; natural conversational voice mode	Free and subscription-based options
Claude AI	Requires effective prompt engineering; uncurated outputs	Offers flexibility and unlimited practice	Limited visual and tonal cues; limited voice interaction	Free and subscription-based options
Body Interact	Requires effective prompt engineering; curated clinical cases	Facilitates skill development through realistic scenarios	Patient avatars; lacks voice interaction	Subscription or licensing fees
Oscer AI	Requires effective prompt engineering; wide range of curated clinical cases	Focus on history-taking skills with limited versatility	Limited visual cues; voice interaction possible	Free. Subscription for full access
Soma Lab	Requires effective prompt engineering; wide range of curated clinical cases	Counseling-focused; supports repeated practice with tailored feedback	Static patient avatars; natural conversational voice mode	Variable costs based on usage and features

Discussion

Principal Findings

This study investigated the use of ChatGPT as an SP by qualitative analysis of students' responses to a questionnaire, preinteraction and postinteraction, with ChatGPT performing the role of SP. In terms of diagnostic skill development, our conclusions were drawn from a combination of faculty observations and student self-report. Faculty members who observed the sessions noted that students demonstrated more structured reasoning and improved question formulation after repetitive practice with ChatGPT. In postsession interviews, students themselves expressed feeling more confident and organized in their clinical reasoning steps. This alignment between external observation and self-assessment suggests that the interaction with ChatGPT, although lacking nonverbal cues and certain realistic elements, still provides a valuable platform for honing diagnostic interviewing skills. Thematic analysis provided insights into student perceptions. Major themes identified were technology limitations, learning efficacy, and verisimilitude. Our results suggest that the current version of ChatGPT (ChatGPT version 4.0 at the time of this study) can function effectively as an augmentation to traditional SPs but cannot fully substitute for SPs. These results are broadly in line with those of other studies using LLMs in the role of SP [24-29].

The technological limitations of LLMs in the context of SP exercises were both anticipated and confirmed in our study. The subtheme of prompt engineering was particularly important. Students were made aware of the importance of correctly worded prompts before the exercise, and we found that the faculty-provided prompt, developed through a trial and error process, proved effective in this regard.

The significance of prompt engineering when using LLMs as virtual SPs, or in developing related materials, is also supported by other studies [28,30-33]. It has been suggested that prompt engineering could be incorporated into medical curricula through, for example, hands-on workshops, simulation-based learning, and courses on AI in health care [28,30-32].

The postinteraction interviews also revealed an additional subtheme of alignment. Alignment refers to the problem of ensuring that AI acts in accordance with human intentions and human values [34]. Students noted that the LLM did not provide a response when asked about a patient's sexual history, a standard question in any medical consultation. Ensuring that ChatGPT does not output material which could be considered offensive under societal norms is a component of alignment [35]. However, our results demonstrate an "alignment tax," in that the model becomes less useful due to constraints imposed by the alignment. The development of LLMs designed specifically for medical education may overcome this issue [36].

Learning efficacy was also a major theme identified in this study. Important subthemes in this category were repetition and convenience. Students noted the benefits of having access to ChatGPT for practice at any time or place and having virtually unlimited ability to repeat the exercises. As mentioned earlier, access to SPs is limited in many medical schools [15]. The ability to augment this shortfall with a virtual SP may be a positive option for many medical students and medical schools.

Interestingly, some students expressed that they experienced considerable anxiety as much as a day before they were scheduled to interact with an SP, although they were aware that the SP was not a real patient. The ability to practice with an LLM such as ChatGPT was seen as beneficial, because students could develop questioning techniques to a point where even during the session with a real SP they could still perform well.

Some differences between preinteraction and postinteraction in terms of subthemes were evident under the major theme of learning efficacy. Before the exercise students were focused more on anticipated or previous experiences in using LLMs for personalized learning materials, for example, developing mnemonics, practice questions, or flash cards. This reflects the experience of other medical students [37]. Responses following the exercise were focused on diagnostic patient interaction skills. This is to be expected as students now had actual experience of ChatGPT in this role and knew that this was to be the focus of our study.

Verisimilitude was a major theme in both preinteraction and postinteraction responses. All students mentioned this as a limiting factor. Absence of facial cues, changes in tone, or body language and an inability to develop rapport were all seen as drawbacks of the virtual SP. Some students also mentioned that this impacted their role as physician. For example, a student physician leaning into the patient to show interest, or other types of body language, was redundant in the exercise. Other studies have also highlighted that the output from ChatGPT cannot replicate the true stimuli a physician relies on in a patient visit [28,31,38,39]. We note that virtual patients are developing rapidly, so issues with verisimilitude may be overcome in future, although it may take some time before ChatGPT, specifically, is able to incorporate a visual or physical layer.

Trust as a theme was evident in preinterview responses but had disappeared in postinterview responses. We note that our faculty team, consisting of clinicians and PhD-qualified members, did not notice any "hallucinations" in output, despite multiple repetitions of the exercise. Yanagita et al [40] recently found that high-quality illness scripts, used for improving medical student's clinical reasoning, could be generated by ChatGPT with relatively few errors. Magalhaes et al [25] also found that a majority of students trusted ChatGPT's output. Nevertheless, even a single error in ChatGPT output, given multiple health care providers may receive the same output, could affect many patients. It is therefore imperative that the veracity of AI output be thoroughly tested before it is fully integrated into health care and medical education settings [28].

Other subthemes for learning efficacy evident postinteraction were feedback and information overload. Our prompt included a direction for ChatGPT to provide feedback on how students could improve their performance. We note that it was necessary to revise the prompt several times during the study, as initially it provided only positive feedback, which did not help in identifying areas for improvement. Responses under the information overload subtheme suggested that students found that the LLM tended to provide more information in regard to

a given question than perhaps a real patient or SP would. This presumably related to the depth of medical knowledge of the LLM but should be considered in further iterations of this exercise. It may be possible to refine the prompt to reduce this effect.

Table 4 compares various platforms able to be used as SPs in medical education, highlighting strengths and limitations across technology, learning efficacy, verisimilitude, and cost. ChatGPT and Claude AI offer affordable, flexible options for unlimited practice but face challenges with uncurated outputs and limited realism in visual and tonal cues. In contrast, platforms such as Body Interact and Soma Lab provide curated cases and interactive features, although often at a higher cost. These findings reinforce that while ChatGPT is a valuable and accessible tool for augmenting SP training, it cannot fully replicate the nuances of human SPs. Addressing limitations such as effective prompt engineering and enhancing realism through improved visual and auditory features could significantly improve its use.

It is possible that the use of ChatGPT as a virtual SP may influence trainees' sensitivity toward patients through the absence of the genuine human interaction students may have with SPs and real patients [41]. The rapid evolution of AI technologies is addressing these gaps to an extent. For instance, the advanced voice mode (AVM) in newer versions of ChatGPT incorporates natural speech patterns and emotional intonations, which may help simulate more realistic interactions. While AI cannot yet replicate the full nuances of real patient encounters, it serves as a consistent and flexible supplementary tool for medical training. Future advancements in AI capabilities may further enhance their ability to foster empathy and connection, thereby reducing potential concerns around decreased sensitivity in trainees.

A number of recent studies have confirmed the use of ChatGPT, or similar LLMs, as virtual SPs [28,29,42]. Similarly to our study, these studies have highlighted ChatGPT's potential to reduce resource constraints and improve accessibility in medical training while offering immersive, flexible practice opportunities. At the same time, limitations created by a lack of verisimilitude were also noted.

Both the necessity and challenges of integrating AI, including LLMs, into medical curricula have also been widely acknowledged [43-47]. Addressing inequities in AI models derived from biased training data is crucial, as these can perpetuate disparities in patient care. Strategies to ensure fairness and equitable outcomes, such as transparency in algorithmic design, have been emphasized in recent studies [45,48]. Additionally, resource allocation, faculty training, and the development of tailored content for medical applications add layers of complexity to curricula integration [46,48]. To move forward, curricula must incorporate foundational AI competencies, including ethical considerations, algorithmic fairness, and practical skills such as prompt engineering. Embedding these competencies into existing core courses, rather than as electives, will ensure comprehensive and equitable learning opportunities [43,44,46,48].

To effectively integrate AI into medical curricula, assessments should be designed to balance the use of AI tools while maintaining the integrity of evaluation processes [44]. Educators should implement secure examination protocols, such as locked-down computers and stricter proctoring, to prevent misuse of AI during assessments. However, assessments can also creatively incorporate AI by engaging students in critiquing AI-generated responses or using these tools to identify knowledge gaps and provide tailored feedback. Generative AI can enhance formative assessments by offering immediate and individualized feedback, guiding students' learning trajectories. We note that our results demonstrate the efficacy of this approach, with the virtual SP providing valuable insights to each student individually on how to improve their patient interactions.

Study Limitations

The small sample size, comprising only 9 participants from a single institution, and potential ascertainment bias, with tech-savvy volunteers possibly skewing results, limited the study's generalizability. This lack of diversity in the sample highlights the need for future studies to include larger and more diverse participant pools to enhance the robustness and generalizability of the findings. Our team is currently working on a multicenter, randomized controlled trial with a mixed methods approach. The study uses a convergent parallel mixed methods design and will span 8 months across multiple medical schools. It will use the new AVM of ChatGPT to simulate an SP. The AVM offers several advantages over the original voice mode, including reduced latency and an ability to inject emotion into its voice [29]. The study aims to draw conclusions based on robust statistical data comparing the average percentage improvement of the experimental group with the control groups on Observed Structured Clinical Examination scores, as well as qualitative data exploring students' learning and perceptions of the AI through focus groups.

Conclusions

This study found ChatGPT to be an effective supplement, although not a full replacement, to traditional SPs. Students and faculty appreciated its potential, noting benefits such as flexible practice times, reduced stress, and improved diagnostic skills. Some shortcomings were noted, including the need for effective prompt engineering and the lack of nonverbal cues affecting realism. Despite these challenges, its reliability and convenience make it a valuable training tool.

Students' diagnostic skills were not formally assessed in this study. However, based on their self-reported perceptions and observations of their interactions with ChatGPT, it appears that the AI can be a valuable tool for practicing clinical reasoning and problem-solving skills. Future research could explore the impact of ChatGPT on students' diagnostic accuracy and clinical performance.

Overall, ChatGPT offers a significant adjunct to traditional SPs, providing accessible, flexible practice opportunities for medical students. The study underscores the importance of integrating prompt engineering into medical curricula and refining AI interactions for balanced information delivery. Continuous

advancements in virtual patient technology and AI capabilities, including improved verbal and auditory flow, are expected to further enhance ChatGPT's use in medical education. Future studies are planned with a larger sample size and using the recently released ChatGPT version 4.o1 with AVM.

Abstract

Background: Virtual reality simulation (VRS) teaching offers nursing students a safe, immersive learning environment with immediate feedback, enhancing learning outcomes. Before the COVID-19 pandemic, nursing students had limited training and opportunities to care for patients in isolation units with infectious diseases. However, the pandemic highlighted the ongoing global priority of providing care for patients with infectious diseases.

Objective: This study aims to (1) examine the effectiveness of VRS in preparing nursing students to care for patients with infectious diseases by assessing its impact on their theoretical knowledge, learning motivation, and attitudes; and (2) evaluate their experiences with VRS.

Methods: This 2-phased mixed methods study recruited third-year undergraduate nursing students enrolled in the Integrated Emergency and Critical Care course at a university in Taiwan. Phase 1 used a quasi-experimental design to address objective 1 by comparing the learning outcomes of students in the VRS teaching program (experimental group) with those in the traditional teaching program (control group). Tools included an infection control written test, the Instructional Materials Motivation Survey, and a learning attitude questionnaire. The experimental group participated in a VRS lesson titled “Caring for a Patient with COVID-19 in the Negative Pressure Unit” as part of the infection control unit. In phase 2, semistructured interviews were conducted to address objective 2, exploring students’ learning experiences.

Results: A total of 107 students participated in phase 1, and 18 students participated in phase 2. Both the VRS and control groups showed significant improvements in theoretical knowledge scores (for the VRS group t_{46}=–7.47; P<.001, for the control group t_{59}=–4.04; P<.001). However, compared with the control group, the VRS group achieved significantly higher theoretical knowledge scores ($t_{98.13}$=2.70; P=.008) and greater learning attention (t_{105}=2.30; P=.02) at T1. Additionally, the VRS group demonstrated a statistically significant higher regression coefficient for learning confidence compared with the control group (β=.29; P=.03). The students’ learning experiences in the VRS group were categorized into 4 themes: Applying Professional Knowledge to Patient Care, Enhancing Infection Control Skills, Demonstrating Patient Care Confidence, and Engaging in Real Clinical Cases. The core theme identified was Strengthening Clinical Patient Care Competencies.

Conclusions: The findings suggest that VRS teaching significantly enhanced undergraduate nursing students’ infection control knowledge, learning attention, and confidence. Qualitative insights reinforced the quantitative results, highlighting the holistic

benefits of VRS teaching in nursing education, including improved learning outcomes. The positive impact on student motivation and attitudes indicates a potentially transformative approach to nursing education, particularly in the post–COVID-19 era, where digital and remote learning tools play an increasingly vital role.

KEYWORDS

virtual reality; infection control; learning motivation; learning attitudes; nursing education

Introduction

Background

Virtual reality (VR) has emerged as an innovative teaching strategy in nursing education. VR technology leverages simulated scenarios to overcome time and space limitations, offering students opportunities to learn in safe, realistic settings and receive immediate feedback [1]. VR simulation (VRS) teaching strategies enhance learning motivation, student immersion, knowledge and skill acquisition, confidence [2,3], active participation, and learning effectiveness [4-6]. The goal of undergraduate nursing education is to prepare students for clinical practice, making it essential to strengthen their professional competencies and attitudes. Integrating information technology into nursing education enhances students' learning outcomes. Nursing education should align with the broader clinical practice environment, incorporating technology to support students in developing their competencies [7].

The COVID-19 pandemic has profoundly impacted nursing curricula and teaching worldwide. In emergency and critical care, university-level nursing curricula must reflect clinical environments. Emphasizing situated learning enhances students' abilities and confidence in providing emergency patient care [8,9]. Before the pandemic, nursing students rarely had opportunities to care for patients with infectious diseases in isolation units. However, the demand for care related to infectious diseases remains a global priority [9]. Strengthening courses on infectious diseases can help students develop positive attitudes toward clinical practice [10]. Updating infectious disease courses with more practical experiences can further support nursing students in developing positive attitudes when caring for patients with infectious diseases during clinical practice.

Learning theories related to VR teaching include constructivism, situated learning, and experiential learning. In VR learning, learners actively absorb information and construct new knowledge [11]. Situated learning theory emphasizes real-world interactions and activities in authentic contexts, transforming these experiences into applicable knowledge [12]. VR offers an interactive virtual environment, using visual effects to present abstract problems and providing opportunities for active manipulation and repeated practice [11]. Experiential learning theory posits that learning is the transformation of experience, with knowledge creation emerging from interactions, conflicts, and problem-solving between individuals and their environment. This theory highlights the potential of immersive technology to provide meaningful experiences [12]. Compared with other teaching methods, VR teaching is easy to use, generates positive and active learning experiences [13], and enhances learning outcomes, including improvements in knowledge, skills, and clinical decision-making [14,15]. Engagement in VR environments provides students with experiences closely aligned with clinical practice, boosting their motivation and attitudes and leading to better educational outcomes [14,15].

Motivation and attitude play a significant role in influencing learning outcomes. Enhanced motivation strengthens active learning and improves results [12,16]. Studies have shown a positive correlation between motivation and learning outcomes, making learning easier and fostering proactive engagement [17,18]. Keller's Attention, Relevance, Confidence, and Satisfaction (ARCS) model of motivation incorporates a learning motivation scale to assess motivational aspects within a course [12,16]. Designing courses with integrated motivational models can inspire learners, enhance motivation, and increase classroom engagement [19,20]. In nursing education, particularly in emergency and critical care courses, VR can address the limitations of clinical settings and traditional teaching methods caused by resource constraints [21-24]. VR stimulates learners' motivation, promotes active participation, and enhances learning outcomes [25,26]. By incorporating VR teaching, courses can more closely align with clinical practice, providing students with a solid foundation in professional knowledge and skills.

Even long after the pandemic, there will remain a global need for the care of patients with infectious diseases. However, opportunities for students to participate in the actual care of such patients in isolation units remain limited. To date, little attention has been given in the literature to identifying educational strategies that address this gap in developing nursing students' professional knowledge and skills. This mixed methods study was guided by 2 research questions: (1) What is the effectiveness of VRS teaching on nursing students' theoretical knowledge, learning motivation, and attitudes toward the care of patients with infectious diseases? and (2) What are the learning experiences of nursing students in a VRS program? Our a priori hypothesis was that VRS teaching would significantly improve nursing students' infection control theoretical knowledge, learning motivation, and attitudes regarding the care of patients with infectious diseases.

Objectives

This study had 2 objectives: (1) to evaluate the effectiveness of VRS teaching on nursing students' theoretical knowledge, learning motivation, and attitudes toward the care of patients with infectious diseases, and (2) to explore their learning experiences in a VRS program designed for this target population.

Methods

Study Design

This study used a 2-phased mixed methods approach to comprehensively evaluate a VRS teaching program on the care of patients with infectious diseases, which was part of the infection control unit within the Integrated Emergency and Critical Care course. Phase 1 utilized a quantitative study design to assess the learning effectiveness of the VRS teaching method, while phase 2 used qualitative phenomenography to explore students' experiences and perceptions of the program.

Phase 1: Outcomes of the VRS Program on Students' Knowledge, Learning Motivation, and Attitudes to the Care of Patients With Infectious Diseases

Overview

A quasi-experimental design was used to compare learning outcomes—knowledge, motivation, and attitude—between students in the VRS teaching program (experimental group) and those in the traditional teaching course (control group). Data were collected from August 2022 to July 2023.

Participants

This study used convenience sampling and was conducted at a clinical competence center at a university in Taiwan. Third-year undergraduate nursing students enrolled in the Integrated Emergency and Critical Care course were eligible to participate. One class of students was assigned to the experimental group, and another to the control group. The Integrated Emergency and Critical Care course is an elective offered in both the first and second semesters. Researchers used a random selection process to assign students in the infection control unit to the VRS program in the first semester and to traditional teaching in the second semester. The participating school provided a 2-week add/drop period, during which members of the research team gave in-class briefings about the study, and students were free to choose whether to participate in the experimental group. The selection criteria for the experimental group were (1) aged ≥20 years, (2) enrolled in the Integrated Emergency and Critical Care course, and (3) willing to participate in this study. Students with a history of epilepsy were excluded from the VRS. Sample size estimation was conducted using G*Power software version 3.1 [27]. Following Cohen's rule [28], 2 groups were included, with a medium effect size of f=0.25, a correlation of 0.5, a power of 0.8, and an α value of .05, resulting in a required sample size of ≥86, with ≥43 participants per group. A total of 47 students were recruited for the experimental group. None of the students in the experimental group refused to participate in the VRS program. All participants were taught by the same instructor, and the course content was consistent across both groups.

Instruments

Infection Control Written Test

Previous research has shown that VRS teaching can enhance the development of both knowledge and practical skills in undergraduate nursing students, with outcomes effectively assessed using a written test [29]. In this study, the infection control knowledge assessment involved a written test administered to students before (T0) and after (T1) the infection control lesson. The test consisted of 10 questions aligned with the learning objectives of the infection control unit. These included single- and multiple-choice items covering both theoretical knowledge and practical skills, such as donning and doffing personal protective equipment (PPE). The test addressed the same key infection control techniques for all students, aiming to evaluate their baseline abilities and the changes in knowledge following the lesson. To better capture postlearning changes and minimize the influence of memory recall on the posttest results, the order of the questions was adjusted, and some questions were modified. The test items were reviewed by the course instructor and clinical experts (senior emergency nurses) to ensure content validity.

Instructional Materials Motivation Survey

The Instructional Materials Motivation Survey (IMMS) is a self-reported questionnaire administered before (T0) and after (T1) the infection control lesson. Designed primarily to evaluate students' motivation in learning a course [12], the IMMS comprises 36 items distributed across 4 subscales based on the ARCS motivation model: Attention (12 items), Relevance (9 items), Confidence (9 items), and Satisfaction (6 items). Each item is rated on a 5-point Likert scale, with higher scores indicating greater learning motivation. The original IMMS scale has demonstrated high reliability, with Cronbach α values ranging from 0.81 to 0.96 [12]. In this study, the IMMS exhibited excellent reliability, with a Cronbach α of 0.94.

Learning Attitude Questionnaire

A learning attitude questionnaire was administered at T0 and T1. This 20-item self-reported questionnaire was developed by several members of the research team to assess students' attitudes toward caring for patients with infectious diseases and their participation in the infection control unit. Items were rated on a 5-point Likert scale, where 1 indicates "strongly disagree," 2 "disagree," 3 "neutral," 4 "agree," and 5 "strongly agree." Higher scores reflected a more positive learning attitude. The questionnaire demonstrated strong validity and reliability, with an average Content Validity Index of 0.9 and a Cronbach α of 0.955.

VRS Lesson Plan for Caring for a Patient With COVID-19 in the Negative Pressure Unit

In the infection control unit, VRS teaching was implemented for the experimental group. The VRS scenario, developed by several research team members with VR training certification, depicted a real clinical case of a febrile patient visiting the emergency department for triage, later confirmed to have COVID-19, and subsequently admitted to a negative pressure isolation unit (Figure 1). The teaching content emphasized a nurse's role in providing care within a negative pressure isolation room, including the proper techniques for donning and doffing PPE. The lesson's learning objectives were for students to differentiate care for patients with infectious diseases, correctly don and doff PPE, and provide appropriate patient care. The VR Oculus Quest equipment, including a headset and controllers, was supplied by the School of Nursing of the participating university. The VRS lesson plan was reviewed by the course instructor and clinical experts (senior emergency

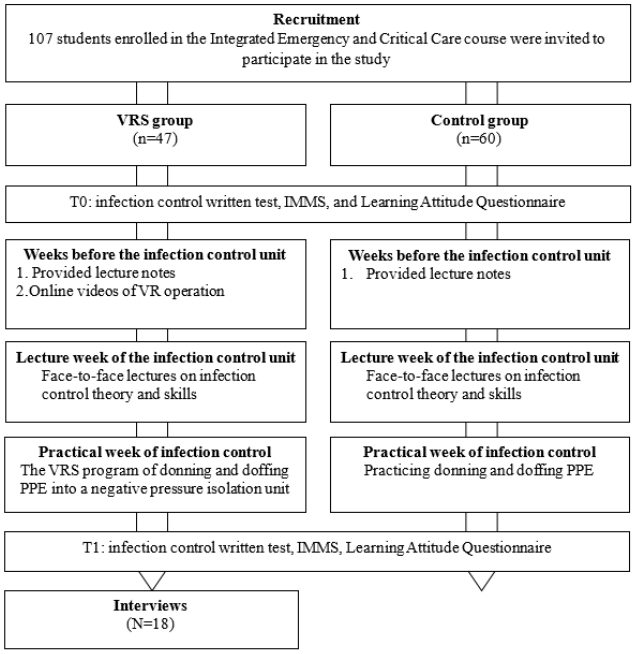
nurses) to ensure content validity. The lesson utilized VR technology to deliver immersive visual effects and interactive scenarios, aiming to enhance students' awareness and provide opportunities for practical exercises, thereby improving learning outcomes [30]. The assessment included the standard procedure for applying PPE, such as N95 masks, goggles, hair caps, and gloves. Upon completing the assessment, students received immediate feedback, with the computer screen highlighting missed items. This direct feedback was intended to reinforce learning effectiveness [1].

Figure 1. Screen captures of virtual reality simulation videos.

Procedure

To maintain neutrality, none of the research team members were involved in teaching either the experimental or control group. Instead, several team members focused on designing the VRS program and creating a VR system operation video to help students become familiar with operating the VR system. During the experimental group's class, research team members were available to address any technical issues that participants encountered. They also met with the unit instructors before the start of the unit to ensure consistency in teaching between the 2 groups and alignment in the course delivery process. The study protocol is illustrated in Figure 2.

Figure 2. Study protocol process. IMMS: Instructional Materials Motivation Survey; PPE: personal protective equipment; VR: virtual reality; VRS: virtual reality simulation.



The infection control unit spanned 2 weeks and included 1 lecture (100 minutes) and 1 practical session (100 minutes). Both the VRS group and the control group received lecture notes before the start of the course. Additionally, the VRS group was provided with prerecorded online VR videos demonstrating donning and doffing PPE in a negative pressure isolation unit, as well as instructions on operating the VR system. For the VRS group, the first week consisted of a 100-minute lesson on

infection control theory and skills, while the second week involved 100 minutes of VRS instruction. The VRS class was divided into 5 groups, each comprising 8-10 students, who worked collaboratively on the drills. The lesson began with an introduction to VR system operation (5-10 minutes), followed by group VRS scenario drills (30-40 minutes). Each student then executed their part of the VRS lesson, which lasted approximately 6-8 minutes. Upon completion, the system provided feedback, serving as the students' learning outcomes. Group members first discussed the session among themselves, followed by a 10-minute instructor-led debriefing session. During this session, students were encouraged to ask questions and share their reflections on the VRS program execution. Feedback and reflection were incorporated to help students consolidate their learning and transform it into meaningful learning outcomes. The groups then switched roles and conducted a second round of drills and discussions for another 30-40 minutes. A pretest (T0) and posttest (T1) on infection scenario cases were conducted to evaluate the students' learning outcomes, motivation, attitudes, and knowledge related to the infection control unit. For the control group, a traditional teaching strategy was used. During the first week, theoretical lectures were delivered, accompanied by a video to aid students in understanding the process. Lecture notes, identical to those provided to the VRS group, were distributed before class and included a video link demonstrating the standard PPE procedure. In the second week, students were divided into 6 groups of 9-11 members to practice donning and doffing PPE. Instructors provided individualized guidance to correct mistakes. Within the same groups, students evaluated and discussed the PPE practice. Although an instructor-led debriefing session was planned for the control group, it was postponed to the following week due to the large number of students and time constraints.

Data collected for this study were individually coded and entered into a computer for analysis using SPSS version 22.0 (IBM Corp.). Descriptive statistics, including frequency, percentage, mean, and SD, were calculated. Inferential statistics, such as independent *t* tests, paired *t* tests, and generalized estimating equations, were applied. Results with a *P* value of <.05 were considered statistically significant.

Phase 2: The Students' Learning Experiences of the VRS in Caring for Patients With Infectious Diseases

Overview

Phase 2 utilized qualitative phenomenography to explore students' experiences and perceptions of the VRS program. The key concepts in phenomenography are "phenomenon" and "experience." This methodology aims to identify the shared and generalized aspects of participants' thoughts or concepts regarding their experiences of a specific phenomenon, with a focus on describing their understanding of these experiences [31]. In this study, phenomenography was applied to understand how learners organize and structure the content they acquire during the learning process [31]. Interviews with students were analyzed to uncover their learning experiences and outcomes, with the goal of providing evidence to support the ongoing improvement of educational programs.

Participants

Students in the experimental group who met the following inclusion criteria were recruited: (1) aged 20 years or older, (2) enrolled in the Emergency and Critical Care course and participating in VRS teaching, and (3) consenting to participate in and have interviews recorded.

Procedure

Participants took part in in-depth semistructured interviews. These interviews facilitate meaningful conversations, providing a detailed understanding of complex issues [31]. In a phenomenographic study, interview questions need to be as open-ended as possible to accurately capture the participants' thoughts. The interview guide is provided in Multimedia Appendix 1. The in-depth interviews in this study contributed to understanding nursing students' experiences with VRS teaching. Each eligible participant received a consent form outlining the study's purpose, the voluntary nature of participation, and the confidentiality of their data. Participants completed the consent forms, and suitable interview times were scheduled. The interviews were conducted by a single researcher (CYH) who had prior experience in qualitative research gained during doctoral studies, had served as a principal investigator on research projects, and had published several qualitative research articles. CYH was not involved in teaching this subject and was unfamiliar with the participants in the experimental group. During the interviews, CYH utilized interview skills to encourage participants to articulate their VR learning experiences. The interviews were audio-recorded and lasted between 42 and 62 minutes. A sample size of 18 students was sufficient to generate rich data and achieve saturation.

Qualitative Analysis and Trustworthiness

Following each interview, the same researcher (CYH) transcribed the audio recordings verbatim to ensure detailed documentation and analyzed the interview data. Data analysis followed the 7 steps of phenomenographic analysis: familiarization, condensation, comparison, grouping, articulating, labeling, and contrasting [32]. The trustworthiness of the research findings was established using Lincoln and Guba's [33] criteria of credibility, transferability, dependability, and confirmability. In terms of credibility, phenomenographic research emphasizes the precise description of each stage of the study process, the application of the researcher's ideas to the phenomena, the careful formulation of interview questions and processes, and the thorough analysis and presentation of conclusions. Peer debriefing, which involves collaborative data analysis to explore diverse interpretations, enhances data interpretation and credibility, contributing to the development of credible research outcomes. Transferability is supported by providing in-depth data that represent a comprehensive view of the research, highlighting its relevance and context. Dependability is ensured by supporting categorizations with excerpted interview content, illustrating the similarities and differences among participants in relation to the phenomenon, and confirming the logical connection between the collected data and the phenomena captured by the descriptive categorization. Confirmability is established by documenting the interviewer's feelings and thoughts during the interview

process, thereby creating an audit trail. The data analysis is thoroughly described, with detailed records of decisions made and strategies adopted during concept formation. These reflections on theoretical and methodological aspects further contribute to the audit trail and the confirmability of the findings [34].

Ethical Consideration

Ethical approval was obtained from the Institutional Review Board of Chang Gung Medical Foundation (approval number 202002386B0). Potential participants were fully informed about the nature and purpose of the study, emphasizing that participation was entirely voluntary and that they had the right to withdraw from the study at any time. They were explicitly assured that their academic results would not be affected by their decision to participate or not. Participants were also guaranteed that their data would remain confidential and that they would not be identifiable in any reports. All participants provided written informed consent, and none of the students withdrew from the study.

Results

Phase 1: Outcomes of the VRS Program on Students' Knowledge, Learning Motivation, and Attitudes to the Care of Patients With Infectious Diseases

Overview

Participants in phase 1 consisted of 107 third-year undergraduate students: 47 in the experimental group, who received VRS teaching, and 60 in the control group, who participated in traditional practical sessions on donning and doffing isolation gowns. As shown in Table 1, the majority of participants (99/107, 92.5%) were female, with an average age of 21.14 (SD 0.69) years.

Table 1. Demographic characteristics of participants in phase 1 (N=107).

Participant demographics	Study groups		Total participants (N=107)
	Virtual reality simulation (n=47)	Control (n=60)	
Gender, n (%)			
Male	2 (4.3)	6 (10)	8 (7.5)
Female	45 (95.7)	54 (90)	99 (92.5)
Age (years), mean (SD)	N/A[a]	N/A	21.14 (0.69)
Male	22.00 (1.41)	20.50 (0.55)	20.88 (0.99)
Female	21.40 (0.54)	20.96 (0.70)	21.16 (0.67)

[a]N/A: not applicable.

Effectiveness of VRS in Infection Control Theoretical Knowledge

Pre- and posttest assessments of infection control knowledge were conducted at T0 and T1, with a maximum score of 10 points. The combined results of all participants showed an average pretest knowledge score of 7.58 (SD 1.13) and a posttest knowledge score of 8.58 (SD 1.16), indicating improved knowledge after course completion (t_{106}=–7.08; P<.001). Both the VRS and control groups demonstrated significant improvements in theoretical knowledge scores (for the VRS group t_{46}=–.747; P<.001 and for the control group t_{58}=–4.04; P<.001). However, the VRS group achieved significantly higher posttest scores compared with the control group ($t_{98.13}$=2.70; P=.008), suggesting that VRS teaching was more effective in enhancing students' knowledge (Table 2 and Figure 3).

Figure 3. Change in infection control knowledge in the two groups. T0: pretest; T1: posttest; **: *P*<.01.

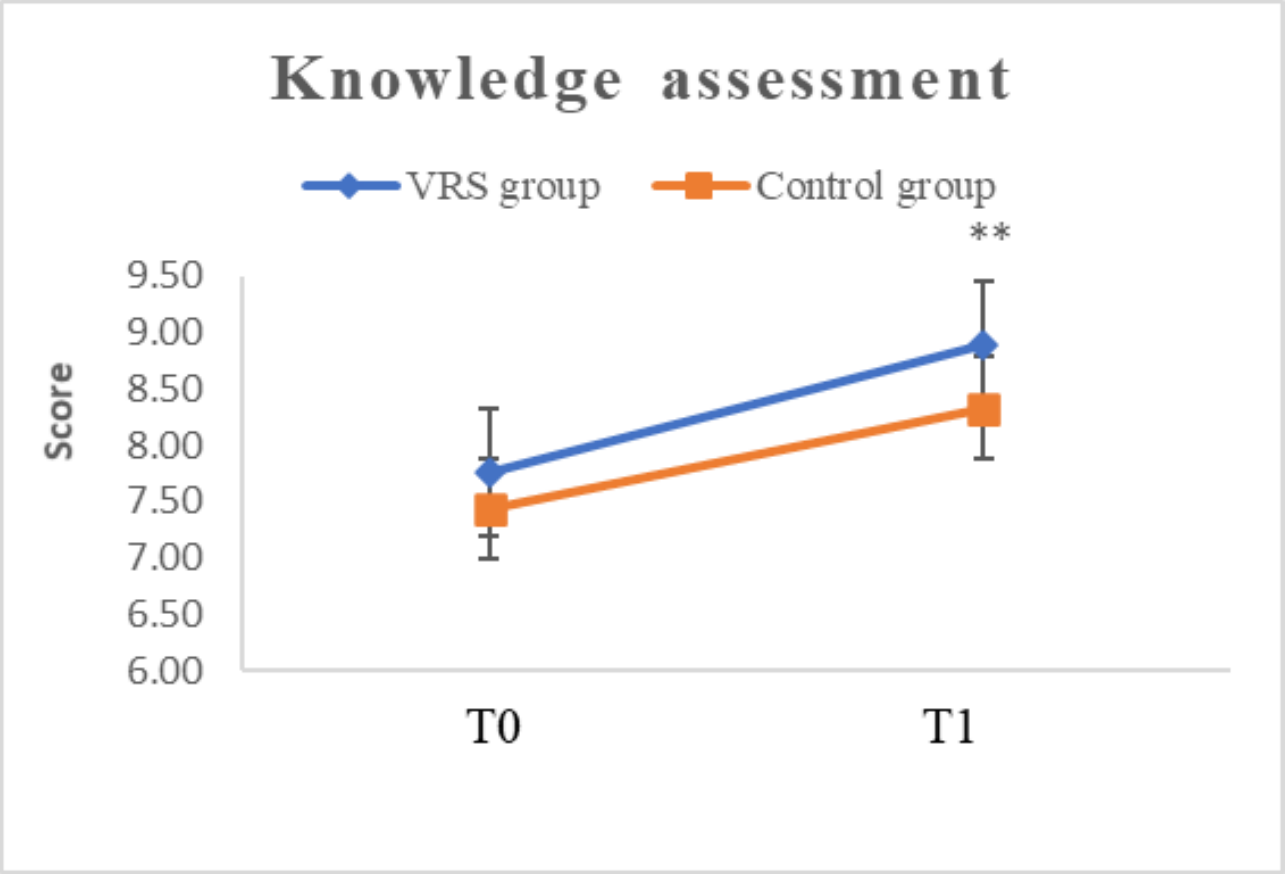


Table 2. Comparison of theoretical knowledge scores in the 2 groups (N=107).

Variable	T0[a], mean (SD)	T1[b], mean (SD)	*t* test (*df*)	*P* value
Knowledge assessment				
Virtual reality simulation	7.77 (1.05)	8.89 (0.79)	–7.47 (46)	<.001
Control	7.43 (1.18)	8.33 (1.34)	–4.04 (58)	<.001
t test (*df*)	1.52 (105)	2.70 (98.13)	N/A[c]	N/A
P value	.13	.008[d]	N/A	N/A
Total	7.58 (1.13)	8.58 (1.16)	–7.08 (106)	<.001

[c]N/A: not applicable.

Effectiveness of VRS on Learning Motivation

The learning motivation of all students increased slightly from T0 (mean 3.84, SD 0.47) to T1 (mean 3.94, SD 0.40) (t_{106}=–3.10; *P*=.002), with no significant differences between the groups at either T0 ($t_{76.50}$=0.09; *P*=.93) or T1 ($t_{80.95}$=1.43; *P*=.16). At T0, except for the Confidence dimension—which was lower in the VRS group compared with the control group ($t_{78.53}$=–2.12; *P*=.04)—the other dimensions of the ARCS model (ie, Attention, Relevance, and Satisfaction) did not differ significantly between the groups. At T1, only the Attention dimension differed significantly between the VRS and control groups, being higher in the VRS group (t_{105}=2.30; *P*=.02), as shown in Table 3.

Table 3. Comparison of learning outcomes between the 2 groups at different time points (N=107).

Variable and groups	T0[a]			T1[b]		
	Mean (SD)	*t* test (*df*)	*P* value	Mean (SD)	*t* test (*df*)	*P* value
Motivation		0.09 (76.50)	.93		1.43 (80.95)	.16
Virtual reality simulation	3.84 (0.57)			4.01 (0.46)		
Control	3.83 (0.38)			3.89 (0.34)		
Attention		0.91 (105)	.36		2.30 (105)	.02[c]
Virtual reality simulation	3.84 (0.67)			4.03 (0.52)		
Control	3.74 (0.48)			3.82 (0.42)		
Relevance		0.76 (82.99)	.45		0.88 (105)	.38
Virtual reality simulation	4.15 (0.54)			4.21 (0.48)		
Control	4.07 (0.41)			4.14 (0.37)		
Confidence		–2.12 (78.53)	.04[c]		0.86 (105)	.39
Virtual reality simulation	3.45 (0.58)			3.65 (0.49)		
Control	3.66 (0.40)			3.58 (0.43)		
Satisfaction		0.51 (78.30)	.61		0.48 (105)	.63

Control	3.92 (0.44)			4.13 (0.50)		
Attitude		–0.60 (105)	.55		0.03 (105)	.98
Virtual reality simulation	4.09 (0.57)			4.34 (0.52)		
Control	4.15 (0.50)			4.34 (0.56)		

[a]T0: pretest.

[b]T1: posttest.

[c]*P*<.05.

To address potential bias stemming from the differences in the Confidence dimension between the VRS and control groups at T0, the Generalized Estimating Equations model was applied to analyze and compare changes in both groups throughout the study period and to evaluate the outcomes of the VRS intervention. For the VRS group, the regression coefficients for the Confidence dimension were significant (β=.29; *P*=.03), with positive parameter estimates compared with the control group. This finding indicates that the VRS intervention enhanced students' learning confidence.

Effectiveness of VRS on Learning Attitude

The learning attitude score increased slightly in the VRS group from T0 (mean 4.09, SD 0.57) to T1 (mean 4.34, SD 0.52) and in the control group from T0 (mean 4.15, SD 0.50) to T1 (mean 4.34, SD 0.56). However, no significant differences were observed between the groups at either T0 or T1, as shown in Table 3.

Phase 2: The Students' Learning Experiences of the VRS in Caring for Patients With Infectious Diseases

Overview

In phase 2 of this study, 18 students from the VRS group who had expressed willingness to be interviewed were recruited for qualitative interviews. All interview participants were female. Data analysis followed the phenomenographic steps of familiarization, condensation, comparison, grouping, articulating, labeling, and contrasting [32]. Each theme elicited from the participants' pool of meaning represented a concept of their learning experiences associated with engaging in the VRS program. The core theme captured the relationship between each theme and participants' overall understanding of their VRS learning experiences. The students' learning experiences were categorized into 4 themes: (1) Application of Professional Knowledge to Patient Care, (2) Enhanced Infection Control Skills, (3) Demonstrated Confidence in Patient Care, and (4) Participation in Real Clinical Cases. The core theme was identified as Strengthening Clinical Patient Care Competencies.

Theme 1: Application of Professional Knowledge to Patient Care

The students described how they applied their theoretical knowledge of infection control during the VRS teaching process, particularly regarding the various factors that need to be considered when entering and exiting the negative pressure isolation unit. Through the feedback and debriefing provided by the VRS teaching, they were able to reflect on the content of their infection control learning, thereby deepening their professional knowledge in this area.

Theme 2: Enhanced Infection Control Skills

The participants shared their experiences of using VRS to practice the care skills learned in the infection control unit. Through hands-on practice and observing their classmates, they noted improvements in their skills. They also reported that the course's practical and interactive scenarios enhanced their learning interest, which translated into positive learning outcomes.

Theme 3: Participation in Real Clinical Cases

Most of the students in the integrated care course for Emergency and Critical Care expressed a desire to intern or work in emergency departments or intensive care units. However, during the pandemic, many hospitals' critical care units halted the acceptance of nursing interns or prevented students from participating in the care of patients with infectious diseases during their ward internships. The participants reported that the realistic, scenario-based case studies in the VRS enabled them to practice clinical skills that would otherwise have been unavailable, thereby bridging the gap between theory and practice. The experience of providing care for simulated patients in a context closely resembling clinical settings enhanced their learning experience.

Theme 4: Demonstrated Confidence in Patient Care

During the interviews, participants shared that they had been concerned about their ability to provide effective clinical care for patients with infectious diseases due to the impact of the pandemic. However, after participating in the VRS course, they reported a boost in their confidence in providing this type of care.

Core Theme: Strengthening Clinical Patient Care Competencies

The core theme that emerged from the analysis of the qualitative data on students' learning experiences in the VRS teaching program was the strengthening of their clinical care competencies. The VRS learning program allowed students to apply the professional knowledge and skills they had learned in the course to carefully design patient scenarios. Through VRS practical exercises, students improved the skills required to care for patients with infectious diseases. By engaging with clinical cases and performing learning tasks in a realistic setting, they gained greater confidence in caring for patients with infectious diseases. In other words, this approach of connecting learning experiences enhanced their clinical care competence, better preparing them for the future care of patients with infectious diseases.

Discussion

Principal Findings

The results of this study showed significant improvements in infection control knowledge scores in both groups, with the VRS group achieving higher scores, highlighting the effectiveness of VRS teaching in enhancing theoretical knowledge. The VRS group also achieved a higher attention score at T1 compared with the control group. Additionally, the VRS intervention enhanced students' learning confidence. Students' reflections on their learning experiences and perceptions of the VRS teaching emphasized the following themes: Application of Professional Knowledge to Patient Care, Enhanced Infection Control Skills, Demonstrated Confidence in Patient Care, Participation in Real Clinical Cases, and Strengthening Clinical Patient Care Competencies.

This study made every effort to control variables to ensure consistency in learning content and teaching quality between the 2 groups, including the use of the same teaching materials and the same instructor for both groups. The VRS provided immediate feedback, allowing students to actively engage in the care process within a VR patient scenario, which contributed to enhanced learning outcomes in the VRS group. However, due to the larger number of students in the control group, their debriefing session was delayed. Future studies could investigate the impact of debriefing timing on the effectiveness of VRS-based teaching.

Comparison With Prior Work: Effectiveness of VRS in Infection Control Knowledge

The results of this study demonstrated significant improvement in infection control knowledge in both groups after the learning process. The VRS group achieved significantly higher scores on the infection control written test compared with the control group at T1, indicating that VRS teaching was more effective in enhancing students' theoretical knowledge. This finding aligns with previous research. Systematic reviews and meta-analyses on VR in nursing education have demonstrated its effectiveness in improving knowledge [5,35]. Another review reported a moderate effect size (g=0.47) for VR teaching in knowledge acquisition [29]. Additionally, this review noted that subgroup analysis showed VR training involving multiple self-practice sessions of less than 30 minutes was effective in imparting procedural knowledge to undergraduate nursing students [29]. This finding is consistent with the results of our study, where each student engaged in VRS learning for 6-8 minutes, with the option for continued practice for those wishing to further develop their skills. An integrative review also concluded that VRS teaching is effective in enhancing the acquisition of clinical skills and knowledge [36]. An extensive review of 29 randomized controlled trials involving 2722 students found that VR, augmented reality, and mixed reality were as effective as traditional methods in enhancing knowledge, highlighting their potential role in preclinical education [37]. Similarly, a German study on teaching tracheal suction skills observed no statistical differences among various teaching methods in terms of knowledge and skill improvement, suggesting that VR can serve as a supplementary resource to existing learning strategies, supporting students in preparing for clinical practice [23].

Impact of VRS on Learning Motivation and Attitude

A systematic review and meta-analysis of 26 studies found no significant impact of VR on nursing students' motivation and cognitive load compared with traditional teaching methods [38]. This aligns with the findings of our study, which also showed no significant difference in learning motivation. However, other studies have reported higher motivation and satisfaction with VR, though it may also increase cognitive load [39].

Additionally, several studies have shown that VR positively impacts learners by enhancing attention and motivation, building self-efficacy, and reinforcing learning confidence and performance [5,6,21,25]. A Taiwanese study comparing traditional and VR teaching on nasogastric tube feeding found nonsignificant higher scores in the VR group, which demonstrated greater motivation and satisfaction but also experienced a higher cognitive load [39]. These findings highlight the need to carefully consider cognitive load in future course designs [39].

A South Korean study reported higher neonatal resuscitation knowledge, motivation, problem-solving skills, and confidence in the VR group compared with the control groups, along with lower anxiety levels [26]. An integrative review on VR teaching for emergency patients also revealed increased confidence in handling emergencies [25]. Although some studies have reported no significant differences in anxiety and confidence [3,40], further research is needed to determine VR's impact on learning confidence and stress. A Chinese study on disaster nursing courses found significant improvements in preparedness, confidence, and performance in the experimental group, highlighting VR's potential as a cost-effective simulation method [41]. Technical issues with VR were noted as disadvantages, which may explain the lower precourse confidence in the VRS group compared with the control group. Ensuring that students are familiar with the VR system before the course begins may help improve their confidence [1,27,42,43].

Student's Learning Experiences of VRS

Analysis of the qualitative data obtained in this study revealed 4 themes in students' experiences and perceptions of VR learning: Application of Professional Knowledge to Patient Care, Enhanced Infection Control Skills, Demonstrated Confidence in Patient Care, and Participation in Real Clinical Cases. The core theme identified was the Strengthening Clinical Patient Care Competencies. Similarly, previous qualitative studies have demonstrated a positive impact of VR learning on knowledge [23,24,43], skills [21,23,24], confidence [23], and engagement [4]. Some of these studies focused on VR learning as a tool, while others examined the characteristics of the VR environment [21,23,43]. By contrast, our study applied a phenomenographic methodology to explore students' experiences and perceptions of VR learning, linking these to various outcomes. As a result, our findings provide unique insights into students' conceptions of VR learning.

Strengths and Limitations

The strength of this study lies in its combination of quantitative and qualitative methods, providing a comprehensive understanding of the effectiveness of VRS teaching. However, some potential limitations and weaknesses should be considered. Although the sample size was adequate, it may not fully represent the diversity of nursing students, as it was drawn from only 1 university. The course in which the VRS program was applied was an elective unit offered in both the first and second semesters, with a maximum enrollment of 60 students per class. The number of students enrolled in each class was beyond the researchers' control, resulting in an imbalance in the number of students between the 2 groups. It is recommended that future studies compare the effectiveness of VRS using groups of equal size and a larger number of participants. This study did not conduct a formal survey on potential side effects among students in the experimental group. However, during the VRS session, research team members and the instructor periodically checked in with the students. None of the students reported any discomfort that required them to pause or stop the activity. The control group engaged in practical exercises for donning and doffing PPE, which differs from the traditional nursing classroom teaching methods used in previous studies. Future research is needed to build on our findings and develop a more detailed understanding of the effectiveness of VRS programs.

Conclusions

This study highlights the effectiveness of VRS teaching in enhancing infection control knowledge, learning motivation, attitudes, and course satisfaction among undergraduate nursing students. By combining insights from qualitative data with quantitative information, we have provided a holistic understanding of the potential role of VRS in nursing education. Despite its limitations, this study opens avenues for future research and presents a compelling case for the broader implementation of VR in nursing education curricula. Future studies should consider longitudinal designs to evaluate the long-term impacts of VRS teaching on nursing education. Additionally, expanding the participant pool to include a more diverse range of students could yield more generalizable results. The findings have significant implications for nursing education, suggesting that VRS teaching can effectively enhance learning outcomes, particularly in areas that require high levels of practical knowledge and skills. The positive impact on student motivation and attitudes also points to a potentially transformative shift in how nursing education can be delivered, especially in a post–COVID-19 era, where digital and remote learning tools are becoming increasingly important.

Use of Generative Artificial Intelligence

During the preparation of this work, the authors used ChatGPT (OpenAI) to enhance the clarity of the content. After using ChatGPT, the authors reviewed and edited the content as needed and took full responsibility for the content of the published article.

Acknowledgments

This research was funded by the National Science and Technology Council (grants MOST 110-2511-H-255-013 and MOST 111-2410-H-255-010). The authors thank those students who participated in this research.

Data Availability

The data that support the findings of this study are available on reasonable request from the corresponding author.

Authors' Contributions

The conception and design of the study were carried out by WC, CCL, and CYH, while data acquisition and collection were performed by WC and CYH. The analysis and interpretation of data involved WC, CCL, LCC, and CYH. WC, CCL, and CYH drafted the manuscript, and critical revisions were made by WC, CCL, JC, HLL, LCC, and CYH. The final approval of the manuscript was provided by WC, CCL, JC, HLL, LCC, and CYH. Administrative, technical, or material support was provided by WC, CCL, and CYH, with resources provided by HLL and LCC. Supervision and validation were undertaken by CCL and CYH, and funding for the study was obtained by CYH.

Conflicts of Interest

None declared.

Abstract

Background: Technological innovation is reshaping the landscape of medical education, bringing revolutionary changes to traditional teaching methods. In this context, the upgrade of the teaching model for microscopy, as one of the core skills in medical education, is particularly important. Proficiency in microscope operation not only affects medical students' pathology diagnosis abilities but also directly impacts the precision of surgical procedures and laboratory analysis skills. However, current microscopy pedagogy faces dual challenges: on one hand, traditional teaching lacks real-time image sharing capabilities, severely limiting the effectiveness of immediate instructor guidance; on the other hand, students find it difficult to independently identify technical flaws in their operations, leading to inefficient skill acquisition. Although whole-slide imaging-based microscopy system technology has partially addressed the issue of image visualization, it cannot replicate the tactile feedback and physical interaction experience of the real world. The breakthrough development of 5G communication technology—with its ultrahigh transmission speed and ultralow latency—provides an innovative solution to this teaching challenge. Leveraging this technological advantage, Tongji University's biology laboratory has pioneered the deployment of a 5G local area network (LAN)–supported digital interactive microscopy system, creating a new model for microscopy education.

Objective: This study aims to investigate the efficacy of an innovative 5G LAN-powered interactive digital microscopy system in enhancing microscopy training efficiency, evaluated through medical students' academic performance and learning experience.

Methods: Using a quasi-experimental design, we quantify system effectiveness via academic performance metrics and learning experience dimensions. A total of 39 students enrolled in the biology course were randomly assigned to 2 groups: one using traditional optical microscopes (control) and the other using the digital microscopy interactive system (DMIS). Their academic performance was evaluated through a knowledge test and 3 laboratory reports. A 5-point Likert-scale questionnaire was used to gather feedback on students' learning experiences. In addition, the DMIS group was required to evaluate the specific functions of the system.

Results: In the knowledge test, no statistical difference was found between the 2 groups; however, the DMIS group scored significantly higher in Lecture 2 (P<.05). In the laboratory reports, the DMIS group performed significantly better than the control group (mean 90.33, SD 2.63 vs mean 80.53, SD 3.52, P<.001). Questionnaire results indicated that the DMIS group has a positive evaluation of the system and expressed greater confidence in its future application. For the evaluation of the laboratory lectures, the DMIS group received higher evaluations on the course content and self-efficacy (P<.05), and higher satisfaction with the laboratory lectures (P<.05).

Conclusions: Overall, the digital microscope interactive system enhances students' learning experiences and improves their academic performance. It offers various interactive functions to facilitate the organization of teaching activities and promote immediate feedback in the classroom. Thus, it is a promising tool for microscopy laboratory teaching.

KEYWORDS

microscopy technique; digital interactive system; 5G; medical education; undergraduate

Introduction

Emerging technologies are rapidly proliferating, elevating the quality of medical training and better preparing students for future clinical practice [1]. For instance, whole-slide imaging-based microscopy system is accepted as a major technique in the teaching of pathology, anatomy, and histology in several countries [2]. A multimedia-supported manikin system capable of simulating a real clinical operating environment was reported to help students reduce barriers to entering the clinic [3]. Furthermore, 3D printing technology, in addition to its application in clinical practice, provides educators with a cost-effective and efficient educational tool [4]. The maturity of multiple technologies has enabled the potential for technical upgrades to microscopy as a fundamental teaching tool.

Microscopy provides a methodological foundation for high-resolution observation and quantitative analysis of microscopic phenomena [5]. As a core competency for medical students, this technique enhances skill acquisition in pathological diagnostics through microstructural visualization, improves intraoperative spatial localization precision via microscope operational adjustments, and supplies essential analytical capabilities for indispensable scientific experimentation. However, current microscopy instruction faces significant challenges: traditional optical training suffers from delayed feedback, as instructors cannot monitor student operations in real time. This leads to undetected technical errors until learners proactively seek guidance [6]. Compounding this issue, beginners lack the expertise to self-identify technical deficiencies [7], creating a dual problem of instructor feedback absence and limited student self-assessment. Such gaps risk entrenching structural misconceptions. While whole-slide imaging-based microscopy system enables image visualization, its inherent limitations remain critical: it fails to replicate optical parameter adjustment processes and lacks tangible tactile feedback [8], thereby undermining practical skill development. Microscopy expertise necessitates not only the physical ability to visualize specimens but also the cognitive capacity to explore and discriminate among potential morphological variations for accurate characterization of target samples. This dual requirement implies that both knowledge internalization and operational proficiency constitute core learning objectives in microscopy instruction, whereas current pedagogical approaches demonstrate limitations in concurrently achieving these competencies.

The digital microscope interactive system, based on optical microscopes, is a multiterminal digital imaging device connected by 5G local area network (LAN). The system retains the tactile sensation of physical operation while enabling the display of microscopic images on software-equipped devices (such as computers, tablets, or mobile phones) through analog-to-digital conversion. Leveraging 5G's high-bandwidth connectivity, the system enables instantaneous image transmission between terminals. Consequently, instructors can simultaneously observe all students' microscope images on the teacher-terminal computer. This real-time monitoring capability enables immediate detection of operational errors, even in the absence of student feedback. Beyond real-time oversight, the multiplatform compatibility supports interactive pedagogical functions such as distributing laboratory instructions, uploading resulting images, demonstrating operations, and so on. The high popularity of smartphones among students currently makes this mode both flexible and economical [9].

Previous reports have documented the application of 5G technology in multiple educational scenarios [10,11]. While a digital microscope system has been implemented in the pathogenic biology laboratory in China [12], no research has yet reported the deployment of 5G LAN-based digital interactive microscopy systems in laboratory teaching. Consequently, investigating 5G-enabled interactive microscopy systems embodies significant innovative potential to enhance instructional efficacy by addressing the aforementioned limitations in microscopy instruction.

Microscopy instruction in medical education faces challenges of delayed instructor feedback and limited student self-correction capabilities, which impact skill acquisition efficiency. To address this challenge, Tongji University innovatively deployed a 5G LAN-based digital microscopy interaction system (DMIS). This system preserves the tactile sensation of physical operation while leveraging digital microscopy for procedural visualization. Capitalizing on 5G's high-speed transmission, it establishes an immediate feedback mechanism, thereby enhancing instructional efficiency in microscopy training. Using a quasi-experimental design—frequently applied in education [13,14]—this study compared the instructional efficacy between this digital system and conventional optical microscopy training. We hypothesize that these technological features will significantly improve pedagogical outcomes. A comparative analysis of academic performance and learning experience questionnaire data between the DMIS group and the traditional training control group provides evidence-based guidance for medical educators reliant on microscopy technology to optimize pedagogical approaches.

Methods

Experimental Procedures and Participants

The biology course for medical undergraduates at Tongji University is a second-year component of the curriculum, comprising 10 theoretical sessions and 3 laboratory sessions. These laboratory sessions are aligned with the theoretical learning schedule and consist of 4 periods for each session, including the use of microscopes and cell cycle analysis, cell counting and cell culture, and mouse chromosome preparation and karyotype analysis (see Table 1). Students are organized into classes of 20, with 2 classes running simultaneously. In each class, the instructor introduces the experimental content and principles, followed by a demonstration of the procedure. Students then work in pairs to conduct the experiments and complete their laboratory reports according to the requirements outlined in the Microsoft PowerPoint slides provided by the

instructor. All activities described in this article have received informed consent from the students.

Table 1. Laboratory experiments.

Experiment name	Experimental activities
The use of a microscope and cell cycle analysis.	• Microscopy training with commercially prepared slides. • Capture clear and accurate images of each stage of mitosis.
Cell counting and cell culture.	• Prepare the cell sample and count viable cells using microscopy. • Cell passaging.
Preparation and observation of mouse chromosomes.	• Prepare and stain mouse chromosomes. • Capture clear images of mouse chromosomes.

Digital Microscopy Interactive System

The digital microscopy interaction system primarily consists of 3 parts: Panthera I series optical microscopes (Motic Corp), Motic Digilab 3.0 software (Motic Corp), and a computer or mobile device, all of which can connect via a 5G LAN (see Figure 1). In class, students need to download and install the software from the app store onto their digital devices (eg, smartphones and tablets), connect to the designated 5G LAN, and enter their microscope number in the software to view live microscopy images. This setup enables real-time sharing of all microscopic images across the network. Simultaneously, the instructor's terminal computer with the installed software can display all microscope images currently in use, allowing both students and the instructor to visualize the live microscopic manipulations at the same time (see Figure 2A).

Figure 1. The framework of a digital microscopy interactive system based on 5G local area network (LAN).

The Motic Digilab 3.0 software supports 4 functions for both instructors and students (see Table 2). On the student side, students can capture live images, record videos, and ask questions within the interface (see Figure 2C). On the instructor side, instructors can monitor the progress of all students and address issues based on their live images. Since both sides are connected to the same 5G LAN, they can transfer files to each other, thereby enhancing the efficiency of teaching activities (see Figure 2B).

Figure 2. The function of digital microscopy interactive system.

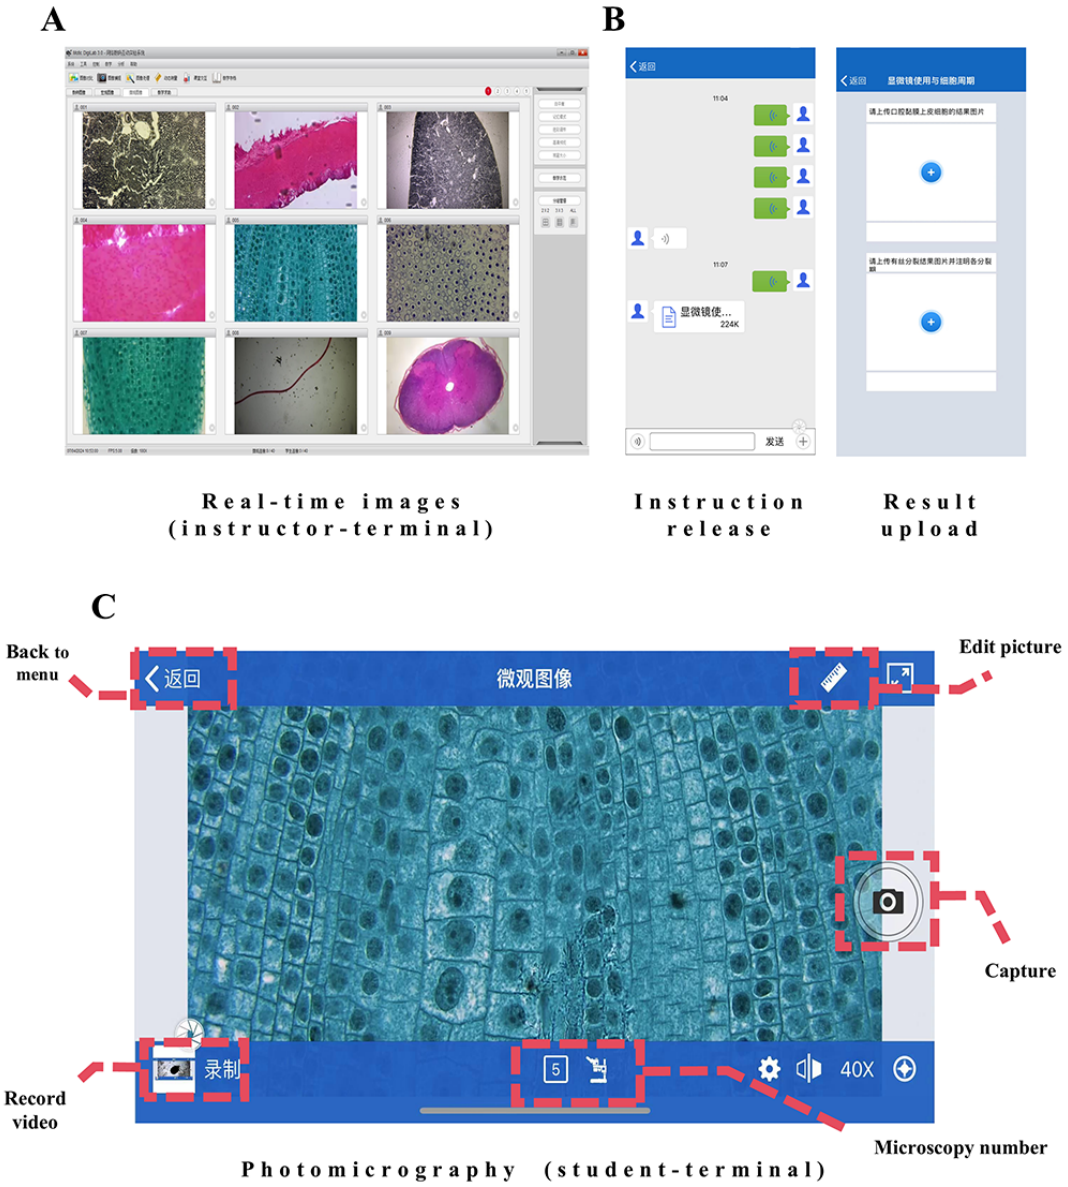

Table 2. The functions of the digital microscopy interactive system.

Function	Instructors' terminal	Students' terminal
Microimage	• View images observed by all student-terminal microscopes in real time.	• View live images observed under the microscope on its mobile app.
Macroimage	• View videos recorded by all student-terminal mobile phones.	• Record the experimental process with a mobile phone camera.
Demonstration	• Use the instructor-terminal microscope to demonstrate proper operation in either forced or unforced mode.	• Continue to use the microscope, while students who have difficulties can refer to the instructor's demonstration.
Interaction	• Deliver the protocol and requirements of this experiment. • Instruct students through their real-time microscope images.	• Upload the result images of this experiment as required. • Ask questions by text or voice in their mobile app.

Grouping

The biology course, conducted in the second semester of the 2023-2024 academic year, involved a total of 39 medical freshmen. In this study, randomization was performed using a computer-generated randomization program integrated within the school education management system. Concealment was ensured by implementing the allocation through the school's system without any manual intervention or researcher influence. Participants were randomly assigned to 2 groups: the DMIS group, which used the digital microscope interactive system, and the control group, which used the traditional optical microscope.

Evaluation

The assessment framework (see Table 3) for the DMIS, designed around the instructional objectives of mastering operation and internalizing knowledge, comprises 4 key components. Specifically, student academic performance was jointly assessed using 1 knowledge test and 3 laboratory reports used to evaluate the internalization of knowledge and proficiency in operation. Furthermore, student learning experience feedback is collected via a 5-point Likert scale questionnaire. In addition, students in the DMIS group complete a supplementary 5-point Likert scale questionnaire specifically designed to evaluate the system's functional features.

Table 3. The evaluation framework of the digital microscopy interactive system.

Dimension	Testing method	Participants	Measure analyzed
Knowledge	Knowledge test	All students	Comprehension of knowledge and mastery of operational protocols.
Skill	Laboratory reports	All students	Microscope operation proficiency and accuracy in result analysis.
Attitude	A 5-point Likert scale questionnaire	All students	Course satisfaction.
Functional evaluation	A 5-point Likert scale questionnaire	DMIS[a] group	System capabilities and future applications.

[a]DMIS: digital microscopy interactive system.

The knowledge test was jointly designed by all instructors participating in the Biology course instruction. To assess comprehension of structural knowledge and mastery of operational protocols, 6 questions were implemented per laboratory lecture. It has been reported that multiple true-false questions are superior in revealing students' misunderstanding of knowledge [15,16]. Therefore, a total of 18 true-false questions were designed. After class, each student anonymously completed the online test through the Sojump platform at the same time.

Their laboratory reports were submitted to the Canvas learning management system at Tongji University, enabling all course instructors to access and evaluate these documents online. The assessment rubric, collaboratively developed by the faculty members, primarily emphasizes microscope operation proficiency and accuracy in result analysis. Each dimension was assessed using a 4-tier performance scale: excellent (45 points), proficient (40 points), satisfactory (35 points), and unsatisfactory (30 points). This contributed to a maximum of 50 points per dimension, thereby yielding a total possible score of 100 points. Student competence in microscopy techniques was evaluated through the scoring of micrographs presented in the reports. High-quality microscopic images reflect proper adjustment of the microscope to achieve optimal resolution, appropriate magnification, and adequate illumination during image capture. Interpretation of results demonstrates students' understanding of target cell biological characteristics and their proficiency in identifying and locating cellular structures through microscopic techniques.

All participants anonymously completed a 5-point Likert scale questionnaire assessing their learning experiences in laboratory lectures. It encompassed four domains: (1) course content, (2) teaching quality, (3) self-efficacy, and (4) teaching effectiveness, with 3-4 items per domain. Specifically, course content assessed the difficulty level, scheduling, interest, and challenge of the laboratory lectures; teaching quality evaluated classroom organization, instructional clarity, and comprehensibility; self-efficacy measured students' confidence in completing tasks and resolving challenges; and teaching effectiveness gauged whether students had a better understanding of knowledge, techniques, and laboratory safety. Finally, an open-ended item invited students to share which technology they have benefited the most from in their classroom learning.

Functional evaluation of the digital microscopy interactive system was conducted by the DMIS group via a 5-point Likert scale questionnaire. This anonymously collected questionnaire assessed user perceptions of system capabilities and future applications.

Analysis

The Sojump platform automatically scored students' responses against predetermined answers and converted results to percentage scores. The Canvas learning management system recorded laboratory report grades based on instructors' online assessments. Open-ended responses regarding "What technology has benefited you the most in classroom learning?" were analyzed through word frequency analysis provided by the Sojump platform. All data were statistically analyzed using IBM SPSS Statistics (version 26). Group comparisons were performed using the independent samples *t* test for normally distributed continuous variables, while the nonparametric test, such as the Mann-Whitney *U* test, was used for categorical variables or continuous variables deviating from normality. The internal consistency of questionnaire items was evaluated using the Cronbach alpha coefficient (Cronbach α), with Cronbach $\alpha \geq 0.70$ considered acceptable for scale reliability. Statistical significance was determined at $P<.05$. Data are presented as mean (SD).

Ethical Considerations

This study was conducted in accordance with established ethical principles, with participation being voluntary in nature. All participants received comprehensive information regarding the study's objectives, procedures, and potential implications. They were assured of their right to withdraw at any stage without penalty. The confidentiality of the data was rigorously maintained through the anonymization of all responses, which were subsequently analyzed and reported in aggregated form.

All procedures involving human subjects were carried out in compliance with the ethical standards set forth by relevant national research committees [17]. The study strictly followed applicable ethical guidelines and data protection laws, thereby safeguarding participants' rights and privacy throughout the research process.

Results

Participants' Demographics

A total of 39 students participated in this course, with 19 in the control group and 20 in the DMIS group. All participants were approximately aged 20 (mean 19.56, SD 0.50) years, with the control group aged 19.74 (SD 0.45) years and the DMIS group aged 19.40 (SD 0.50) years. The demographics of all participants are presented in Table 4. The two groups had a similar composition in terms of gender and GPA (grade point average), which were confirmed to show no statistically significant difference (P>.05). Previous academic performance (mean score of previous courses) also showed no significant difference between the groups (P>.05), with mean scores of 82.09 (SD 5.49) and 80.69 (SD 5.58) for the control and DMIS groups, respectively.

Table 4. The demographics of the participants.

Variable	Total (n=39), n (%)	Control group (n=19), n (%)	DMIS[a] group (n=20), n (%)	*P* value
Students	39 (100)	19 (100)	20 (100)	—[b]
Sex				.66[c]
Male	15 (38.5)	6 (37.5)	7 (35)	
Female	24 (61.5)	10 (62.5)	13 (65)	
GPA[d]				.71[e]
≧4.0	12 (30.8)	6 (37.5)	5 (25)	
3.5-3.9	18 (46.2)	7 (43.8)	10 (50)	
＜3.5	9 (23.1)	3 (18.8)	5 (25)

[b]Not applicable.

[c]Independent sample *t* test.

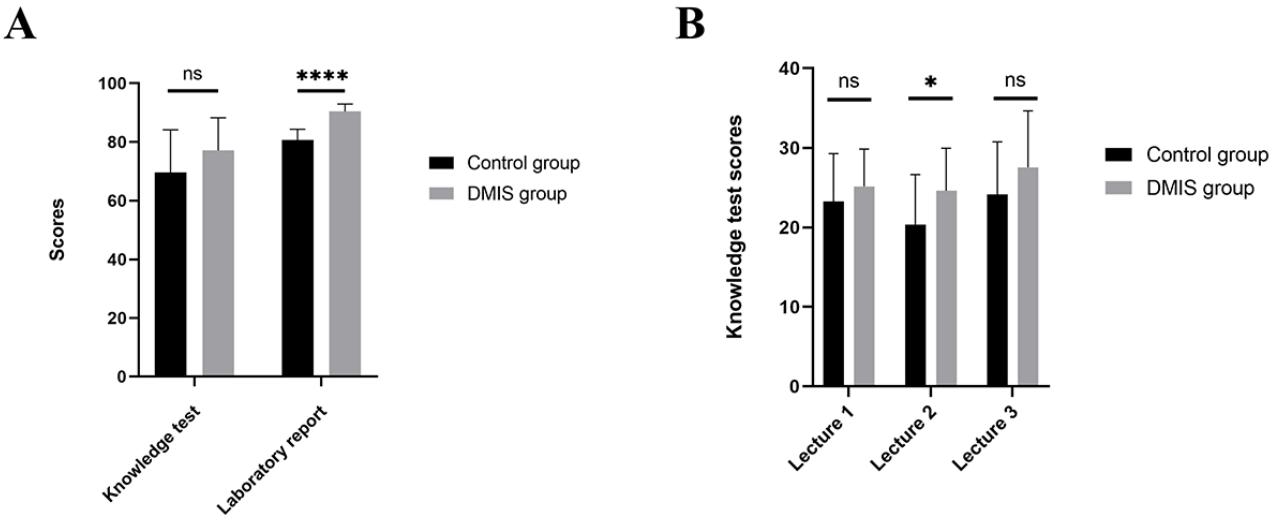
[d]GPA: grade point average.

[e]Chi-square test.

Comparison of the Academic Performance Between the Control Group and the DMIS Group

All 39 students took the knowledge test and submitted their laboratory report. In the knowledge test, the DMIS group had a higher mean score of 77.15 (SD 11.10) compared to 69.58 (SD 14.56) for the control group; however, this difference was not statistically significant (P=.075; see Figure 3A). To evaluate the system's potential impact, we assessed group performance across lectures. The DMIS group demonstrated significantly higher mean scores than controls in Lecture 2 (P<.05; see Figure 3B), which focused on microscopy-based enumeration of viable cells in prepared samples. For the performance of laboratory reports, the DMIS group scored 90.33 (SD 2.63) versus 80.53 (SD 3.52) for the control group (P<.001; see Figure 3A). Overall, the DMIS group achieved better results in both tests and reports.

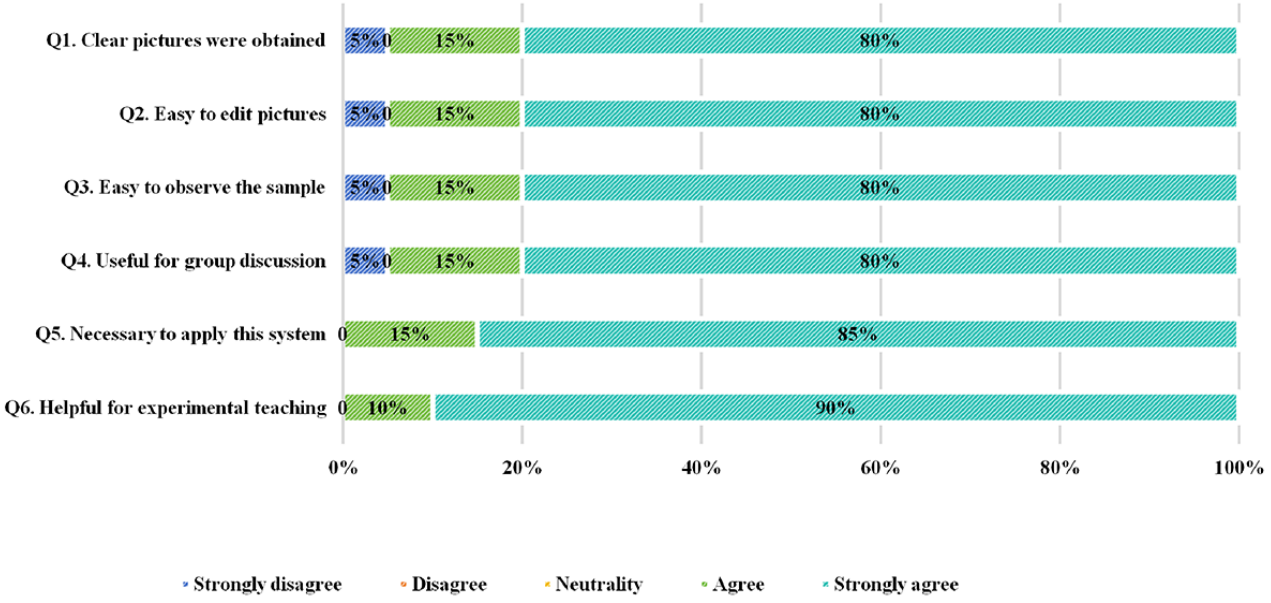
Figure 3. Comparison of scores between the control group and the DMIS group. DMIS: digital microscopy interactive system.



Functional Evaluation of This Digital Microscopy Interactive System

To capture user perspectives regarding the system's capabilities and future application, we distributed a questionnaire survey to the DMIS group. All participants (100%, 20/20) completed the questionnaire, and its Cronbach α was 0.91, indicating good reliability. In their feedback, most students provided positive evaluations and expressed satisfaction with its functions (see Figure 4 Q1-Q4). They indicated that it contributed positively by capturing clear images, providing easy-to-edit images, facilitating sample observation, and promoting group discussions. (95% agree or strongly agree). Furthermore, the students expressed confidence in its future application, and all agreed that this system is necessary and useful for biological experiments (100% agree or strongly agree; see Figure 4 Q5-Q6).

Figure 4. Responses of the digital microscopy interactive system (DMIS) group students regarding the DMIS.



Comparison of Students' Views on the Laboratory Lectures Between the Control Group and the DMIS Group

In addition to evaluating the function of this system, its impact on laboratory lectures was also assessed through the questionnaire. A total of 36 out of 39 (92.3%) students completed the survey, including 20 from the DMIS group (100%, 20/20) and 16 from the control group (84.2%, 16/19). Given its Cronbach α of 0.98, the questionnaire demonstrates high reliability. The results showed a statistically significant difference in two of the four areas addressed in the survey (see Table 5). The first area is course content. Compared to the control group, the DMIS group more strongly supported the appropriateness of the course difficulty, the reasonableness of the schedule, and found it both enjoyable and challenging (P<.05). Similarly, students in the DMIS group reported higher self-efficacy and greater confidence in facing difficulties and challenges after finishing the lectures (P<.05). Notably, there was a statistical difference in overall satisfaction between the

two groups, with the DMIS group scoring higher (mean 4.63, SD 0.50 vs mean 4.95, SD 0.22; $P<.05$). In the open-ended question, when discussing their biggest gains, 30% (6/20) of the DMIS group mentioned microscope technology, compared to 12.5% (2/16) in the control group. From the results, the implementation of this system has significantly improved the effectiveness of microscopy teaching. Furthermore, students have started to recognize the importance and application value of the microscopy technology.

Table 5. Students' perceptions regarding the laboratory lectures.

Domains	Control group (n=16), mean (SD)	DMIS[a] group (n=20), mean (SD)	*P* value
Course content	18.25 (1.88)	19.6 (1.00)	.02[b]
Teaching quality	18.75 (1.92)	19.75 (1.12)	.07
Self-efficiency	18.56 (1.93)	19.8 (0.89)	.03[b]
Teaching effectiveness	14.06 (1.44)	14.85 (0.67)	.07

[a]DMIS: digital microscopy interactive system.

[b]$P \leq .05$ was considered statistically significant.

Discussion

Principal Findings

The core competency in microscopy lies in the precise manipulation of physical components (and potentially software interfaces) to optimize optical system parameters. This process, integrated with internalized knowledge of sample microstructure, enables accurate localization, clear identification, and effective visualization of target structures within the field of view, thereby yielding reliable scientific data or diagnostic evidence. Consequently, it yields reliable scientific data or diagnostic evidence. Therefore, the core objectives of microscopy education lie in knowledge internalization and mastery of operational skills—goals that have remained a persistent challenge for traditional teaching methods. This study implements a 5G-enabled digital interactive microscopy system in biological laboratory instruction, evaluating its effectiveness through students' academic performance, learning experiences, and user evaluations of system functionality.

Our research findings indicate that, regarding academic performance, the knowledge test scores of the DMIS group were generally higher than those of the control group, with a significant difference observed in lecture 2. This disparity likely stems from the greater challenge associated with the microscope operation for counting unstained viable cells covered in that session. The high transparency of unstained viable cells renders them difficult to distinguish from the background, demanding a more robust comprehension of knowledge for identification and proficient operational skills for precise localization. This complex situation notably enhanced the value of the DMIS's technical assistance. Real-time image sharing facilitated group discussion to reach a consensus on accurate identification. Furthermore, the laboratory report scores for the DMIS group were significantly higher than those of the control group, indicating that the DMIS group obtained higher quality microscopic images. This suggests that they effectively chose the objective lens for magnification, captured the images at the correct focal plane, and adjusted the light for the brightness of the images. In addition, they correctly found the cells of interest. Actually, the microscope is a complex tool that requires not only the users' skilled operation but also a solid understanding of morphological concepts for effective image analysis [7]. In the absence of immediate instructor feedback, students are prone to developing persistent misconceptions, often remaining unaware of these errors. More critically, such misunderstandings may lead to systematic misinterpretations, resulting in erroneous interpretations of the information conveyed by images. The real-time imaging capability of the DMIS enhances classroom interactivity, a factor consistently demonstrated by multiple studies [18,19] to improve student learning outcomes. Furthermore, this system retains the tactile feedback and direct manipulation experience that students value, which is missing in whole-slide imaging-based microscopy system [20,21]. These elements contribute to effective learning of microscopy skills and a deeper understanding of image analysis. The observed improved academic performance of the DMIS group supports this conclusion.

In the questionnaire survey, students in the DMIS group provided overwhelmingly positive feedback about the digital microscope interactive system. They generally agreed that it made capturing images clear, facilitated sample observation and picture editing, and supported group discussions. Only a single student reported issues due to his mobile device being incompatible with the app, which negatively impacted his experience. Similar compatibility issues can occur with applications [22] and warrant further optimization. However, this shortcoming did not diminish students' confidence in the system's future application, reflecting their recognition of its benefits. Notably, the DMIS group expressed higher satisfaction with laboratory lectures compared to the control group, especially regarding course content and self-efficacy. This may be attributed to their ability to independently navigate the challenges of microscope technology, enhancing their skills and confidence. As a result, students in the DMIS group identified that the microscope technique was what they gained the most from the class. Given the well-known positive impact of self-efficacy on learning [23], this experience will undoubtedly enable medical students to perform better in high-intensity medical training in the future.

For medical students, proficiency in microscopy is not merely a laboratory technique but a critical component in developing core professional competencies that profoundly influence future clinical practice. First, microscopy skills enhance morphological identification capabilities, serving as a prerequisite for accurate clinical diagnosis. Second, the process of adjusting microscope parameters helps establish efficient and precise visuospatial-motor coordination, thereby improving spatial positioning accuracy in future surgical procedures. In addition, it should be noted that microscopy remains fundamental to experimental research—an essential skill for physicians in China during their clinical practice.

For instructors, this digital microscope interactive system makes the organization of classroom teaching more convenient and efficient. Previously, due to limited laboratory funding, each room was only equipped with one microphotography device, which inevitably led to insufficient usage time for each student group. Now, students can take pictures with at least one available device at any time, greatly reducing the waiting time for equipment. Digital technology can achieve real-time monitoring and feedback, providing students with a personalized learning experience [1,24]. The convenience of 5G networks lies in their ability to transmit multimedia files without delay, enabling rapid feedback between teachers and students. This immediate communication helps resolve issues promptly and significantly enhances the quality of teaching. In addition, the interactive functions provided by the software's main interface are valuable for personalized learning. For example, students can record operation videos using the function of macro image for postclass review and results analysis. If they have questions, these videos can be sent to the instructor for further improvement suggestions. More than that, the demonstration function offers 2 modes: students can freely view the synchronized transmission demonstrated by the teacher, while others can continue to use the system without disruption. While this study primarily centers on investigating how real-time operational visualization enhances microscopy technique acquisition through immediate feedback mechanisms, the system's inherent classroom interaction features—such as video recording—prove instrumental in tracking learning progression and enabling formative assessment. These capabilities offer enhanced potential for developing precision-oriented pedagogical approaches in future microscopy instruction.

Limitations

In this study, although it was observed that the digital microscope interaction system can enhance students' academic performance and learning experience, the sample size might be insufficient. In order to study the impact of this system more specifically, we only investigated the biology course where microscopy is most commonly used. This can lead to some application problems and differential performance that may arise in a large student population being overlooked. In addition, when the number of users increases, whether the system can maintain the stability of the current real-time transmission needs further analysis.

Conclusions

The digital microscopy interaction system presented in this study represents a powerful tool for laboratory instruction. By implementing digital transformation and information technology enhancements to traditional optical microscopy, the system enables real-time visualization of student operations and facilitates immediate instructor feedback. These capabilities provide effective support for achieving the pedagogical objectives of microscopy skill development in medical students. Significant improvements in learning outcomes are evidenced by enhanced academic performance and superior learning experiences. Notably, students exhibited high satisfaction with the system and demonstrated markedly increased engagement during instructional sessions. As a teaching tool, the system's rich interactive functionalities not only assist instructors in organizing teaching activities more efficiently but also support formative assessment of the learning process. This thereby creates favorable conditions for implementing personalized teaching models in the future. Collectively, these findings demonstrate the system's considerable potential as a highly promising instructional aid within medical education.

Abstract

Background: The impact of Pass/Fail or Tiered grade assessment for exams in undergraduate medical education has caused much debate, but there is little data to inform decision-making. The increasing number of medical schools transitioned to a Pass/Fail assessment has raised concerns about medical students' academic performance. In 2018, during the undergraduate medical curriculum reform at the Faculty of Medicine, Aalborg University changed some exams from Pass/Fail to Tiered grade and vice versa for other exams. These changes provide an opportunity to evaluate the different assessment forms.

Objective: This study aimed to evaluate medical students' academic performance at the final licensing exam in relation to the exam grading principle.

Methods: This single-center cohort study at Aalborg University Medical School, North Denmark Region, assesses the change from 2-digit Tiered grade to Pass/Fail evaluation and vice versa of undergraduate medical students' exams after the 4th and 5th year clinical training modules from Autumn 2015 through Spring 2023. The primary outcome was (1) the average grades at the final licensing exam and (2) the number of students failing exams during the previous two years.

Results: Among the total of 7634 exams, 7164 4th and 5th year clinical training exams were included in the comparisons, of which 3047 (42.5%) were Pass/Fail exams and 4117 (57.5%) were Tiered grade exams. The frequency of students failing exams was 3.3% (n=101/3047) at Pass/Fail and 1.97% (81/4117) with Tiered grade exams (P<.001). This difference was leveled out when counting the near-failure tiered grade as Fail. Tiered grade exams did not differ between semesters (P=.99) nor show a time trend at the 4th year (P=.66). The final licensing exam grades were unaltered (P=.47).

Conclusions: Contrary to our expectation, Pass/Fail exams exhibited a higher fail rate compared to Tiered grade exams without lowering the final academic performance. These results suggest that a shift from Tiered grades to Pass/Fail assessment redirects the focus from rewarding high performance to ensuring standards are maintained among underperforming students.

exam assessment methods; pass/fail; tiered grade; evaluation methods; undergraduate; medical education; exam; academic achievement

Introduction

The importance of exams for undergraduate medical education cannot be overestimated [1], and scores in assessments is a delicate matter gaining much attention [2]. Pass/Fail grading has the benefits of reduced stress, enhanced well-being, supporting a less competitive learning environment with a greater focus on learning [3,4]. This is of interest as a narrative review reported a high number of medical students experienced test anxiety [5]. Furthermore, Tiered grading systems do not consistently correlate with future academic performance [6], which may support a transition towards Pass/Fail grading. Accordingly, a number of medical schools have transitioned to Pass/Fail and the National Board of Medical Examiners in the United States has changed reporting the Step 1 United States Medical Licensing Examination (USMLE) from a scored test to a Pass/Fail assessment.

While these changes support a learning environment in which students learn to become excellent physicians rather than exam-experts, the impact on academic performance has been a major concern. Even though the shift to Pass/Fail grading in the USMLE Step 1 resulted from good intentions, it might have had unintended consequences. Exam-related anxiety might even increase, as medical students now only have one chance to obtain a top score on Step 2 of the USMLE [7]. This might have consequences in the selection for residency programs as top scores have been used as a predictor for a successful residency [8] and as an important selection parameter [9]. However, presumptions and preconceptions may blur a clearer view on grading at exams, and data are needed to support decision-making.

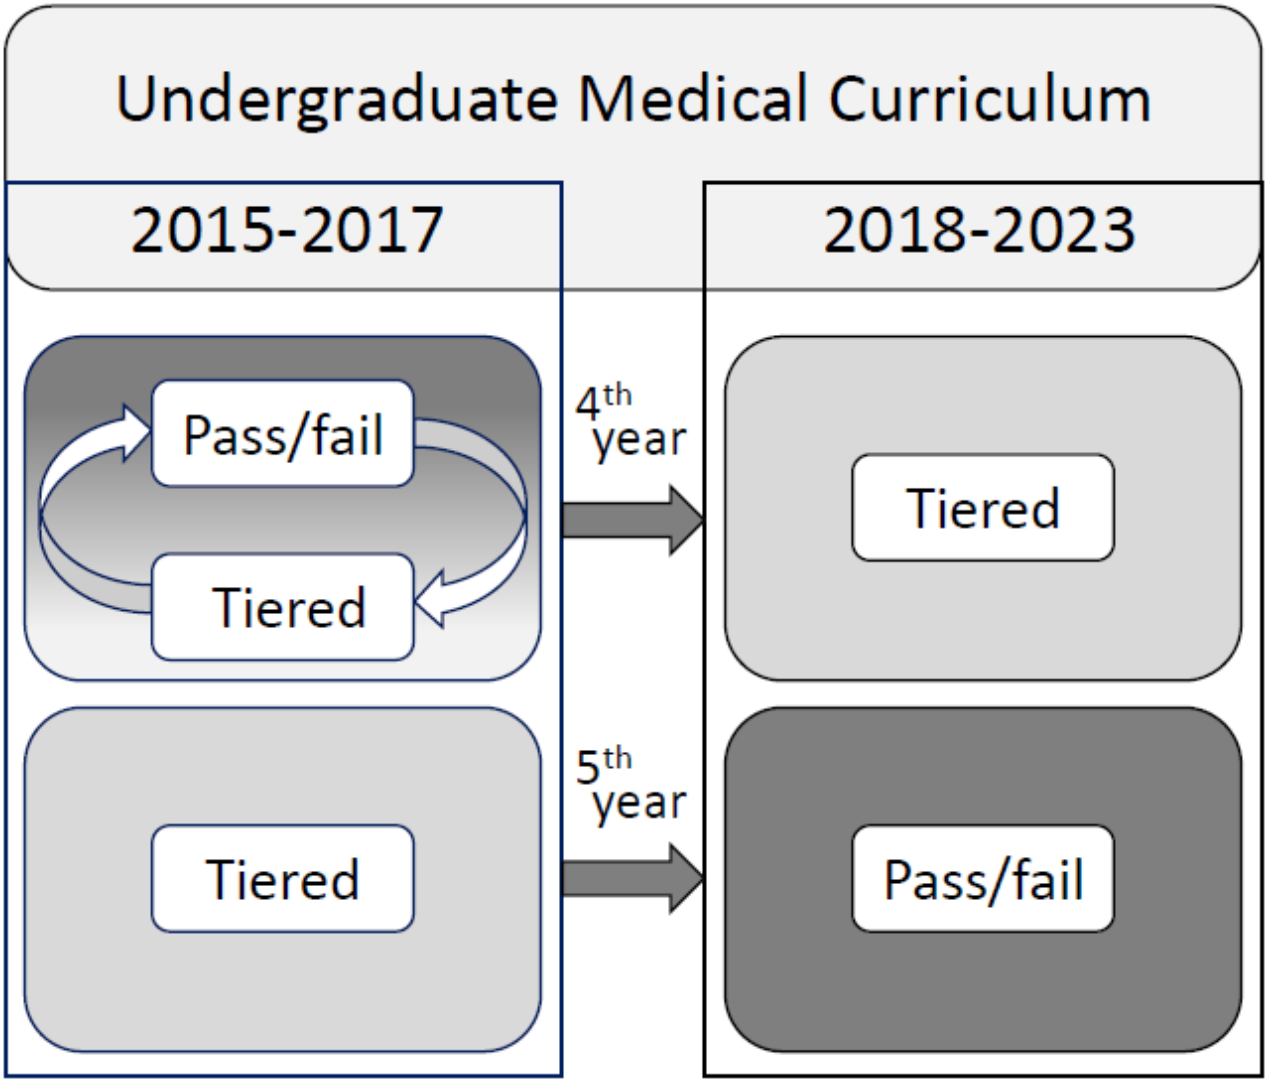
Exam outcomes are readily available as all assessments can be retrieved from Digital Exam, thus supporting quality control by regularly evaluating study outcomes. The curriculum reform of 2018 at Aalborg University Medical School changed assessment at exams between Pass/Fail and Tiered grades while retaining learning objectives, learning principles, and module organization for the 4th and 5th year. Study Board discussions and reflections among a study lead group, leading up to the decision of revising grading principles, inspired the present evaluation, as the changed grading principles provided a unique opportunity for empirically grounded evaluation of the shift from Tiered grades to Pass/Fail assessment in undergraduate medical education.

The aim of this study was to evaluate the shift from Tiered grades to Pass/Fail assessment in undergraduate medical education by comparing the outcome of Tiered grades and Pass/Fail grading at exams at the 4th and 5th year from a large, longitudinal dataset with a crossover design, and to evaluate medical students' academic performance at the 6th year final licensing exam.

Methods

Medical undergraduate education in Denmark is a six-year program split into a Bachelor's program of three years focusing on basic sciences, and a Master's program of three years with a clinical focus. The transformation from basic sciences into clinically based learning included the medical students entering the clinical environment from day 1 in their 4th year. The first clinical year, being the 4th year in the undergraduate medical education, alternated between Pass/Fail at winter exams and Tiered grades at summer exams until the 2018 curriculum reform (Figure 1).

Figure 1. Change of grading in the exams with the 2018 reform of the undergraduate medical curriculum at Aalborg University.



Year-4 exam assessments (upper, left) changed from alternating Pass/Fail and Tiered grades to Tiered grades for all exams (upper, right). Year-5 exam assessments changed from Tiered Grades (lower, left) into Pass/Fail (lower, right).

The 2018 reform [6] changed all 4th year exam assessments to use Tiered grades with the aim of supporting students' awareness of their academic level when entering the clinical years. Year-4 exams were oral exams with patients for Internal Medicine and Surgery, and a multiple choice questionnaire for Pathology (Table 1).

Table . Overview of exam type, scoring, and number of examinations split by the two time periods before and after the 2018 curriculum reform.

Study year and specialty	Examination type	Scoring				Number of examinations		Total number
		2015 - 2017		2018 - 2023		2015 - 2017	2018 - 2023	2015 - 2023
		Autumn	Spring	Autumn	Spring			
4th								
Surgery	Oral patient based[a]	Pass/ Fail	Tiered grades	Tiered grades	Tiered grades	327	593	920
Internal Medicine	Oral patient based[a]	Pass/ Fail	Tiered grades	Tiered grades	Tiered grades	327	602	929
Pathology	Multiple-choice questionnaire[b]	Pass/ Fail	Tiered grades	Tiered grades	Tiered grades	334	1204	1538
5th								
Gynecology/ Obstetrics	Oral case based	Tiered grades	Tiered grades	Pass/ Fail	Pass/ Fail	209	425	634
Neurology/ Neurosurgery	Oral case based	Tiered grades	Tiered grades	Pass/ Fail	Pass/ Fail	201	421	622
Ophthalmology	Oral case based	Tiered grades	Tiered grades	Pass/ Fail	Pass/ Fail	202	429	631
Otorhinolaryngology	Oral case based	Tiered grades	Tiered grades	Pass/ Fail	Pass/ Fail	203	422	625
Pediatrics	Oral patient based[c]	Tiered grades	Tiered grades	Pass/ Fail	Pass/ Fail	209	426	635
Psychiatry	Written case based	Tiered grades	Tiered grades	Pass/ Fail	Pass/ Fail	203	427	630
6th								7164
Final licensing exam	Oral patient based	Tiered grades	Tiered grades	Tiered grades	Tiered grades	—[d]	470	470
								7634

[a]Students handed in a portfolio of 12 admission papers to be granted access to the oral exam.

[b]MCQ, Multiple Choice Questionnaire of a case and photo with 4 - 5 options for an answer.

[c]The patient could be swapped for a case.

[d]Not applicable.

In the succeeding 5th year, students were expected to have adjusted to clinically based learning, and the 2018 reform changed all exam assessments from Tiered Grades to Pass/Fail for all modules (Figure 1). The aim of switching to Pass/Fail evaluation for all exams during the 5th year was to support the students' focus on learning to be a medical doctor rather than studying for exams. The year-5 exams were case-based oral exams for Gynecology/Obstetrics, Neurology, Neurosurgery, Ophthalmology, and Otorhinolaryngology, oral exam with patients for Pediatrics, and a written stepwise case-based exam for Psychiatry (Table 1).

The final 6th year used Tiered Grades throughout the observation period (Table 1) for this study to comply with legislation for final medical exams in Denmark.

Admission criteria in Denmark are set by legislation, and they rely heavily on average grade points from high school. Thus, the admission principle was unchanged throughout the study period, making the students entering medical school on similar terms during the years of the present study.

At Aalborg University Medical School, problem-based learning (PBL) is the learning principle practiced during the three years of the Bachelor's program, which feeds into the Master's program's patient-based learning [10]. The first two years of the Master's program comprises a series of clinical placements in the morning, supported by patient-based, theory-led small-group PBL-tutorials engaging in discussions with their tutors in the afternoon. Medical students are referred to as apprentice-doctors to support a learning focus on what is needed to be a doctor at the basic level. The final year is theory based aiming to foster deep learning when revisiting all aspects of medicine from the previous five years, thus supporting a spiral curriculum.

The learning objectives, module organization, and teaching principles were unaltered throughout the study period. The

academic staff did not change during the years of the study, and examiners were unaware of the present evaluation.

The 4th year consisted of internal medicine, surgery, and pathology. The 5th year comprised Pediatrics, Gynecology/Obstetrics, Neurology, Neurosurgery, Otolaryngology, Ophthalmology, and Psychiatry. All exams for all modules were included in the present evaluation, and the modules were unaltered except for the grading principles. The subgroup with alternating evaluation and the subgroup with permanent change from Tiered Grades to Pass/Fail grading were analysed. Licensing exams in the 6th year were included in the analysis for evaluation of final academic performance.

The Danish grading scale has seven steps, and it is almost comparable to the European Credit Transfer and Accumulation System (ECTS) scale A-F: 12; 10; 7; 4; 02; 00; and −03. While 02 is a Pass, it is the lowest of five pass grades and represents near-fail. Conversely, 00 and −03 represent a clear Fail without modification, and the delineation of failing exams is quite distinct. Thus, Pass/Fail was computed from the 2-digit Tiered grade exam assessments.

Statitical analysis

Results are reported in percent and in the crude numbers, and comparisons were performed using the χ^2 test for comparison of proportions, the Kruskal-Wallis test for comparing numerical grades between semesters, and the Kendall test to test for trend in Tiered grade exams over time. Internal validity was explored by monitoring grade point averages at the 4th year exams using tiered grades. As student cohorts, examiners, and formats remained stable across the years of the study, no additional adjustment for confounders was performed. Student-level variables were not available for the analysis, but in accordance with unaltered entry criteria, age and gender distributions were similar across the study years. Statistical analyses were performed using SPSS Statistics for Windows (version 13.0; IBM Corp).

Ethical Considerations

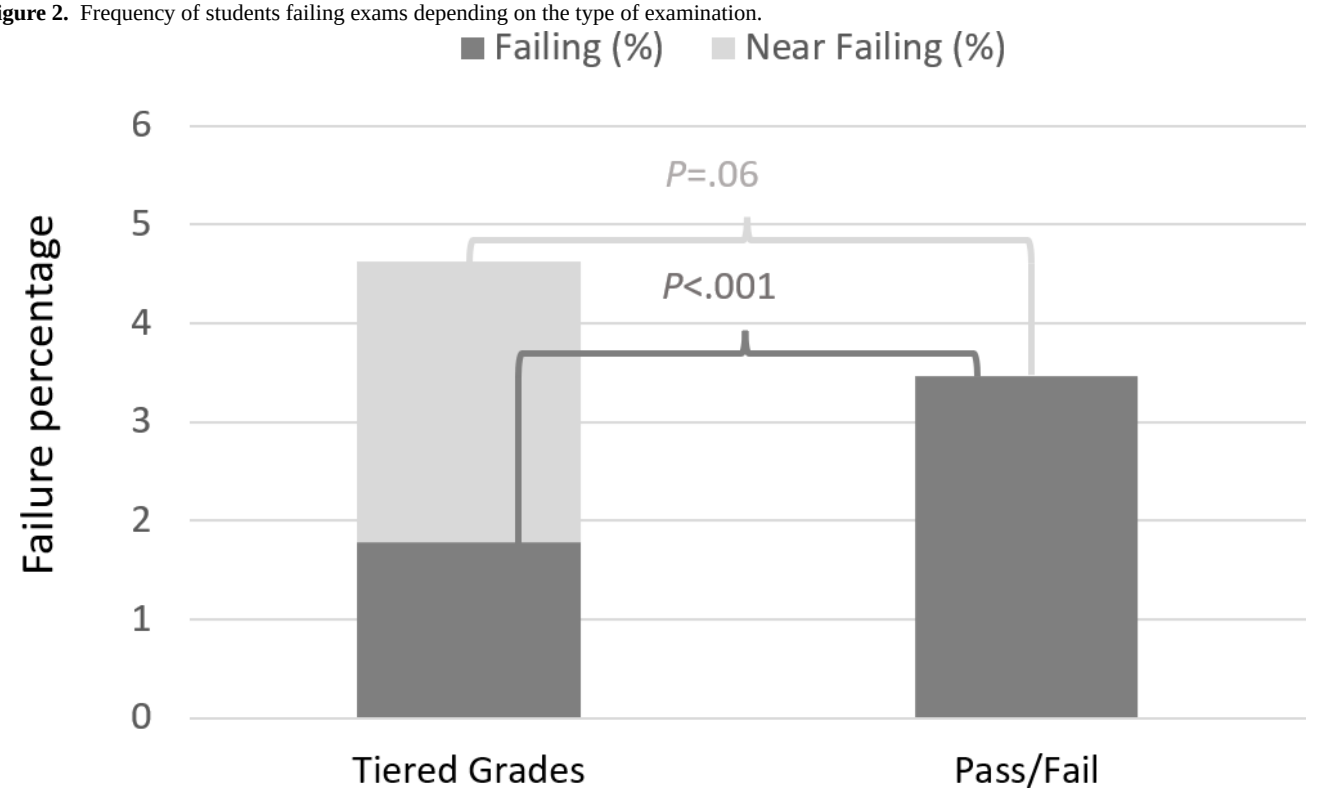
All data on grades was retrieved and reviewed for quality assurance in medical education, and grades were reported anonymously to Aalborg University using a digital solution (Digital Eksamen, Arcanic A/S, Copenhagen). The need for ethical approval or informed consent was waivered for anonymous data retrieved for quality assurance. Still, the presented research meets the recommendations by The Danish Code of Conduct for Research Integrity, with the primary material being digital raw data provided as an anonymous list of grades. Participants or the public were not involved in the design, conduct, reporting or dissemination plans for this study.

Results

Our evaluation comprises 7634 exams for 16 semesters from the Autumn of 2015 through Spring of 2023. In total, 7164 exams with 66 exam sessions prior to, and 78 exam sessions following the 2018 curriculum reform, were included in the comparisons during the 4th and 5th year. Of these 3047 (42.5%) were Pass/Fail exams and 4117 (57.5%) were Tiered grade exams. Additionally, 470-Tiered grade final licensing exams at the 6th year were included for evaluation of the final academic performance.

The overall frequency of students failing exams is illustrated in Figure 2.

Figure 2. Frequency of students failing exams depending on the type of examination.



The frequency of students failing exams (dark gray bars) was 3.3% (n=101/3047) when using Pass/Fail and 2.0% (81/4117) with Tiered grade evaluations (χ^2 test, P<.001). This difference was leveled out (χ^2 test, P=.055) when including the near-failure Tiered grade as fail (light gray bar).

In the subgroup of 988 examinations alternating between Tiered grade and Pass/Fail (upper left box in Figure 1), the frequency of students failing exams was 1.8% (9/497) with Pass/Fail and 0.8% (4/491) with Tiered grade exams (χ^2 test, P=.20). In the subgroup of 5th year students switching permanently from Tiered grade to Pass/Fail (lower boxes in Figure 1), the frequency of students failing exams was 3.6% (92/2550) with Pass/Fail and 1.1% (13/1227) with Tiered grade assessments (χ^2 test, P<.001).

The level of grades at the Tiered grade exams did not differ between semesters (Kruskal-Wallis test, P=.99) nor show a time trend at the 4th year (Kendall test, P=.66). The average grades of the 6th year final licensing exam (Kendall test, P=.47) and SD of about 3 were unchanged over the entire study period (Table 2).

Table . Average grades at year-4 before and after the 2018 reform and the final licence exams at year 6.

Years	Year-4 grades, mean (SD)	Year-6 grades, mean (SD)
2016	8.8 (2.7)	—
2017	8.5 (2.8)	—
2018	8.5 (2.9)	—
2019	8.4 (2.9)	9.3 (2.8)
2020	8.5 (2.9)	8.5 (3.0)
2021	8.3 (3.0)	9.1 (2.8)
2022	8.3 (3.2)	8.4 (3.4)
2023	8.6 (3.0)	8.7 (3.1)

The Danish Tiered Grade scale is numerical, and categories are comparable to the ECTS scale A-F: 12; 10; 7; 4; 02; and 00, −03 are the equivalent of A; B; C; D; E; and F.

Discussion

Principal Findings

Changing from Tiered grades to Pass/Fail assessment for exams in undergraduate medical education during the 4th and 5th years increased the number of students failing exams. This difference leveled out when including the near-fail Tiered grade as Fail. The final academic performance did not change.

A recent meta-analysis reported limited data from the previous millennium and showed no difference in performance when comparing tiered and Pass/Fail examinations [11]. Similar results were found in more recent data reported by Ange et al [12]. Alternating assessment was recently reported to cause higher average grades when using Tiered grades, but data on the number of students passing exams were lacking [13]. Despite these uncertainties [14], a number of medical schools are transitioning to Pass/Fail grading to improve psychological well-being and satisfaction among medical students [15]. This change raises concerns about academic performance and the risk of overlooking underperforming students [16]. Our study addresses these points and may inform decision-makers on the transition from Tiered grades to Pass/Fail in medical education.

Contrary to our expectation, the number of students not passing exams was higher with Pass/Fail compared to Tiered grades. A similar trend was found in the subgroups when Pass/Fail and Tiered grade exams were alternating over the same academic year, and when looking over time. In both comparisons, more students passed the Tiered graded exams compared to the Pass/Fail exams. One possible explanation is the lack of opportunity to address underperformance with a low grade, prompting examiners to shift their focus from rewarding high achievers to ensuring standards are met by underperforming medical students. Another reason might be related to learning differences among students, in that Tiered grades might support students' self-evaluation of performance linked with higher extrinsic motivation. However, we saw no change in the average final licensing exam grades, which suggests an absence of influence on the students' final academic performance.

The choice of grading principles is made by the study board. The curriculum reform in 2018 changed the grading principles based on discussions on study board meetings in the year leading up to the decision, with evaluation of and input to these discussions by members of a study lead group (BM, JE, SA). Only two members of the study board were academic staff representatives of the clinical study years (2013 - 2025, SA). Some clinical academic staff expressed reservations on the switch from Tiered grades to Pass/Fail, but accepted this decision following information on the discussions in the study board, providing a background for the decision. Hence, the evaluators at the 7634 exams implemented the decision on the grading principle without opposing this. Moreover, the final exams all included an external evaluator to oversee if the examination covered the learning objectives and if the grading met the standards set by the curriculum. All external evaluators were academic staff from other universities knowledgeable about the topic being tested. None of these were involved in the change in grading principles at the 4th and 5th years, and the external observation contributed to solid evaluations at the final exams, illustrating that grading principles did not influence the final academic performance by medical students.

Strength and limitations

The study's credibility was strengthened by the large, longitudinal dataset, crossover design, and the broad range of medical specialties included. The retrospective collection of assessment data has likely prevented observer bias, as the assessors were unaware of the present evaluation. Grading is a definite variable, and it strengthens the credibility that all assessments over the years under study were included. The internal validity was strengthened by unaltered admission criteria, teaching principles, learning objectives, and module organization throughout the study period. Still, we cannot rule out confounding factors not accounted for. The overall low failure rate in the Master's program stands out, and it may be attributed to the fact that only medical students passing the Bachelor's program progress into the Master's program. The single-center design may limit the generalizability of the findings. However, medical students are high achievers across settings, and we consider the core results applicable in other settings. We used digital reporting of assessment, which may have reduced observer bias. Many medical schools and educators have transitioned to digital exams. Most of our exams included real patients with a focus on clinical reasoning and demonstration of skills, which restricted us to the use of digital reporting of grades. Extending this thought, the use of the overview of grades provided by the digital reporting of grades for proxy assessment of quality of teaching and learning inspired the present evaluation by making grades easily accessible, a distinct benefit of digital reporting of assessments.

Conclusion

This empirically grounded evaluation of the shift between Tiered grades and Pass/Fail assessment in undergraduate medical education, utilizing a natural experiment following curriculum reform, was strengthened by the large, longitudinal dataset and crossover design.

Pass/Fail grading at exams in undergraduate medical education was related to a higher risk of failing than tiered grad exams, a difference that leveled out when including the near-fail Tiered grade as fail. The data suggested no influence on the students' final academic performance. Thus, we argue that a shift from Tiered grades to Pass/Fail assessment causes a shift in focus from rewarding high performance to upholding standards among underperforming medical students. As Pass/Fail evaluations correlate with enhanced well-being and reduced stress compared to Tiered grade, Pass/Fail may be preferred over Tiered grade assessments in high-stakes exams.

Abstract

Background: Stomatology education has experienced substantial transformations over recent decades. Nevertheless, a comprehensive summary encompassing the entirety of this field remains absent in the literature.

Objective: This study aimed to perform a bibliometric analysis to evaluate the research status, current focus, and emerging trends in this field over the last two decades.

Methods: We retrieved publications concerning teaching and learning in stomatology education from the Web of Science core collection covering the period from 2003 to 2023. Subsequently, we conducted a bibliometric analysis and visualization using R-Bibliometrix and CiteSpace.

Results: In total, 5528 publications focusing on teaching and learning in stomatology education were identified. The annual number of publications in this field has shown a consistent upward trend. The United States and the United Kingdom emerged as the leading contributors to research. Among academic institutions, the University of Iowa produced the highest number of publications. The *Journal of Dental Education* was identified as the journal with the highest citation. Wanchek T authored the most highly cited articles in the field. Emerging research hotspots were characterized by keywords such as “deep learning,” “machine learning,” “online learning,” “virtual reality,” and “convolutional neural network.” The thematic map analysis further revealed that “surgery” and “accuracy” were categorized as emerging themes.

Conclusions: The visualization bibliometric analysis of the literature clearly depicts the current hotspots and emerging topics in stomatology education concerning teaching and learning. The findings are intended to serve as a reference to advance the development of stomatology education research globally.

Introduction

In recent years, innovations and restructuring in stomatology education have triggered global reforms in the field. In stomatology education, teaching and learning are both interdependent and mutually reinforcing. Effective education demands not only that instructors possess robust professional knowledge and use sound pedagogical strategies but also that students actively participate, provide feedback (FB), and engage in self-directed learning. The dynamic interaction between teaching and learning facilitates the effective transfer and application of knowledge, ultimately resulting in the cultivation of stomatology professionals who are equipped with both advanced technical skills and strong clinical reasoning abilities.

Teaching and learning in stomatology education have undergone profound and meaningful changes in the past two decades. For instance, significant research efforts have been dedicated to using digital and artificial intelligence (AI) tools to enhance the quality of education and exploring the effectiveness and response of online and distance teaching modalities. Hence, it is crucial to understand the latest trends and developments in teaching and learning in stomatology education. However, keeping up with the rapid changes in stomatology education research is challenging. Scientific publications are important for academic communication and clinical practice guidelines. Evaluative bibliometrics, a quantitative science, assesses research performance to identify influential works in medical practice and research. Unlike literature reviews, which offer qualitative insights, bibliometric analysis provides quantitative data on citations, authorship, and research collaboration [1,2].

Although various fields have been studied, teaching and learning in stomatology education research are limited, with few quantitative analyses. Therefore, bibliometric analysis is essential to fill this gap, offering critical data to identify trends and guide future research.

In this study, we conducted a comprehensive bibliometric analysis of teaching and learning in stomatology education using Citespace software (developed by Chaomei Chen, College of Computing and Informatics, Drexel University, Philadelphia, PA, USA) to generate visual representations. The aim was to systematically evaluate the research landscape, current focal areas, and emerging trends in teaching and learning in stomatology education over the past two decades, emphasizing key achievements and outlining potential future research directions in this field.

Methods

Search Strategy and Eligibility Criteria

Scholarly articles and literature on teaching and learning in stomatology education were retrieved using the Web of Science Core Collection (WoSCC), encompassing the Science Citation Index Expanded and other relevant citation indices. To ensure the validity and reproducibility of our search strategy, we implemented a multistep validation process. A pilot search was conducted in 2023 using a subset of keywords, yielding 200 randomly selected articles that were manually screened by the authors. This process resulted in a precision rate of 92% based on which minor refinements were made to keyword synonyms. Second, the search strategy was developed in accordance with the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses extension for Scoping Reviews) checklist to ensure methodological rigor and transparency. Third, to assess the comprehensiveness of our chosen database and minimize selection bias, we cross-validated the WoSCC coverage with PubMed and Scopus using a random sample of 100 articles, confirming a 95% overlap in relevant literature. Finally, both controlled vocabulary (MeSH terms) and free-text keywords were used to ensure the search captured a wide range of relevant studies across varying indexing practices. To ensure comprehensive literature retrieval, we designed the search strategy by mirroring MeSH hierarchies and incorporating their synonymous expressions ('Oral medicine' [Mesh] → dentistry/stomatology); ('Education' [Mesh] → teaching/training/learning).

The final search string combined controlled vocabulary (MeSH terms) and free-text terms, as follows:

1# :(((TS=(teaching)) OR TS=(training)) OR TS=(learning)) OR TS=(education)

2# :(((TS=(oral medicine)) OR TS=(stomatology)) OR TS=(dentistry))

3# :1# and 2#

The duration of this span is from January 2003 to December 2023. Articles lacking unique content and those published in languages other than English were excluded.

Ethical Considerations

As the data were directly obtained from the database, ethical approval was not required.

Bibliometric Analysis

The data from these articles were imported and integrated using the bibliometrix package (version 4.4.0) in the R programming language. Our research applied several bibliometric analysis techniques, including keyword co-occurrence and historical direct citation analyses. For this study, we used CiteSpace (version 6.2R6) to perform social network analysis and to identify developmental dynamics, hotspots, future trends, and key aspects within the scientific literature on a specific topic. Burst detection methodology was applied to pinpoint significant keywords or references that experienced a notable surge in frequency within a defined period. In addition, we conducted a clustering (co-citation) analysis of references using a metric based on co-authored publications, allowing for the grouping of institutions or keywords that showed higher levels of collaboration within the same cluster. Clusters of related publications were generated using CiteSpace's fully automated cocitation clustering algorithm with the following parameters:

- Clustering method: Louvain modularity optimization (to maximize intracluster connectivity and intercluster distinction)
- Similarity threshold: default cosine similarity (0.5) to balance sensitivity and specificity
- Time slicing: 2-year intervals (2003–2023) to capture temporal trends
- Node type: author keywords+cited references to integrate semantic and bibliometric signals
- Labeling: algorithm-generated labels via Term Frequency-Inverse Document Frequency (TF-IDF)weighting of high-frequency keywords within each cluster.

No manual adjustments were made to cluster labels to avoid subjective bias. Network maps were used to illustrate variations in the quantity or frequency of published records across clusters of similar research topics, with node size and color indicating these differences. The strength of collaborations between nodes was depicted by connecting lines, where thicker lines indicated stronger collaborations. To further enhance data visualization, we used an overlay visualization technique in which the color of each node represented the average year of occurrence for each institution or keyword. The data were saved in plain text format with full record and cited references from WoSCC and then imported into CiteSpace for further analysis.

The bibliometric data for this study were retrieved from Web of Science, and no additional filtering was applied to remove self-citations. However, as none of the authors have previously published related articles in this field, self-citations do not impact the findings of this analysis.

Results

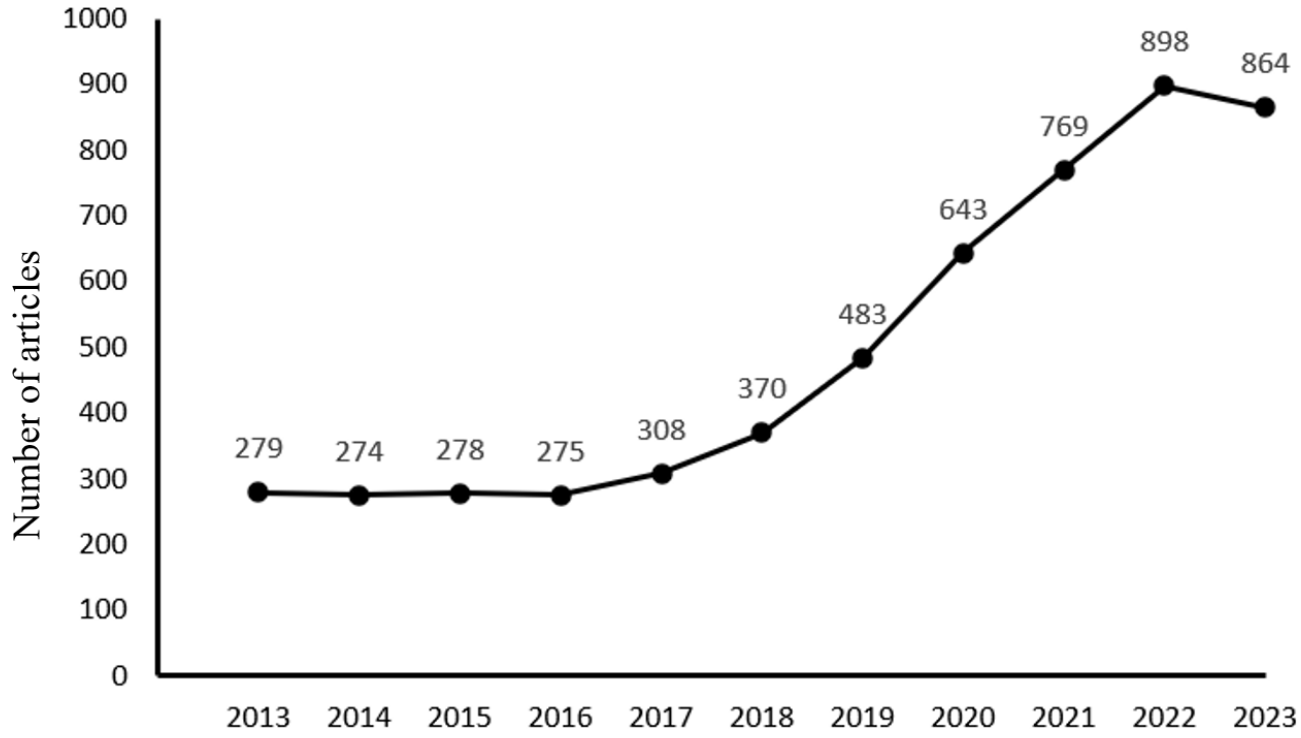
Brief Description of Teaching and Learning in Stomatology Education Literature

As of December 31, 2023, a total of 8831 articles were retrieved from the WoSCC database. Of these, 6532 were published between 2003 and 2023, with 6381 articles written in English. The dataset includes 5528 research papers, representing 86.6% of the total, and 593 review articles, constituting 9.3%. The 5 leading WOS disciplines identified are dentistry oral surgery medicine (n=3375), education scientific disciplines (n=844), medicine general internal (n=510), public environmental occupational health (n=500), and health care sciences services (n=413).

Productivity Analysis

As demonstrated in 1, the annual publication volume from 2013 to 2023 exhibited distinct temporal patterns. The platform period (2012-2017) maintained stable output with minor fluctuations (270-308 articles per year), followed by an exponential growth phase (2018 - 2022) that saw publications surge from 370 to 898 articles per year. Although there was a slight decline in the number of publications from 2022 to 2023, the overall trend remains upward, with the growth rate generally following an exponential pattern. This indicates that international attention to research in stomatology education is steadily increasing and holds promising prospects (Figure 1).

Figure 1. Annual scientific production in teaching and learning of stomatology education.



Countries and Cooperation Networks Analysis

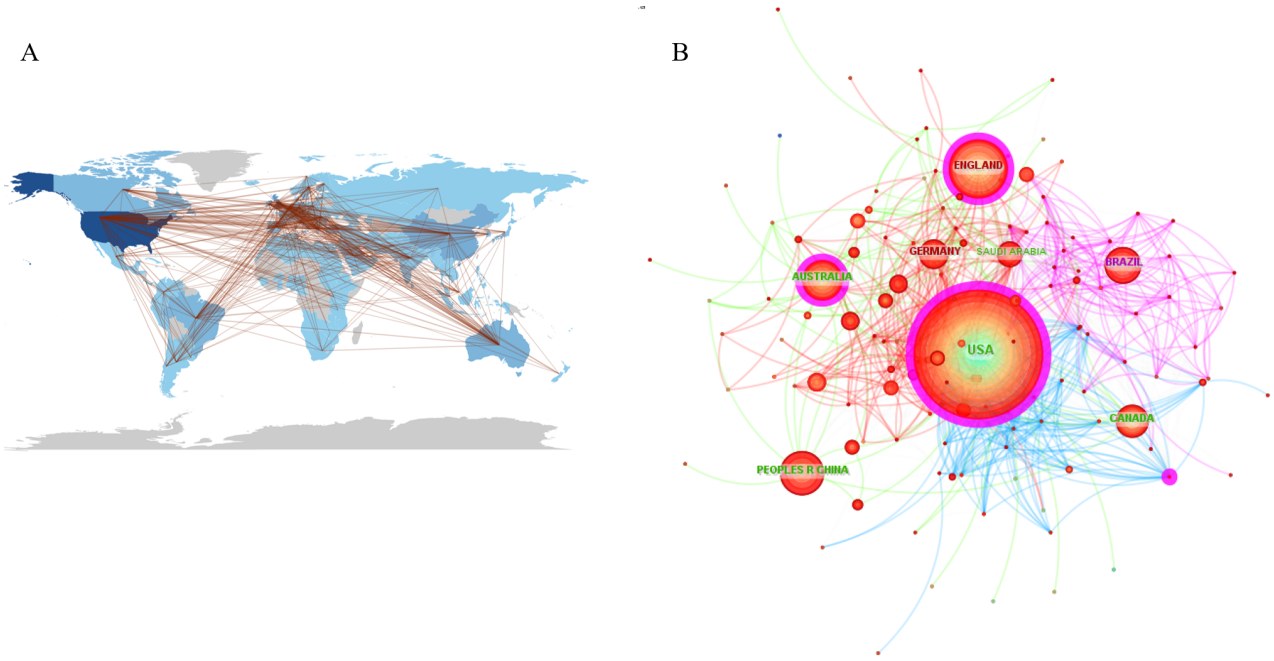
Since 2003, the literature on the research of teaching and learning in stomatology education has been published in 145 countries, mainly led by the following few countries: the United States, the United Kingdom, and China. The number of publications and the frequency of citations are 2 dimensions for analyzing the strength of scientific research, reflecting the attention and impact of a country or institution in a certain field. From the perspective of the number of publications, the top 5 countries are the United States (n=2085), the United Kingdom (n=400), China (n=443), Australia (n=435), and Brazil (n=361). From the perspective of literature citation frequency, the top 5 countries are the United States, the United Kingdom, China, Germany, and Canada. It is worth noting that the United States, the United Kingdom, and China all rank among the top 3 in terms of the number of publications and the frequency of citations, which proves that these 3 countries have strong scientific research capabilities in this field (Table 1).

Table . Top 10 productive countries concerning teaching and learning in stomatology education.

Country	Documents, n (%)	Citations	Average citations	Centrality
The United States	2085 (37.7)	25,599	16.00	0.24
The United Kingdom	800 (14.5)	7942	14.10	0.13
China	443 (8.0)	6125	15.30	0.04
Germany	310 (5.6)	4405	20.10	0.02
Canada	348 (6.3)	3053	14.30	0.02
Australia	435 (7.9)	3023	12.80	0.11
Brazil	361 (6.5)	2756	11.10	0.03
Turkey	161 (2.9)	2387	16.80	0.00

The data were imported into CiteSpace for a cooperation network analysis, where the centrality of each country was calculated. As illustrated in Figure 2B and detailed in Table 1, each circle represents a country; a darker center color indicates earlier publication dates. Higher centrality values reflect stronger collaboration with other nations. Circles with purple outer rings signify particularly high centrality. Research on teaching and learning in stomatology education began earlier in the United States, the United Kingdom, and Australia. The United States exhibits the highest centrality (0.20), followed by the United Kingdom (0.13) and Australia (0.11), suggesting these countries prioritize international collaboration in this field. Notably, while China (0.04), Germany (0.02), Canada (0.02), Brazil (0.03), and Turkey (0.00) rank among the top 10 in terms of publication and citation counts, their centrality is significantly lower than that of the United States, the United Kingdom, and Australia (Table 1). “Centrality” reflects a country’s role as a hub in global research collaboration. A higher centrality value (eg, the United States with 0.20) indicates stronger connectivity and influence in bridging diverse research communities. Therefore, the United States served as a central node connecting European and Asian institutions in stomatology education research. The national cooperation network analysis reveals that the connections between these countries and others are relatively robust, indicating extensive international cooperation (Figure 2).

Figure 2. Leading countries in teaching and learning of stomatology education. (A) Countries’ collaboration world map. (B) Countries’ cooperation network.



Institutions and Cooperation Analysis

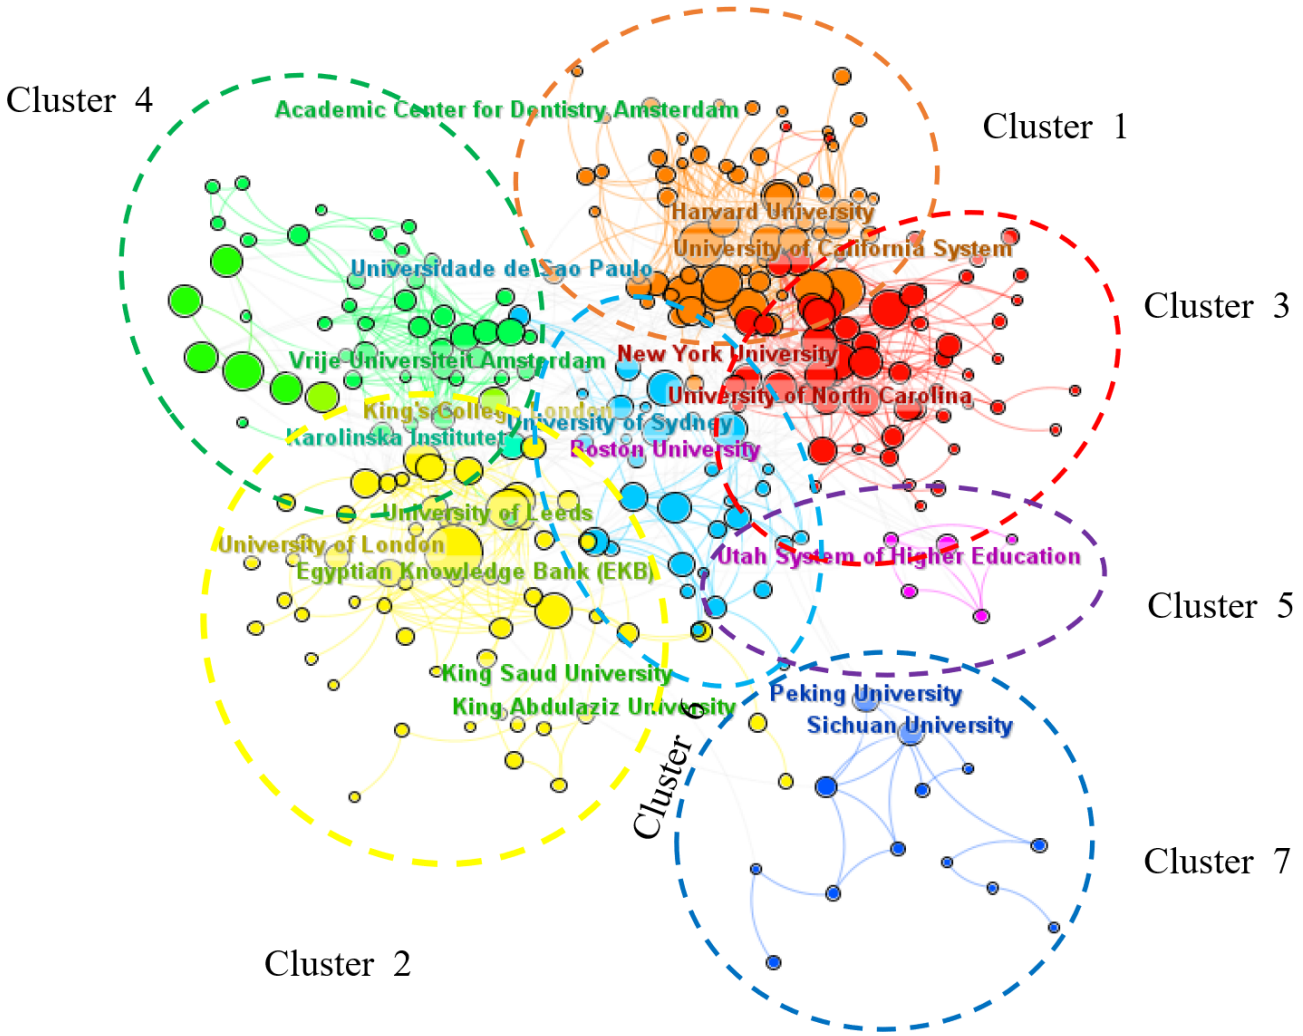
As presented in Table 2, the top 10 institutions in teaching and learning in stomatology education–related research are listed. The top 3 institutions are all from the United States, namely UNIV IOWA (n=305), UNIV MICHIGAN (n=288), UNIV N CAROLINA (n=257, Table 2), while KINGS COLL LONDON (n=236) from the United Kingdom, UNIV SYDNEY from Australia (n=155), and KING SAUD UNIV (n=160) and UNIV HONG KONG (n=153) from Asia have also made outstanding contributions. A comprehensive analysis of cooperative networks among institutions or universities was conducted. In the cooperative network analysis chart, a larger font size signifies that the institution not only began relevant research earlier but has also made more significant contributions to the field (Figure 3). As shown in Figure 3, the University of London,

the University of California, King's College London, Boston University, Harvard University, and Peking University have played an important role in the development of this field. In the network map, cluster analysis of cooperation among institutes and overlay visualization of the largest 7 clusters was shown in Figure 3. The top-ranked item by centrality is the National and Kapodistrian University of Athens (0.14, cluster 2). The second one is the Cleveland Clinic (0.09, cluster 6). The third is the Case Western Reserve University (0.08, cluster 6). The fourth is the University of Sheffield (0.07, cluster 4). The fifth is the Pennsylvania Commonwealth System of Higher Education (0.07, cluster 1).

Table . Top 10 productive institutions concerning teaching and learning in stomatology education.

Affiliation	Country	Publication counts
UNIV IOWA	USA	305
UNIV MICHIGAN	USA	288
UNIV N CAROLINA	USA	257
KINGS COLL LONDON	The United Kingdom	236
UNIV ILLINOIS	USA	185
KING SAUD UNIV	Saudi Arabia	160
UNIV SYDNEY	Australia	155
UNIV HONG KONG	China	153
UNIV WASHINGTON	USA	153

Figure 3. Visualization of active institutes and cluster analysis of cooperation among institutes.



Authors' Analysis

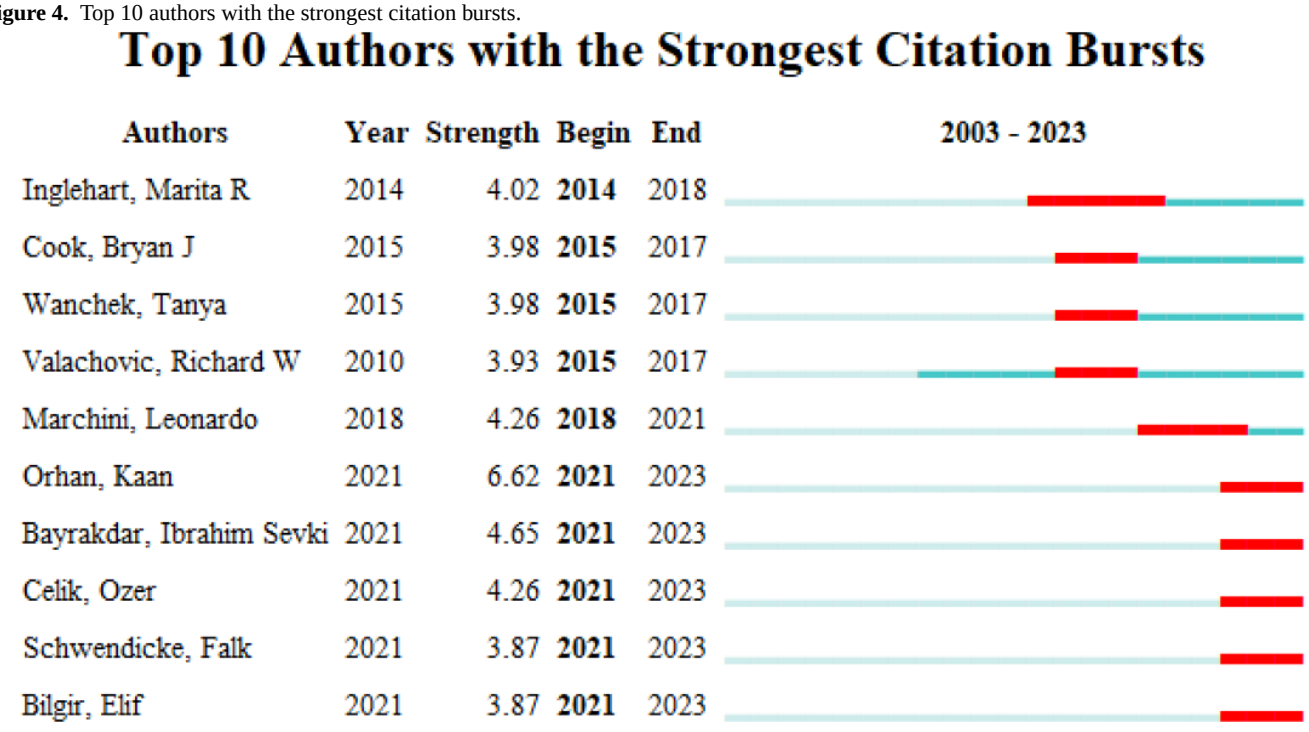
We conducted an analysis of the authors of the published articles and identified the top 5 authors by citation count: Wanchek T (n=132), Cook BJ (n=123), Valachovic RW (n=114), Mattheos N (n=91), and Lynch CD (n=91). The affiliations of these authors, including their respective countries and institutions, are detailed in Table 3. Notably, 3 of these authors are affiliated with the University of Virginia, the United States (Table 3).

Table . Top 10 most productive authors in teaching and learning in stomatology education.

Author	Country	Institution	Citations
Wanchek T	USA	University of Virginia	132
Cook BJ	USA	University of Virginia	123
Valachovic RW	USA	University of Virginia	114
Mattheos N	Sweden	Karolinska Institute	91
Lynch CD	Ireland	University Dental School and Hospital Wilton	88
Kalenderian E	USA	Harvard School of Dental Medicine	72
Anderson EL	USA	American Dental Education Association	71
Lee JY	South Korea	Wonkwang University College of Dentistry	70
Divaris K	USA	University of North Carolina	63
Wilson NHF	The United Kingdom	King's College London Dental Institute	63

Using the "urst" function, we identified the most active authors in the field, as illustrated in Figure 4. Analysis of the burst detection results indicates that teaching and learning in stomatology gained prominence starting in 2014, with significant contributions from Inglehart MR (USA). During 2021 to 2023, Orhan K emerged as the most active author in the field, achieving the highest burst strength of 6.62. Bayrakdar IS, with a burst strength of 4.65, ranked second and had an active period from 2021 to 2023. Consequently, Orhan K and Bayrakdar IS not only demonstrated strongest citation bursts but also positioned themselves as a leading researcher in recent years. In addition, Celik O, Schwendicke F, and Bilgir E have recently held prominent positions in this research frontier (Figure 4).

Figure 4. Top 10 authors with the strongest citation bursts.



Journal Analysis

The top 10 journals with the highest citation counts are presented in the table below. The 5 most cited journals include the *Journal of Dental Education* (n=9120), *European Journal of Dental Education* (n=4963), *Journal of Dental Research* (n=2679), *British Dental Journal* (n=2618), and *Journal of the American Dental Association* (n=2238). Impact factors (averaged over the past 5 years) and Journal Citation Reports (JCR) are detailed in Table 4. When examining the H-index of the cited articles, the leading 5 journals are *Journal of Dental Education* (H=36), *European Journal of Dental Education* (H=31), *British Dental Journal* (H=25), *Journal of the American Dental Association* (H=25), and *BMC Oral Health* (H=23), as presented in Table 4. Consequently, the *Journal of Dental Education* and the *European Journal of Dental Education* have been particularly influential, with a strong focus on research related to teaching and learning in dental education.

Table . Top 10 core journals on teaching and learning in stomatology education.

Journal	H_index	Counts	Citations	IF[a]	JCR[b]
Journal of Dental Education	36	841	9120	1.7	Q3
European Journal of Dental Education	31	444	4963	2.2	Q2
British Dental Journal	25	267	2618	2.1	Q2
Journal of the American Dental Association	25	87	2238	3.4	Q1

Research Focus and Frontiers Analyses on the Nonthermal Plasma Medicine

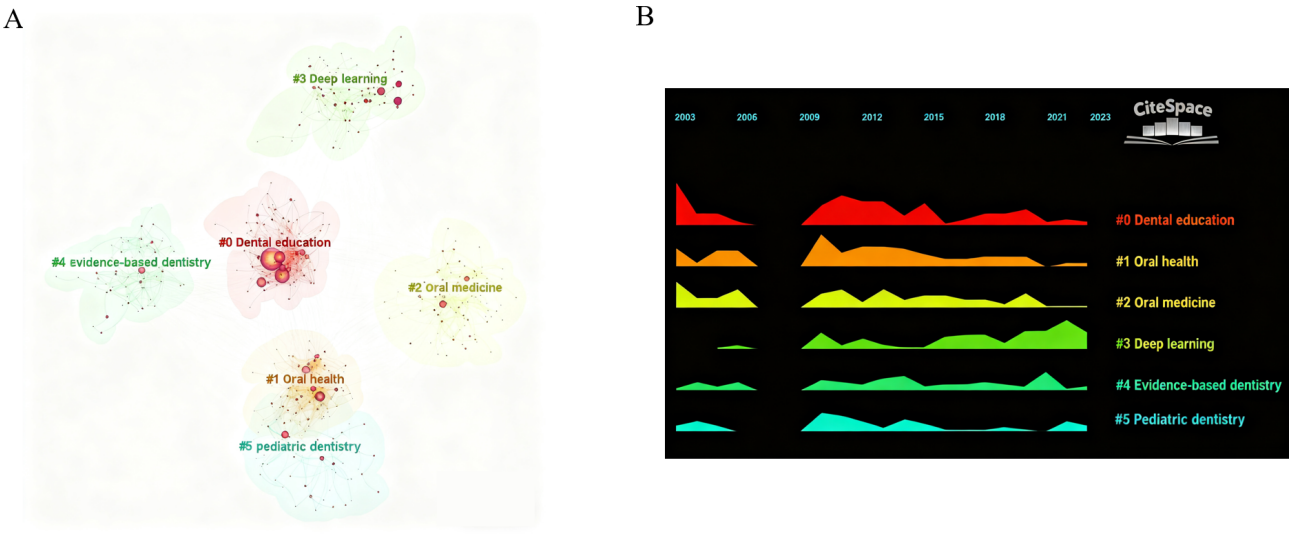
Research Focus Analysis

The word frequency and centrality of keywords reflect the hot topics that researchers have focused on and studied over a period. Keywords mark the core meaning of an article, and conducting keyword analysis can help deeply grasp the core content of this field. In the topic and keyword co-occurrence analysis, nodes reflect the frequency of keywords. Centrality is a basic indicator to measure the weight of nodes, reflecting the importance of nodes in the network. The more prominent the co-occurrence frequency and centrality of keywords, the stronger the importance of nodes. The keyword co-occurrence analysis is shown in Figure 5A. Node size reflected the frequency of keywords. In Figure 5A, the nodes with purple outer circles were those with higher centrality, among which “disease” (0.10), “access” (0.07), “performance” (0.06), “diagnosis” (0.06), and “model” (0.06) possessed higher centrality and frequency, indicating these key contents that have been paid attention to in the promotion and development process of the field (Table 5). Meanwhile, through further sorting and summarizing high-frequency keywords, it was found that the research hotspots in the field of nonthermal plasma medicine from 2003 to 2023 were mainly concentrated in 4 categories. The keyword with the highest level of attention in cluster 0 is “dental education,” the keyword with the highest level of attention in cluster 1 is “oral health,” the keyword with the highest level of attention in cluster 2 is “prevalence,” the keyword with the highest level of attention in cluster 3 is “artificial intelligence,” the keyword with the highest level of attention in cluster 4 is “knowledge,” and the keyword with the highest level of attention in cluster 5 is “impact” and (Figure 5A). Through a timeline analysis of keywords, a chronological map of dental education research was generated. Keywords belonging to the same cluster are aligned horizontally, with their corresponding periods displayed at the top. In this timeline, the density of keywords indicates the significance of the respective clustering domain. Over the past 3 years, “deep learning” has emerged as a prominent research focus in the field of dental education (Figure 5B).

Table . Top 10 highest centrality keywords.

Keywords	Centrality	Counts
Disease	0.10	74
Access	0.07	58
Performance	0.06	90
Diagnosis	0.06	104
Model	0.06	75
Management	0.05	186
Dentists	0.05	126
Quality	0.05	83
Teeth	0.04	67
Adolescents	0.05	59

Figure 5. Visualization of keywords analysis. (A) Keywords co-occurrence and centrality. (B) Timeline of keywords co-occurrence.

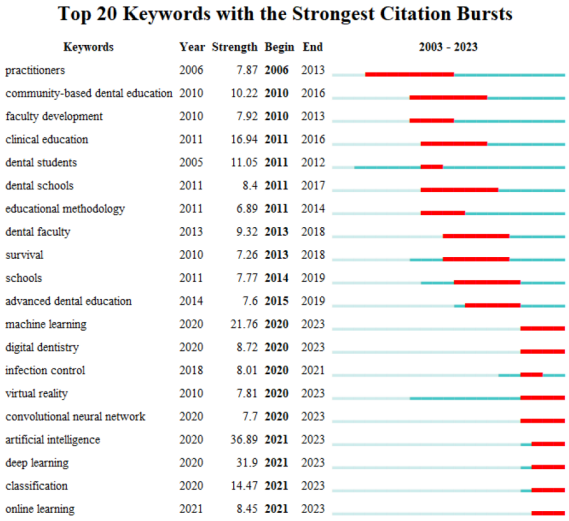


Research Frontiers Analysis

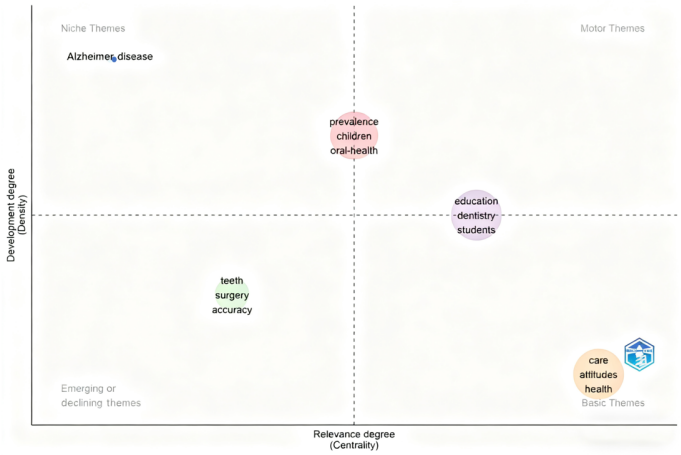
Burst detection identifies keywords or authors that experienced sudden surges in citations over a short period. Keywords with the strongest citation bursts mean that the keywords appear more frequently or are cited more frequently in a relatively short period. The detection indicators of keyword citation bursts generally include intensity and age distribution, which reflect the forefront and development trend of research over a period. Figure 6A lists the top 20 keywords with the strongest citation bursts. “Practitioners” appeared the earliest and lasted the longest (2006 - 2013), with a strength of 7.87. During this period, “faculty development” and “dental students” are also keywords with high attention. Subsequently, “community-based dental education,” “clinical education,” “dental school,” “educational methodology,” and “advanced dental education” began to become a research hotspot for many scholars after 2011 and lasted until 2019. During this period, “clinical education” (2011 - 2016, 16.94), “dental students” (2011 - 2012, 11.05), and "community-based dental education" (2010 - 2016, 10.22) all received more attention. In the past 4 years, “artificial intelligence” showed the highest burst strength (36.89) from 2020 to 2023, signaling its rapid rise as a cutting-edge topic in teaching and learning of stomatology education. In addition, “deep learning,” “machine learning,” “classification,” “digital dentistry,” “online learning,” “infection control,” “virtual reality,” and “convolutional neural network” have also received much attention from scholars in the past 4 years.

Figure 6. (A) Keywords with the strongest citation burst. (B) Thematic map of keywords in teaching and learning of stomatology education.

A



B



This article uses the Bibliometrix package in the R language environment to describe the history of topic evolution based on keywords (Thematic Map). The results show that “care,” “attitudes,” and “knowledge” were in the “basic themes” area, indicating that these are basic concepts for research in this field. In Figure 6B, the analysis revealed that “teeth,” “surgery,” and “accuracy” were classified as “emerging themes,” indicating that researchers are relatively active in these areas, which may have good prospects in the field of teaching and learning in stomatology education.

Co-Cited References Analysis

The historiographic map, proposed by E. Garfield in 2004, graphically represents a chronological network of key direct citations from a bibliographic collection. It illustrates the diachronic evolution of highly cited documents, highlighting shifts in research hotspots. Bibliometrix’s historical citation analysis offers 2 metrics: the local citation score (LCS) for citations within the current database and the global citation score (GCS) for total citations in the Web of Science database. LCS counts how often a paper is cited by other studies in the same field, whereas GCS tracks total citations across all disciplines. These metrics assess the impact of documents and reveal connections across research fields. Use the following command to generate the historical citation network: [options (width=130)] [histResults<- histNetwork (M, min. citations=2, sep=“;")] [net<- histPlot (histResults, n=10, size=5, labelsize=3)].

The analysis results of the historical direct citation network indicated that there were 11 landmark documents in this field, and Table 6 and Figure 7 summarize the relevant information of important documents in the historical cited network atlas. According to the statistics of the 4 articles labeled 4, 5, 8, and 9, the LCS and GCS indices are relatively high, indicating that these 4 articles have a significant impact in the corresponding years, and the research content is highly correlated with the relevant research about teaching and learning in stomatology education.

Table . Eleven landmark documents in teaching and learning of stomatology education.

Code	Title	Author	Journal	Country	Year	LCS[a]	GCS[b]
1	Feedback and motor skill acquisition using a haptic dental simulator	Al-Saud et al [3]	Eur J Dent Educ	Denmark	2017	24	67

Discussion

General Information

This study uses bibliometric analysis to examine the key areas of knowledge and emerging trends in stomatology education. Notably, several breakthrough achievements have been identified through these bibliometric methods. The findings reveal a general upward trend in annual publications related to teaching and learning in stomatology education. Furthermore, the geographic distribution of these publications was analyzed based on the country and institutional affiliations of the authors. The results indicate that institutions from the United States, the United Kingdom, China, and Australia are dominant in this field. Specifically, the University of Iowa, the University of Michigan, and the University of North Carolina in the United States; King's College London in Europe; the University of Sydney in Australia; and King Saud University and the University of Hong Kong in Asia have played pivotal roles in the development of stomatology education. In terms of productivity and influence, Wanchek T from the United States has been at the forefront over the past two decades. His focus on how education debt affects career choices among dental students and professionals has earned him numerous citations [14,15]. The primary objective of this study is not to provide exhaustive precision data on teaching and learning in stomatology education but to stimulate interest and encourage further research in this domain. This article also serves as a valuable resource for researchers new to the field, offering a concise overview of current trends and developments in stomatology education.

The observed increase in publications within this field can likely be attributed to the emergence of specialized journals in stomatology education and the growing interest among researchers in the professional and academic evolution of teaching methodologies. Among the top 10 journals, the Journal of Dental Education and the European Journal of Dental Education stand out, having published the highest number of articles and achieving the highest H-index. These journals have become highly esteemed among researchers worldwide, as they highlight the latest advancements and significant discoveries

in stomatology education. In recent years, these journals have particularly focused on the application of AI and its potential impact on stomatology, as well as the role of online learning during the COVID-19 pandemic. These topics align with the findings from keyword bursts, where terms such as "artificial intelligence," "deep learning," "machine learning," "classification," "digital dentistry," "online learning," and "infection control" have emerged as active themes in the field. It is worth mentioning that "artificial intelligence" showed the highest burst strength (36.89) from 2020 to 2023, signaling its explosive growth as a game-changing tool in teaching and learning dental educational skills.

Current Research Focus

In the current research related to stomatology education, the relatively advanced landmark literature was the article published by Al-Saud et al [3] in 2017, which investigated the effect of qualitatively different types of pedagogical FB on the training, transfer, and retention of basic manual dexterity dental skills using a virtual reality (VR) haptic dental simulator. It is reported that the acquisition and retention of basic dental motor skills in novice trainees is best optimized through a combination of instructor and VR-driven FB. Subsequently, Mirghani et al [4] further emphasized the value of haptic VR simulators in dental education. From here on, virtual teaching was paid attention to dental education, and its FB in teaching and learning was investigated by dental educators.

In the realm of teaching and learning in stomatology education, virtual and AI-based instructional methods serve as complementary approaches. Their integration has the potential to substantially enhance educational outcomes. In 2018, Lee et al [5] demonstrated the potential of a deep learning–based convolutional neural network algorithm for the detection and diagnosis of dental caries. This study marked a significant advancement in the application of deep learning technologies within the domain of dental education, garnering substantial attention. Following this, Watt et al [6] highlighted the potential benefits of integrating deep learning and other intelligent systems into dental education, such as personalized learning experiences and predictive analytics. Nonetheless, they cautioned that the adoption of these technologies must be accompanied by ethical considerations to ensure that they augment rather than replace human judgment in educational contexts. Consequently, deep learning, as a facet of AI, is progressively transforming traditional oral medicine education through enhanced image analysis, virtual simulations, personalized learning, and intelligent systems. The incorporation of AI-driven coaching and doctor–patient communication training has notably improved both the quality and efficiency of dental education. In 2020, Schwendicke et al [7] and Chen et al [8] further explored the integration of AI within dentistry. They asserted that future dental education needs to advance alongside the introduction of clinical AI solutions by cultivating digital literacy among emerging dental professionals. They also emphasized that AI will increasingly interface with dentistry from a holistic perspective, driven by the demand for precise treatment procedures and immediate information exchange.

The COVID-19 pandemic has profoundly impacted dental education by accelerating the adoption of digital and remote learning modalities. With physical distancing measures and health concerns limiting in-person interactions, institutions have increasingly turned to virtual platforms and online resources to ensure continuity of education. This shift has highlighted the necessity for adaptable and resilient teaching methods in oral medicine, fostering the development of new pedagogical strategies and technologies. This has also stimulated a large number of studies, including landmark research by Schlenz et al [9,10], who found that students and lecturers have positive attitudes toward the implementation of online learning. Meng et al [11] also encouraged researchers and dentists treating COVID-19 patients to connect with each other online to carry out collaborative research in this field. The pandemic has underscored the significance of integrating digital tools into the curriculum, which not only addresses immediate challenges but also offers long-term benefits in creating more flexible and accessible educational environments. However, experts believe that there are also some potential problems with online teaching or distance learning. Hung et al [13] suggested that students are experiencing increased levels of stress and feel their clinical education has suffered during the COVID-19 pandemic. Hattar et al [12] found that students somewhat appreciated the online system but did not view it as a substitute for face-to-face clinical practice. While their overall self-perceived preparedness was promising, they had reservations about independent practice after graduation. Lee et al [16] found that in the realm of continuing education in oral and maxillofacial radiology for dentists, the online interactive education emerges as an effective tool, fostering positive academic achievements through active learning.

Future Frontiers

The future of teaching and learning in stomatology education will be shaped by advancements in AI, digital simulations, and machine learning strategies. Our bibliometric analysis highlights key emerging trends, including deep learning, convolutional neural networks, VR, and surgical accuracy, which are driving innovation in dental education. These developments indicate a growing emphasis on improving diagnostic accuracy, enhancing clinical training, and integrating AI-driven technologies into educational curricula.

One notable trend is the increasing application of VR and AI-assisted simulations in surgical education. Virtual surgical planning and real-time FB systems allow students to rehearse complex procedures in a risk-free environment, thereby improving both skill acquisition and patient outcomes [17]. Similarly, robotic surgery, which offers enhanced precision and control, is gaining traction in advanced dental training [18]. These findings align with our bibliometric results, which identified "surgery" and "accuracy" as emerging themes. To translate these insights into practice, educators should prioritize competency-based training models that integrate VR-based surgical practice and AI-assisted procedural assessments [19]. For example, Huang et al [20] demonstrated that repeated VR training significantly enhanced students' implantology skills, with positive FB from participants highlighting the technology's effectiveness. Al-Saud et al [3] demonstrated that haptic dental

simulators significantly enhance motor skill acquisition, whereas Mirghani et al highlighted their role in replicating real-world dental procedures, improving student performance and confidence [4]. A study on an inferior alveolar nerve block simulator also found that students who practiced with the simulator were more confident during their first clinical injections, required fewer syringe adjustments, and achieved greater success in numbing patients [21]. These findings highlight the effectiveness of technology-enhanced learning, supporting our bibliometric analysis that identified "VR" and "AI" as emerging trends in stomatology education. Moving forward, further research should explore the long-term impact of these technologies on clinical proficiency and patient care outcomes.

Another key area of transformation is AI-driven diagnostic training. The use of machine learning models to analyze dental imaging data has significantly improved diagnostic precision in fields such as pediatric dentistry and prosthodontics [22]. AI-powered convolutional neural networks have demonstrated high accuracy in detecting caries and occlusal abnormalities [23]. Moreover, the use of AI in dental education is advancing, with studies such as Chen et al discussing its applications in clinical decision-making and personalized training programs [8]. Given this trend, educators should integrate AI-based analysis into preclinical coursework, allowing students to develop advanced diagnostic skills before entering clinical practice.

While AI-driven learning systems enhance efficiency and accessibility, their implementation also raises ethical considerations. Existing research on AI in dentistry exhibits notable deficiencies, impeding its reproducibility and practical implementation. AI should complement, rather than replace, traditional instructor–student interactions [9]. Future research should focus on ethical frameworks for AI integration in education, addressing issues such as student autonomy, decision-making processes, and the potential bias in AI-generated FB. In addition, the interdisciplinary nature of AI-driven education requires stronger collaboration between dental educators, AI developers, and clinical practitioners. Research efforts should focus on optimizing AI algorithms for educational use, ensuring that these technologies align with the pedagogical needs of dental students. By fostering such collaborations, the field can move toward more effective and human-centered educational frameworks.

By aligning bibliometric insights with actionable strategies, educators and researchers can better navigate the evolving landscape of stomatology education. Bibliometric analysis provides a data-driven foundation for curriculum innovation and policy development by identifying emerging trends, evaluating influential studies, and uncovering knowledge gaps. For educators, it helps optimize curriculum design by integrating AI-driven diagnostics, competency-based learning, and virtual simulation training. For researchers, it serves as a strategic tool for identifying high-impact studies, fostering interdisciplinary collaborations, and addressing underexplored areas such as AI ethics and hybrid education models. By leveraging bibliometric methods, stakeholders can make informed decisions that enhance both teaching quality and learning outcomes, ensuring that technological advancements are effectively integrated into stomatology education.

Limitations and Strengths

This study possesses several notable strengths. Primarily, it represents the first bibliometric analysis of publications on teaching and learning in stomatology education using both the Bibliometrix package and CiteSpace. This analysis offers clinicians and scholars a comprehensive overview of the current landscape in stomatology education. In addition, the simultaneous use of 2 bibliometric tools, CiteSpace and Bibliometrix, enhances the robustness of our findings. CiteSpace, in particular, is a widely recognized tool that provides valuable insights into evolving research priorities and trends.

However, this study also has certain limitations. First, the search strategy was specifically focused on teaching and learning in stomatology education, which, despite efforts to expand the search terms, may have resulted in the exclusion of some relevant studies. Second, our study primarily uses bibliometric methods, which focus on citation patterns, co-occurrence networks, and research trends but do not directly assess the pedagogical effectiveness of emerging technologies. While our findings highlight the increasing focus on machine learning, VR, and AI-driven education, further empirical research is needed to evaluate how these innovations impact student learning outcomes, clinical decision-making, and practical skill acquisition. Conducting comparative studies between traditional and technology-enhanced teaching methods could provide deeper insights into their educational value. In addition, our analysis relies on data from WoSCC, which may exclude relevant publications indexed in other databases such as Scopus or PubMed. This could result in a partial representation of the research landscape. Future studies could incorporate multiple databases to ensure a more comprehensive assessment of publication trends. Finally, emerging research areas related to teaching and learning in stomatology education may have been inadvertently overlooked due to the constraints of the used algorithms.

Conclusions

In conclusion, the exploration of innovative teaching and learning methodologies holds significant potential for advancing stomatology education. For example, the integration of deep learning models can enhance diagnostic precision and clinical practice, whereas intelligent teaching systems can facilitate more efficient acquisition of oral medicine knowledge and improve educational outcomes. These technological advancements present new challenges for educators in the field. It is imperative that educators remain informed about the latest research developments and evolving trends in stomatology education. This awareness will not only aid in the dissemination of contemporary concepts but also enable the timely identification of emerging issues, thereby fostering the ongoing development and advancement of stomatology education.

Abstract

Background: Digital tools, services, and information in patient care demand new competencies in outpatient care, and the workforce is faced with the need to deal with digitalization.

Objective: In a targeted certificate course (Certification of Digitalization Officers in Medical Practices and Psychotherapeutic Practices, Digi-Manager), medical assistants are trained to serve as digitalization officers, enabling them to implement the requirements of digitalized health care within their practices.

Methods: As part of an accompanying study, the course is evaluated by the participants, and the change in their digital literacy is recorded. We measured different knowledge, skills, and attitude dimensions at 3 different times—before, during, and after the course—and used ANOVA to examine significant changes.

Results: Digi-Managers started the course with an already high self-assessment of their digital literacy. Skills and knowledge increased significantly in all categories (cognitive, technical, ethical, and health information) from the initial to the final measurement, as did self-confidence in the use of general software and hardware. Positive attitude remained stable over the training period, and the course was rated very positively by participants across all areas.

Conclusions: Training programs on digital topics for health care professionals are necessary, and this certification course is a role model for successful further education through a mixture of theoretical knowledge transfer and practical application. Especially, the use of a digital maturity model and a digital laboratory was a unique and useful feature. Further research needs to go into alternative assessment methods of digital literacy, as the results suggest that self-assessment measures self-efficacy and confidence, rather than pure competence. Nevertheless, the increase in self-assessed competence suggests that the training was successful.

Introduction

Background

The use of digital innovations with different tools, services, and information in patient care is associated with new requirements for day-to-day work in outpatient medical care, and the spectrum of them is expanding more and more. Not only physicians but also other medical professionals are faced with the need to deal with digitalization [1]. Telemedicine, eHealth, and mobile health (mHealth) enable access to health information, improve communication, allow personalized care, make remote monitoring possible, and support self-management of patients [2]. Administrative processes are also increasingly supported digitally [1].

The digital transformation in Germany's health care system has led to a few important digital tools in recent years: the electronic patient record (ePA), electronic sick leave certificates (eAU), electronic prescription (eRezept), the electronic medication plan

(eMP), electronic communication systems (KIM and TIM), telehealth applications, and digital health applications (DiGA). Additionally, various legal initiatives to establish more technologies in health care are currently coming into force in Germany [3]. On the side of the outpatient medical practices in Germany, the level of digitization or digital maturity depends heavily on the individual personality, motivation, and competence of the people involved [4-6]. You will find mostly outdated IT systems within the practices [3], and many things still happen in paper form, such as the storage of data or communication with other health care providers or patients [4].

Besides the availability of digital tools, services, and information, individuals need more motivation to use these technologies. Following the self-determination theory [7], the feeling of competence is one of the three pillars to develop motivation. Otherwise, feelings of incompetence regarding the use of health informatics technology tools lead to reluctance in using these tools and are one of the main reasons to avoid them. Digital competence or digital literacy in health care could be defined as the ability to integrate and apply context-appropriate knowledge, skills, and psychosocial factors—such as attitudes, beliefs, values, and motivation—to perform within the health care domain [8]. Especially when health care workers were not given enough time to learn on-the-job or did not have enough support from peers, they were not willing to use new technology [9]. To enable individuals to gain digital literacy in health care, education is needed.

In their focus group study, Mannevaara et al [10] identified knowledge and skill issues regarding IT-related management and IT background knowledge as the main challenges faced in health care. Competencies related to direct patient care, communication, ethics in health IT, project- and change management, digital literacy, information and knowledge management, teaching, and education were essential in today's health care practice. Especially, competencies in decision-making, information and knowledge management, teaching, training, and data security were highlighted as important by German participants in this study [10]. Hübner et al [11] identified the top 3 core competency areas that need to be addressed for employees in the health care sector that work in direct patient care: (1) communication, (2) documentation, and (3) information and knowledge management in patient care, which coincides with the focus of the Digi-Manager training course.

Goal of This Study

With this in mind, the project "Certification of Digitalization Officers in Medical Practices and Psychotherapeutic Practices (Digi-Manager)," funded by the Federal Ministry of Health in Germany, launched an educational program for medical assistants to train them as digitalization officers. In Germany, medical assistants make appointments for patients, document treatment procedures for patient files, take care of billing for services rendered, and organize practice procedures. They apply bandages, prepare syringes, or draw blood for laboratory tests. They also inform patients about pre- and posttreatment options, maintain medical instruments, and carry out laboratory work [12].

Digitalization officers, or how they are called in this certification program, "Digi-Managers," create digitalization strategies for their own practices, can get digitalization projects off the ground, and act as a point of contact for the digitalization of patient care.

To evaluate if the digital literacy of the participants could be increased through participation in the Digi-Manager course, their digital literacy before (t0), during (t1), and after (t2) the course was measured and compared. To measure the whole concept of digital literacy, participants are asked about their knowledge, skills, and attitudes regarding digital health technologies.

Hypotheses

The transfer of skills and abilities should be verifiable in a successful training program, which is why hypothesis H1 is formulated. A scoping review [13] suggests that discussions, group workshops, self-directed learning materials, and providing practice opportunities, among other things, help to grow digital confidence, which are provided within the Digi-Manager training. This leads to our hypothesis H2. Other studies show that increased usage causes a rise in computer confidence, which also increases positive attitudes toward computers [14], which supports the assumption of hypothesis H3.

- H1: Attending the Digi-Manager training course significantly improves the specific knowledge and skills imparted to participants.
- H2: Attending the Digi-Manager training course significantly improves participants' general confidence level for technology usage.
- H3: Attending the Digi-Manager training course significantly improves participants' attitude toward digital (health) applications.

Methods

Ethical Considerations

The ethics application was reviewed and approved by the ethics committee of Witten/Herdecke University on April 20, 2023, and no ethical or legal concerns were raised (application/approval no. S-93/2023). The participants received no further compensation for participating. Before each survey, the participants received information about the duration, procedure, and content of the study and had to provide consent. For each question, there was the option to refuse to answer. The responses of the participants were pseudonymized using an identification code, and no identifying information was queried.

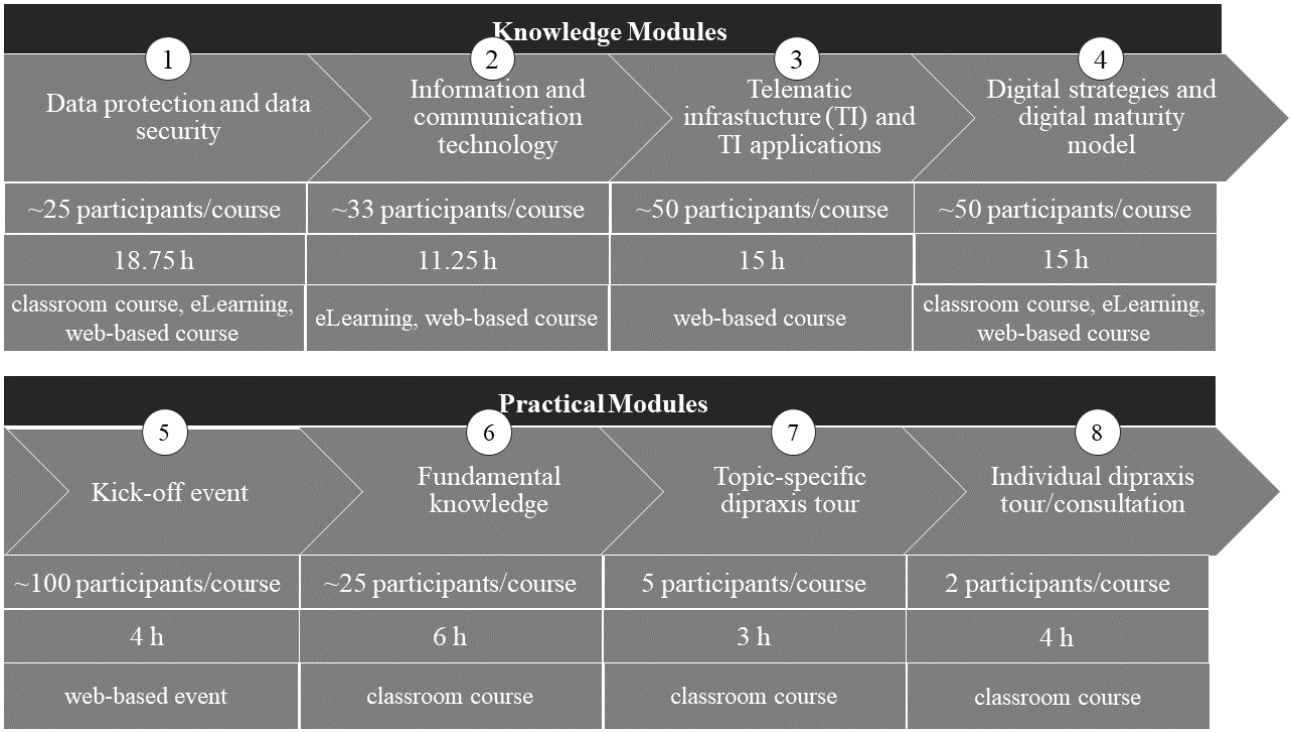
Course Concept

The aim of the Digi-Manager certificate course was to enable medical assistants in outpatient medical practices to derive and implement digitalization strategies and projects for their own practices and become contact persons for the digitalization of patient care. Therefore, they had to acquire skills in the areas of technology, data use, IT security, and data protection.

The participants were released from work for a total of 205 hours during the certificate course and received no further incentives for participation. The participants spend 60 hours on the knowledge modules and 17 hours on the practical modules

in web-based and on-site classroom courses. Approximately 128 hours were planned additionally for orientation, organization, self-study, exams, and creating a digitalization strategy (Figure 1). Different time slots (2 - 4 slots per module) were offered for each course, and participants were allowed to choose them freely. Participation in each module was mandatory to pass the certificate course, and attendance was assessed through an attendance list. The content of the course was developed based on an existing certified course of ÄKWL (Ärztekammer Westfalen-Lippe, a medical association representing 40,000 doctors of the Westphalia-Lippe region) that has been running for many years and was adapted and supplemented by a panel of experts with regard to the requirements of digitalization officers (Multimedia Appendix 1).

Figure 1. Schedule of the certificate course.



The course consisted of so-called knowledge and practical modules. The knowledge modules lasted from May until September 2023 and were held as blended learning courses with e-learning materials and web-based and on-site courses. The e-learning materials and web-based classes were distributed by the learning management platform ILIAS.

The practical modules lasted from October 2023 until May 2024 and consisted of a kick-off event, a fundamental knowledge course, and consultations in smaller groups. The courses took place at the dipraxis, a digital laboratory for testing digital tools and analyzing processes in outpatient care. A major component of the practical modules was the digital maturity model of the KVWL (Kassenärztliche Vereinigung Westfalen-Lippe, an association of statutory health insurance physicians of the Westphalia-Lippe region). The model was developed on the findings of Neunaber and Meister [15] for this project. It measures the digital maturity of the practices on 5 assessment categories: corporate management, infrastructure (IT security, data protection, interoperability, data processing, telematic infrastructure, and data collection), treatment and therapy, patient management, and administration. Course participants classified their own practice by answering 25 items. A digital tool visualized the digitalization status of the practice based on the answers using a radar chart. The model could be used by Digi-Managers to assess the current level of digitalization in the practice and identify potential for improvement of the digital situation. With the results of the digital maturity model and the consulting in the dipraxis, the digital managers developed practice-specific digitalization strategies.

Recruitment

The respondents for the survey were the participants of the Digi-Manager training course. Of the total of 100 participants, all were asked to take part in the surveys.

Guideline

The GREET (Guideline for Reporting Evidence-Based Practice Educational Interventions and Teaching) checklist was used to describe the educational intervention in detail [16]. It comprises 17 items to describe why, what, who, how, where, when, how much, and how well an educational intervention took place and what planned and unplanned changes occurred.

Questionnaires

Within the initial survey (Multimedia Appendix 2), participants were asked about their basic demographic information to describe the study population and identify possible biases: their age, gender identity, duration of employment, and the medical field of the doctor's office they work at. Various studies indicate that age and gender are associated with different usage behavior and perception of digital tools [17,18], but other studies show that the influence of these variables is often overestimated

[19,20]. In order to control these possible effects, demographic information was collected and analyzed.

Digital literacy of the participants was measured using 2 existing questionnaires, which recorded both the skills and knowledge relating to digital (health) systems as well as attitudes toward digital (health) systems. Since digital literacy is understood as the competence to deal with digital tools in the everyday professional life of medical assistants in this study, an instrument was needed that operationalizes different dimensions of competence and refers to the wide range of digital tools in medical practices. Fitting tools in terms of content and quality criteria were identified using the results of a preceding scoping review [21]. The first questionnaire used was the Public Health Informatics Competencies for Primary Health Care (PHIC4PHC) questionnaire [22], with a total of 42 items on a 5-point Likert scale. The items are divided into the following dimensions: *cognitive proficiency* (digital health system knowledge and digital health system skills), *technical proficiency* (general computer skills, office application skills, and network skills), *ethical proficiency* (privacy, security, and legal knowledge), and *health information literacy* (health information access, management, integration, and evaluation).

In addition to knowledge and skills, the questionnaire by Kuek and Hakkennes [23] was used to record the attitude toward the use of digital health care systems via items on (1) confidence in usage behavior, (2) technology acceptance, and (3) acceptance and use of technology.

The first part of the questionnaire required participants to indicate their confidence level for different commonly used hardware and software devices on a 5-point scale from not at all confident to completely confident. The devices and applications in question were computers, office applications, smartphones, tablets, email, and social media. The second and third parts of the questionnaire were based on the TAM (technology acceptance model) and UTAUT (unified theory of acceptance and use of technology) questionnaires, which have been used and validated in various studies. Technology acceptance of health information systems was measured using the dimensions *perceived usefulness* and *perceived ease of use* of the TAM, with 12 items, and supplemented with the dimensions *attitude toward technology*, *social influence*, *facilitating conditions*, and *anxiety* of the UTAUT, with 15 items, all on a 7-point Likert scale.

The system usability scale (SUS) was used as an established, standardized, and quick questionnaire for the assessment of perceived usability of the digital maturity level tool (Brooke, 1996, quoted from [24]). The 10 items were measured on a 5-point Likert scale.

Procedure

Digital literacy was assessed in the form of a longitudinal study parallel to the certificate course. The measurement points were based on the participants' progress in the course: before completing the first knowledge module (t0), after completing all 4 knowledge modules (t1), and after completing the practical modules (t2). The links to the questionnaires were distributed via the learning management platform ILIAS, which was used to provide communication and content for the Digi-Manager training. This made it easier for participants to access the surveys, and the integrated reminder and activation functions ensured that participation in the surveys was not forgotten. In addition, the completion of the evaluation surveys could be used as a condition for further progress within the learning material in ILIAS. As no further learning content was planned after the final survey, reminder emails were sent to the participants for this purpose.

Before starting every survey, the participants were informed about the content of the study, data processing, and data protection and were asked for their written consent to participate. To statistically evaluate the change in digital literacy without violating anonymity, participants were asked to provide each survey with their individual identification code. This code was a 6-digit character string made up of time-stable personal characteristics.

The first questionnaire for t0 collected basic demographic information and measured the participants' existing digital skills. The second questionnaire for t1 was intended to assess the digital literacy of the participants again and additionally asked about the evaluation of the first part of the training. At this second measurement point, the Digi-Managers also had the opportunity to evaluate the certificate course in terms of support and design (participant support, technical moderation, quality of scripts, and atmosphere), content (topicality of content, content structure, selection of speakers and authors, discussion/interaction, practical relevance, and personal goal achievement), planning and organization (program announcement, selection of dates, and time frame), and the web conferencing system (technical functionality, user friendliness of the screen, sound quality, and image quality). Participants were able to rate the various aspects of these dimensions on a scale of 1 to 6, with 1 as the best and 6 as the worst rating option. In addition, there were free-text questions in which the participants were asked what they perceived as particularly positive or particularly negative about the training. In the final questionnaire for t2, digital literacy was assessed one last time, the second part of the training was evaluated, and the applicability and comprehensibility of the digital maturity level tool were recorded.

Data Analysis

The datasets of the different surveys were matched through the 6-digit individual identification code. Since some data records did not have fully matching codes, data records were also assigned that were at most 2 characters different or in a reversed order.

The collected data were analyzed with the IBM SPSS Statistics 28 analysis software. To analyze the data descriptively, the frequency, mean values, and standard deviations were reported. Normal distribution as a prerequisite was tested by the Shapiro-Wilk test because it is more powerful than the Kolmogorov-Smirnov test [25], and sphericity was tested with the Mauchly test. The Levene test was used to test the homogeneity of variances.

Correlations were tested through Pearson *r* and rated with the classification from Cohen [26], with $|r|=0.1$ as weak correlation, $|r|=0.3$ as moderate correlation, and $|r|=0.5$ as strong correlation. ANOVA with repeated measures was used to test if the mean values of digital literacy at different measurement points differ significantly. Post hoc tests were used to determine between which measurement times significant differences exist. For evaluation of effect sizes, the classification according to Cohen [26] was chosen with 0.01 as a weak effect, 0.06 as a moderate effect, and 0.14 as a large/strong effect. As η^2 systematically overestimates the effect size, ω^2 and ε^2 are also calculated, as these have lower bias [27]. Between-subject effects such as age, gender, and education level were also tested to gain insights into their additional effect.

The SUS score was calculated as the sum of item scores with the negative worded items inverted and multiplied by 2.5, resulting in a value between 0 and 100 [24].

The free-text answers were formed into inductive categories, and only the top 3 of particularly positive or particularly negative aspects were reported. All other named categories could be seen in Multimedia Appendix 3.

Results

Digi-Manager Characteristics

A total of 100 participants started the Digi-Manager training course. The participants were aged between 20 and 61 years, with an average age of 37.4 (SD 11.3) years, and the vast majority identified as female (95/100, 95%). Only 4 (4%) identified as male, and 1 (1%) did not provide any information on their gender identity. The participants worked at doctors' offices with different primary medical fields, as shown in Table 1.

Table . Participants' demographic data (N=100).

Characteristics	Participants (N=100)
Age (years), mean (SD)	37.4 (11.3)
Gender, n (%)	
Woman	95 (95)
Man	4 (4)
Prefer not to say	1 (1)
Primary medical field of doctor's office, n (%)	
General practice	50 (50)
Gynecology	9 (9)
Dermatology	5 (5)
Orthopedics	5 (5)
Psychiatry or psychotherapeutic practice	4 (4)
Pediatrics	3 (3)
Internal medicine	3 (3)
Neurology	3 (3)
Urology	2 (2)
Ophthalmology	2 (2)
Gastroenterology	2 (2)
Child and adolescent psychiatry	2 (2)
Oral and maxillofacial surgery	2 (2)
Otorhinolaryngology	1 (1)
Pneumology	1 (1)
Nuclear medicine	1 (1)
Radiology	1 (1)
Reproductive medicine	1 (1)
Not specified	3 (3)

For the first survey, the participation rate was 100%. In the second survey, 97 out of the 100 Digi-Managers participated. For the third and last survey, only 64 of the 100 answered the entire questionnaire, despite repeated reminders via email and ILIAS.

Gender as a between-subject effect was not further monitored because of the vast majority (95/100, 95%) of female-identifying participants. The variables that showed a significant correlation with age were all 3 measurement points for confidence in usage behavior with a medium negative effect (r_{t0}=–0.422, P<.001; r_{t1}=–0.423, P<.001; r_{t2}=–0.381, P=.005). The other correlation values can be seen in Multimedia Appendix 4.

Evaluation of the Certificate Course

The course was evaluated separately for the knowledge and the practical modules, but for both, the review was very positive. Most ratings were equal to or above a mean value of 2; only the *selection of dates* for the knowledge modules and the *time frame* for both the knowledge and practical modules were just below this value. All other categories for support and design, content, and web conferencing systems were ranked 1.4 - 2 (Table 2).

Table . Evaluation of the certificate course aspects by the Digi-Managers (scale from 1 (very good) to 6 (very bad)).

Evaluation categories	Knowledge modules, mean (SD)	Practical modules, mean (SD)
Support and design		
Participant support	1.7 (0.9)	1.4 (0.7)
Technical moderation	1.6 (0.7)	—[a]
Quality of scripts	1.9 (0.9)	—
Atmosphere	1.7 (0.8)	1.4 (0.7)
Content		
Topicality of content	1.6 (0.6)	1.4 (0.7)
Content structure	1.8 (0.8)	1.7 (0.8)
Selection of speakers/authors	1.9 (0.8)	1.6 (0.8)
Discussion/interaction	2 (1)	1.8 (0.9)
Practical relevance	2 (1)	1.7 (1)
Personal goal achievement	1.9 (0.9)	1.7 (0.8)
Planning and organization		
Program announcement	1.9 (1.1)	1.5 (0.7)
Selection of dates	2.2 (1.1)	1.7 (0.8)
Time frame	2.1 (1)	2.1 (1.1)
Web conferencing system		
Technical functionality	1.8 (0.7)	—
User friendliness of the screen	1.9 (0.9)	—
Sound quality	1.8 (0.9)	—
Image quality	1.8 (0.8)	—

[a]Not applicable.

The most named positive aspects of the knowledge modules were the content (n=24), with comprehensive scripts, refreshment of knowledge, and new impulses in a comprehensible manner, and the possibility to have access before and after the materials. The second most named was the good support (n=24), which was fast, friendly, and competent, gave individual help, and was very helpful with further questions. The practical relevance and application orientation were named as a positive aspect, the third most (n=14). In turn, most participants said that they could not name any negative aspects (n=25). Some mentioned that it was too much input for the short period of time (n=7), and others said that the modules had too much frontal teaching (n=6), which made the courses dry, difficult to follow, boring, and with too little interaction.

For the practical modules, the exchange with other participants in small groups was particularly positively highlighted by the Digi-Managers (n=26) for offering new perspectives or solutions in conversations. Furthermore, positively perceived was the very informative and instructive nature of the practice modules (n=10) and direct transfer to everyday practice (n=9). When asked about negative aspects, the most common response was that the participants could not name any (n=12). Some participants said that they wished for better day and time selection options (n=4), because the option selections were confusing, could not always be set up, and the always-changing slots were problematic. Some participants wished for more feedback on the tasks they had completed (n=4).

Evaluation of the Digital Maturity Tool

The usability of the digital maturity tool was ranked via SUS score with a mean value of 85 (SD 12.9), which could be classified as an A+ grade after the Sauro-Lewis grading scale [28]. The content of the tool was evaluated very positively in the different aspects with values between 1.39 and 1.79 (Table 3).

Table . Evaluation of the digital maturity tool content aspects by the Digi-Managers (scale from 1 (very good) to 6 (very bad)).

Content evaluation categories	Content rating, mean (SD)
Topicality of content	1.4 (0.6)
Content structure	1.6 (0.7)
Practical relevance	1.6 (0.7)
Personal goal achievement	1.8 (1)

Regarding the digital maturity tool, the participants especially liked the visual representation as a radar chart (n=23) because it was appealing, clear, and colorful; showed all relevant information at a glance; and made the digitalization tangible. A lot of participants positively highlighted the possibility to determine the "status quo" of their practice (n=15) and the potential to uncover gaps and deficits (n=11). Most had no negative aspects (n=16), but some mentioned that the answer options to the items were not always clearly distinguishable, or there were no answer options that fitted their practice perfectly, but it was possible to clarify answers through free-text fields (n=8). Some participants had problems with lots of technical jargon (n=5).

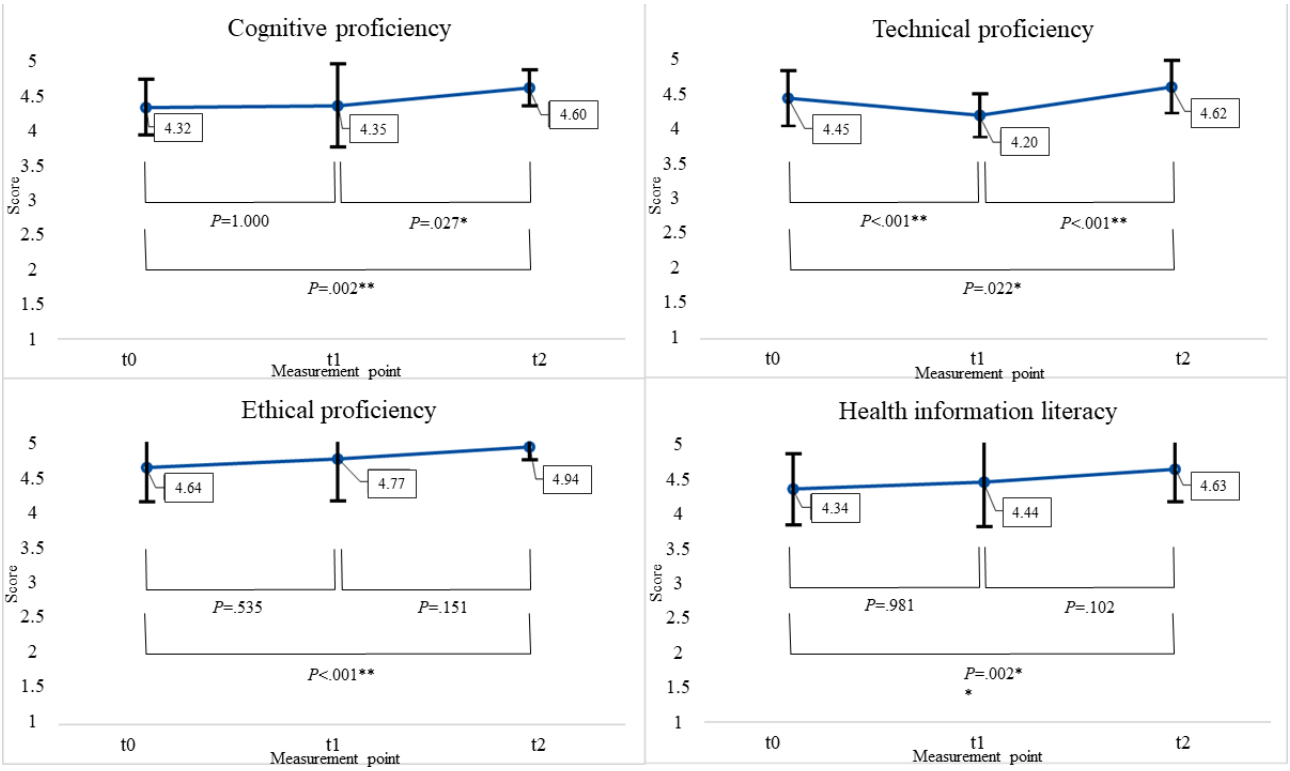
Progression of Digital Literacy

An ANOVA with repeated measures showed that *cognitive proficiency* changed significantly ($F_{1.67,63.55}$=5.5, P<.009; partial η^2=0.13). ω^2=0.1 and ε^2=0.1 could be classified as a medium effect. Because of violations of sphericity (P=.018), the Greenhouse-Geisser adjustment was used. Bonferroni-adjusted post hoc analysis revealed a significant increase (P=.027) in cognitive proficiency from the second to last measurement point ($mean_{Diff}$ –0.25, 95% CI –0.48 to –0.22) and a significant increase (P=.002) between the first and last survey ($mean_{Diff}$ –0.28, 95% CI –0.46 to –0.09) ($mean_{t0}$ 4.3, SD_{t0} 0.4; $mean_{t1}$ 4.4, SD_{t1} 0.6; $mean_{t2}$ 4.6, SD_{t2} 0.3) (Figure 2).

Technical proficiency initially decreased before rising again at the last measurement point ($mean_{t0}$ 4.5, SD_{t0} 0.4; $mean_{t1}$ 4.2, SD_{t1} 0.3; $mean_{t2}$ 4.6, SD_{t2} 0.4). None of the variables were normally distributed. Because of violations of sphericity, the Greenhouse-Geisser adjustment was used to correct the repeated measures ANOVA, and it showed significant differences ($F_{1.83,75.05}$=31.7, P<.001; partial η^2=0.44). ω^2=0.42 and ε^2=0.42 showed a large effect. Bonferroni-adjusted post hoc analysis revealed significant differences between all measurement points: a significant decrease (P<.001) between the first and second survey ($mean_{Diff}$ 0.25, 95% CI 0.14 to 0.36), as well as a significant increase (P<.001) between the second and third survey ($mean_{Diff}$ –0.41, 95% CI –0.54 to –0.28), and an overall significant increase (P=.022) between the first and third survey ($mean_{Diff}$ –0.17, 95% CI –0.31 to –0.02).

Ethical proficiency increased over the entire training period ($mean_{t0}$ 4.6, SD_{t0} 0.5; $mean_{t1}$ 4.8, SD_{t1} 0.6; $mean_{t2}$ 4.9, SD_{t2} 0.2), with a statistically significant difference between measurements, assessed by repeated measures ANOVA with the Greenhouse-Geisser correction (Mauchly test P=.003; $F_{1.68,94.3}$=6.54, P=.004; partial η^2=0.11). ω^2=0.09 and ε^2=0.09 could be classified as a medium effect. Bonferroni-adjusted post hoc analysis showed a significant increase (P<.001) from the first to last measurement point ($mean_{Diff}$ –0.30, 95% CI –0.46 to –0.14).

Figure 2. Means, SDs, and post hoc results for the 4 PHIC4PHC (Public Health Informatics Competencies for Primary Health Care) domains. *P<.05, **P<.01.



The change in *health information literacy* was assessed as significant through repeated measures ANOVA ($F_{2,102}$=5.71, P=.004; partial η^2=0.1). ω^2=0.08 and ε^2=0.08 show a medium effect. Sphericity could be assumed (P=.361). Post hoc analysis with the Bonferroni correction revealed a significant increase (P=.002) from the first ($mean_{t0}$ 4.3, SD_{t0} 0.5) to last ($mean_{t2}$ 4.6, SD_{t2} 0.5) measurement point ($mean_{Diff}$ –0.29, 95% CI –0.49 to –0.10).

The confidence level for technology usage increased from one measuring time to the next ($mean_{t0}$ 3.6, SD_{t0} 0.8; $mean_{t1}$ 3.7, SD_{t1} 0.6; $mean_{t2}$ 4.1, SD_{t2} 0.6). None of the variables were normally distributed, as assessed by the Shapiro-Wilk test, but since the sample size was sufficiently large (n>30) and due to the robustness of the ANOVA with repeated measures, no further actions need to be taken [29]. The Greenhouse-Geisser adjustment was used to correct the violations of sphericity due to a significant result of the Mauchly test (P=.002) [30]. A repeated measures ANOVA with a Greenhouse-Geisser correction determined that the confidence level showed a statistically significant difference between measurements ($F_{1.6,71.72}$=22.59, P<.001; partial η^2=0.33). ω^2=0.32 and ε^2=0.32 could be classified as a large effect.

Bonferroni-adjusted post hoc analysis revealed significantly (P<.001) higher confidence scores in the comparison between the first and last measurement points ($mean_{Diff}$ –0.48, 95% CI –0.32 to 0.03), and significantly (P<.001) higher between the second and last measurement points ($mean_{Diff}$ –0.34, 95% CI –0.48 to –0.20).

The attitude toward (health) technology was assessed by TAM and UTAUT items. There was no statistically significant difference for the different measurement points of the TAM ($F_{1.65,70.91}$=1.89, P=.166) as assessed by repeated measures ANOVA with the Greenhouse-Geisser correction (Mauchly test P=.007). The mean TAM score was already high in the first survey ($mean_{t0}$ 6, SD_{t0} 0.7) and remained at a similar height for the second ($mean_{t1}$ 6.2, SD_{t1} 0.7) and third ($mean_{t2}$ 6.3, SD_{t2} 0.8) surveys.

For the UTAUT scores, normal distribution (P_{t0}=.174; P_{t1}=.200; P_{t2}=.200) and sphericity (P=.080) could be assumed. The repeated measures ANOVA showed no significant differences ($F_{1.65,70.91}$=1.89, P=.166). The UTAUT score remained—similar to the TAM score—high over the entire data collection period ($mean_{t0}$ 6, SD_{t0} 0.3; $mean_{t1}$ 6.1, SD_{t1} 0.7; $mean_{t2}$ 6.2, SD_{t2} 0.4).

Discussion

Principal Results

The study results showed that the training was both successful and satisfactory for the participants of the certificate course “Certification of Digitalization Officers in Medical Practices and Psychotherapeutic Practices (Digi-Manager).” Although the Digi-Managers already started with a high level of self-evaluated digital literacy, this increased significantly from the beginning to the end of the training program. Hypothesis H1 was confirmed: after the training course, the Digi-Manager had significantly higher values in the cognitive proficiency, ethical proficiency, and health information literacy with a medium effect. The significant increase in technical proficiency even had a large effect. Hypothesis H2 was also confirmed, and attending the Digi-Manager training course significantly improved participants’ general confidence level for technology

usage with a large effect. The attitude toward digital (health) applications remained stable at a high positive level over the entire course duration. Therefore, hypothesis H3 was rejected because the attitude toward digital (health) applications did not improve during and after the Digi-Manager training course. We assumed that this was because the practices had to actively apply for the course. Although the participants were finally drawn by lot, it is likely that practices that were interested in digital topics anyway applied more often and sent their most digitally savvy colleague. The very positive perception of the training—both for the knowledge and practical modules—also remained stable throughout the course. Age had no effect on most of the variables. The only variable that was negatively influenced by older age was self-confidence in use. This effect was stable for all 3 measurement times. Similar results of lower self-confidence when dealing with digital topics in older adults were found in other studies [20]. Our survey therefore reflects the state of research that there are hardly any age effects in the use of digital tools. Gender effects could not be examined because of the vast majority of female-identifying participants. However, the low participation rate of men reflects the real gender proportion of men in this occupational field, which was only 2% in the year 2023 in Germany, as reported by the federal employment agency (Bundesagentur für Arbeit).

To our knowledge, this is the first training program for medical assistants for general digital literacy that was scientifically evaluated. Multiple review papers show that training courses for health care staff teach mostly about specific technologies such as electronic medical records or telehealth [31,32], take place for the most part in an academic context [33], or are intended for physicians [34]. Many authors criticize the lack of sufficient training [34-36].

A competence measure study in the more digital-savvy country of Finland [37] showed that further education for health professionals is needed not only in Germany but all over the world. The level of digital competence among health care professionals also varies in other countries. Especially, human-centered remote counseling competence was identified as the category with the weakest score. Health care professionals' knowledge of ethical, legal, and regulatory requirements, as well as privacy and security issues regarding digital tools, was named as a mandatory subject matter in training. In the study of Jarva et al [37], higher age was associated with lower evaluation of digital solutions as part of work and a decrease in self-evaluated competence. This was not further confirmed in our study.

Limitations

One limitation of the results is that, despite repeated reminders both digitally and in person, there was a high level of nonparticipation at the time of the last survey. Only 64% (64/100) completed the last survey. It cannot be ruled out that this might slightly distort the results as it is more likely that the committed participants, who got a lot out of the training anyway, participated until the end than those who perceived the training as less enriching. In future training courses, an attempt will be made to combine the evaluation with the last content-related work in the course in order to increase participation in the final evaluation.

As a further limitation on the part of the participants, it should be considered that, as already briefly mentioned above in the discussion of H3, a self-selection bias could exist through the application process and registration through the practice owner. Participants were either self-motivated to take part or were perceived by their practice owner as the "most suitable" and therefore probably the most interested person of the practice in digital topics.

Furthermore, it must be questioned whether the self-assessment questionnaires were really suitable for measuring competence. According to the results, competence in the domain of technical proficiency decreased when participating in this training course, which appears illogical. Since the questionnaire measures how capable the participants see themselves, this value can decrease if they learn what they do not yet know. Self-perception does not always match actual performance [38]. This is further backed up by another study that questions the suitability of self-assessment scales for measuring competence: "Perceived skills [...] do not predict actual performance," as van der Vaart et al [39] stated in their paper, comparing the results of self-assessment scales that aim to measure the eHealth literacy of participants, with their actual performance in different skill tests [39]. In this study, correlations between the used eHEALS (eHealth Literacy Scale) measure and successfully completed tasks were nonsignificant and weak, and no group differences between participants who scored below and above the median in the performance tests for the eHEALS scores were found. Jarva et al [37] supported this thesis by using the specified term "self-evaluated competence" in their study. The reliability and validity of estimating one's own competence have already been questioned by many authors [40-42]. Despite this, self-assessment of specific skills and knowledge is, to date, the most commonly used form of measuring digital competence [21]. The question arises as to whether the questionnaires—tested for quality characteristics such as reliability—are in fact simply measuring a different concept than competence. Ulfert-Blank and Schmidt [43] suggested *digital self-efficacy* as a possible characteristic that could be measured through these instruments, defined as "an individual's perception of efficacy in performing tasks related to the use of digital system." Bancroft et al [13] proposed that self-assessment of competence measures a mixture of competence and confidence and that both concepts are closely related and sometimes conflated, but also could be out of alignment, and a lack of confidence could hold back people who are per se competent. New paths must be found to measure the actual digital competence of health care professionals.

Future Research Directions

As mentioned above, new alternative ways to measure digital literacy/competence—besides self-assessment scales—must be found. One promising approach could be the use of performance measures, which were already used for the measurement of other concepts, like eHealth literacy [39] or data literacy [44,45].

It is noticeable among the participants of the training course that they all started with a very positive attitude. This is probably

because there was an active application process for the training, and people who were already digitally interested were more likely to want to be trained as Digi-Managers. It would be interesting to see whether further training would lead to an improvement in the attitudes of people who are not yet so positively disposed.

Learnings for Future Courses

The success in positive learning outcomes and satisfaction of the participants shows the relevance of the continuation of the course. The training program will be carried on with slight changes, following the feedback of participants, instructors, and organizers. Future courses will be shorter in time to enable smaller practices to participate with fewer lost hours of their employees and more e-learning and web-based courses in order to travel less. That should also improve the day and time selection options. Course sizes are to be reduced to enable more active involvement of participants and, above all, to further support practical networking and the exchange of experience. A streamlined concept with consistent quality should focus on the unique selling points of the Digi-Manager training: the digital laboratory and maturity model. The additional focus on soft skills (project management, communication, and conflict management) is helpful for the effective transfer and realization of digital projects in practice.

Conclusions

The Digi-Manager program was a successful and long-needed training program for health care professionals in the German region of Westfalen-Lippe. More training programs and courses for health care professionals are needed not only in Germany but all over the world. The mixture of transferring theoretical knowledge and practical applications with reference to one's own everyday work through soft skill training, the maturity model, and digitalization strategy results in a unique and effective further education concept.

Abstract

Background: Traditional Chinese medicine (TCM) education in China has evolved significantly, shaped by both national policy and social needs. Despite this, the academic community has yet to fully explore the long-term trends and core issues in TCM education policies. As the global interest in TCM continues to grow, understanding these trends becomes crucial for guiding future policy and educational reforms. This study used cutting-edge deep learning techniques to fill this gap, offering a novel, data-driven perspective on the evolution of TCM education policies.

Objective: This study aimed to systematically analyze the research topics and evolutionary trends in TCM education policies in China using a deep learning–based topic modeling approach, providing valuable insights to guide future policy development and educational practices.

Methods: TCM policy–related documents were collected from major sources, including the Ministry of Education, the National Administration of Traditional Chinese Medicine, PKU Lawinfo, and archives of TCM colleges. The text was preprocessed and analyzed using the BERTopic model, a state-of-the-art tool for topic modeling, to extract key themes and examine the policy development trajectory.

Results: The analysis revealed 27 core topics in TCM education policies, including medical education, curriculum reform, rural health care, internationalization, and the integration of TCM with modern education systems. These topics were clustered into 5 stages of policy evolution: marginalization, standardization, specialization, systematization, and restandardization. These stages reflect the ongoing balancing act between modernizing TCM education and preserving its traditional values, while adapting to national political, social, and economic strategies.

Conclusions: This study offers groundbreaking insights into the dynamic and multifaceted evolution of TCM education policies in China. By leveraging the BERTopic model, it provides a comprehensive framework for understanding the forces shaping TCM education and offers actionable recommendations for future policy making. The findings are essential for educators, policymakers, and researchers aiming to refine and innovate TCM education in an increasingly globalized world.

KEYWORDS

traditional Chinese medicine education policy; BERTopic; policy evolution; descriptive study; topic analysis

Introduction

Traditional Chinese medicine (TCM) is an important part of China's 5000-year-old culture. Its education policy not only concerns the inheritance and development of TCM but also has a profound impact on the global health system [1]. In the modernization process of China, the evolution of TCM education policies reflects the country's emphasis on and adjustment of traditional medical education, as well as the complex interaction between social demands, political environment, and cultural confidence. With the enhancement of China's comprehensive national power and its rising international status, TCM education has gradually become an important part of global health governance. The direction and effectiveness of its policies directly affect the influence and adaptability of TCM globally [1]. Against this backdrop, in-depth research and analysis of the evolution and development path of TCM education policies are of great academic and practical significance. By tracing the evolution of TCM education policies, we can reveal the driving forces and logical relationships behind the policies, providing a solid basis for decision makers. Moreover, analyzing the

evolutionary trends of TCM education policies can also help educational institutions and researchers better understand the future direction of TCM education, thereby promoting the reform and innovation of TCM education to meet the diverse needs of modern society and international challenges.

Text mining technology, as an advanced data analysis method, can extract potential topics and patterns from a large number of policy texts, providing a new perspective for understanding the evolution of TCM education policies. Through systematic analysis of policy texts, we can identify the changing trends, weight distribution, and logical structure of policy topics, thereby revealing the focus and orientation of TCM education policies in different historical stages. This analysis not only provides empirical support for the theoretical research of TCM education but also offers scientific references for policymakers when formulating future TCM education policies [2]. This study uses Bert and dynamic topic modeling (DTM) and other text mining methods to conduct topic mining [3,4], identification, and analysis of TCM education policy texts to study the development direction and evolutionary path of TCM education policies, providing guidance and references for scientific research and scientific management practices in relevant fields.

Methods

Data Sources

This study obtained more than 200 national-level policy texts related to TCM education from 1902 to 2024 from the official websites of the Central People's Government of the People's Republic of China, the Ministry of Education, the National Health Commission, and the National Administration of Traditional Chinese Medicine; China National Knowledge Infrastructure (including yearbooks, mainly the China TCM Yearbook); publicly published books, journals, and newspapers; and internal material compilations and archive files of relevant departments, supplemented by important policies mentioned in literature studies. These data cover key stages and important nodes of TCM education policies, ensuring the comprehensiveness and systematic nature of the study.

Inclusion Criteria

Only national-level policy documents directly related to TCM education were included. This means policies that explicitly addressed TCM educational objectives, curriculum design, teaching methods, teacher qualifications, student enrollment, or educational resource allocation in the context of TCM education were selected. Policies that were tangentially related, such as general health policies with only a passing mention of TCM without specific educational implications, were excluded.

Exclusion Criteria

Documents that were not official policies, such as opinion pieces, academic commentaries, and nongovernmental reports on TCM education, were excluded. Additionally, policies that were duplicates, drafts, or had been superseded by subsequent policies were not included in the final dataset.

The data collection focuses on national-level policy documents, combined with TCM education reform plans and guiding opinions issued by the Ministry of Education and health departments, as well as relevant historical records and academic research reports, to build a complete policy evolution database.

Overall Research Framework

The overall research framework of this paper is divided into data collection, model improvement, data cleaning, BERTopic data processing, result output, and result interpretation. BERTopic is a topic modeling technique based on BERT word vectors [5], which creates dense clusters using Transformers and class-based Term Frequency–Inverse Document Frequency (c-TF-IDF) while retaining important words in topic descriptions. The topic modeling analysis using this model can be carried out in the following 5 steps: embeddings, dimensionality reduction, clustering, tokenizer, and weighting scheme [6]. The model has modular features, and processing methods can be chosen autonomously at each step according to research needs [7].

Compared with traditional topic models such as Latent Dirichlet Allocation (LDA), BERTopic exhibits distinct advantages in analyzing TCM policies. Traditional models rely on statistical co-occurrence of words, which often fails to capture semantic relationships effectively. For instance, LDA assumes that topics are generated from a Dirichlet distribution over words, struggling to differentiate between polysemous terms [8]. In contrast, BERTopic leverages pretrained BERT embeddings, enabling it to understand the context of words, thus better handling TCM-specific terminologies that are often ambiguous and context-dependent. BERTopic, by integrating c-TF-IDF, emphasizes the importance of words within topics based on semantic similarity, leading to more interpretable and accurate topic representations in the TCM policy domain [5].

When compared with existing TCM policy research using methods such as LDA-based analysis, BERTopic demonstrates significant superiority in semantic understanding. Traditional LDA-based studies often produce topics with overlapping meanings and struggle to distinguish between terms with similar statistical distributions but different semantic interpretations [9]. For example, in TCM policies, terms such as "herbal medicine" may have multiple connotations, such as medicinal plant resources, prescription formulations, or quality control standards. BERTopic, powered by its deep bidirectional Transformer architecture, can analyze the surrounding text to disambiguate these polysemous terms accurately [10]. Moreover, TCM has a rich set of domain-specific jargon, and BERTopic's pretraining on extensive language corpora allows it to recognize and leverage these specialized terminologies more effectively, providing a more nuanced and comprehensive understanding of TCM policy documents [11].

Data Cleaning and BERTopic Model Improvement Methods

After obtaining the TCM education policy-related texts, since the BERTopic model itself has a limit on text length, it will truncate texts exceeding 512 characters. However, most policy texts have more than 1000 characters. Therefore, this study improved the BERTopic model by extracting BERT features

for every 512 characters of long texts and then calculating the mean value as the text feature.

In addition, conventional data cleaning of policy texts is also required. First, the text content of Word and PDF policy documents is extracted, and obvious recognition errors and redundant invalid data are removed or replaced. Then, using the Jieba library and the HIT stop word list, common Chinese stop words are removed. Furthermore, a specialized word dictionary for the TCM policy field is used to segment the text, obtaining preprocessed text data.

Data Processing Methods

Text Vectorization

The first step in processing the text input into the model is text vectorization, that is, embedding. Before conducting topic modeling and clustering, it is necessary to convert text data into numerical vector representations, which is the basis of topic modeling [12]. In the BERTopic constructed in this study, the preprocessed documents are converted into dense vector representations based on the Sentence-BERT framework. By adding pooling operations in the output of BERT, fixed-size sentence embeddings are obtained. This study uses the paraphrase-multilingual-MiniLM-L12-V2 sentence vector model to represent the preprocessed text embeddings. This model supports more than 50 languages, including Chinese, and is very effective for most use cases. It not only greatly improves training speed but also maintains superior performance.

Dimensionality Reduction

After text vectorization, dimensionality reduction is required, that is, mapping high-dimensional data to low-dimensional space. The purpose of dimensionality reduction is to reduce the dimension of the embedding vectors, thereby simplifying computation and storage and enhancing clustering effects [13]. Common dimensionality reduction techniques include Uniform Manifold Approximation and Projection (UMAP), Principal Component Analysis, and t-Distributed Stochastic Neighbor Embedding, with UMAP being the default choice for BERTopic. This method effectively reduces dimensions while retaining the local and global structure of the data, ensuring the accuracy of clustering semantically similar documents. Compared with other dimensionality reduction algorithms, UMAP is better at preserving the characteristics of the original data in low-dimensional space, making it the preferred method for text clustering dimensionality reduction.

Clustering

After text dimensionality reduction, the next step is to use clustering algorithms to assign embedding vectors to different topics. In this study, the HDBSCAN (Hierarchical Density-Based Spatial Clustering of Applications with Noise) algorithm is used for topic clustering of the reduced dimension document embeddings [14]. HDBSCAN extends DBSCAN (Density-Based Spatial Clustering of Applications with Noise) into a hierarchical clustering algorithm, which can automatically select the optimal clusters and treat noise as outliers, thereby avoiding the incorrect allocation of unrelated documents. This algorithm can generate dynamic topic representations, allowing the same topic to be expressed in different forms at different times, providing flexibility for studying the temporal changes of policy topics [15].

Topic Word Extraction

After topic clustering is completed, the next step is to extract and represent topic words using the Bag-of-Words model. This study used the c-TF-IDF method, which combines all documents in each cluster into a long document and calculates the frequency of each word [5]. To improve the coherence and diversity of topics, maximal marginal relevance is further applied to optimize the selection of topic words, reducing the repetition of synonyms and ensuring the diversity and accuracy of topic representation.

Dynamic Topic Modeling

DTM takes into account the changes in topics over time and can better capture the evolution of policies than static topic modeling [16]. BERTopic combines temporal factors by calculating topic representations at each time point to achieve DTM. First, the model is fitted globally and then the topic representations at each time point are fine-tuned. This allows for more precise analysis of topic evolution through global and evolutionary adjustments, providing an effective tool for understanding changes in policy topics over different periods.

Results

TCM Education Policy Topic Extraction Results

Using the BERTopic model for topic modeling of policy abstracts, this study adjusted the model parameters based on multiple experimental results. Under the set parameter conditions, a total of 27 main research topics in TCM education policies were identified (from topic 0 to topic 26), covering 183 policy texts in the dataset. Another 27 policy texts were classified as noise data (assigned to the −1 category). The noise data, aside from a few outlier policy texts, mainly consisted of research topics that did not reach the set parameter cluster size. These were mostly secondary or minor topics under the main themes, and their impact on the main research topics of TCM education policies was minimal. The representative keywords generated by the model for each topic are shown in Table 1.

Table . Topic identification results and related document counts based on BERTopic.

Topic number	Document count	Percentage	Keywords
Topic 0	20	10.9	“Training,” “Medical Education,” “Clinical,” “Method,” “Major,” “Outpatient,” “Technology,” “Principle,” “Content,” and “Trainee”
Topic 1	14	7.7	“Class Hours,” “Lecture,” “‘Chinese Medicine,” “Labor,” “Teaching Plan,” “Student,” “Basic,” “Assessment,” “Teaching,” and “Medic”

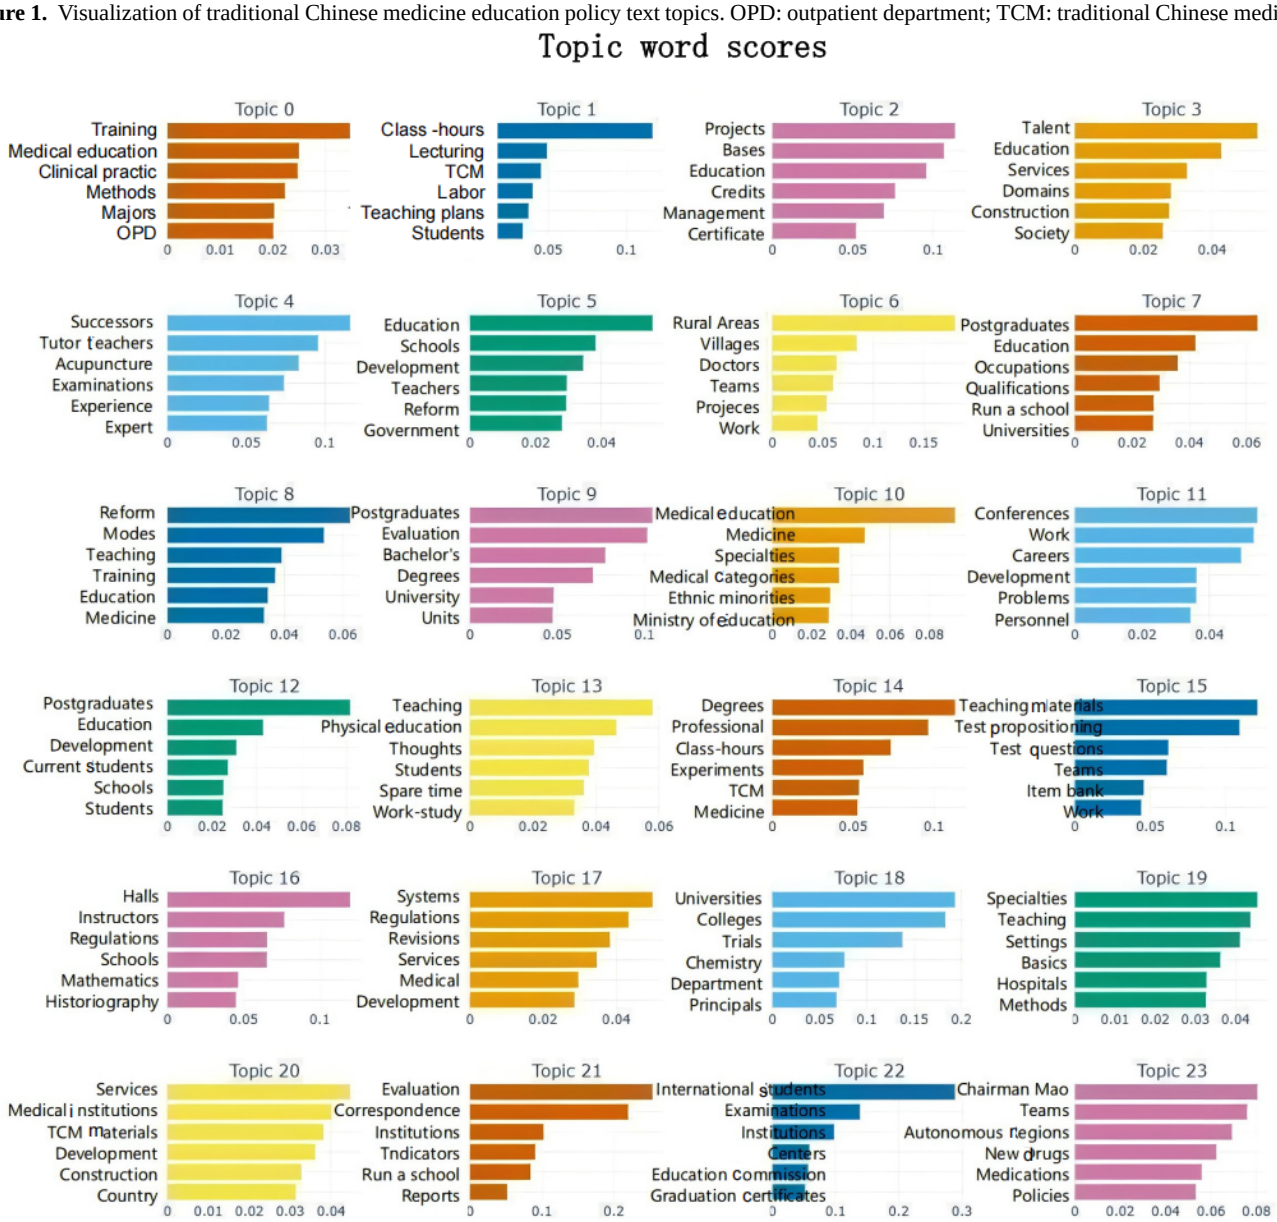
Topic 11	7	3.8	“Meeting,” ”Work,” “Enterprise,” “Development,” “Problem,” “Personnel,” “National,” “Reform,” “Western Medicine,” and “Comrade”
Topic 12	6	3.3	“Graduate,” “Education,” “Development,” “Student,” “School,” “Student,” “Vocation,” “Education,” “Guidance,” and “Society“

Topic number	Document count	Percentage	Keywords
Topic 13	5	2.7	“Teaching,” “Physical Education,” “Ideology,” “Student,” “Part-time,” “Half-work,” “Medical Skill,” “Physical Education Class,” “Work,” and “Patient”
Topic 14	5	2.7	“Degree,” “Professional Degree,” “Class Hours,” “Experiment,” “Chinese Medicine,” “Medicine,” “Master’s Degree,” “Set,” “Clinical,” and “Assessment”
Topic 15	5	2.7	“Textbook,” “Question Setting,” “Question,” “Group,” “Question Bank,” “Work,” “Course,” “Database Construction,” “Question Bank,” and “Planning”
Topic 16	5	2.7	“School,” “Teaching,” “Regulation,” “School,” “Mathematics,” “History,” “Physics,” “Graduation,” “Geography,” and “Student”
Topic 17	4	2.2	“Research,” “Construction,” “Chinese Medicine,” “Service,” “Medicine,” “Development,” “AIDS,” “Advantage,” “Medical,” and “Key”
Topic 18	4	2.2	“University,” “College,” “Experiment,” “Chemistry,” “Department,” “President,” “Subject,” “Lecture Notes,” “Dean,” and “Enrollment”
Topic 19	4	2.2	“Major,” “Teaching,” “Setting,” “Basic,” “Hospital,” “Method,” “Full-time Teacher,” “Course,” “Pathogenesis,” and “Clinical”
Topic 20	4	2.2	“Service,” “Medical Institution,” “Chinese Medicinal Materials,” “Development,” “Construction,” “National,” “Medical,” “System,” “Research,” and “Institution”
Topic 21	3	1.6	“Assessment,” “Correspondence Education,” “Institution,” “Indicator System,” “Education,” “Report,” “Level,” “Work,” “Aspect,” and “Experience”
Topic 22	3	1.6	“International Student,” “Exam,” “Institution,” “Center,” “Education Commission,” “Graduation Certificate,” “Regulation,” “Time,” “Academic Certificate,” and “Question Setting”
Topic 23	3	1.6	“Chairman Mao,” “Team,” “Autonomous Region,” “New Medicine,” “Medical Science,” “Policy,” “Medicine,” “Work,” “Lack of Successors,” and “Important Instruction”
Topic 24	3	1.6	“Credit,” “Committee,” “Education,” “Academic Conference,” “Score,” “Chairman,” “Project,” “Secretary-General,” “Assessment,” and “Method”

Topic number	Document count	Percentage	Keywords
Topic 25	2	1.1	"Talent," "Construction," "Service," "Medicine," "Development," "Standardization," "Chinese Medicine," "Ethnic," "Culture," and "Talent Team"
Topic 26	2	1.1	"Professional Degree," "Master," "Standardization," "Graduate," "Base," "Family Planning Commission," "Training," "Office," "Collaboration," and "Medicine and Education"

According to the results shown in Figure 1, the BERTopic model successfully extracted the main topics from the TCM education policy literature and effectively expressed these topics through feature words and weights. The following are specific descriptions of several topics in the figure: topic 3, with feature words such as "talent," "education," "service," and "construction," indicates that this topic focuses on the cultivation of TCM talents and the improvement of educational quality, showing the policy's emphasis on enhancing the capabilities of TCM talents. Topic 6, with feature words including "rural," "village," "doctor," and "team," indicates that this topic is related to rural medical services and grassroots hospital construction, reflecting the efforts of TCM policies in promoting grassroots medical services. Topic 10, with feature words such as "medical education," "Ministry of Education," "medical major," and "professional," indicates that this topic mainly involves educational planning and professional construction related to the Ministry of Education, reflecting the focus of TCM education policies on overall planning and disciplinary development. Topic 14, with feature words such as "class hours," "experiment," and "degree," indicates that this topic is mainly related to the degree settings and graduate education in TCM education, reflecting the policy inclination toward specialized cultivation in higher education. Topic 18, with feature words such as "university," "college," "department," and "president," focuses on the academic development and overall educational quality of TCM higher education institutions, showing the role of policies in promoting the systematic development of TCM education. Topic 21, with feature words such as "assessment," "institutions," "indicator system," and "education," indicates that this topic is related to the assessment policies of TCM education, focusing on the standardization of TCM education. Through these feature words and their weight distributions, it can be seen that the BERTopic model has effectively captured the differences between various topics and can accurately express the core content of each topic. These topics reflect the multiple dimensions of concern in TCM education policies, including educational planning, talent cultivation, grassroots medical services, systematization, specialization, and standardization. This provides a clear direction and basis for subsequent policy analysis and improvement.

Figure 1. Visualization of traditional Chinese medicine education policy text topics. OPD: outpatient department; TCM: traditional Chinese medicine.

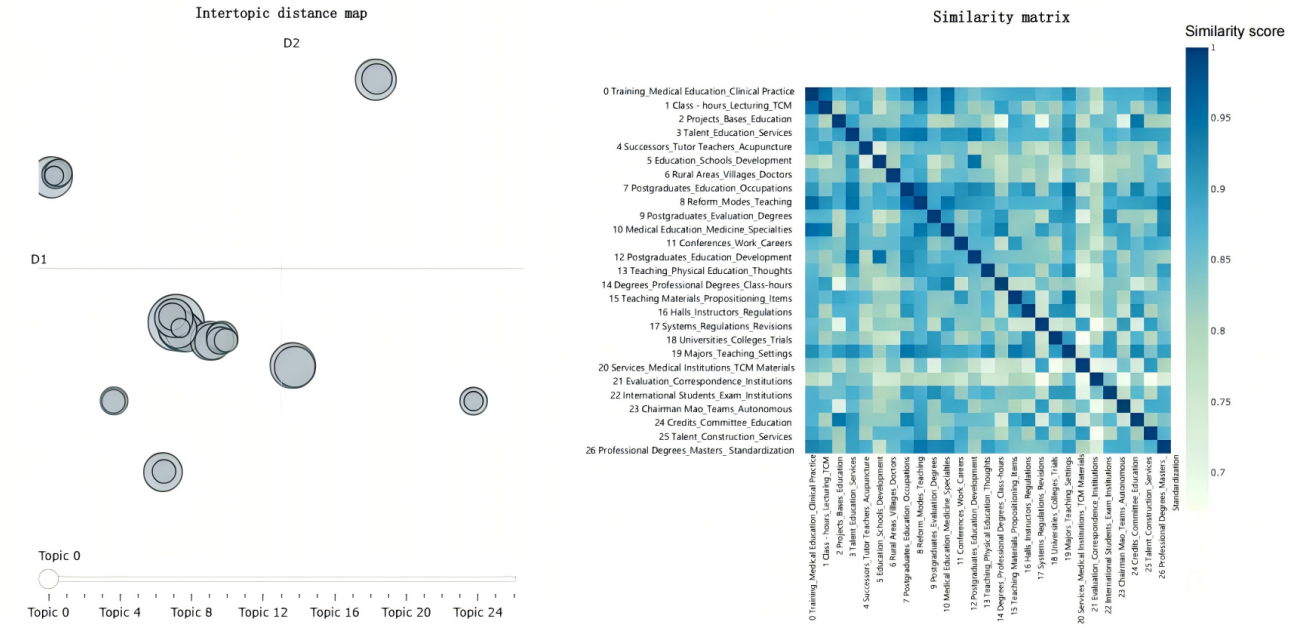


According to the 2D visualization distribution results of the topic-related documents shown in Figure 2, the clustering of different topics in the 2D space can be observed. The documents in the figure are roughly distributed in 4 quadrants, with each quadrant concentrating a category of topic documents, showing a clear trend of classification concentration. The first quadrant mainly focuses on topics related to educational curriculum reform and development. These documents involve the optimization of the educational system, curriculum reform, and the improvement of graduate education, reflecting the attention of TCM education policies on the development of the educational system. The second quadrant gathers topics related to academic research and teaching quality. These documents mainly focus on improving teaching quality and promoting academic research, showing the efforts and achievements of TCM education in the academic and teaching practice aspects. The third quadrant mainly concentrates on topics related to grassroots medical services and talent cultivation. These documents emphasize the role of TCM in grassroots medical services and how to cultivate suitable talents through educational policies to meet the needs of grassroots medical services, reflecting the policy's focus on strengthening rural medical services. The fourth quadrant gathers topics related to the specialization of TCM education and degree settings. These documents discuss the professionalization, institutionalization, and degree settings in TCM education, reflecting the strategies of TCM education in specialized and higher education development. From the figure, it can be seen that the topic documents in each quadrant have a clear trend of classification concentration, reflecting the targeted adjustments and optimizations made by TCM education policies in multiple dimensions. The first quadrant focuses on the development of the educational system and curriculum reform, the second quadrant highlights the improvement of academic research and teaching quality, the third quadrant pays attention to the strengthening of grassroots medical services and talent cultivation, and the fourth quadrant focuses on the specialization and higher education development of TCM education. This classification concentration trend further verifies the diversified promotion of TCM education policies at different levels.

Figure 2. Thematic—term-clustering diagram. TCM: traditional Chinese medicine.

Based on the identified topics, the study used the model.visualize-topics() function to generate an interactive visualization of all topics, as presented in Figure 3. Each circle in the graph represents a topic, with its size indicating the frequency of the topic's appearance in all documents. The distance between circles represents the similarity between topics, with closer distances indicating higher similarity. It can be seen that topic 0 and topic 1 are the most frequently occurring topics, involving key issues such as curriculum settings, clinical teaching, and teaching methods in TCM education. In addition, multiple topics such as topic 5, topic 7, topic 8, and topic 9 are clustered in the lower left corner of the graph, indicating higher similarity among these topics. They cover common aspects of TCM education policies, such as educational reform, improvement of teaching methods, and educational management.

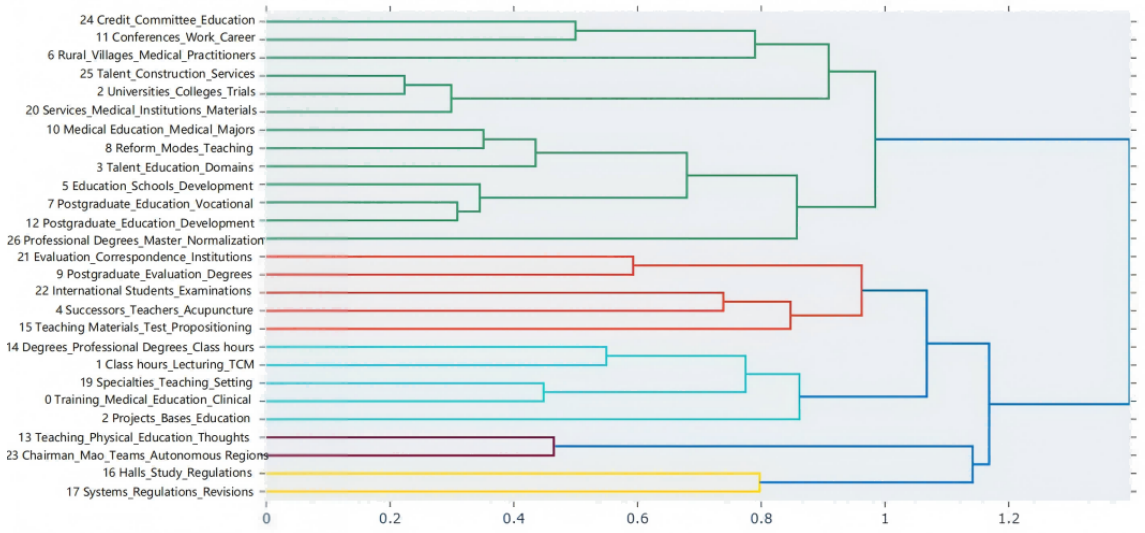
Figure 3. Visualization of traditional Chinese medicine education policy topic distance and cosine similarity. TCM: traditional Chinese medicine.



To understand the potential hierarchical structure of the topics, hierarchical clustering was performed on the relationships between topics based on cosine similarity, and the clustering results were visualized, as shown in Figure 4. The hierarchical relationships between topics can be intuitively understood from the figure. For example, topic 18 and topic 24 are located on the same clustering branch. These topics mainly involve academic development, degree settings, and overall educational development in higher education, which are important components of the systematic construction of TCM education. Topic 21 and topic 9 are clustered together, reflecting the policy's emphasis on standardization processes such as

professional assessment, educational standards, and school management. This ensures consistency in educational content and management methods, thereby improving educational quality and professional standards. Topic 14 and topic 1 form a distinct clustering branch, indicating the policy's focus on maintaining and developing the unique disciplinary advantages of TCM education through specialized education, curriculum design, and professional education content. Topic 13 and topic 23 are clustered together, showing a common focus on academic inheritance and team building. The policy promotes the standardized management of TCM education through these topics. Topic 16 and topic 17 are clustered together, involving topics such as schools, regulations, old medicine, and abolition, indicating the marginalization and stagnation of TCM education.

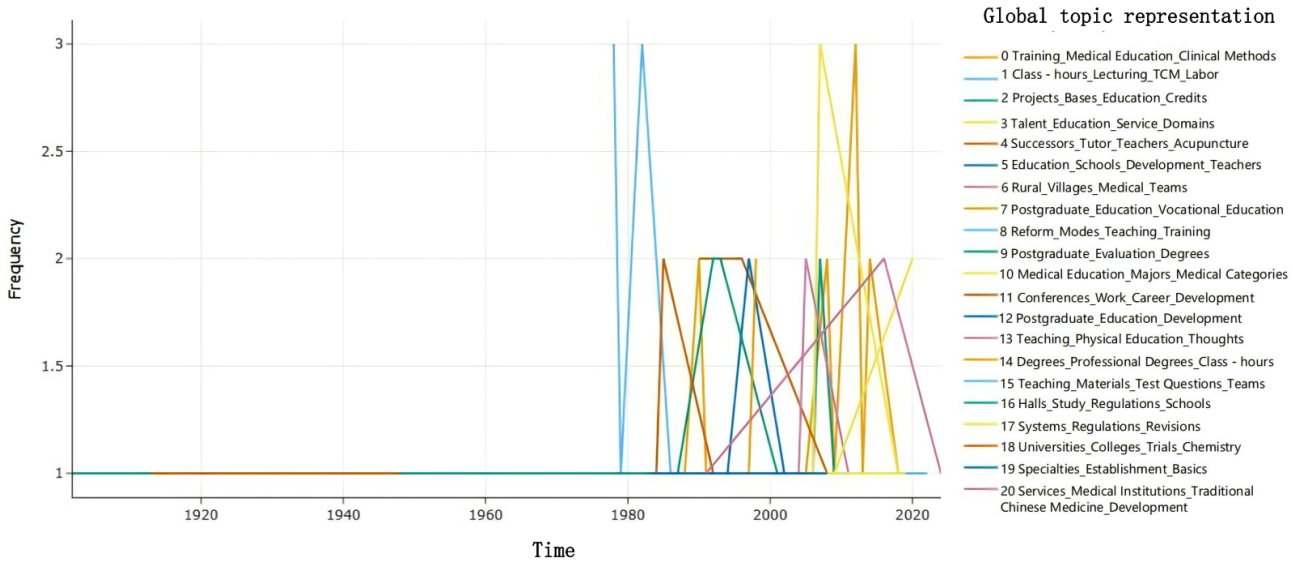
Figure 4. Hierarchical clustering of topics based on cosine similarity. TCM: traditional Chinese medicine.



Evolutionary Analysis of TCM Education Policy Topics

The DTM of BERTopic can intuitively present the research hotspots and scholar attention changes in the field, facilitating the analysis of the evolutionary trends of various research directions in information resource management. Based on the model results outlined in the preceding analysis, further analysis was conducted on the historical evolution and trends of the extracted topics over time, as shown in Figure 5. It can be seen that before the 1970s, the occurrence of topics was relatively sparse, mainly focusing on basic education and training issues. After the reform and opening up, the frequency of topic occurrence increased significantly, indicating high policy activity during this period. The alternating appearance of topics suggests that TCM education policies underwent numerous reforms and adjustments during this period. For example, topic 2 and topic 10 frequently appeared during this period, indicating increasing attention to the specialized development of TCM education, such as the construction of education bases, project management, and professional education. In the 21st century, the frequency of multiple topics increased significantly and alternated frequently, indicating the complexity and diversity of policies during this period. This suggests that with the development of society, the field of TCM education is continuously adapting to new demands, and policies are constantly being adjusted and evolved accordingly. Overall, over time, the themes of TCM education policies have become richer and more complex, reflecting the developmental trajectory and evolving academic focus of TCM education policies.

Figure 5. Evolutionary trends of traditional Chinese medicine education policy topics. TCM: traditional Chinese medicine.



Discussion

Evolutionary Trajectory of TCM Education Policies

Drawing on the policy cycle theory [17] and the multiple streams framework [18], this study systematically analyzes the evolutionary trends of TCM education policies across multiple key topics. These theoretical frameworks offer a structured lens to interpret how policy problems are identified, solutions formulated, and implemented over time, thereby enhancing the interpretability of the 5-stage division of TCM education policy evolution [19].

Policy cycle theory posits that policies undergo sequential stages of agenda setting, formulation, implementation, evaluation, and termination or continuation. In the context of TCM education, this theory helps understand how policy makers have navigated challenges and opportunities at each stage to advance the systematization, standardization, specialization, and normalization of TCM education [20]. The multiple streams framework, on the other hand, emphasizes the confluence of problem streams, policy streams, and political streams in driving policy change. This perspective elucidates how external factors, such as social needs, technological advancements, and political climates, have interacted to shape the evolution of TCM education policies [21]. Through the analysis of national-level policy texts using the BERTopic model, we have identified the following evolutionary stages of TCM education policies.

Through the analysis of national-level policy texts using the BERTopic model, we have identified the following evolutionary stages of TCM education policies:

Marginalization Stage (1840-1949)

During this period, influenced by the social and political upheaval and the influx of Western medicine, TCM education faced marginalization. The lack of a stable political environment and the dominance of Western medical concepts in the policy agenda hindered the development of TCM education, aligning with the problem stream and political stream dynamics described in the multiple streams framework.

During this period, policy themes focused on “abolishing traditional Chinese medicine” and “prohibiting old medical schools” [22]. Specifically, policymakers believed that TCM could not be verified within the framework of modern science and thus did not conform to contemporary educational principles. This perspective was reflected in several important educational policy documents, such as the “Regulations for the Establishment of Universities (Gui Mao School System)” and the “University Regulations (Ren Zi Gui Chou School System),” which explicitly called for the abolition of traditional TCM education and prohibited the establishment of any form of old medical schools [23,24]. During this time, the government’s attitude toward TCM education was extremely negative, considering it unscientific and unsystematic, and attempted to exclude it entirely from the national formal education system through coercive educational reforms. Under government suppression, TCM educational institutions were closed one after another, and the traditional TCM education model fell into a state of stagnation. This situation led to a sharp decline in the overall influence of TCM in Chinese society, and its very existence was facing unprecedented challenges. However, despite the systemic suppression of TCM education at the policy level, the demand for and support of TCM among the public did not completely disappear. Many TCM practitioners and supporters continued to preserve and develop this ancient medical system through private tutoring and family inheritance, trying to sustain TCM in a difficult environment. Although this informal education model was far smaller in scale and influence compared with the government-supported modern education system, it preserved the basic knowledge and skills of TCM to a certain extent, providing an important foundation for the later revival of TCM education.

Normalization Stage (1949-1978)

After the founding of the People’s Republic of China, the government began to recognize the value of TCM, and policies were formulated to normalize TCM education. This stage reflects the agenda-setting and formulation phases of the policy cycle, as policy makers worked to integrate TCM into the national education system.

The policy themes during this period mainly focused on "restoring TCM education," "Western medicine practitioners learning TCM," "master-apprentice TCM education," and "inheriting the academic experience of senior TCM practitioners" [25]. With the establishment of the new China, the national ideology reevaluated the value of TCM and began to protect and develop it as an important part of Chinese culture. Against this backdrop, the government issued a series of policies aimed at restoring and standardizing TCM education. For example, the "Notice on the Regulations for the Organization of TCM Advanced Study Schools and Classes" and the "Instruction on Carrying Out Master-Apprentice TCM Education" clarified the measures for the restoration of TCM education and attempted to combine modern education with traditional master-apprentice inheritance to ensure the effective transmission and development of TCM knowledge and skills. The policy of "Western medicine practitioners learning TCM" was a significant orientation during this period. The government hoped to integrate the strengths of both traditional and modern medicine by encouraging Western medical practitioners to study TCM, thereby addressing the shortage of medical resources at the time. Additionally, the government advocated for the continuation of traditional TCM knowledge through the "master-apprentice" approach, providing a dual safeguard for the revival of TCM education [26]. Furthermore, recognizing that the essence of TCM was often preserved in the experience of senior practitioners, the government issued the "Urgent Notice on Inheriting the Academic Experience of Senior TCM Practitioners" to ensure that this valuable knowledge would not be lost over time. This policy demonstrated the government's emphasis on balancing inheritance and innovation in TCM education and its commitment to preserving and promoting the core aspects of TCM through institutional means [27]. During this stage, the normalization of TCM education was reflected not only in policy making but also in the gradual improvement of the educational system. The government established TCM colleges nationwide and formulated unified teaching syllabuses and textbooks, such as the "Opinions on the Compilation of Teaching Syllabuses and Textbooks for TCM College Courses." These measures ensured the standardization of TCM education, leading to its expansion in scale and enhancement in content and quality.

Specialization Stage (1978-1999)

With the reform and opening-up policy, TCM education entered a stage of specialization. The emphasis on developing specialized TCM education programs and improving the quality of TCM education can be seen as a response to the evolving social needs and technological progress, in line with the implementation and evaluation stages of the policy cycle.

After China implemented the reform and opening-up policy in 1978, TCM education entered a new stage characterized by specialization. The policy themes during this period mainly focused on "promoting and developing TCM education," "seven-year programs," "teaching content," and "academic inheritance." These themes not only reflected the government's attention and investment in TCM education but also demonstrated the deepening and expansion of TCM education within the modern educational system. "Promoting and developing TCM education" was the core policy orientation of this stage [28]. The government recognized the unique value of TCM education in the modern medical system and issued a series of policies aimed at supporting and developing TCM education. For example, the "Report on Seriously Implementing the Party's TCM Policy and Solving the Problem of Succession in the TCM Workforce" emphasized the issue of TCM talent cultivation and proposed strengthening education to address the shortage of successors in the TCM field [29]. The "seven-year program" was a significant innovation in TCM education during this period. To improve the quality of TCM education, the government began to extend the duration of TCM education from the traditional 5-year program to a 7-year program. This measure not only increased the students' learning time but also broadened and deepened the educational content, enabling students to graduate with more solid theoretical knowledge and practical skills in TCM. The "Notice on the Trial Implementation of Seven-Year Higher TCM Education" officially launched this educational reform, marking a step toward higher academic standards in TCM education. In terms of teaching content and academic inheritance, the government ensured the integrity and systematic nature of TCM education through a series of policies. For example, the "Opinions on Strengthening Clinical Teaching in Higher TCM Education" emphasized the importance of clinical teaching, ensuring that students gained sufficient clinical practice experience in addition to theoretical learning. This combination of theory and practice made TCM education more practical and capable of cultivating TCM talents that met societal needs. Moreover, the government focused on the academic inheritance of TCM education, ensuring the intergenerational transmission of traditional TCM knowledge and skills [30]. The "1988 - 2000 TCM Education Development Strategy Plan" set clear academic inheritance goals, using apprenticeship and other inheritance methods to ensure that the core knowledge of TCM was not diluted by the modernization process.

Systematization Stage (1999-2012)

Entering the 21st century, TCM education entered a new stage of systematization. During this stage, policies aimed at systematizing TCM education, integrating various aspects of education, including curriculum design, teaching methods, and teacher training. This comprehensive approach to policy development is consistent with the continuous improvement and refinement process within the policy cycle.

The policy themes during this period mainly focused on "continuing education in TCM," "reform of management systems and mechanisms," and "internationalization of TCM education." These themes reflected the government's intention to improve the overall level and international competitiveness of TCM education through the perfection of the educational system, deepening of management system reforms, and promotion of international cooperation [31]. "Continuing education in TCM" was a key focus of policies during this period. With the development of society and the changing medical demands, the government realized that traditional TCM education alone was insufficient to meet the complex needs of modern medicine. Therefore, continuing education became an important component of TCM education. For example, the

"TCM Continuing Education Fifteenth Five-Year Plan" and the "Regulations on TCM Continuing Education" clarified the goals and implementation methods of TCM continuing education, requiring the enhancement of TCM practitioners' knowledge and skills through continuing education to address new medical challenges. "Reform of management systems and mechanisms" was another important theme in the development of TCM education during this stage [32]. As educational system reforms deepened, the management and operation mechanisms of TCM education also underwent significant adjustments. For example, the "Opinions on Several Issues Concerning TCM Education" and the "TCM Innovation Development Plan Outline (2006 - 2020)" proposed the direction of management system reform in TCM education, aiming to improve the efficiency and quality of TCM education through educational system and mechanism reforms. "Internationalization of TCM education" was also an important policy orientation during this stage. With the enhancement of China's international status and the growing global influence of TCM, the government began to actively promote the internationalization of TCM education [33]. Policy documents such as the "Several Opinions of the State Council on Supporting and Promoting the Development of the TCM Cause" and the "Basic Requirements for the Establishment of TCM Undergraduate Education in Colleges and Universities (Trial)" clarified the goals and strategies for the internationalization of TCM education, encouraging TCM colleges and universities to cooperate with international academic institutions to promote the globalization of TCM education and research.

Standardization Stage (2012 to Present)

In recent years, TCM education policies have focused on standardization, aiming to establish unified standards for TCM education at home and abroad. This stage reflects the efforts to enhance the international competitiveness of TCM education and ensure its quality and consistency, in line with the ongoing evaluation and potential continuation phases of the policy cycle.

Since 2012, TCM education in China has entered a new stage of standardization. The policy themes during this period mainly focused on "standardization," "integration of medical and educational collaboration," "cultivation of general practitioners," and "high-quality development." These themes reflected the government's intention to ensure the high quality and level of TCM education through standardization, further enhancing its international competitiveness. "Standardization" has been a core theme of TCM education policies during this stage. To achieve the normalization and scientification of TCM education, the government has issued a series of policy documents specifying the standardization requirements for TCM education [34]. For example, the "Law of the People's Republic of China on Traditional Chinese Medicine" and the "Several Opinions on Further Promoting the '5+3' Integrated Medical Talent Training Work" detailed the teaching standards, curriculum settings, and talent training models for TCM education. "Integration of medical and educational collaboration" has been an important development model for TCM education during this stage. The government realized that further development of TCM education required a closer combination with medical practice. Therefore, the "Guiding Opinions on Deepening the Reform and Development of TCM Education through Medical and Educational Collaboration" was issued, specifying the requirements for medical and educational collaboration and emphasizing the improvement of TCM students' practical abilities and comprehensive quality through the integration of teaching and clinical practice. "Cultivation of general practitioners" has been another important theme in TCM education policies during this stage. With the increasing demand for general practitioners in society, the government began to introduce a general practitioner training model into TCM education. For example, the "Implementation Measures for the Standardized Training of TCM Resident Physicians (Trial)" and the "Guiding Opinions on Deepening the Succession Education of TCM" proposed a combination of standardized training and master-apprentice education to cultivate general TCM practitioners with comprehensive capabilities. "High-quality development" has been the overall goal of TCM education during this stage. Against the backdrop of the rapid development of the global health sector, the government required TCM education to focus on quality and promote high-level, high-standard development [35]. For example, the "Notice on the Implementation of the 'Double Ten Thousand Plan' for First-Class Undergraduate Major Construction" and the "Several Policy Measures for Accelerating the Characteristic Development of TCM" emphasized the improvement of teaching quality, optimization of curriculum settings, and strengthening of scientific research innovation to achieve high-quality development in TCM education.

Logic Behind the Evolution of TCM Education Policies

Logic of Balancing Modernization and Traditional Inheritance

The evolution of TCM education policies in China centers on the balance between modernization and traditional inheritance [36]. Since the mid-19th century, the invasion of Western powers and the introduction of modern science had a profound impact on traditional Chinese culture. In an effort to adapt to the new external environment, policymakers introduced the Western medical education system and attempted to abolish traditional TCM education to promote the modernization of Chinese medicine. This reflected the then-prevailing belief that modernization was the only path to national strength, and traditional TCM education was seen as an obstacle to this process. However, this logic of excluding tradition did not fully succeed. Despite the policy attempts to suppress TCM education, TCM, as an important part of Chinese culture, did not disappear due to policy pressure. Many TCM practitioners continued to preserve and spread TCM knowledge through private tutoring and apprenticeship, laying the foundation for the survival of TCM [37]. After the founding of the People's Republic of China in 1949, the state reevaluated the value of TCM and began to restore and standardize TCM education. For example, the "Notice on the Regulations for the Organization of TCM Advanced Study Schools and Classes" was a typical example, reflecting the state's emphasis on TCM education and aiming to restore the legitimate status of TCM in the medical system through the reconstruction of the educational system. This logic reflects the state's gradual recognition in the modernization

process that Western medicine alone could not meet China's needs, and a balance between modernization and traditional inheritance had to be found [38].

Logic Driven by Political and Social Demands

The evolution of TCM education policies in China has been deeply influenced by both political environment and social demands, with each stage of policy change reflecting the political background and social needs of the time. After the founding of New China, the government rerecognized the importance of TCM as an important part of Chinese traditional culture, and policies such as the "Instruction on Carrying Out Master-Apprentice TCM Education" were issued in the 1950s to restore the legitimate status of TCM education and address the challenge of medical resource shortages. During the reform and opening-up period, with rapid economic development and changes in social structure, TCM education policies began to emphasize specialized development to meet the diverse medical service needs. The "1988 - 2000 TCM Education Development Strategy Plan" was a representative policy of this period, proposing to extend the academic system, enrich the curriculum content, and strengthen clinical practice to cultivate high-quality talents with TCM characteristics. Entering the 21st century, with the enhancement of China's international status and the acceleration of globalization, the international demand for TCM increased, and the government integrated international considerations into educational policies. For example, the "Several Opinions of the State Council on Supporting and Promoting the Development of the TCM Cause" explicitly proposed to promote the internationalization of TCM education, encouraging TCM colleges and universities to cooperate with international academic institutions to enhance its global influence. These policies not only responded to domestic and international demands for TCM but also reflected the strategic goal of enhancing China's cultural soft power through the internationalization of TCM education.

Logic of Adaptation to Reform and Innovation

Reform and innovation are key logics in the evolution of TCM education policies in China. With social development and technological progress, TCM education faces new challenges and opportunities, and policymakers have gradually placed reform and innovation at the core of policymaking. Since the reform and opening-up, Chinese society has undergone tremendous changes, and TCM education policies have also entered a new stage oriented by innovation. In the mid-1980s, the government realized that merely restoring and standardizing TCM education was insufficient to meet modern demands, and it was necessary to enhance the quality and international competitiveness of education through reform and innovation. For example, the "Report on Seriously Implementing the Party's TCM Policy and Solving the Problem of Succession in the TCM Workforce" emphasized educational model innovation through academic system reform, curriculum enrichment, and teaching method improvement. The introduction of the 7-year program was a specific manifestation of this innovative logic [39], and the "Notice on the Trial Implementation of Seven-Year Higher TCM Education" marked a milestone in the modernization of TCM education. With the upgrading of medical service demands, standardization became a focus of reform in the early 21st century. The government implemented standardization policies such as the "Law of the People's Republic of China on Traditional Chinese Medicine" and the "Several Policy Measures for Accelerating the Characteristic Development of TCM" to ensure the consistency and global competitiveness of educational quality. This standardization not only guaranteed high-quality output but also made TCM education more acceptable and recognizable by the international community.

Logic of Integration of Cultural Confidence and National Strategy

The deep logic of TCM education policies includes the integration of cultural confidence and national strategy. As an important part of Chinese traditional culture, TCM education policies are not only related to medical education but also bear the mission of cultural inheritance and national strategy. In the early days of New China, the restoration of cultural confidence was a key driving force for the revival of TCM education policies. With the enhancement of China's comprehensive national power, the government has gradually strengthened its emphasis on TCM education, consolidating its important position in national culture and social development through institutional means. For example, the "Urgent Notice on Inheriting the Academic Experience of Senior TCM Practitioners" emphasized the protection and inheritance of the valuable experience of senior TCM practitioners, laying the foundation for the long-term development of TCM. At the national strategy level, the evolution of TCM education policies has always been closely linked to the overall national development strategy. After the reform and opening-up, with the enhancement of China's economy and international influence, the government has paid more attention to the globalization and standardization of TCM education. This not only reflects cultural confidence but also demonstrates the important role of TCM education in showcasing China's soft power [40]. The integration of cultural confidence and national strategy runs through all stages of TCM education policy evolution, promoting the modernization and internationalization of TCM education and enhancing the global influence of Chinese culture.

Policy Effectiveness in TCM Education

Assessing policy effectiveness is crucial as it reveals the practical impact of policy initiatives and provides insights for future improvements, aligning with the tenets of policy evaluation research. During the Standardization Stage (2012 to Present), TCM education policies aimed to establish unified standards both domestically and internationally. A notable case is the implementation of the "Undergraduate Medical Education Standards-Traditional Chinese Medicine Major (Provisional) (2012)" in China. This policy stipulated specific requirements for curriculum design, teaching resources, and faculty qualifications, leading to a significant improvement in the quality of TCM education. For instance, Henan University of Chinese Medicine achieved a 99.33% course evaluation coverage rate in 2018 - 2019, while Zhejiang University of Chinese Medicine reported an 89.22% national licensing

examination pass rate in 2020, 24.6 percentage points above the national average [41].

In the Specialization Stage (1978 - 1999), policies promoting the development of specialized TCM education programs also demonstrated remarkable effectiveness. For example, the establishment of TCM clinical specialization courses in major TCM universities across China was a direct result of policy support. These courses focused on in-depth training in areas such as acupuncture, Chinese herbal medicine, and TCM diagnosis. Take Beijing University of Chinese Medicine as a case. Beijing University of Chinese Medicine enrolled its first group of 36 master's students in 1978, and clinical program enrollment increased by 40% from 1985 to 1995 [42]. Moreover, 65.17% of Chengdu University of Traditional Chinese Medicine graduates serve at the grassroots level, with more than 80% relevance to their major [43]. This case study illustrates how specialization-oriented policies successfully cultivated high-quality TCM professionals, meeting the practical needs of the industry.

However, policy effectiveness was not uniformly positive across all stages. During the Marginalization Stage (1840 - 1949), due to social unrest and the influence of Western medicine, TCM education policies struggled to achieve their intended goals. The lack of stable political support and limited resources meant that TCM education institutions faced difficulties in maintaining educational quality and scale. For instance, many traditional TCM private schools were forced to close, and the number of TCM students declined sharply during this period [44]. This historical case highlights the importance of a conducive social and political environment for policy implementation and effectiveness.

In conclusion, by analyzing these case studies, it is evident that TCM education policies have achieved varying degrees of success. Effective policies often require a combination of clear goals, adequate resource allocation, and a supportive social context. Insights from these case studies can inform future policy making, helping to optimize TCM education development and better meet the needs of society and the medical field.

Future Trends of TCM Education Policies

First, the deepening of standardization and internationalization. In the future, TCM education needs to further promote standardization, especially in the context of globalization, where alignment with international standards will become crucial. With China's increasing influence in the international community, TCM, as a representative of Chinese culture, will face more international cooperation demands in its educational system. Accelerating the formulation and promotion of TCM education standards and incorporating TCM courses into the international medical education system will be key to promoting its global dissemination, attracting more international students and researchers, and enhancing the international influence of TCM, thereby promoting the diversification and innovation of education.

Second, the strengthening of innovation and integration with technology. TCM education needs to place greater emphasis on the integration with modern technology, with information technology and biotechnology becoming important drivers. The development of artificial intelligence, big data, blockchain, and other technologies will greatly improve the efficiency and quality of TCM education. Digital platforms and web-based education tools may be more widely applied in TCM education, providing convenient ways to access knowledge and virtual laboratories to enhance students' learning outcomes and practical abilities.

Third, the balanced development of cultural confidence and globalization. With the enhancement of China's international status, TCM education needs to maintain cultural confidence in the context of globalization. This confidence should be reflected not only in the inheritance and innovation of TCM educational content but also in how to play a greater role in global health governance. Future policies will place greater emphasis on the cultural export of TCM, showcasing its unique value through international exchanges, academic cooperation, and cultural activities to enhance the international image of TCM and China's discourse power in international medical education.

Fourth, the expansion of policy support and diversified cooperation. Future TCM education policies should place greater emphasis on policy support and diversified cooperation. Through measures such as financial investment, legal protection, and talent introduction, support should be provided for TCM colleges and universities in their exploration of scientific innovation, international cooperation, and digital transformation. At the same time, cooperation with international organizations, multinational corporations, and nongovernmental organizations should be strengthened to promote the global allocation and sharing of TCM educational resources. This diversified cooperation will attract more global resources for TCM education, promoting its continuous innovation and development.

Conclusions and Outlook

The evolution of TCM education policies is not only the result of historical development and social demands but also a comprehensive reflection of cultural inheritance, innovative reform, and international strategy in China's modernization process. From the early marginalization to the normalization after the founding of New China, from the specialized development during the reform and opening-up period to the standardization and internationalization in the 21st century, each adjustment and evolution of TCM education policies reflects China's rethinking and redefinition of the positioning of TCM education in different historical stages. The core logic of this policy evolution process not only provides an effective framework for understanding the past of TCM education but also offers important clues for predicting its future development direction. In the future, the formulation of TCM education policies should maintain the traditional advantages of TCM while actively addressing new challenges brought by modern technology and globalization, promoting the continuous optimization and improvement of the TCM education system. It is necessary not only to meet the domestic demand for medical services but also to inherit and promote Chinese culture globally, becoming an important bridge connecting Eastern and Western

medicine. Through continuous policy innovation and improvement, TCM education will contribute more to the development of health care in China and around the world.

Abstract

Background: Emergency obstetric simulation-based training has increasingly been used to improve emergency obstetric care provision in sub-Saharan Africa. For determining the optimal methodology for effective training sessions in resource-constrained settings, it is crucial to conduct high-quality research.

Objective: We aim to investigate the impact of a train-the-trainer model for providing technology-enhanced, mono-professional, simulation-based training in obstetrics in a resource-constrained setting on maternal and perinatal outcomes.

Methods: A stepped-wedge cluster randomized trial was conducted from October 2014 until March 2016 at the medium- to high-risk ward at Mulago National Referral Hospital, Uganda, with an annual delivery rate of over 23,000. The intervention consisted of a train-the-trainer model in which training was cascaded down from master trainers to local facilitators (obstetric senior staff members) to learners (senior house officers). The training of senior house officers was provided to 7 fixed clusters by a computer-generated random sequential roll-out. The training comprised a 1-day (8 h), mono-professional, simulation-based training in obstetrics, and half-day repetition training sessions targeted at every 7 weeks. Both medical technical skills and teamwork skills were taught. The primary outcome comprised a combined maternal and perinatal mortality rate. Secondary outcomes comprised the maternal mortality rate, the perinatal mortality rate, the percentage of births by vacuum extraction and cesarean section, and the Weighted Adverse Outcome Score.

Results: Overall, there were 17,496 births. The combined mortality rate was 9.05% (95% CI 8.37% - 9.77%) in the intervention group, and 8.73% (95% CI 8.21% - 9.28%) in the control group (odds ratio [OR] 0.98, 95% CI 0.86 - 1.12; *P*=.81). No statistically significant change was found in the maternal mortality rate (OR 0.80, 95% CI 0.27 - 2.32; *P*=.68) or the perinatal mortality rate (OR 0.99, 95% CI 0.87 - 1.13; *P*=.87). This study did not identify any difference in the percentage of vacuum extractions, the percentage of cesarean sections, or Weighted Adverse Outcome Scores.

Conclusions: This train-the-trainer model for providing technology-enhanced, mono-professional, simulation-based training in obstetrics was not able to change maternal and perinatal mortality outcomes. This study, in combination with literature, suggests that future research should consider multiprofessional team training in obstetrics involving all staff within their units.

Introduction

Emergency Obstetric Care in Uganda

Uganda continues to face challenges in providing safe obstetric care. Despite an increase in the rate of institutional births from 59% to 74%, the maternal mortality ratio was still high at 375 per 100,000 live births in 2017, accompanied by a neonatal mortality rate of 21 deaths per 1000 live births [1]. Key barriers for providing safe childbirth include shortcomings in the management of emergency obstetric care, delays in referral practices, and insufficient coordination among health care staff, all of which obstruct the provision of adequate emergency obstetric care [2].

Simulation-Based Obstetric Training

To address these challenges, simulation-based training for emergency obstetric care has evolved as a promising approach in sub-Saharan Africa. Growing evidence suggests that this type of training improves health care providers' knowledge and skills, while also leading to positive changes in their behavior [3-5]. Additionally, evidence from other studies has shown encouraging effects on patient outcomes, including reported reductions in neonatal and perinatal mortality rates, as well as potential decreases in maternal mortality and postpartum hemorrhage [6-9]. Despite these promising findings, assessments of patient outcomes remain infrequent, and the results are often inconsistent [3,4].

Evaluating Simulation-Based Training

One limitation of current evaluations is the reliance on 1-group pretest-posttest designs, which often fail to control for external variables that may influence the results. Furthermore, significant variability exists in training length, content, and design, with programs ranging from mono-professional to multi-professional approaches. This variation makes it difficult to identify which components most effectively contribute to the success of the training. Additional challenges, such as resource constraints, difficulties in sustaining training programs, staff shortages, and high turnover rates, further hinder the implementation and long-term impact of simulation-based training in sub-Saharan Africa. To overcome these challenges, high-quality research is essential to determine the most effective methodologies for emergency obstetric simulation-based training in sub-Saharan Africa.

This study aimed to evaluate the effect of a train-the-trainer program designed to provide technology-enhanced, mono-professional, simulation-based obstetric training on patient outcomes in Uganda [10].

Methods

Setting

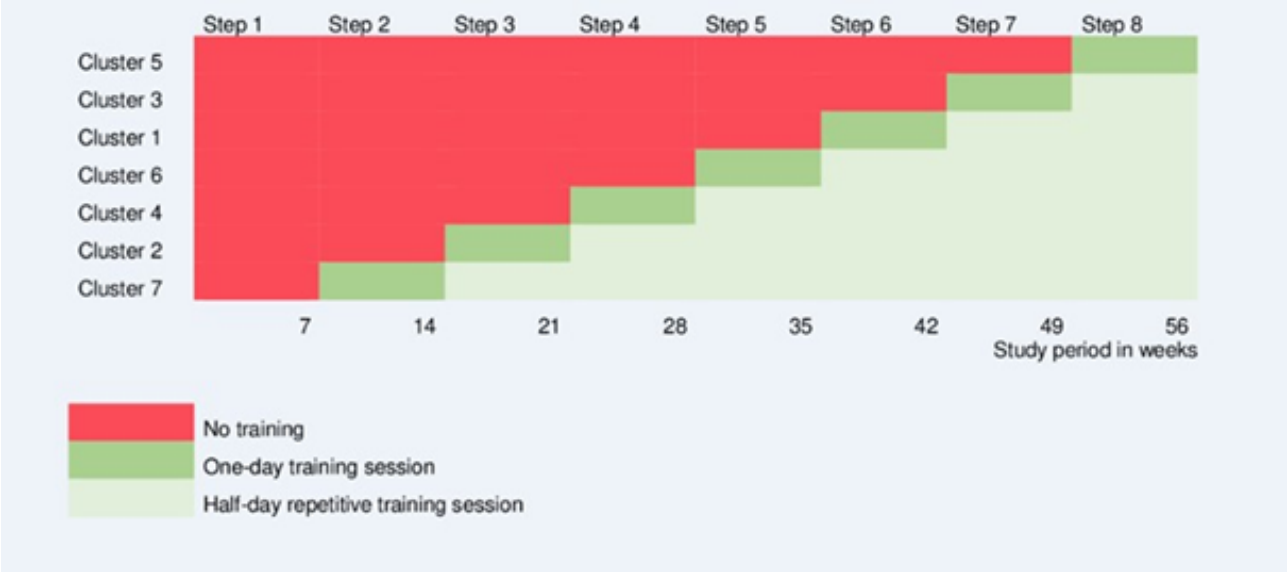
A stepped-wedge cluster randomized trial was conducted from October 2014 until March 2016 at the medium- to high-risk labor ward at Mulago National Referral Hospital in Uganda. This hospital also functions as the main teaching facility for Makerere University College of Medicine and Health Sciences. During this study's period, over 23,000 women gave birth annually at the medium to high-risk labor ward.

Design and Recruitment

The stepped-wedge cluster randomized trial design facilitated the phased implementation of the training program, with different clusters receiving the intervention at different periods to assess its impact on patient outcomes. This approach allowed for the measurement of the intervention's effect both within and between clusters. Additionally, it enabled the intervention to be provided as a standard service to all participants, while being implemented in stages [11]. As training of all obstetric ward staff was not feasible due to financial and logistical challenges, senior house officers (SHOs) were chosen as the target group for the training program due to their coordinating role in providing emergency obstetric care.

In October 2014, a total of 7 fixed clusters of SHOs were recruited to receive the training. All participants provided written informed consent before this study began. A computer-generated random sequential roll-out of the training program was conducted to determine the order in which the different clusters would receive the intervention (Figure 1). Examination and holiday periods were excluded from the schedule, as fixed clusters could not be maintained in the SHOs' work schedules during these times.

Figure 1. Stepped-wedge cluster randomized design with 7 clusters and 8 steps.



Train-the-Trainer Model

The training program was conducted using a train-the-trainer model, in which training was cascaded down from master trainers to local facilitators, and then to the learners, who were the SHOs. In this model, the master trainers, who were obstetricians from a high-resource setting, had been previously certified as simulation-based trainers by institutions such as EuSim or the Center for Medical Simulation. These master trainers provided a 4-day train-the-trainer program to 14 local facilitators. The facilitators, all gynecologists, were selected based on their clinical and teaching experience by the head of the department. The program included both lectures and practical teaching sessions using simulation-based obstetric scenarios. The train-the-trainer course concluded with an assessment session. During this session, the local facilitators trained intern doctors using a draft SHO training program. Afterward, the master trainers provided feedback to the facilitators. Based on this, 12 of the facilitators were certified as simulation trainers. The SHO training program was then adjusted based on feedback from both trainers and trainees. Subsequently, the local facilitators delivered the training to fixed clusters of 6 to 9 SHOs, comprising first-, second-, and third-year SHOs. A 1-day annual refresher training was offered to all local facilitators. The local facilitators were compensated for lost clinical income by being paid for their participation in the training sessions.

Course Content

Course content was developed by Medsim, a medical simulation center in the Netherlands, in cooperation with senior staff members of Mulago National Referral Hospital. The SHO training program included a 1-day (8 h) mono-professional, simulation-based sessions, followed by half-day refresher sessions every 7 weeks. These refresher sessions started after the switch from the control to the intervention group. Each training session was provided by 2 local facilitators. Scenarios were based on the main local causes of maternal and perinatal mortality and tailored to local clinical protocols and availability of medical equipment. This led to the creation of 2 different scenarios for postpartum hemorrhage, a scenario for eclampsia, a scenario involving fetal distress with a ventouse delivery, and a breech delivery scenario. Both medical-technical and teamwork skills were included in the training, with the difficulty level increasing throughout the day. Every SHO participated in at least 2 scenarios during the 1-day training, while having an observer role in the nonparticipating scenarios. During the repetition training sessions, a single clinical scenario was executed and repeated until skills were mastered.

Data Collection and Outcomes

The primary outcome of this study was the combined maternal and perinatal mortality rate, expressed as a percentage of maternal and perinatal deaths per total number of births. Perinatal deaths were defined as stillbirths and deaths occurring within the first week of life in the special care unit. Data about each delivery and maternal and perinatal outcomes were prospectively registered using the maternity register and transcribed without identification of the subjects. Data about maternal deaths in the high dependency unit, and neonatal deaths in the special care unit were obtained from registration books in these units. These data were matched to and merged with data from the maternity register of the medium to high-risk ward into 1 final electronic database.

Secondary outcomes comprised the maternal mortality rate (maternal deaths per 100,000 births), the perinatal mortality rate (perinatal deaths per 1000 births), percentage of births by vacuum extraction, percentage of births by cesarean section, and the Weighted Adverse Outcome Score (WAOS). The WAOS was defined as the total weighted score of each adverse outcome divided by the total number of births [12]. Four out of 10 index measures (maternal death [750 points], intrapartum or perinatal death [400 points], uterine rupture [100 points], Apgar score less than 7 after 5 minutes [25 points]) were available for registration and assessment. Finally, the maternal mortality ratio (maternal mortality per 100,000 live births), and the perinatal mortality ratio (perinatal mortality per 1000 live births) were calculated for the control and intervention group. As data were analyzed on the cluster level, the authors could not identify individual participants' results.

To provide a comprehensive understanding of the training's effectiveness, additional secondary outcomes were included and published separately, such as the evaluation of the instructional design, participants' reactions (corresponding to Kirkpatrick level 1), and the effects on knowledge, teamwork, and medical-technical skills (corresponding to Kirkpatrick level 2) [13].

Sample Size Calculation

The power calculation was conducted following the methods described by Hussey et al [14] and Woertman et al [10,15,16]. Initially, the sample size for a standard randomized clinical trial was calculated. To show a 20% reduction in combined maternal and perinatal mortality with an α of .05 and a power of 80%, a total of 6398 births would be required for a simple randomized clinical trial design. The design effect was then determined, assuming an intracluster correlation of 0.05, a cluster size of 3343 births per year, and 7 clusters in total. Accounting for the design effect, 2367 births per measurement period would be required. To meet this target, each measurement period would need to last at least 5 weeks. However, for logistical feasibility, the duration of each step was set at 7 weeks, resulting in a total study duration of 56 weeks. Statistical significance was defined as a 2-sided *P* value of <.05.

Statistical Analysis

Patient baseline characteristics were summarized with medians and IQRs for continuous variables and with counts (percentages) for categorical variables. A generalized linear mixed-effects model was used for the estimation of an intervention effect. Here, the outcome is the binary event on the individual (whether a birth was or was not complicated by maternal mortality, perinatal mortality, or both), and a logit link function was used to model the probability of the event. In the logit scale, the cluster indicator served as a random effect on the intercept, and the period of the stepped wedge was treated as a fixed effect, as well as the intervention effect. The effect of the intervention was reported as an odds ratio, and the performance per treatment group was reported as a percentage or as an incidence rate ratio with 95% CI.

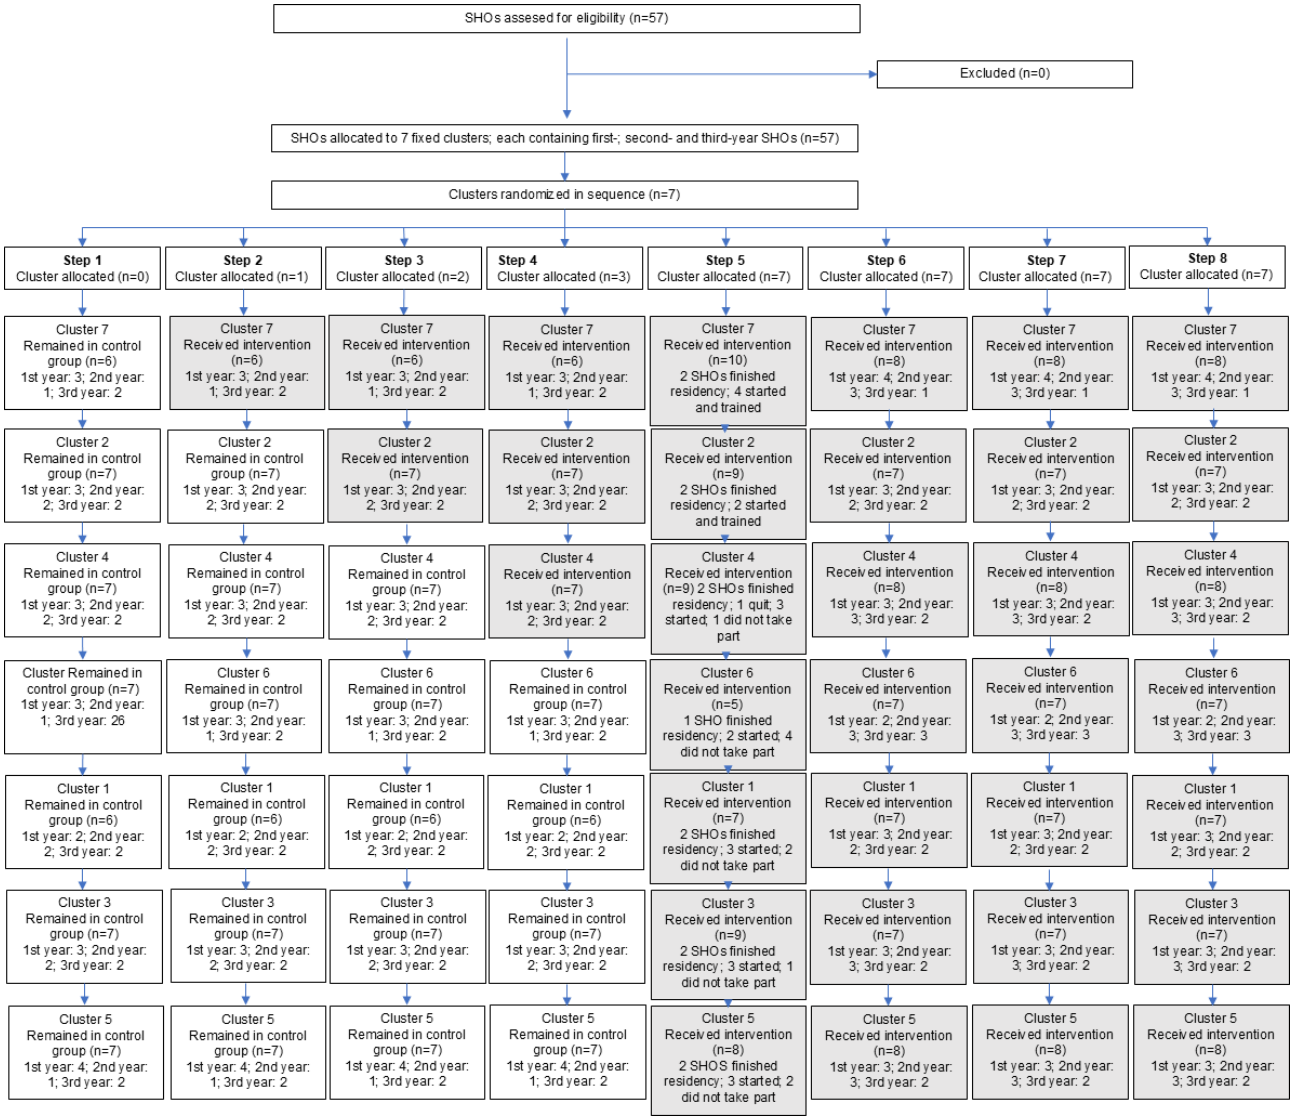
Ethical Considerations

Ethical approval was obtained from the Mulago Research and Ethics Committee (Protocol MREC: 674), and the Uganda National Council for Science and Technology (UNCST, SS 3927). Written informed consent to participants in this study was obtained at the beginning of the first training day, and all participants had the ability to opt out during this study's period. No compensation was provided for the participants. All data were anonymized.

Results

From October 2014 until March 2016, a total of 57 SHOs were randomized into 7 clusters. The first 3 included clusters received the main training on schedule according to protocol. Afterward, when SHOs heard about the training experience from their peers, they requested to expedite the training schedule, rather than waiting for the allocated time slot. Therefore, these 4 remaining clusters were trained within the same week and they simultaneously switched from the control group to the intervention group during this week (Figure 2). After the deviation from the stepped-wedge design in the timing of the intervention, no amendment was needed by the ethical committee, as the intervention itself had not changed.

Figure 2. Flowchart of stepped-wedge cluster randomized design. SHO: senior house officer.



Baseline characteristics are shown in Table 1. Overall, there were 17,496 births. There were fewer female and more male neonates in the intervention group compared to the control group. The results on maternal and perinatal mortality rates, mode of delivery, and the WAOS are shown in Table 2. No differences were found between the intervention and the control group in the combined maternal and perinatal mortality rate, the maternal mortality rate, and the perinatal mortality rate. Results on the percentage of vacuum extractions, the percentage of cesarean sections, and the WAOS did not show any difference between the intervention and the control group. The maternal mortality ratio in the control and intervention group was, respectively, 160.4 (95% CI 94.9 - 266.6) and 116.9 (95% CI 51.2 - 252.4). The perinatal mortality ratio in the control and intervention group was 94.4 (95% CI 88.8 - 100.4) and 98.7 (95% CI 91.3 - 106.6).

Discussion

Principal Results

This train-the-trainer model for providing technology-enhanced, mono-professional, simulation-based obstetric training to SHOs did not result in changes to maternal and perinatal mortality outcomes. The training program also had no impact on the number of instrumental births, the number of cesareans, or the WAOS.

Strengths and Limitations

A strength of this study was the use of a randomized stepped-wedge trial design, enabling the training for all SHOs in one of the busiest labor wards worldwide. Unlike 1 group pretest-posttest designs commonly used in prior research on obstetric simulation-based training, this approach minimized bias from natural changes in health care outcomes because it could eliminate systematic period effects. Another strength was the use of the train-the-trainer model. Research has shown that training delivered by local trainers results in greater improvements in knowledge and skill acquisition [17]. Furthermore, simulation-based learning is likely to be more effective when tailored to the local context and culture [18]. A third strength of the evaluated training program was the inclusion of teamwork skills. Teamwork skills are increasingly recognized as a critical factor in reducing preventable, substandard care and are viewed as an essential competence for hospital teams [19]. These skills had not been part of previous SHO training programs at Mulago National Referral Hospital.

Limitations of our study should also be considered. First, the intended stepped-wedge design was altered during the study, as clusters requested earlier training. Although this deviation interfered with the planned study design, it was deemed unethical to withhold training further. The change in design did not affect the statistical analysis because the mean features of the stepped wedge design were maintained. Other studies have highlighted ethical concerns with the stepped-wedge design, including justifying the delayed rollout of the intervention to the control group, which is inherent to this design [20,21]. A potential solution in the future could involve using different hospitals as clusters. This approach would also address the challenge of maintaining fixed clusters of individuals during working hours, which was one of the difficulties we encountered. Interaction between trained and nontrained SHOs during shifts in examination and holiday periods may have introduced bias into the results, but our analysis was chosen conservatively, making sure that such biases would affect the treatment effect negatively. Another challenge in the work schedules of the fixed clusters was the repetition of sessions, which led to some sessions not being scheduled according to the protocol. Establishing fixed clusters of multidisciplinary obstetric team members within 1 hospital is anticipated to be even more challenging. Including different hospitals in the design could eliminate these issues and allow all health care providers involved in maternity and neonatal care at a single hospital to be trained within a short period. However, it may be difficult to include hospitals with comparable levels of care and delivery volumes, which should be accounted for in the intracluster correlation coefficient and the statistical analysis.

Comparison With Prior Work

The results of our study on maternal and perinatal outcomes do not align with those of recent studies on simulation-based emergency obstetric training in sub-Saharan Africa. Since the start of this study, 6 studies reported improvements in maternal outcomes, mainly related to postpartum hemorrhage and mortality [22-27], and 7 studies showed improvements in neonatal or perinatal outcomes after simulation-based obstetric training [25,28-33]. One of these studies showed that initial improvements declined over time [29].

When comparing our simulation-based training program to others that were effective, we want to highlight the mono-professional nature of our program. While previous research showed that simulation-based team leader training improved teamwork and communication during clinical resuscitations, our study found that training only SHOs as the leaders during obstetric emergencies did not improve patient outcomes. This aligns with the findings of Siassakos et al [34], who noted that units showing improvements had trained nearly 100% of their staff and implemented training programs within their own units. Additionally, all but 2 of the previously described effective studies were multi-professional training programs [22-31]. An exception to justify a mono-professional training program can be when the focus is on a specific technical task performed by a single health care provider, such as repairing an episiotomy. In such cases, the focus on a specific task allows for deliberate practice, where the trainee improves the task through immediate feedback, problem-solving, evaluation, and repeated performance. However, when the task involves teamwork, the training approach should shift toward a multi-professional model. In conclusion, our results, alongside the literature, suggest that future research should consider multi-professional team training in obstetrics, involving all staff within their units.

Another difference between our training program and others is that ours was a stand-alone program, while simulation-based training as part of an integrated package may be more effective in improving health outcomes [4,8,28]. Integrated packages often include equipment, maternal death reviews, health information system improvements, modified protocols, supportive supervision, mobile mentoring, and peer-assisted learning. Although we included a train-the-trainer model, restructured local protocols, and created posters with flowcharts for obstetric emergencies, the intensity and, ultimately, the training frequency of our intervention may not have been sufficient to impact maternal and neonatal outcomes.

Another notable variance between evaluated simulation-based training programs is the location of training. Our study used an off-site medical simulation center, while on-site training may be more beneficial, as it reaches more staff and generates more suggestions for organizational changes. Sorensen et al [35] found no significant differences in knowledge, patient safety attitude, motivation, or stress between on-site and off-site training, but the on-site group suggested more organizational changes. In low-resource settings, these changes may be more

valuable, although on-site training could be disrupted by clinical situations. Further research comparing on-site versus off-site training in low-resource settings would be valuable.

A further difference in previous studies on simulation-based obstetric training is the definition of mortality ratios. Some studies, including the mortality ratios in the introduction, used maternal mortality per live birth, while others used maternal mortality per number of births [8,22,26,36,37], making comparisons difficult. Additionally, the World Health Organization defines maternal and perinatal mortality ratios with different denominators, complicating statistical analyses of a combined mortality ratio. As a result, we analyzed the combined mortality rate and reported the maternal and perinatal mortality ratios separately. Moreover, the ratios are based on live births, so improving perinatal care can also affect maternal mortality outcomes. A standardized approach to mortality ratios could improve the comparability of future training programs.

A final note should be made regarding improvements in data administration. It took considerable time to manually collect, verify, and process all the data. In some cases, determining the time and cause of death was challenging, potentially leading to the inclusion of more macerated babies and higher perinatal mortality rates. This study's setting in a national underresourced referral hospital may also explain the high perinatal mortality rate. Options to address some data challenges include the development of digital data registration systems and active surveillance of data. While these solutions require initial investments of both time and money, they offer significant potential benefits in terms of efficiency and accuracy. Additionally, digital data registration and continuous data monitoring can be enhanced by the use of dashboards, which provide clinicians with an overview of current practices and can help identify deviations from targets early on [38]. This approach not only benefits the evaluation of obstetric simulation-based training but can also inform ongoing training sessions, contributing to continuous learning and improvements in obstetric training.

Given the complexity of simulation-based obstetric training implementation and evaluation in low-resource settings, future studies should consider conducting implementation and action research. This approach would be valuable for identifying barriers to effective implementation, refining training programs, and ensuring that improvements are successfully integrated into the local health care system.

Conclusions

This train-the-trainer model for providing technology-enhanced, mono-professional, simulation-based training in obstetrics to SHOs did not change maternal and perinatal mortality outcomes in a national referral hospital in a low-resource setting. This study, along with existing literature, suggests that future research should consider conducting and evaluating multi-professional team training in obstetrics, involving all staff within their units.

Acknowledgments

We thank Rob Steinweg, MSc, for all the support from Medsim, a research and training center for medical care in the Netherlands. This study was supported by Máxima Medical Center, Veldhoven, the Netherlands, and Rotary Clubs in the Netherlands and Uganda. They both supported this study by providing training supplies. The Rotary Foundation was not involved in this study's design or interpretation of study results.

Conflicts of Interest

None declared.

Abstract

Background: Current e-learning evaluation focuses on learners' knowledge gain, satisfaction, perceptions, and attitudes; few assess the implementation outcomes of e-learning resources in teaching and learning.

Objective: In this study, we used the RE-AIM (Reach, Effectiveness, Adoption, Implementation, and Maintenance) framework to systematically evaluate the implementation outcomes of reusable learning objects (RLOs) in the context of health care education.

Methods: This study is a part of the Advancing Co-creation of RLOs to Digitise Healthcare Curriculum (ACoRD) project, wherein we developed and implemented 23 RLOs across 3 Malaysian universities for medical, pharmacy, and biomedical curricula. Implementation and dissemination strategies were employed. Data were collected using a self-administered web-based questionnaire and Google Analytics.

Results: This study reports a cumulative RLO access of 7622 users from 48 countries (reach). Users rated RLOs as very helpful (1452/2071, 70.1%) or helpful (601/2071, 29.1%). Preassessments and postassessments showed a significant improvement in the knowledge score (21 RLOs, $P<.05$) and confidence level (17 RLOs, $P<.05$) (effectiveness). All 3 Malaysian universities adopted RLOs in the fields of professional development, primary care medicine, medicine, pediatrics, nursing, pharmacy, and biomedicine (adoption). The percentage of users who completed RLOs ranged from 5.6% (10/179) to 85% (78/92), with nonbounced users (users who viewed more than one page) ranging from 16.3% (165/1014) to 88.5% (370/418) (implementation). In the 4 months following the completion of the ACoRD project, a total of 2107 users accessed RLOs (maintenance).

Conclusions: We systematically evaluated the implementation of e-learning resources by using the RE-AIM framework, informing future strategies to integrate e-learning innovations in real-world teaching and learning practices.

KEYWORDS

e-learning; RE-AIM; implementation; dissemination; reusable learning objects; medical education; reach; effectiveness; adoption; maintenance

Introduction

The use of technology in medical education and health sciences is on the rise, aiming to enhance the knowledge, skills, and practice of medical students. e-Learning, the process of acquisition and use of knowledge distributed and facilitated by electronic means [1], has been shown to be effective in not only improving knowledge but also increasing students' satisfaction in medical education [2,3]. The application of e-learning objects in medical education promotes self-directed and personalized learning, serving as a complement to the conventional didactic teaching method in medical schools [4]. An e-learning object refers to a collection of digital materials structured in a meaningful way, aligned with a specific learning objective, and designed as independent, self-contained units of instructional materials [4].

Although institutions are devoting substantial resources to the development of e-learning, successful implementation of e-learning remains challenging and is often not systematically measured [5]. A systematic review showed that the evaluation of e-learning tends to focus on the assessment of learners' knowledge, satisfaction, perceptions, and attitudes, and there is a lack of rigorous evaluation of its implementation outcomes in the real-world environment [6]. Implementation outcomes are the effects of deliberate and purposive action to implement a new intervention or practice [7]. In the context of e-learning, implementation outcomes include the acceptability, adoption, appropriateness, feasibility, fidelity, and sustainability of e-learning resources in teaching and learning [8]. When e-learning objects are released as open content, reach and discoverability become important.

To date, several models have been used to evaluate the effectiveness and implementation of e-learning resources. The Kirkpatrick model, an outcome-focused model, has been widely employed to evaluate the effectiveness of an educational program across 4 levels: reaction, learning, behavior, and results [9]; however, it does not evaluate the implementation outcomes. The Context-Input-Process-Product model [10] is designed to evaluate both the process and product to determine the success of an educational program. Nevertheless, this model primarily focuses on defining the contextual factors to improve performance [11]. The Analysis, Design, Development, Implementation, and Evaluation model [12], an instructional design model, offers a structured approach to guide the development and implementation of educational programs but falls short of providing metrics for measuring implementation. Therefore, there is a need for an e-learning implementation outcome framework that provides a comprehensive and objective evaluation of the implementation of e-learning resources.

RE-AIM (Reach, Effectiveness, Adoption, Implementation, and Maintenance) is an established implementation science framework used in the health care setting to measure how effectively an evidence-based intervention is implemented [13]. It has been used in several studies to evaluate the implementation outcomes of health care provider education programs [14,15]. In this study, we aimed to use the RE-AIM framework to evaluate the implementation outcomes of reusable learning objects (RLOs), which are bite-sized, stand-alone interactive web-based resources with multimedia that focus on a single learning objective [16]. The findings from this study would provide evidence on the feasibility of using the RE-AIM framework in the context of health care education, describe the implementation strategies used in this project, and propose recommendations to improve the evaluation of e-learning resource implementation in higher educational institutions.

Methods

Study Design

This study is a part of the Advancing Co-creation of RLOs to Digitise Healthcare Curriculum (ACoRD) project, which was funded by the European Union Erasmus+ project [17]. It is a capacity building project involving Universiti Malaya, Universiti Putra Malaysia, Taylor's University, University of Nottingham, Karolinska Institutet, and University of Stavanger. The ACoRD project aimed to introduce innovative digital pedagogy methods by developing, evaluating, and disseminating high-quality, peer-reviewed RLOs that benefit health care and biomedical science learners in Malaysia. RLOs were developed, implemented, and evaluated over 3 phases (Figure 1). The implementation strategies of RLOs were developed and performed in both the development (preimplementation phase) and implementation phases.

RLO Development Phase (Preimplementation)

RLOs were developed following the ASPIRE (Aim, Storyboarding, Populating, Implementing, Release, and Evaluation) framework [18]. The development phase began by establishing a coalition between international institutions within the project. We evaluated the process and challenges of transnational partnerships and knowledge transfer by using a qualitative study, providing insights on guiding effective partnership in e-learning development in the future [17]. This was followed by stakeholder engagement at 3 Malaysian institutions, involving higher education institution management, medical education units, respective departments, and curriculum coordinators. To identify the gaps and topics for RLO development, the ACoRD team reviewed the existing curricula and determined how RLOs can be integrated into the existing topics, learning activities, and teaching delivery methods in the curricula. We also conducted a needs assessment by using a Delphi survey to compare the differences between educators and learners in prioritizing topics for RLO development [19]. After determining the topics and scope of 23 RLOs, we engaged the learners in RLO cocreation, especially in the storyboard development step. We evaluated learners' knowledge, confidence, and satisfaction of the storyboarding session by using a pre-post survey and explored their perception and experience of the cocreation process qualitatively [20]. We provided RLO specification writing training to the educators who subsequently wrote the content for RLOs. Once RLO specifications were finalized, a content review was conducted before moving on to technical development. A small pilot test was conducted with student champions on RLO usability before full implementation.

RLO Implementation Phase

The 23 RLOs (Table 1) were made available through the open-access ACoRD repository website [21], Health e-Learning and Media-Open under the University of Nottingham [22], Multimedia Educational Resource for Learning and Online Teaching [23], and the institutional online learning portal and curriculum guidebook.

The focus was on the actual integration of RLO resources into the health sciences curricula. At Universiti Malaya, RLOs were incorporated into various block postings for medicine and an undergraduate semester course for nursing. In Universiti Putra

Malaysia, RLOs were used in a professionalism module block, and at Taylor's University, they were embedded as part of semester courses in pharmacy and biomedical science. Various strategies were implemented to improve the usage of RLOs, including identifying early adopters (department and educators) to use RLOs in teaching, integrating RLOs into the existing curricula, sending reminders to educators, receiving feedback from students, establishing an effective dissemination team, monitoring RLO performance and feedback to educators, and periodic re-examining of the implementation strategies.

Table . The list of reusable learning objects developed for undergraduate students in health care professions.

University, course	RLO[a] titles (n=23)
Universiti Malaya, Kuala Lumpur, Malaysia	
Medicine	• RLO 1: Prescription Writing—Back to Basics • RLO 2: Treatment of Acute Illness • RLO 3: Principles of Family Medicine • RLO 4: Factors Affecting Nutrition in the Older Person • RLO 5: Growth Faltering in Children • RLO 6: Identify Challenging Behavior in Health Care Settings • RLO 7: How to Conduct a Literature Search
Universiti Putra Malaysia, Selangor, Malaysia	
Medicine	• RLO 8: Confidentiality • RLO 9: Breaking Bad News • RLO 10: Doctor-Patient Relationship • RLO 11: Consent • RLO 12: Verbal and Nonverbal Skills • RLO 13: Counseling Skills • RLO 14: Ethical Reasoning • RLO 15: Social Media Professionalism
Taylor's University, Selangor, Malaysia	
Pharmacy	• RLO 16: Using Nicotine Gum for Smoking Cessation • RLO 17: Using Nicotine Patches for Smoking Cessation • RLO 18: Using Varenicline for Smoking Cessation

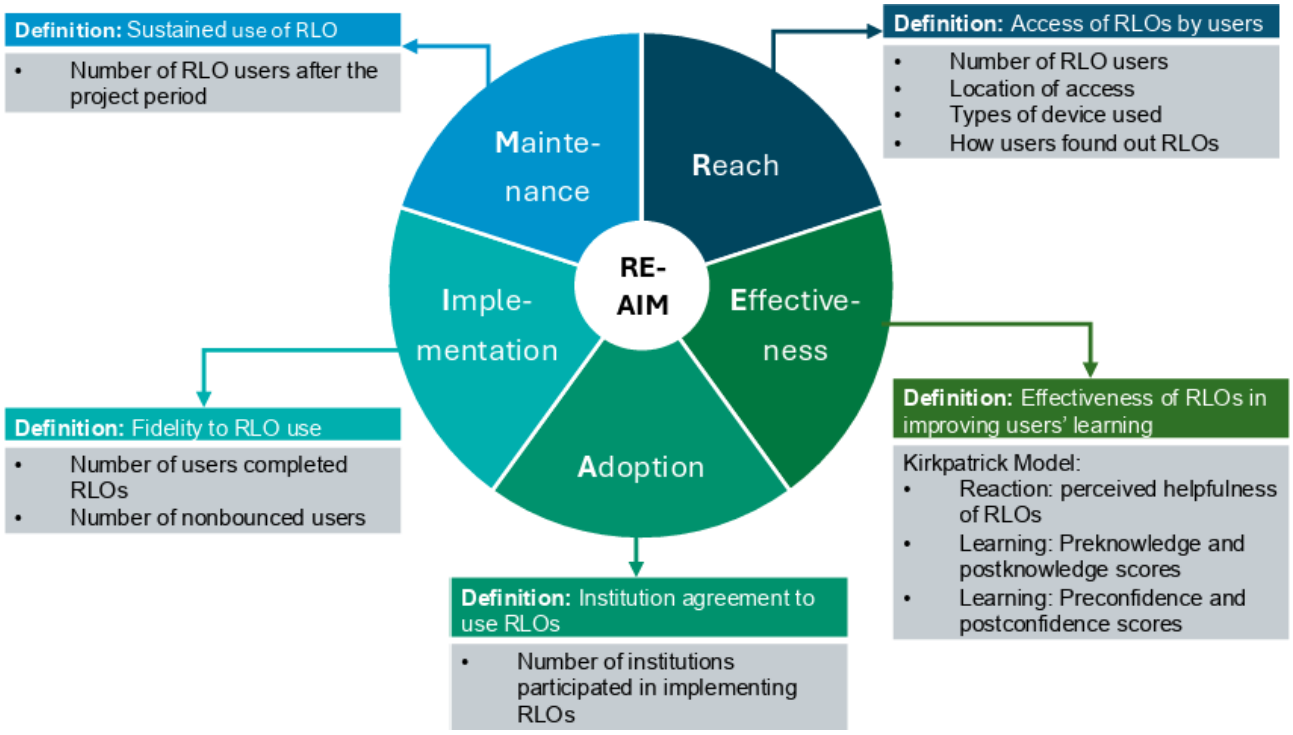
[a]RLO: reusable learning object.

Evaluation Phase

This study was performed across 3 Malaysian institutions (Universiti Malaya, Universiti Putra Malaysia, and Taylor's University). Participants in this evaluation were users who used RLOs during the implementation period from May 1, 2020, to February 24, 2022. We used a universal sampling method for data collection.

We evaluated the implementation of RLOs by using the RE-AIM framework (Figure 2). The reach domain is defined as the access of RLOs by the users. We assessed reach by measuring the absolute number of RLO users, location of access, types of devices used by the users, and how users found out about our RLOs.

Figure 2. Definitions and outcomes measures of the RE-AIM framework. RE-AIM: Reach, Effectiveness, Adoption, Implementation, and Maintenance; RLO: reusable learning object.



For the effectiveness domain, we applied the 4-level Kirkpatrick model: Reaction, Learning, Behavior, and Results [24]. It is a model that is commonly used in medical education to evaluate the effectiveness of a training program [25]. Reaction was assessed by gauging learners' perceived helpfulness of RLOs, and learning was measured using pre-RLO and post-RLO knowledge and confidence scores. Behavior measures whether learners are applying the newly acquired knowledge from RLOs in clinical practice, while results measure the ultimate impact of training using RLOs, which includes impact at an organizational level. We did not measure the behavior and results domains in this study due to limitations in the study design.

Adoption refers to the number of institutions that agreed to use RLOs in teaching and learning activities. We captured information on the institutions, departments, and existing modules in which RLOs were implemented. The implementation domain refers to users' fidelity in using RLOs for their learning. We measured the number of users who completed RLOs and the number of nonbounced users. Nonbounced users are those who are engaged with the site either by clicking on links, visiting multiple pages, or triggering events that indicate interaction, while bounced users are those who visited the RLO web page but only viewed a single page without interacting further before exiting.

The maintenance domain refers to the extent to which the sustained use of RLOs becomes institutionalized or part of the routine teaching and learning practice. We measured the number of users who visited the RLO web page 4 months after the project ended.

Research Instruments and Data Collection

We used 2 instruments to capture the RLO implementation outcomes: questionnaires and Google Analytics (Table 2). The questionnaires were designed to gather user feedback and usage patterns. We used 2 types of questionnaires: (1) a web-based questionnaire was administered at the completion of each RLO to assess users' perception of its usefulness (using a 4-point Likert scale: 1-very unhelpful, 2-unhelpful, 3-helpful, and 4-very helpful) and how they discovered RLOs, and (2) a confidence Likert scale and RLO-specific knowledge questionnaire were administered before and immediately after RLO usage. For the knowledge score, RLOs 16, 17, and 18 (using nicotine gum, nicotine patches, and varenicline for smoking cessation) were assessed using 1 set of knowledge questions, while RLOs 20 and 21 (DNA repair and replication) were assessed using another set of knowledge questions related to specific RLO topics. We used GAMM1-Google Analytics in Universiti Malaya and Universiti Putra Malaysia and Moodle monitoring in Taylor's University to capture the patterns of access (location, number of users, number of completing users).

Table . RE-AIM (Reach, Effectiveness, Adoption, Implementation, and Maintenance) outcome measures and assessment methods.

RE-AIM measures	Assessment methods
Reach	
Number of RLO[a] users	Google Analytics
Location of access	Google Analytics
Types of devices used	Google Analytics
How do users find out RLOs	Questionnaire: multiple-choice
Effectiveness	
Perceived helpfulness of RLOs in learning (Kirkpatrick level 1: reaction)[b]	Questionnaire: 4-point Likert scale
Knowledge and confidence (Kirkpatrick level 2: learning)	Questionnaire 1: pre- and post-RLO knowledge score; Questionnaire 2: pre- and post-RLO confidence score
Adoption	
Number of institutions who adopted RLOs in teaching and learning	N/A[c]
Implementation	
Number of users who completed RLOs	Google Analytics
Number of nonbounced users[d]	Google Analytics
Maintenance	
Number of RLO accesses 4 months after the ACoRD[e] project implementation (from February 24 to June 22, 2022)	Google Analytics

[a]RLO: reusable learning object.

[b]Perceived helpfulness is measured using a 4-point Likert scale (1-very unhelpful, 2-unhelpful, 3-helpful, and 4-very helpful).

[c]N/A: not applicable.

[d]Nonbounced users are defined as users who viewed more than one page.

[e]ACoRD: Advancing Co-creation of Reusable Learning Objects to Digitise Healthcare Curriculum.

Data Analysis

For the questionnaire items, categorical data were reported descriptively using proportion and percentage. The mean difference in the pre-RLO and post-RLO scores on knowledge and confidence were analyzed using Mann-Whitney *U* test, as the data were skewed. Statistical analysis was considered significant when $P<.05$. Google Analytics data were reported descriptively using proportion and percentage. All the data were analyzed using SPSS (version 27; IBM Corp) and Microsoft Excel.

Ethics Approval

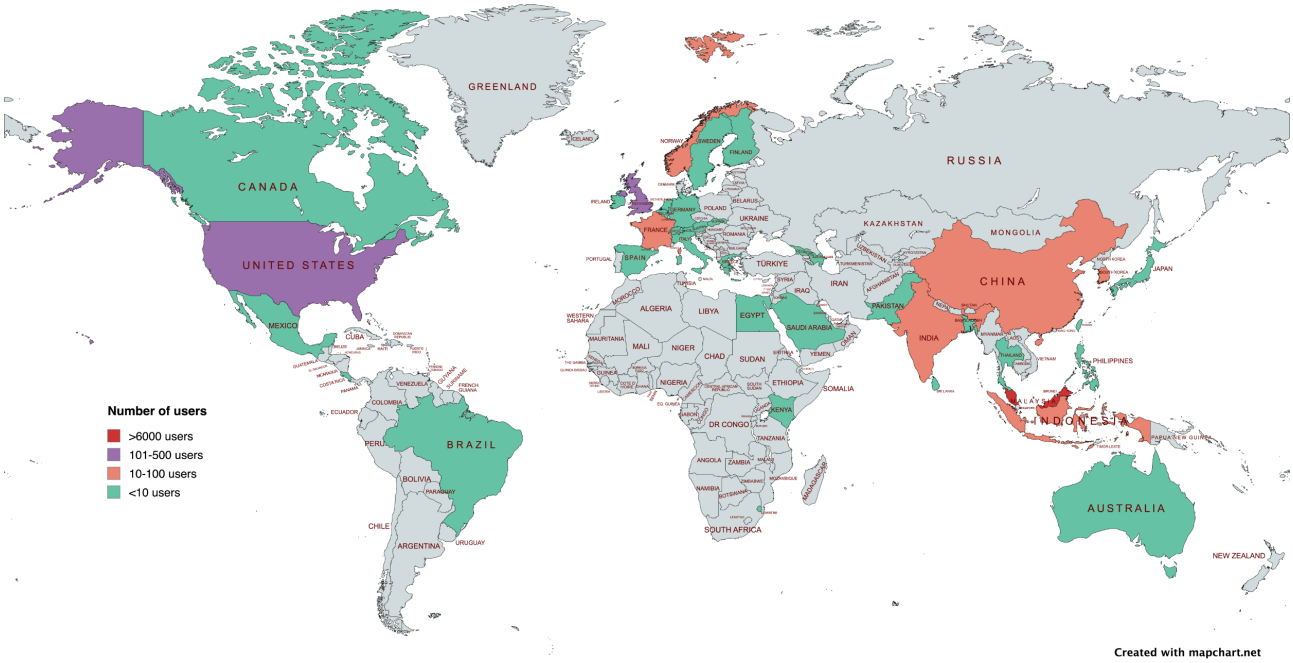
Ethics approval was granted by the Universiti Malaya Research Ethics Committee (reference UM.TNC2/UMREC-997). All participants provided their written consent. All participant information has been anonymized and deidentified. There was no financial compensation provided to the participants.

Results

Overview

From the launch of the first RLO on May 1, 2020, until February 24, 2022, Google Analytics recorded a cumulative 7622 users from 48 countries (Figure 3). We have reported the results according to the RE-AIM framework.

Figure 3. Geographical distribution of the reusable learning object users from 48 countries. There was no country with users between 500 and 6000.



Reach

Among the 7622 global users, the majority (n=6817, 89.4%) were from Malaysia, while 10.6% (n=805) were from other countries. Desktop computers were the predominant devices used to access RLOs (6045/7622, 79.3%); 20.7% (1577/7622) used portable devices such as mobile phones or tablets. The number of users for each RLO varied from 92 to 1014 (Table 3). The RLOs attracting the highest number of users were RLO 7 (How to Conduct Literature Research, n=1014), RLO 1 (Prescription Writing: Back to Basics, n=530), and RLO 17 (Using Nicotine Patches for Smoking Cessation, n=511). RLOs with fewer than 100 users were RLO 10 (Doctor-Patient Relationship) and RLO 23 (Nervous Regulation of the Heart).

Out of 2118 respondents to the questionnaire, the majority used RLOs because they were part of the course learning resource (n=1901, 89.8%), while others received a recommendation from peers, colleagues, or lecturers (n=87, 8.8%). A small proportion of the respondents (30/2118, 1.5%) found RLOs through the Health e-Learning and Media open database, open educational catalogs, or general internet searches.

Table . Number of users for each reusable learning object during project implementation.

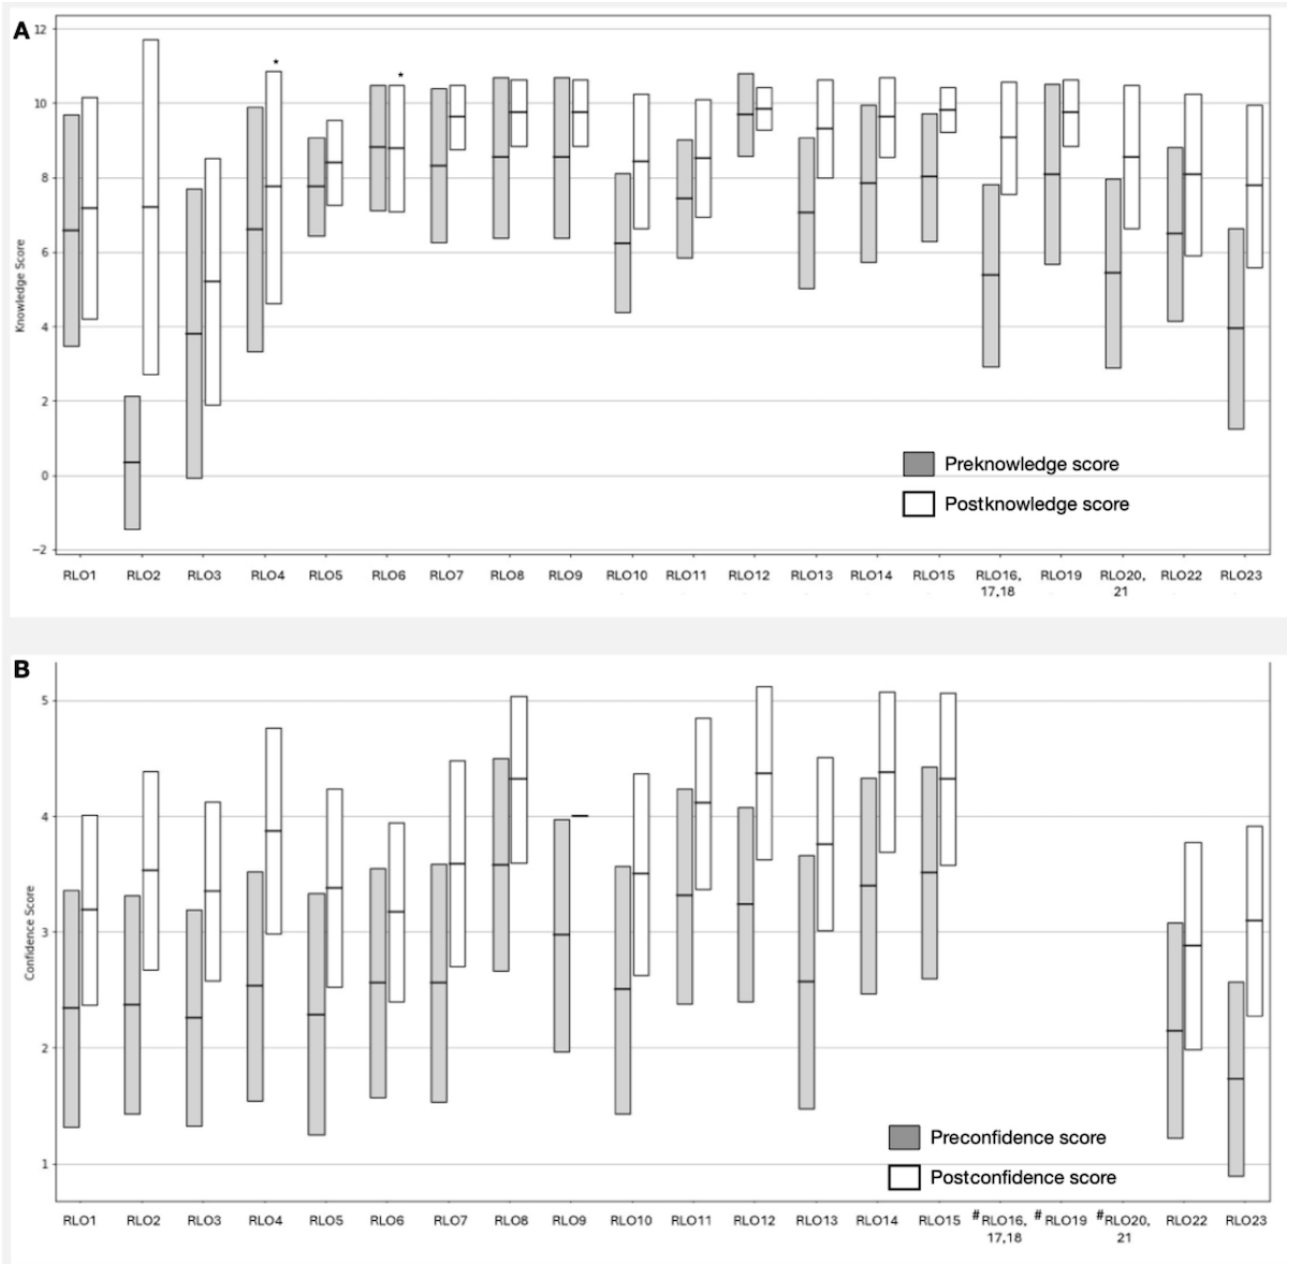
RLO[a] type	Users, n
RLO 1	530
RLO 2	366
RLO 3	467
RLO 4	310
RLO 5	363
RLO 6	184
RLO 7	1014
RLO 8	234
RLO 9	187
RLO 10	97
RLO 11	212
RLO 12	336
RLO 13	187
RLO 14	335
RLO 15	388
RLO 16	432
RLO 17	511
RLO 18	418
RLO 19	191
RLO 20	365
RLO 21	179
RLO 22	224
RLO 23	92

[a]RLO: reusable learning object.

Effectiveness

Most users rated RLOs as very helpful (1452/2071, 70.1%) and helpful (601/2071, 29%). We evaluated the preknowledge and postknowledge scores across all RLOs. The mean preknowledge score ranged from 0.33 to 9.6, while the postknowledge score ranged from 5.20 to 9.85. A significant improvement in the knowledge scores was reported for all RLOs after their use (P<.05) (Figure 4), except for RLO 4 and RLO 6, which had high mean baseline preknowledge scores of 6.61 and 8.80, respectively (Table S1 in Multimedia Appendix 1). Additionally, we assessed the confidence scores for 17 RLOs (excluding 5 RLOs, ie, RLOs 16-21 due to missing data) and found a significant improvement in the mean confidence scores after utilization for all 17 RLOs (P<.05) (Table S2 in Multimedia Appendix 1).

Figure 4. (**A**) Comparison of preknowledge and postknowledge scores for each reusable learning object. (**B**) Comparison of preconfidence and postconfidence scores for each reusable learning object. *P>.05. # indicates missing data. RLO: reusable learning object.



Adoption

All RLOs have been adopted by the 3 Malaysian universities (Universiti Malaya, Universiti Putra Malaysia, and Taylor's University). At Universiti Malaya, the departments of primary care medicine, medicine (geriatrics), pediatrics, and nursing have incorporated RLOs into their teaching and learning curricula. Universiti Putra Malaysia has used RLOs within its professional development module, while Taylor's University has implemented them in the pharmacy and biomedical undergraduate courses.

Implementation

The completion rates for RLOs varied widely, with percentages ranging from 5.6% (10/179) to 85% (78/92) as shown in Table 4. Only RLO 8 (Confidentiality), RLO 15 (Social Media Professionalism), and RLO 23 (Nervous Regulation of the Heart) had a completion rate exceeding 50%. The proportion of nonbounced users, defined as users who viewed more than one page, ranged from 16.3% (165/1014) to 88.5% (370/418). Notably, data on nonbounced users for RLOs 8-15 from Universiti Putra Malaysia were unavailable due to the absence of a tracking function on each RLO page in Google Analytics (because of technical errors).

Table . Number of users who completed reusable learning objects and number of nonbounced users during the implementation period.

RLO[a] type	Accesses, n	Users who completed RLOs, n (%)	Nonbounced[b] users, n (%)
RLO 1	530	205 (38.7)	129 (24.3)
RLO 2	366	90 (24.6)	97 (26.5)
RLO 3	467	116 (24.8)	143 (30.6)
RLO 4	310	46 (14.8)	64 (20.7)
RLO 5	363	53 (14.6)	71 (19.6)
RLO 6	184	33 (17.9)	49 (26.6)
RLO 7	1014	75 (7.4)	165 (16.3)
RLO 8	234	170 (72.7)	—[c]
RLO 9	187	68 (36.4)	—
RLO 10	97	35 (36)	—
RLO 11	212	100 (47.2)	—
RLO 12	336	164 (48.8)	—
RLO 13	187	60 (32.1)	—
RLO 14	335	116 (34.6)	—
RLO 15	388	204 (52.6)	—
RLO 16	432	121 (28)	352 (81.5)
RLO 17	511	113 (22.1)	351 (68.7)
RLO 18	418	109 (26.1)	370 (88.5)

RLO 20	365	61 (16.7)	271 (74.3)
RLO 21	179	10 (5.6)	111 (62)
RLO 22	224	76 (33.9)	147 (65.6)
RLO 23	92	78 (84.8)	30 (32.6)

[a]RLO: reusable learning object.

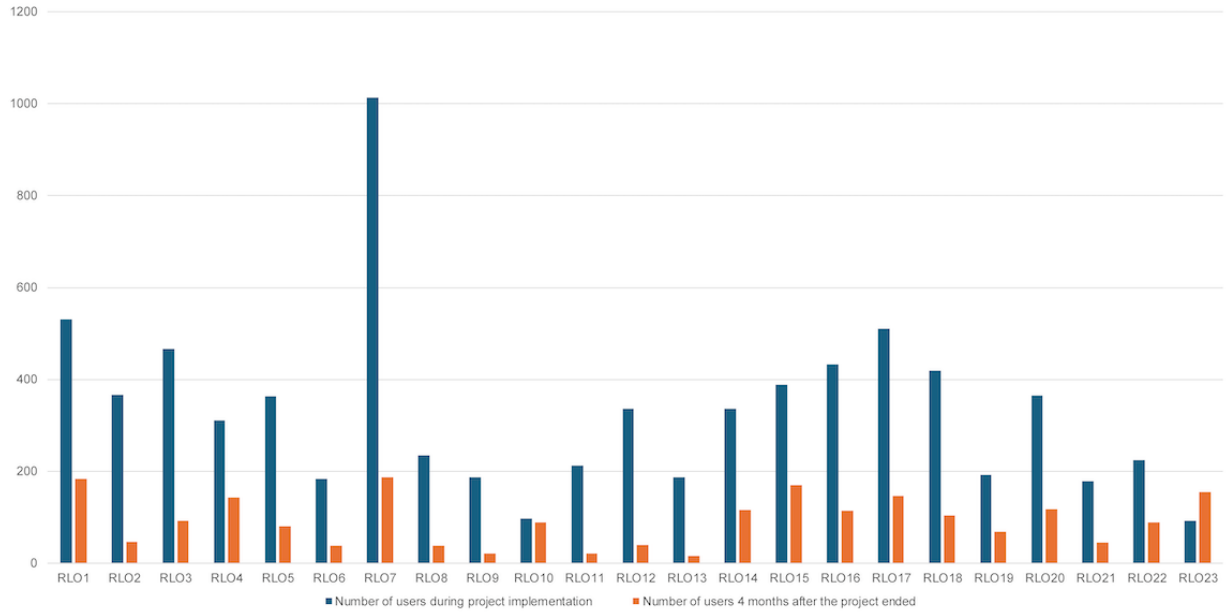
[b]Users who viewed more than one page.

[c]Not available.

Maintenance

After the ACoRD project ended on February 24, 2022, a total of 2107 users continued to access RLOs in the subsequent 4 months, ranging from 15 to 187 accesses per RLO (Figure 5).

Figure 5. Number of users who accessed reusable learning objects 4 months after the end of the project.



Discussion

Principal Findings

This study reports the successful implementation of RLOs in health care education across 3 Malaysian higher educational institutions by using the RE-AIM framework. Our findings offer a broad perspective on how the impact and outcomes of e-learning objects can be measured and evaluated systematically to inform e-learning implementation strategies.

Our study shows that RLOs were accessed by a more diverse group of learners than initially anticipated, extending beyond the Malaysian institutions, where RLOs were intended to be used. Leveraging on the unique characteristics of reusability in RLOs [26], we adopted an open educational resource approach in their deployment. This strategy significantly broadened the reach of RLOs, making them available to learners across different disciplines. Consequently, RLOs addressing more general subjects such as literature review, prescription writing, and smoking cessation attracted a larger user base compared to those focusing on discipline-specific topics.

Throughout the ACoRD project, pragmatic implementation and dissemination strategies were employed to engage a broader audience. These strategies encompassed identifying early adopters and educator champions, sending of reminders to educators about incorporating RLOs in their teaching, monitoring of RLO performance at regular intervals, and providing feedback to educators. A study on mobile health e-learning courses highlighted the advantages of iterative feedback among developers, early adopters, and end users, which aid in the refinement of existing e-learning implementation strategies and the development of new ones [27]. The ACoRD project featured a dedicated dissemination team that organized and executed activities to promote RLOs through conferences and engagement workshops, extending beyond our institutions. Establishing collaborative partnerships with other higher educational institutions is an important strategy to boost visibility and ensure the long-term use of e-learning resources [28].

In our study, users perceived RLOs as beneficial for their learning, with most RLOs demonstrating an improvement in users' knowledge and confidence levels. These findings are aligned with previous studies that have reported improvements in knowledge and understanding following RLO usage [16,29,30]. However, evaluating the effectiveness of e-learning resources remains a challenge. Most studies measured learners' reactions and learnings such as knowledge, usefulness, confidence, satisfaction, and motivation [31]. Some studies examining the effectiveness of RLOs demonstrated behavior change in relation to prescribing behavior and hearing aid use [32,33]. Measuring higher levels of learning such as behavior change and impact of learning is complex due to the time and cost involved [34]. We propose that the evaluation of RLO effectiveness should go beyond individual learning outcomes to assess their impact within the wider teaching and learning ecosystem. This could include evaluating RLOs' effectiveness from educators' perspectives and examining how RLOs contribute to student empowerment in self-directed learning [6].

In the adoption domain of RE-AIM, RLOs developed by the ACoRD project were adopted by all 3 Malaysian institutions. Our study underscores the significance of planning and initiating implementation strategies during the development phase (preimplementation) with stakeholders and institutional engagement. Engaging institutional faculty, students, and stakeholders is critical for the successful adoption of e-learning [35]. The cocreation process and involvement of stakeholders throughout the ASPIRE process facilitates the feeling of ownership of the materials produced, thereby leading to use and reuse. To ensure the widespread adoption of e-learning innovation, it is crucial to engage with and consider the

perspectives of diverse stakeholders, as the implementation of e-learning necessitates changes in teaching, learning, management, and infrastructure within the institution [36].

In our study, although RLOs reached a significant number of users, the proportion of users who completed RLOs (5.6% - 84.4%) and nonbounced users (16.3% - 81.5%) was relatively low for most RLOs. Chen et al [37] reported a similar finding, with a low nonbounced rate of 40% for an undergraduate online course. The wide discrepancy in the completion and nonbounced rates among RLOs may be attributed to the different levels of learning across various learner groups. RLOs integrated into the curriculum as teaching and learning materials achieved a completion rate greater than 70% (RLO 8 and RLO 23), suggesting that learners are more invested in completing these RLOs. Conversely, RLO 7 attracted the highest number of users (n=1014); yet, its completion rate was only 7.4% (75/1014). Our findings show that Google Analytics is beneficial for examining the fidelity of RLO usage, as it provides insights into learners' behaviors. Assessing the fidelity of RLO usage is crucial for educators and institutions to gauge the effectiveness of RLOs in teaching and learning [38].

Users continued to access RLOs after the conclusion of the ACoRD project, which indicates the sustainability of RLOs. The main strategies that we identified were the integration of RLOs into the existing health care curriculum and developing RLOs by using a robust cocreation methodology. Identifying the learning needs of teachers and learners prior to the development of RLOs facilitated their integration into the curriculum [19]. We also implemented the educator-as-champion strategy, which involves educators in content development and subsequently utilizing RLOs in their teaching. e-Learning champions among academicians in higher educational institutions are the key players in fostering the integration of technology into teaching and learning [39].

Limitations

Our study has several limitations. Since each RLO was developed and launched at different times, discrepancies in the implementation periods made data interpretation challenging. We used Google Analytics to capture the reach of our RLOs. However, we could not confirm whether access came from unique users or unique IP addresses. There is a possibility that some users could have accessed RLOs multiple times by using different IP addresses. As this study employs a pragmatic approach to capture evaluation outcomes in real-time, missing data were inevitable; however, it did not substantially impact the overall findings. Strategies were implemented pragmatically throughout the project, with practical consideration and changes made to address implementation issues; as a result, we were unable to identify and measure the effectiveness of each implementation strategy.

Conclusion

We employed the RE-AIM framework to systematically evaluate the implementation success of e-learning resources, identifying gaps and strategies for improvement. This study highlights the development, implementation process, and implementation outcome indicators of open-access RLOs in health care education. To enhance future e-learning implementation efforts, we recommend incorporating the RE-AIM framework into outcome evaluations to provide a more comprehensive evaluation of e-learning implementation.

Abstract

Background: Traditional assessments of clinical competence using multiple-choice questions (MCQs) have limitations in the evaluation of real-world diagnostic abilities. As such, recognizing non-verbal cues, like tachypnea, is crucial for accurate diagnosis and effective patient care.

Objective: This study aimed to evaluate how detecting such cues impacts the clinical competence of resident physicians by using a clinical simulation video integrated into the General Medicine In-Training Examination (GM-ITE).

Methods: This multicenter cross-sectional study enrolled first- and second-year resident physicians who participated in the GM-ITE 2022. Participants watched a 5-minute clinical simulation video depicting a patient with acute pulmonary thromboembolism, and subsequently answered diagnostic questions. Propensity score matching was applied to create balanced groups of resident physicians who detected tachypnea (ie, the detection group) and those who did not (ie, the non-detection group). After matching, we compared the GM-ITE scores and the proportion of correct clinical simulation video answers between the two groups. Subgroup analyses assessed the consistency between results.

Results: In total, 5105 resident physicians were included, from which 959 pairs were identified after the clinical simulation video. Covariates were well balanced between the detection and non-detection groups (standardized mean difference <0.1 for all variables). Post-matching, the detection group achieved significantly higher GM-ITE scores (mean [SD], 47.6 [8.4]) than the non-detection group (mean [SD], 45.7 [8.1]; mean difference, 1.9; 95% CI, 1.1 - 2.6; *P*=.041). The proportion of correct clinical simulation video answers was also significantly higher in the detection group (39.2% vs 3.0%; mean difference, 36.2%; 95% CI, 32.8 - 39.4). Subgroup analyses confirmed consistent results across sex, postgraduate years, and age groups.

Conclusions: Overall, this study revealed that detecting non-verbal cues like tachypnea significantly affects clinical competence, as evidenced by higher GM-ITE scores among resident physicians. Integrating video-based simulations into traditional MCQ examinations enhances the assessment of diagnostic skills by providing a more comprehensive evaluation of clinical abilities. Thus, recognizing non-verbal cues is crucial for clinical competence. Video-based simulations offer a valuable addition to traditional knowledge assessments by improving the diagnostic skills and preparedness of clinicians.

KEYWORDS

clinical competence; clinical simulation video; general medicine in-training examination; non-verbal information; tachypnea

Introduction

Detecting non-verbal cues is an essential skill that resident physicians must acquire during their clinical training. However, accurately assessing detection ability is challenging [1]. In traditional text-based examinations, non-verbal information, such as respiratory rate or breathing patterns, is written, making true recognition of these cues clear.

The Japan Institute for Advancement of Medical Education Program (JAMEP) created the General Medicine In-Training Examination (GM-ITE) to evaluate resident physicians' clinical knowledge across Japan [2]. This 2-hour exam comprising 80 multiple-choice questions (MCQs) [2] provides practical feedback on training programs by identifying areas for improvement through objective and reliable clinical competency assessment [3]. The GM-ITE is a validated examination that effectively assesses core medical knowledge and skills. However, its text-based design makes it difficult to evaluate the examinee's ability to detect non-verbal cues [4]. A sample GM-ITE question illustrating the typical MCQ format and content is provided in Multimedia Appendix 1 [5].

To address this gap, we developed and integrated a clinical simulation video into the GM-ITE [6], offering an effective assessment tool by providing contextualized real-world scenarios that require resident physicians to apply knowledge dynamically, mirroring actual patient interactions [7,8]. By incorporating non-verbal information with verbal cues, video simulation offers a more authentic evaluation of clinical practice. This simulation involved a medical interview and a physical examination scenario, requiring participants to actively identify critical non-verbal cues, such as tachypnea. The clinical simulation video successfully assessed multiple domains of clinical competencies [8]. However, the association between the ability to detect non-verbal cues and clinical competency remains unknown.

Herein, we explored whether the ability to detect non-verbal cues, like tachypnea, in the clinical simulation video correlates with higher GM-ITE scores and correct clinical simulation video answers. We hypothesized that resident physicians who could accurately identify tachypnea would demonstrate superior clinical competence, yielding higher GM-ITE scores.

Methods

Study Design, Setting, and Participants

We conducted a multicenter cross-sectional study of GM-ITE for the academic year 2022 (GM-ITE 2022). GM-ITE employs a methodology similar to that of internal medicine (IM)-ITE. In Japan, the GM-ITE 2022 includes many residency programs in teaching hospitals, with other hospitals allowing voluntary participation. Consequently, 9011 resident physicians from 662 Japanese hospitals participated between January 17 and January 30, 2023. After the final question, participants were asked to voluntarily watch the clinical simulation video to provide a diagnosis, followed by a questionnaire to collect information on demographics and residency programs. This study included all resident physicians who participated in GM-ITE 2022 at one of the study sites, excluding those who did not participate in or answer the clinical simulation video question, or did not provide informed consent for study participation.

Ethical Considerations

This study was approved by the Ethical Review Committee of the Japan Organization for Advancing Medical Education (approval no. 23‐26). All participants provided informed consent before participating. The study was conducted in accordance with the ethical standards and principles of the Declaration of Helsinki. Informed consent was obtained from all participants for the publication of identifying information in an online open-access publication. All participants read and signed an informed consent form before participating. To ensure confidentiality, all data were anonymized prior to analysis. No compensation was provided for involvement in the study. In accordance with ethical standards and journal policies, we obtained explicit informed consent from all actors appearing in the video material associated with this study. The actors acknowledged and agreed that the videos would be published as part of the study.

Procedures

Innovative Examination Using High-Quality Video Simulation

This study used a clinical simulation video developed and introduced in a prior study [9]. In the 5-minute video filmed from a resident physician's perspective, the resident physician conducted a medical interview and physical examination, with the camera capturing the patient's and family members' verbal and non-verbal responses. The video depicts a 40-year-old male patient with a recent history of lower limb fracture who presented to the emergency room with fainting as the chief concern. The correct diagnosis was acute pulmonary thromboembolism. This scenario was designed to challenge residents' clinical reasoning skills. The patient exhibited physical signs, including tachypnea, jugular venous distension, and a right lower limb fracture, with actual heart sounds presented during auscultation. Crucially, tachypnea (28 breaths per minute) and respiratory patterns were not highlighted in the text, but presented as non-verbal cues, requiring participants to recognize these signs through observation, without explicit textual focus.

The video was produced by a professional television production company under the guidance of three JAMEP medical supervisors and three authors who ensured the medical accuracy and educational relevance. The use of professional actors and their added effects, such as heart sounds, enhanced the scenario realism of the scenario and aligned it with the objectives of clinical residency training in Japan.

After watching the clinical simulation video, participants answered the following clinical simulation video questions [10]:

Q1. Please state the most likely diagnosis for this patient (free text).

Q2. Please state the three pertinent positive clinical information related to the most likely diagnosis (free text).

For Q1, multiple disease name patterns indicating "acute pulmonary thromboembolism" (eg, acute pulmonary embolism or pulmonary thromboembolism) were accepted as correct. For Q2, the pertinent positive clinical findings included tachypnea, jugular venous distension, and a history of right lower limb fracture. Answers were evaluated based on whether key clinical signs were correctly identified, further contributing to diagnostic ability assessment. Two authors independently assessed, discussed, identified, and agreed upon the answers. The interrater reliability was measured using the κ coefficient, which indicated almost perfect agreement for Q1 (κ=0.91) and substantial agreement for Q2 (κ=0.82) [11].

Data Collection

This study used information from the GM-ITE score and questionnaire, including sex, postgraduate year (PGY 1 or 2), rotation in the general medicine department, duration of rotation, number of monthly night shifts, average number of assigned inpatients, self-study time per day, and categorized weekly duty hours.

Exposure and Outcome Measurement Data

The exposure of interest was whether the resident physicians detected tachypnea in the innovative examination clinical simulation video. This non-verbal cue was critical for the correct diagnosis. The primary outcome was the total GM-ITE score, which ranged from 0 to 80 points. The secondary outcome included the results of the clinical simulation video (correct or incorrect).

Statistical Analyses

Initially, we described participant-level information by groups that detected tachypnea (ie, tachypnea-detection group) and did not detect tachypnea (ie, tachypnea-non-detection group) in the clinical simulation video using appropriate summary statistics.

To adjust for potential confounders, we conducted propensity score matching analysis. Propensity scores for the probability of detecting tachypnea were calculated using a logistic regression model incorporating sex, PGY, rotation in the general medicine department, rotation duration, number of night shift duties per month, average number of assigned inpatients, self-study time, and weekly duty hours. We applied a greedy matching algorithm using a logit of propensity scores with calipers equal to 0.2 of the standard deviation of logit-propensity scores [12]. We assessed the balance of covariates between the groups before and after matching using the standardized mean difference (SMD) [13]. Covariates were considered well-balanced if the absolute SMD was <0.1.

The GM-ITE scores and clinical simulation video results were compared before and after propensity score matching. T-tests were applied to assess differences in the GM-ITE scores, while the χ^2 test was used for the clinical simulation video results. Stratified subgroup analyses by gender (male or female), grade (PGY-1 or 2), and age (unknown, <27 years, and ≥27 years) were conducted to evaluate robustness.

All analyses were conducted using the Statistical Analysis System version 9.4 for Windows (SAS Institute Inc., Cary, NC, USA) and JMP version 17 for Windows (SAS Institute Inc., Cary, NC, USA) according to the Strengthening the Reporting of Observational Studies in Epidemiology guidelines. A complete case analysis was performed. The mean differences and 95% CI were reported for all analyses.

Results

Baseline Characteristics

Overall, 5105 first- and second-year resident physicians participated in this study (Figure 1). There were no missing data for any covariates or outcome variables. Resident physicians were divided based on their ability to detect tachypnea, the critical non-verbal cue (Table 1). Among the non-verbal cues included in the clinical simulation video, tachypnea exhibited the largest difference in the identification rates between correct and incorrect responders (Multimedia Appendix 2). Overall, tachypnea was overlooked and detected in 4146 and 959 residents, respectively. Before matching, several covariates demonstrated notable imbalances between the tachypnea non-detection and detection groups. Specifically, the proportion of male residents was higher in the non-detection group (69.2% vs 64.7%; SMD=0.219), while the proportion of first-year postgraduate residents was higher in the non-detection group (51.7% vs 45.3%; SMD=0.309). Age distribution also showed discrepancies, with younger residents, particularly those aged 26 years, being more common in the detection group (34.1% vs 31.1%; SMD=0.312). These imbalances were addressed through propensity score matching identifying 959 participants to achieve well-balanced covariates across groups (SMD <0.1 for all covariates).

GM-ITE Scores

Before matching (Table 2), resident physicians in the tachypnea-detection group exhibited significantly higher GM-ITE scores (mean [SD] 47.6 [8.4] points vs 45.3 [8.0] points), with a mean difference of 2.3 points (95% CI 1.7 - 2.8). After propensity score matching, the tachypnea-detection group maintained a higher GM-ITE score (mean [SD] 47.6 [8.4] points vs 45.7 [8.1] points; mean difference 1.9 points [95% CI 1.1 - 2.6]). These results were consistent across all subgroup analyses.

Table . Comparison of General Medicine In-Training Examination (GM-ITE) scores between the tachypnea non-detection and detection groups after propensity score matching.

Characteristic	GM-ITE score, mean (SD)		
	Tachypnea non-detection group	Tachypnea detection group	Difference in the mean value (95% CI)
Before matching			
Total participants	45.3 (8.0)	47.6 (8.4)	2.3 (1.7 to 2.8)
After matching			
Total participants	45.7 (8.1)	47.6 (8.4)	1.9 (1.1 to 2.6)
Subgroup analyses after matching			
Sex			
Male	46.0 (8.4)	48.1 (8.8)	2.1 (1.2 to 3.1)
Female	45.2 (7.6)	46.6 (7.5)	1.4 (0.2 to 2.5)
Grade			
PGY-1[a]	45.2 (7.8)	46.5 (7.9)	1.9 (1.1 to 2.6)

Age (years)			
<27	47.2 (7.8)	48.6 (8.1)	2.6 (1.4 to 3.8)
≥27	43.5 (8.2)	46.2 (8.5)	1.0 (-2.5 to 4.5)
Unknown	42.1 (5.8)	47.8 (8.7)	5.7 (-2.0 to 13.3)

[a]PGY: postgraduate year.

Clinical Simulation Video Results

The proportion of correct answers within the tachypnea-detection group was significantly high both prior to matching (39.2% vs 3.1%; difference 36.1% [95% CI 33.0 - 39.2]) and following matching (39.2% vs 3.0%; differences 36.2% [95% CI: 32.8 - 39.4]; Multimedia Appendix 3). The proportion of correct clinical simulation video answers was consistently greater in the tachypnea detection group across subgroup analyses. Formal interaction tests were conducted to evaluate the association between tachypnea and the correct answer rate divided by sex, PGY level, and age (Multimedia Appendix 4). The interaction tests revealed no statistically significant difference between male and female participants (P=.692), indicating that sex did not substantially influence the relationship between the tachypnea detection performance and the correct answer rate. In contrast, a significant interaction was identified between PGY-1 and PGY-2 participants (P=.003). Furthermore, a significant interaction was observed between participants aged <27 years and those aged ≥27 years (P=.021).

Discussion

Principal Findings and Comparison With Previous Works

This study highlights the importance of recognizing non-verbal cues, such as tachypnea, in clinical reasoning. Resident physicians who identified tachypnea achieved significantly higher GM-ITE and correct clinical simulation video answers. Although identifying tachypnea as a non-verbal cue in the clinical simulation video was important, it was not the sole determinant of correct diagnosis. Achieving a correct response required integrating multiple findings, including jugular venous distension, cardiac murmur, and limb injury. Therefore, tachypnea detection was associated with—but not equivalent to—correctly answering the clinical simulation video question. Furthermore, the primary analysis examined the relationship between tachypnea detection and overall GM-ITE scores, which are independent of the video-based assessment and reflect broader clinical knowledge. Consistent results in propensity score-matched and stratified subgroup analyses emphasized the direct relationship between the ability to detect non-verbal information and clinical competence, underlining the need to train resident physicians to observe and interpret non-verbal cues during patient interactions. These skills are essential for accurate diagnosis and effective patient care [14-17].

The substantial GM-ITE score difference between the two groups demonstrates the value of non-verbal cue recognition in clinical competency. Video-based simulations provide a unique opportunity to address this gap, offering realistic scenarios that mirror actual clinical encounters [18]. By integrating non-verbal with verbal information, video simulations enhance diagnostic capabilities potentially underdeveloped through text-based evaluations alone.

Our findings further indicated that clinical experience, as reflected in PGY, significantly influence the ability to recognize non-verbal cues. PGY-2 residents outperformed PGY-1 residents, indicating that experiential learning plays a pivotal role in developing these perceptual skills [19]. Beyond the PGY level, analysis of the unmatched cohort revealed additional factors associated with improved cue recognition. For example,

the detection group more frequently reported a strong interest in general medicine and prior experience with video-based clinical reasoning, indicating that both motivational and educational factors may enhance observational accuracy. Furthermore, residents with greater monthly patient exposure demonstrated higher detection rates, indicating that regular clinical exposure helps refine perceptual skills. Together, these findings highlight several modifiable factors that could be targeted through future educational interventions. Further research should explore how medical training and curricula can be optimized to foster the development of diagnostic observation skills early in clinical education.

Including video-based assessments in the GM-ITE reinforces its potential to complement traditional MCQs. Video simulations enable a more comprehensive evaluation of diagnostic abilities by integrating complex, real-world scenarios [20]. They assess clinical knowledge and challenge resident physicians to process subtle cues, bridging the gap between theoretical understanding and practical application [21-23]. This also reinforces the value of integrating video-based assessments with traditional MCQ examinations to comprehensively evaluate a physician's diagnostic capabilities [21,22]. Overall, this finding suggests potential areas for further investigation into whether perceptual abilities, training experiences, or other underlying factors contribute to differences [24]. The significant proportion of second-year resident physicians in the detection group indicates the impact of clinical experience on non-verbal cue recognition, emphasizing the importance of developing skills during medical training.

Although our results showed that resident physicians who detected tachypnea also had higher GM-ITE scores; this association does not indicate redundancy between video- and text-based assessments. Rather, it suggests that the ability to recognize non-verbal cues is an important component of clinical reasoning that complements traditional knowledge-based assessments. GM-ITE MCQs primarily evaluate declarative knowledge and structured reasoning, whereas the clinical simulation video captures real-time perceptual and interpretive skills, such as visual observation and contextual integration. Therefore, this video-based format offers added value by assessing diagnostic competencies that may not be fully captured through text-based questions alone.

Using video-based simulations like clinical simulation videos significantly enhances traditional MCQ examinations by enabling the assessment of resident physicians' ability to integrate verbal and non-verbal information, thereby replicating real-world clinical scenarios, and improving the assessment of clinical competence [24]. Our findings support the inclusion of video-based simulations in medical education assessments [21]. Video simulations can better prepare resident physicians for the complexities of patient care by mimicking actual clinical situations [25,26]. However, future studies should investigate how repeated exposure to video-based assessments impacts diagnostic accuracy and confidence, as well as their influence on clinical outcomes.

The consistency in GM-ITE scores and clinical simulation video results after propensity score matching and subgroup stratification indicated the robustness of our findings [27]. Furthermore, our findings advocate for the broader adoption of video simulations in medical education, as they offer an innovative and effective means to improve diagnostic skills and preparedness among future clinicians [20,28].

In addition to repeated exposure to video-based examinations, future research should explore methods of training human raters to reliably assess non-verbal cue detection. Standardized rater-training programs or calibration protocols should ensure consistent evaluations in video-based objective structured clinical examination-type assessments. Furthermore, advances in artificial intelligence and machine learning could enable the automated recognition of visual and auditory cues in clinical simulations, supporting scalable and objective assessment of non-verbal diagnostic skills.

Limitations

This study has certain limitations. First, the cross-sectional design limited our ability to infer causality between the detection of non-verbal cues like tachypnea and higher GM-ITE scores. Future research should consider longitudinal or interventional study designs, to more definitively evaluate causality. Specifically, intervention studies could assess whether targeted training in non-verbal cue recognition—such as simulation-based educational programs—facilitates measurable improvements in the diagnostic accuracy and GM-ITE performance. Longitudinal approaches may clarify whether enhanced cue recognition skills contribute to sustained improvements in clinical competence. Second, the study relied on self-reported data from resident physicians, which may be subject to response bias. Although we used objective measures such as the GM-ITE scores, the accuracy of the self-reported demographic and training information could not be independently verified. Third, this study was conducted in Japan, where medical education and training systems may differ from other countries. Consequently, these findings may not be generalizable to resident physicians in different healthcare systems with varying educational structures. However, the highlighted diagnostic challenges—particularly the recognition or interpretation of subtle clinical cues and prevention of diagnostic errors—are likely to be relevant across a broad range of training contexts [29]. Therefore, while the GM-ITE context is unique, our findings offer insights that may resonate with global generalist training programs. Fourth, although propensity score matching was applied to control potential confounders, unmeasured variables may have influenced the results. While propensity score matching strengthened the validity of our findings by controlling for potential confounders [30], unmeasured factors, such as prior training in video simulation or baseline observational skills, may still influence the results [31]. A deeper understanding of these variables could provide further insights into the mechanisms underlying the differences in GM-ITE scores. Finally, the innovative examination using video simulations was a relatively new GM-ITE addition, and the novelty of the format might have influenced participants' performance. Ongoing evaluation of the reliability and validity of video-based assessments is essential to ensure their effectiveness as tools for measuring clinical competence.

Conclusions

The ability to recognize non-verbal cues, such as tachypnea, is a critical determinant of clinical competence among resident physicians, as evidenced by higher GM-ITE scores. Video-based simulations exhibit a transformative addition to traditional MCQ examinations, enabling a comprehensive evaluation of diagnostic abilities by integrating real-world complexities and non-verbal information.

Acknowledgments

We wish to thank the members of JAMEP for their valuable assistance and Dr. Kentaro Sakamaki from the Faculty of Health Data Science at Juntendo University for his statistical guidance. We also thank Editage for the English language review. This work was supported by the Health, Labor, and Welfare Policy Grants of Research on Region Medical (21IA2004, 24IA2016) from Japan's Ministry of Health, Labor, and Welfare. The funder had no role in the design or conduct of the study, the collection, management, analysis, and interpretation of the data, the preparation, review, or approval of the manuscript, or the decision to submit the manuscript for publication.

Conflicts of Interest

JAMEP was involved in collecting and managing data as a GM-ITE administrative organization. It did not participate in designing and conducting the study, data analysis and interpretation, preparation, review, approval of the manuscript, or the decision to submit the manuscript for publication. YN received an honorarium from JAMEP as GMITE project manager. YT is the director of JAMEP. HK received an honorarium from JAMEP as a speaker of JAMEP lecture. KS received an honorarium from JAMEP as a reviewer for the GMITE. KS, TS, and YY received honoraria from JAMEP as exam preparers for the GMITE. The authors declare no competing interests.

Abstract

Background: Artificial intelligence (AI) is set to shape the future of medical practice. The perspective and understanding of medical students are critical for guiding the development of educational curricula and training.

Objective: This study aims to assess and compare medical AI-related attitudes among medical students in general medicine and in one of the visually oriented fields (pathology), along with illuminating their anticipated role of AI in the rapidly evolving landscape of AI-enhanced health care.

Methods: This was a cross-sectional study that used a web-based survey composed of a closed-ended questionnaire. The survey addressed medical students at all educational levels across the 5 public medical schools, along with pathology residents in 4 residency programs in Jordan.

Results: A total of 394 respondents participated (328 medical students and 66 pathology residents). The majority of respondents (272/394, 69%) were already aware of AI and deep learning in medicine, mainly relying on websites for information on AI, while only 14% (56/394) were aware of AI through medical schools. There was a statistically significant difference in awareness among respondents who consider themselves tech experts compared with those who do not (P=.03). More than half of the respondents believed that AI could be used to diagnose diseases automatically (213/394, 54.1% agreement), with medical students agreeing more than pathology residents (P=.04). However, more than one-third expressed fear about recent AI developments (167/394, 42.4% agreed). Two-thirds of respondents disagreed that their medical schools had educated them about AI and its potential use (261/394, 66.2% disagreed), while 46.2% (182/394) expressed interest in learning about AI in medicine. In terms of pathology-specific questions, 75.4% (297/394) agreed that AI could be used to identify pathologies in slide examinations automatically. There was a significant difference between medical students and pathology residents in their agreement (P=.001). Overall, medical students and pathology trainees had similar responses.

Conclusions: AI education should be introduced into medical school curricula to improve medical students' understanding and attitudes. Students agreed that they need to learn about AI's applications, potential hazards, and legal and ethical implications. This is the first study to analyze medical students' views and awareness of AI in Jordan, as well as the first to include pathology residents' perspectives. The findings are consistent with earlier research internationally. In comparison with prior research, these attitudes are similar in low-income and industrialized countries, highlighting the need for a global strategy to introduce AI instruction to medical students everywhere in this era of rapidly expanding technology.

Introduction

Artificial intelligence (AI) is the capability of machines to simulate intelligence by exhibiting human-like traits such as understanding, deductive reasoning, and problem-solving abilities [1]. In medicine, many specialties have already used AI in clinical practice, such as oncology for cancer detection and grading [2]. AI, particularly deep learning, has garnered a lot of attention in medical education and pathology in recent years [3,4]. These techniques have been mostly used for visual activities such as consultations, seminar presentations, board exams, and archiving [5]. Even before this achievement, many experts predicted that specialized algorithms capable of reading images as well as or better than human observers would dominate the future of medicine. As a result, residents and undergraduate students are becoming increasingly concerned that pursuing medicine training may be an insecure career path [6]. However, the long-awaited expansion of AI in pathology is still underway, and the area of pathology is changing at a far slower rate than other domains (eg, radiology) [7].

The recent approvals of whole slides imaging scanners by the Food and Drug Administration for primary diagnosis, as well as the approval of the prostate AI algorithm, have cleared the road for the first steps in incorporating this new technology for use in pathologic primary diagnosis. AI solutions can serve as a unique platform for breakthroughs and advancements in anatomical and clinical pathology practice [8].

Commercially available AI systems have recently become the focus of a more concentrated evaluation. However, it is unclear whether medical students and pathology residents are afraid that AI may replace pathologists or other clinicians [9]. There is limited knowledge about medical students' perspectives toward AI and deep learning, particularly in underdeveloped nations. To investigate this topic, we conducted a multicenter national survey of undergraduate medical students and pathology residents to assess their perceptions of AI in medicine in general and pathology in particular, as well as their concern that machines will replace pathologists or other physicians soon.

The perspective and understanding of medical students are critical for guiding the development of educational curricula and training. We investigate major medical AI-related attitudes among medical students in general and in pathology in Jordan, with an emphasis on the components that should be included in the medical curriculum.

Methods

Study Design and Population

A randomized, web-based, cross-sectional study was conducted among medical students and pathology residents in Jordan from 5 public universities—Jordan University of Science and Technology (JUST), The University of Jordan, Yarmouk University, Hashemite University, and Mutah University, including about 19,000 medical students—in addition to 4 pathology residency programs: JUST, King Hussein Cancer Center, Jordan University Hospital, and Royal Medical Services, including about 80 pathology residents. The survey was published over a 10-day period from March 4 to March 14, 2024. The required sample size was estimated using the web-based Raosoft sample size calculator [10]. The proposed sample size was 318, with a 5% margin of error, a 99% confidence, a 30% response rate, and a population size of 20,000. Three hundred ninety-four students completed the questionnaire. Students were encouraged to disseminate the questionnaire among their colleagues to create a snowball sample.

Ethical Considerations

The research has been approved by the institutional review board of JUST, Irbid, Jordan (number: 3/167/2024; date: February 13, 2024). All individuals consented to participate. All methods met with the applicable standards and regulations. Participants provided informed consent at the beginning of the survey and had the ability to opt out at any time. Data were anonymized and no compensation was provided to the participants. The results of this study are original, have not been previously published, are not under review elsewhere, and have received approval from all authors. All the authors have approved final version of the manuscript.

The data were obtained using a self-administered open web-based questionnaire produced with Google Forms. To evaluate the questionnaire's applicability and forward validity, our research team translated the questions into Arabic and conducted a pilot survey with 15 randomly selected participants to examine question comprehension and language clarity. The questionnaire was circulated through medical student groups, social media forums (Facebook, WhatsApp, Telegram, and Instagram), and through announcements in lectures. Participation was entirely voluntary and unrelated to the students' educational curriculum. The students consented to participate by completing the survey. Respondent anonymity was assured by design.

Questionnaire Structure

The questionnaire items were adopted from a previously validated study [11] and amended by 2 expert pathologists (AR and MA) at 2 academic centers to apply the questions to the discipline of pathology. The questionnaire was divided into sections, each of which addressed a different issue (Table S1 in Multimedia Appendix 1). The first section of the questionnaire inquired about demographic data and self-reported technological expertise. The second portion inquired about AI and deep learning applications in medicine. The third part evaluated sources to AI in general. The fourth part focused on AI applications in medicine. The fifth section evaluated emotions and perspectives toward AI and deep learning in medicine and pathology. The sixth part inquired about the expected effects of AI on medical education and specific components that should be implemented in medical education (an open-ended question), followed by a question regarding whether basic AI knowledge should be provided in official medical courses (a Yes/No). Finally, the prospective applications of AI in pathology were considered.

Statistical Analysis

Following the completion of questionnaire submissions, the findings were converted to a comma-separated value file. To

simplify statistical analysis, the categories “disagree entirely” and “rather disagree” were summarized as disagreement, while “rather agree” and “agree entirely” were summarized as agreement. Nominal categorical variables were analyzed using the Pearson chi-square test or Fisher exact test, whereas ordinal data were analyzed using Spearman correlation. The statistical analysis was performed using SPSS version 26.0 (IBM Corp) [12], and *P* values of <.05 were considered statistically significant.

Results

Overview

After 10 days of opening the survey, 394 participants completed the questionnaire (328 medical students and 66 pathology residents). Of these respondents, 49% (193/394) were males and 51% (201/394) were females. The median age is 20 (IQR 20 - 21) years. Most medical students surveyed were in their junior years (1, 2, and 3), accounting for around 85% (279/394) of the sample, while approximately 15% (49/394) were in clinical training years (4, 5, and 6). Most pathology residents surveyed were postgraduate year 1 and postgraduate year 2 (63/66, 96%). Of the total, 44.9% (177/394) of the respondents regarded themselves as technological experts (Table 1).

Table . Demographics and self-reported technical expertise (N=394).

		Participants
I consider myself a tech expert person, n/N (%)		
	Agree entirely	46/394 (12)
	Rather agree	131/394 (33.2)
	Rather disagree	73/394 (19)
	Disagree entirely	16/394 (4)
	__[a]	128/394 (32.5)
Age (years)		
	Median	20
	IQR	20-21
	Minimum/maximum	18/34
Gender, n/N (%)		
	Male	193/394 (49)
	Female	201/394 (51)

[a]Not available (or no response).

Awareness of AI and Deep Learning in Medicine

The vast majority of respondents (272/394, 69%) were previously aware of the medical community’s discussion on AI and deep learning. There was a statistically significant difference in awareness among respondents who consider themselves tech experts compared with those who do not (*P*=.03), but no significant differences were found between males and females, medical students, and pathology residents. Furthermore, 67.5% (266/394) of respondents reported having a basic awareness of the technologies used in these fields (Table 2).

Table . First part of the questionnaire—artificial intelligence and deep learning in medicine (N=394).

Questionnaire items		Yes, n/N (%)	No, n/N (%)	*P* value[a]
“Deep learning” and “artificial intelligence” are currently being broadly discussed in the medical field.				
	Were you already aware of these topics?	272/394 (69)	122/394 (31)	.03/.46
	Do you have a basic understanding of the technologies used in these topics?	266/394 (67.5)	128/394 (32.5)	.89/.94

[a]Tech expert versus non–tech expert/medical students versus pathology residents.

The Sources for the Topic of AI

Websites were the primary sources of knowledge on AI, with 73.4% (289/394) of respondents reporting awareness via this source. In contrast, fewer students heard about AI from friends and colleagues (139/394, 35.3%), webinars (59/394, 15%), and medical school lectures (56/394, 14%). The majority of respondents (310/394, 78.6%) acknowledged that they did not learn about AI through formal AI courses (Table 3).

Table . Second part of the questionnaire—different sources of exposure to artificial intelligence as a topic in general (N=394).

Questionnaire items		Yes, n/N (%)	No, n/N (%)	*P* value[a]
Other applications we use in daily life already use artificial intelligence (eg, speech-/text-recognition). Were you aware of this from?				
	Websites	289/394 (73.4)	105/394 (26.6)	<.001/.66
	Social friends and colleagues	139/394 (35.3)	255/394 (64.7)	.20/.74

	Webinars	59/394 (15)	335/394 (85)	.80/.37
	Training (eg, courses) in artificial intelligence	22/394 (6)	372/394 (94.4)	.15/.99
	No answer	—[b]	—	.001/.85

[a]Tech expert vs non–tech expert/medical students vs pathology residents.

[b]Not applicable (ie, total proportion of no answers: 62/394, 16%).

The Applications of AI in Medicine

More than half of respondents thought that AI might be used to diagnose disease in patients automatically (213/394, 54.1% agreement vs 82/394, 21% disagreement), and medical students agreed more than pathology residents on this topic *(P*=.04). Furthermore, 39.5% (156/394) agreed to the use of AI in automated diagnosis. Moreover, three-quarters agreed that AI might automatically indicate appropriate investigations (318/394, 80.7% agreement vs 19/394, 5% disagreement). Table 4 provides more detailed results.

Table . Third part of the questionnaire—applications for artificial intelligence in medicine (N=394).

Questionnaire items		Agree entirely, n/N (%)	Rather agree, n/N (%)	Rather disagree, n/N (%)	Disagree entirely, n/N (%)	N/A[a], n/N (%)	*P* value[b]
What potential applications for AI in medicine do you see?							
	Automated detection of disease	55/394 (14)	158/394 (40.1)	69/394 (16)	13/394 (3)	99/394 (25)	.58/.001
	Automated diagnosis of patients	39/394 (10)	117/394 (29.7)	107/394 (27.2)	19/394 (5)	112/394 (28)	.016/.000

[a]N/A: not applicable.

[b]Tech expert vs non–tech expert/medical students vs pathology residents.

Overall Emotions and Attitudes About AI and Deep Learning in Both Medicine and Pathology

Regarding overall feelings and attitudes toward AI and deep learning in medicine and pathology, most respondents agreed that AI will revolutionize medicine in general (321/394, 81.4% agreement) and pathology in particular (312/394, 79.2% agreement), while a sizable proportion disagreed that human doctors in general (291/394, 73.9% disagreement) and pathologists (248/394, 63% disagreement) could be replaced in the near term. Furthermore, more than one-third of respondents expressed fear about recent AI developments (167/394, 42.4% agreed).

On the other hand, roughly half said that these breakthroughs make pathology or medicine more intriguing to them (184/394, 46.7% and 222/394, 56.4%, respectively), and for those specific questions, tech expert respondents were considerably more likely to say “yes” than non–tech expert respondents (*P*=.002 and *P*=.03, respectively).

Nonetheless, most respondents believed that the adoption of AI would benefit pathology (302/394, 76.7% agreement) and the entire field of medicine (305/394, 77.4% agreement). Notably, two-thirds of respondents disagreed that their medical schools or hospitals had educated them about AI and its uses (261/394, 66.2% disagreed), whereas 46.2% (182/394) expressed an

interest in learning the principles of AI and its applications in medicine. Table S1 in Multimedia Appendix 1 summarizes feelings and attitudes toward AI and deep learning in medicine and pathology.

What Specific Aspects Should Be Implemented in Medical Education?

Students were asked to select from a list of options, each of which allowed for several responses. The majority of respondents (231/394, 58.6%) expressed an interest in learning about AI's applications, potential hazards, and legal and ethical implications. Females were more likely than males to exhibit an interest in learning about AI's possible hazards and legal implications (P=.038 and P=.001, respectively). In addition, 51.8% (204/394) of the students felt that medical education should cover current AI systems and their technical foundations. However, 64.2% (253/394) of respondents expressed no interest in learning about the classification of AI reliability in medical education (Table 5).

Table . Specific aspects that should be implemented in medical education (multiple responses possible) (N=394)[a].

	Yes, n/N (%)	No, n/N (%)	P value[b]
Areas of application	231/394 (58.6)	163/394 (41.4)	.04/.95
Possible risks	231/394 (58.6)	163/394 (41.4)	.25/.83
Technical basics	204/394 (51.8)	190/394 (48.2)	.73/.74
Current AI[c] systems	204/394 (51.8)	190/394 (48.2)	.63/.52
Modes of operation	200/394 (50.8)	194/394 (49.2)	.30/.21
Legal aspects, ethics	198/394 (50.3)	196/394 (49.7)	.094/.35
Potential future developments	195/394 (49.5)	199/394 (51.5)	.45/.36
Classification of AI reliability	141/394 (35.8)	253/394 (64.2)	.77/.23
Basic AI knowledge should be provided in university courses	357/394 (90.6)	37/394 (9.4)	.21/.16

[a]The vast majority of respondents believed that university curricula should cover fundamental AI concepts (357/394, 90.6% said yes).

[b] Tech expert vs non–tech expert/medical students versus pathology residents.

[c]AI: artificial intelligence.

What Potential Applications for AI Do You See in Pathology?

In terms of pathology-specific questions, 3 quadrants (297/394, 75.4%) of respondents agreed that AI could be used to identify pathologies in slides examinations automatically, and more than half (222/394, 56.3%) agreed that AI could be used to diagnose pathologies in slides examinations and indicate appropriate further stains needed. There was a statistically significant difference between medical students, who are more inclined to agree, and pathology residents (P=.02/P<.001 and P<.001/P=.61, respectively). In addition, 79.1% (312/394) of respondents felt that AI might be used to automatically identify appropriate special studies and immunohistochemistry stains in slide examinations (Table 6).

Table . Potential applications for artificial intelligence in pathology (N=394).

	Totally agree, n/N (%)	Agree, n/N (%)	Disagree, n/N (%)	Totally disagree, n/N (%)	Neutral, n/N (%)	P value[a]
Automated detection of pathologies in slides examinations	91/394 (23)	206/394 (52.3)	26/394 (7)	5/394 (1)	66/394 (17)	.56/.001
Automated diagnosis in slides examinations	58/394 (15)	164/394 (41.6)	50/394 (13)	11/394 (3)	111/394 (28.2)	.02/<.001
Automated indication of appropriate special studies and immunohistochemical stains in slides examinations	103/394 (26.1)	209/394 (53)	11/394 (3)	2/394 (1)	69/394 (18)	<.001/.61

[a]Tech expert vs non–tech expert/medical students vs pathology residents.

Discussion

Principal Findings

Findings revealed that a significant majority of medical students were already aware of the ongoing discussion around AI and deep learning in the medical community. This awareness was significantly higher among those who described themselves as tech savvy. The survey results support the conclusion that the majority of respondents did not learn about AI throughout medical school.

The majority of respondents thought that AI had the potential to alter both medicine in general and pathology in particular. However, a significant proportion raised concerns about the potential displacement of human physicians by AI in the near future. This sentiment is consistent with other research revealing worries among medical students and pathology residents regarding the expanding role of AI in medicine. For example, in Lebanon and Kuwait, there was an agreement that AI would not replace doctors but rather significantly transform health care practices [13,14]. Notably, the majority of medical students who responded were in their junior years (279/394, 85%) of the total sample, which may reflect their interest in the subject compared with senior students. Although this allowed us to compare junior medical students' perceptions with those of postgraduate pathology students, it is regarded as a restriction for evaluating senior medical students' perspectives.

The general agreement was that the use of AI would benefit both pathology and the larger field of medicine [8]. Further comparison with prior work is discussed in the section "Comparison With Prior Work." This study provides useful insights into medical students' perspectives and attitudes regarding AI, which are critical for guiding the development of educational curricula and training.

The rapid growth of AI has the ability to change the face of a variety of medical specialties. Specifically in the visual medical disciplines, such as radiology, pathology, ophthalmology, and dermatology, AI has generated significant interest and will particularly affect the developments of these fields due to the visual nature of their occupations [3]. Deep learning applications are autonomously trained to execute certain tasks in response to the availability of large digital datasets. Visual activities include consultations, seminar presentations, board exams, and archiving [5]. Medical students' perspectives are crucial for shaping medical education, especially in rapidly changing professions. This study collects students' opinions on AI in medicine in order to better understand their requirements and expectations from medical schools, as well as add to the dataset so that data from various countries (both low and high income) may be compared to analyze future medical education plans. Learners in the digital era differ from past generations. They are growing increasingly technologically savvy and socially conscious. Pathology and radiology are 2 visual fields that have seen significant advancements in AI technology. Many studies have been conducted in radiology [11], but to our knowledge, this is the first to analyze the attitudes and awareness of pathology residents.

AI-Related Attitudes of Medical Students in Comparison With Pathology Residency Trainees

To the best of our knowledge, this is the first study to discuss pathology residents' awareness and attitudes toward AI in the field of pathology, in addition to comparing it with medical students' perspectives. In Jordan, digital pathology is a relatively new concept that is primarily used for research purposes. A digital scanner is available at one site in Jordan (at JUST), with a focus on research and consulting purposes.

In general, there was no major difference in the responses between undergraduate students and postgraduate pathology residents. Except on 2 occasions, medical students agreed more than pathology residents that AI can be used to diagnose disease in patients automatically (P=.04). There was also a statistically significant difference between medical students, who are more likely to agree than pathology residents regarding AI's ability to diagnose pathologies in slide examinations and indicate appropriate additional stains needed (P=.02/P<.001 and P<.001/P=.61, respectively). The Food and Drug Administration's recent support of whole-slide imaging scanners for primary diagnosis, together with the approval of prostate AI algorithms, marks the beginning of introducing AI technology into primary diagnostics. AI can provide a unique platform for promoting innovation and breakthroughs in anatomical and clinical pathology practice [9].

Otherwise, there was general agreement between medical students and pathology residents that, for example, the adoption of AI would benefit pathology and the entire field of medicine and that they needed to learn about AI's applications, potential hazards, and legal and ethical implications.

In summary, the findings underscore the imperative to integrate AI education into the medical field to adeptly equip future physicians for AI-augmented health care. Subsequent investigations should concentrate on assessing the efficacy of embedding AI education into medical training programs, both undergraduate and postgraduate, and probing the determinants influencing medical students' attitudes toward AI. AI may also be used in pathology to diagnose cancer, predict survival, modify molecular structures, and forecast treatments. More effort is required to navigate these applications. Furthermore, it is worth investigating the relationship between the extent of digital pathology implementation and AI awareness.

Limitations

Some limitations include the sample strategy's use of social media as well as the web-based approach, which limits randomization and generalization. Also, the majority of medical students who responded were in their junior years (279/394, 85%). Although this allowed us to compare junior medical students' perceptions to those of postgraduate pathology students, it is regarded as a restriction for evaluating senior medical students' perspectives.

Comparison With Prior Work

Compared with published work in this regard, similar results were identified in neighboring countries, including Lebanon [13]. In Kuwait, there was also an agreement that AI would not

replace doctors but rather significantly transform health care practices [14]. In the United Arab Emirates, there was a lack of acquaintance with AI found in a study that called for the introduction of specific education and training in medical schools [15]. In addition, identical outcomes were observed in industrialized countries. In Germany, two-thirds of students (539/838, 64.4%) believed that they were not well informed on AI in medicine, and 57.4% (463/807) thought that AI has beneficial applications in medicine, such as drug research, but less so for clinical use [16]. In the United States, a study showed that 91% (353/387) reported receiving no formal education related to AI [17].

Conclusions

Our study highlights a generally favorable attitude toward AI between medical students and pathology residents. A significant number of participants are already familiar with the ideas of AI and deep learning in medicine while the majority sees potential in AI for automated detection of pathologies and indication of appropriate investigations, which is a warning about replacing physicians and pathologists in the nearest future.

The study found that being a tech expert influenced respondents' awareness and attitudes toward AI. This indicates a potential gap in the current medical education system, with a large proportion of respondents expressing interest in learning more about AI and its applications in medicine.

In pathology, there is a prominent agreement on the potential applications of AI, particularly in the automated detection of pathologies in slide examinations and the automated indication of appropriate special studies and immunohistochemical stains. Medical students show that they are more enthusiastic about the integration of AI in pathology than pathology residents.

While most medical students and pathology residents acknowledge the potential of AI to revolutionize medicine and improve the pathology field, there is a clear need for integrating AI education into medical curricula and addressing concerns about its ethical and legal aspects.

Authors' Contributions

AR contributed to writing—original draft, methodology, formal analysis, data curation, conceptualization, and project administration. MAQ, RA, NB, and M Abdaljaleel contributed to writing—review and editing, supervision, methodology, and conceptualization. Abstract

Background: Mobile apps designed for teaching human anatomy offer a flexible, interactive, and personalized learning platform, enriching the educational experience for both students and health care professionals.

Objective: This study aimed to conduct a systematic review of the human anatomy mobile apps available on Google Play, evaluate their quality, highlight the highest scoring apps, and determine the relationship between objective quality ratings and subjective star ratings.

Methods: The Mobile App Rating Scale (MARS) was used to evaluate the apps. The intraclass correlation coefficient was calculated using a consistency-type 2-factor random model to measure the reliability of the evaluations made by the experts. In addition, Pearson correlations were used to analyze the relationship between MARS quality scores and subjective evaluations of MARS quality item 23.

Results: The mobile apps with the highest overall quality scores according to the MARS (ie, sections A, B, C, and D) were Organos internos 3D (anatomía) (version 4.34), Sistema óseo en 3D (Anatomía) (version 4.32), and VOKA Anatomy Pro (version 4.29). To measure the reliability of the MARS quality evaluations (sections A, B, C, and D), the intraclass correlation coefficient was used, and the result was "excellent." Finally, Pearson correlation results revealed a significant relationship (r=0.989; P<.001) between the quality assessments conducted by health care professionals and the subjective evaluations of item 23.

Conclusions: The average evaluation results of the selected apps indicated a "good" level of quality, and those with the highest ratings could be recommended. However, the lack of scientific backing for these technological tools is evident. It is crucial that research centers and higher education institutions commit to the active development of new mobile health apps, ensuring their accessibility and validation for the general public.

KEYWORDS

anatomy; Google Play; mobile health; mHealth; Mobile App Rating Scale; MARS

Introduction

Background

At present, there is a wealth of research on mobile apps focused on various aspects and areas of health, such as musculoskeletal injuries [1]; chronic disease management [2]; pediatric disease care [3]; medication management [4]; oral hygiene [5]; asthma [6]; pediatric ear, nose, and throat surgery [7]; low back pain [8]; neurodegenerative disorders [9]; coronary arteries [10]; neurorehabilitation [11]; nutrition, anemia, and preeclampsia [12]; cancer [13,14]; cerebrovascular diseases [15]; childhood obesity [16]; diabetes [17]; tuberculosis [18]; fibromyalgia [19]; dementia [20]; chronic kidney disease [21]; and epilepsy [22],

among others. These mobile health management apps have transformed the way people access and manage information about their well-being, enabling everything from vital signs monitoring to chronic disease management. This advancement in mobile apps not only benefits patients but also opens new possibilities in health education. In particular, mobile apps for teaching human anatomy have become valuable resources that complement the learning and understanding of the structures and functions of the human body. Similar to personal health apps, these tools are designed with interactive features such as 3D models and detailed simulations that enhance the educational experience for medical students and health care professionals.

The justification for this study is based on three important approaches: (1) the technological approach regarding the use of mobile apps for teaching human anatomy, (2) the pedagogical approach, and (3) the quality evaluation approach of the apps. These approaches together provide a solid foundation to justify the importance of the study.

Technological Approach

The first approach involved reviewing and analyzing scientific publications on the use of mobile apps in teaching human anatomy, with the aim of understanding their results. This approach highlights how mobile technology has revolutionized access to knowledge, enabling students to learn in an accessible and practical manner. In teaching human anatomy, mobile apps with 3D models and simulations facilitate immersive and effective learning, complementing and even enhancing traditional methods in health sciences. One of the studies presented the software Road to Birth, developed by the University of Newcastle, which was designed to teach midwifery students at a Midwestern US university about the dynamic concepts of maternal anatomy and physiology during an obstetrics module. The students used Road to Birth, and 66% of them reported an increase in their knowledge, valuing the software as a useful and practical learning resource [23]. Another study used the mobile app AR in Anatomy, developed by the authors; which allows users to dynamically explore various parts of the human body in 3D, enhancing the educational experience [24]. Similarly, apps such as Anat_Hub, developed by faculty and researchers from the Departments of Computer Science and Medical Sciences at the University of the Western Cape; a mobile app with augmented reality (AR) to improve learning about the musculoskeletal system's anatomy, received positive evaluations. User results indicated that the anatomy system could effectively enhance student engagement and retention of anatomical concepts [25]. In addition, another study conducted with undergraduate health sciences students at the University of Cape Town analyzed the impact of an AR mobile app on learning motivation. The study included 78 students, evaluating motivation levels before and after using the app. The results showed that its use increased motivation, improving aspects such as attention, satisfaction, and confidence [26]. In the field of neuroanatomy, the use of mobile AR facilitated the understanding of complex concepts, increasing academic performance and reducing cognitive load among students [27]. Similarly, HuMAR, developed by researchers affiliated with Murdoch University and Universiti Utara Malaysia; an AR-based prototype for learning skeletal structure, demonstrated high satisfaction among students, highlighting the system's usability and functionality [28]. However, although cadavers remain the gold standard in anatomy teaching, there are financial, ethical, and supervisory limitations. Another study compared the effectiveness of virtual reality, AR, and tablet-based devices in teaching cranial anatomy. A total of 59 students participated who were randomly assigned to one of the 3 learning methods. The results suggest that these technologies can effectively complement anatomical teaching [29]. On the other hand, a recent study presented a human anatomy learning system based on AR using a marker on a mobile platform to capture images and merge them with data from an SQLite database. This system allows for interactive visualization of the human body or its organs in 3D. An evaluation conducted with high school and medical students demonstrated that the app facilitates anatomy learning more effectively due to its ability to provide interactive 3D representations through AR [30]. Another example is AEducaAR, an app developed by researchers affiliated with the University of Bologna, which combines AR with a 3D-printed anatomical model to improve anatomy teaching for medical students. Its effectiveness was evaluated with a group of 62 second-year students, comparing its use to traditional learning methods with anatomical atlas books. Although there were no significant differences in objective test results between the two methods, students expressed enthusiasm for AEducaAR in a survey, valuing its potential to motivate learning and enhance the 3D understanding of anatomical structures. This tool could also prepare students to use advanced medical technologies in their future careers [31]. In addition, a relevant study presents 10 mobile apps for teaching human anatomy, where the results indicate that the technological designs studied exhibit a high degree of usability [32]. Another study analyzed 325 anatomy mobile apps and outlined their features to facilitate dissemination in the academic field. It showcases a broad, diverse, and affordable market for human anatomy mobile apps that can complement students' education [33].

Pedagogical Approach

Medical students frequently face challenges in understanding anatomy through the images found in textbooks [34], which are flat and lack interactivity. In contrast, mobile apps for learning human anatomy can serve as a complementary resource for learning this discipline, offering students the opportunity to interact with content more deeply than in a conventional dissection room. Although traditional cadaver-based teaching remains the preferred learning method [35], anatomy education continues to face numerous challenges, including limited practical hours for students and instructors, restricted access, and the high cost of cadavers and artificial models [36]. The use of mobile apps for learning human anatomy offers significant advantages, such as immediate and continuous access to information anytime and anywhere. These apps include interactive 3D designs that allow for a detailed exploration of the human body. Furthermore, they are often updated regularly and are generally more affordable than traditional textbooks, making them accessible to a broader audience.

Quality Evaluation Approach

The third approach focuses on evaluating the quality of human anatomy mobile apps. The importance of evaluating these apps lies in the fact that higher-rated apps can serve as academic support for medical students, health care professionals, and general users. A specific methodology is required to evaluate the quality of health mobile apps. In this context, the Mobile App Rating Scale (MARS) methodology has been used. Various studies have used the MARS to assess health apps targeting a variety of conditions, such as chronic kidney disease and end-stage renal disease [37], chronic lung diseases [38], stress management [39], psoriasis [40], gastrointestinal diseases [41], pain management [42], oral hygiene [43,44], nutrition [45], genetics and genomics [46], food allergies or intolerances [47], deafness and hearing impairment [48], low back pain [49,50], neurological conditions [51], peritoneal dialysis [52], diabetes [53], COVID-19 [54], cancer [55], anticoagulation [56], dementia [57], specialized diets [58], toric intraocular lenses [59], epilepsy [60], depression [61], coronary diseases [62], dyslexia [63], autism spectrum disorder [64], nutrition [65], and pediatric palliative care [66].

This study aimed to (1) identify human anatomy mobile apps available on the Google Play store, which uses the Android operating system, covering 70.87% of the global mobile operating system market [67]; (2) evaluate these apps using the MARS, which considers engagement, functionality, aesthetics, information, subjective quality, and app specificity; (3) present the human anatomy mobile apps with the highest ratings on the MARS; and (4) determine the correlation between the objective MARS quality rating and the subjective MARS rating by health care professionals (ie, item 23).

Methods

Overview

This study was cross-sectional, as it collected data at a single time point without follow-up over time, evaluated the correlation between variables, and provided descriptive data [68-70]. The study was conducted following the guidelines of the STROBE (Strengthening the Reporting of Observational Studies in Epidemiology) initiative, which aims to improve the communication of results from observational studies among authors, editors, and readers of scientific publications, focusing primarily on cohort, case-control, and cross-sectional studies [71].

Selection Criteria for Human Anatomy Mobile Apps

From April 1 to May 30, 2024, an extensive search for mobile apps was conducted. The search term used was *anatomy*. The inclusion criteria for mobile apps were as follows: (1) available on the Google Play store; (2) related to human anatomy; (3) available in English or Spanish; (4) user rating ≥4.3 to ensure a minimum level of acceptance and satisfaction among users; (5) free to use—an essential factor in educational contexts where students or universities may face budget constraints; and (6) download count exceeding 100,000.

The exclusion criteria were as follows: (1) duplicate apps, either because of different versions or alternative names but containing the same content; and (2) apps not updated for 2 or more years.

The PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) methodology was used to select human anatomy–teaching apps. This methodology is used in systematic reviews and meta-analyses to ensure transparency and rigor in the selection and analysis of relevant studies. The phases were identification, selection, eligibility, and inclusion.

During the identification phase, an exhaustive search for mobile apps dedicated to teaching human anatomy was conducted. In the filtering phase, duplicate apps were discarded. In the eligibility phase, the characteristics of these apps were analyzed to discard those that did not meet the previously established inclusion criteria, and an additional exclusion criterion was applied. Finally, in the inclusion phase, the apps that met all eligibility requirements were integrated for analysis and evaluation.

All selected apps were recorded in Excel (version 2016; Microsoft Corporation) with the following characteristics: app name, identification screen, languages, star rating, total downloads, developer, Android version, last update date, and features.

Evaluation of Mobile Apps

Overview

We used the MARS, developed by Stoyanov et al [72], which has been widely used to evaluate the design and usability of mobile health apps. The MARS consists of 3 dimensions. The first dimension is an objective tool based on 4 main components: engagement (section A), functionality (section B), aesthetics (section C), and information quality (section D). The second dimension assesses subjective quality (section E), and the third dimension evaluates the perceived effectiveness (section F).

Each section of the MARS has several items. An item refers to a specific element, question, or unit of evaluation within a questionnaire or survey. Section A comprises 5 items and evaluates whether the app is engaging, interesting, customizable, interactive, and targeted at a specific population. Section B comprises 4 items and focuses on the app's performance, ease of use, navigation, and gesture design. Section C comprises 3 items and examines the app's design, graphics, and visual appeal. Section D comprises 7 items and analyzes the accuracy of information description, objectives, quality and quantity of information, visual information quality, credibility, and scientific evidence base of the evaluated app. The 4 objective sections of MARS (ie, A, B, C, and D) encompass 19 items. The average scores of sections A, B, C, and D represent the overall MARS quality score [72].

Section E comprises 4 items and focuses on the evaluator's personal perception of the app and typically includes items that ask about the likelihood of recommending the app, the probability of the user continuing to use the app, and the overall perception of its quality. Finally, section F comprises 6 items and focuses on how health care professionals perceive the impact

of the app on their knowledge, attitudes, intentions, and behaviors related to health.

Evaluation Instrument Scale

To evaluate each item, a 5-point Likert scale was used, ranging from 1 to 5 (1=inadequate, 2=poor, 3=acceptable, 4=good, and 5=excellent). A MARS score of more than 3 points indicates acceptable quality.

Selection of Evaluators

A total of 10 evaluators were selected, all health care professionals from the Faculty of Medicine of Tampico Dr Alberto Romo Caballero at the Universidad Autónoma de Tamaulipas, Tampico, Tamaulipas, Mexico. The inclusion criteria were (1) being a top-performing student in the final year of medical school and (2) having a mobile phone with the Android operating system to download human anatomy teaching apps from Google Play.

Evaluation Process

Before starting the evaluation of anatomy-related apps, it was necessary to train the evaluators in the use of the MARS. For this, the authors of this study convened the 10 selected evaluators at the library of the Faculty of Medicine of Tampico Dr Alberto Romo Caballero at the Universidad Autónoma de Tamaulipas, Tampico, Tamaulipas, Mexico, to present a training video in English by Stoyanov et al [72]. Following the video presentation, a training exercise was suggested for all evaluators using an app called Anatomymaster. This app, also focused on human anatomy, was not included in the study sample, as it did not meet the requirement of having a user rating ≥4.3.

The evaluators downloaded and tested the trial app for at least 10 minutes before completing the MARS web-based questionnaire. If any individual evaluation score varied by at least 2 points, the evaluators discussed it to reach a consensus, ensuring a uniform understanding of each item.

After completing the trial exercise, the 10 selected evaluators evaluated the 18 human anatomy mobile apps during June 2024. Each evaluator was provided with a list of apps, which they downloaded and used for 10 minutes before completing a web-based evaluation instrument designed based on the MARS. Each item from the different sections was rated using a Likert scale (1-5). The collected data were initially recorded in Excel.

Statistical Analysis

Overview

Statistical analyses, including the calculation of the intraclass correlation coefficient (ICC) and Pearson correlation coefficient, were performed using SPSS (version 29.0.2.0; IBM Corp).

Intraclass Correlation Coefficient

The ICC was used using a random effects model of 2 factors with consistency to measure the overall agreement between the quantitative measurements obtained by different evaluators [73]. The ICC ranges from 0 to 1, with 0 indicating a total lack of reliability among evaluators and 1 representing perfect reliability. According to the 95% CI for ICC estimation, values below 0.5 are considered “poor” reliability, those between 0.5 and 0.75 are considered “moderate,” those between 0.75 and 0.9 are considered “good,” and those above 0.90 are rated as “excellent” [74].

The individual ICC was calculated for each of the sections A, B, C, and D. The arithmetic means of each section were used to calculate the ICC for the overall MARS quality score (ie, sections A, B, C, and D). In section A, 900 data points were considered, accounting for 10 evaluators, 5 items, and 18 mobile apps. In section B, 720 data points were used (ie, 10 evaluators, 4 items, and 18 mobile apps). In section C, 540 data points were analyzed (ie, 10 evaluators, 3 items, and 18 mobile apps). Finally, in section D, 1080 data points were considered (ie, 10 evaluators, 6 items, and 18 mobile apps). In this last section, item 19 was excluded because of missing values; therefore, only 6 items were considered instead of 7. For each MARS section (ie, A, B, C, and D), the arithmetic mean and SD were calculated.

Pearson Correlation

The statistical technique of Pearson correlation was used to evaluate the relationship between the MARS quality scores (ie, sections A, B, C, and D) and the subjective item 23 from section E. The software used was SPSS.

Ethical Considerations

This study did not involve experiments on humans, animals, or the collection of sensitive personal data. It focused exclusively on evaluating publicly available mobile applications on Google Play through a structured analysis conducted by health care professionals. No direct interaction with developers or users of the applications took place, and no private or identifiable information was accessed or stored.

This type of research, which does not involve mental health e-communities or sensitive data, does not require institutional review board approval. Furthermore, the activities were carried out following the institutional policies and local guidelines of the Universidad Autónoma de Tamaulipas, Mexico, for observational research and technological product reviews.

This decision aligns with international ethical standards and aims to ensure transparency and accountability in the evaluation of publicly available technological products.

Results

Selection Criteria for Anatomy Mobile Apps

Figure 1 shows the PRISMA diagram applied to the selection of mobile apps; a total of 724 apps were identified in the Google Play store under the search criterion *anatomy*. In total, 54 duplicate apps were eliminated either because they had the same name or different names but the same content, leaving 670 in the screening phase. In the eligibility phase, the inclusion criteria were applied, where only 75 apps met these characteristics. In the same way, 57 apps that were more than 2 years old without receiving updates from the developer were excluded, finally leaving 18 apps in the inclusion phase.

In Table 1, the names of the selected apps, their identification screens, developer names, required Android operating system

version, and the date of the last update are presented. All the listed mobile apps focus on human anatomy, are available in English or Spanish, have a user rating above 4.3, can be downloaded for free, and have more than 100,000 downloads.

Evaluation of Mobile Apps

MARS Overall Quality Scores

The average overall MARS quality score (ie, sections A, B, C, and D) was rated as "good" (mean 4.02, SD 0.20) [75]. The 3 mobile apps with the highest overall MARS quality scores (ie, averages of sections A, B, C, and D) were Organos internos 3D (anatomía) (mean 4.34, SD 0.29), Sistema óseo en 3D (Anatomía) (mean 4.32, SD 0.28), and VOKA Anatomy Pro (mean 4.29, SD 0.28). In contrast, the apps with the lowest overall MARS quality scores were Anatomy–3D Atlas (mean 3.66, SD 0.27), Complete Anatomy 2024 (mean 3.73, SD 0.32), and Visual Anatomy Lite (mean 3.80, SD 0.28). The average overall MARS quality scores are listed in Table 2.

Table 2. Average Mobile App Rating Scale quality scores (sections A, B, C, and D).

App name	Section A—engagement (mean 3.69, SD 0.20), mean (SD)	Section B—functionality (mean 4.36, SD 0.22), mean (SD)	Section C— aesthetics (mean 4.14, SD 0.21), mean (SD)	Section D—information (mean 3.90, SD 0.23), mean (SD)	Arithmetic average A, B, C, and D (mean 4.02, SD 0.20), mean (SD)
Organos internos 3D (anatomía)	3.96 (0.19)	4.65 (0.19)	4.43 (0.23)	4.30 (0.13)	4.34 (0.29)
Sistema óseo en 3D (Anatomía)	3.98 (0.28)	4.63 (0.19)	4.47 (0.15)	4.22 (0.17)	4.32 (0.28)
VOKA 3 d Anatomy and Physiology	3.94 (0.11)	4.60 (0.24)	4.37 (0.12)	4.23 (0.05)	4.29 (0.28)
Anatomy Learning-Anatomía 3D	3.88 (0.15)	4.55 (0.13)	4.27 (0.31)	4.20 (0.24)	4.22 (0.28)
Flashcards de Daily Anatomy	3.82 (0.28)	4.55 (0.10)	4.30 (0.20)	4.05 (0.10)	4.18 (0.32)

Complete Anatomy 2024	3.34 (0.09)	4.05 (0.31)	3.93 (0.06)	3.58 (0.08)	3.73 (0.32)
Anatomía–Atlas 3D	3.36 (0.05)	4.00 (0.08)	3.70 (0.30)	3.57 (0.23)	3.66 (0.27)

MARS Section Scores (Sections A, B, C, and D)

The mean (SD) for the "engagement" section (ie, section A) was 3.69 (0.20). The 3 top-rated apps in this section were Sistema óseo en 3D (Anatomía) (mean 3.98, SD 0.28), Organos internos 3D (anatomía) (mean 3.96, SD 0.19), and VOKA Anatomy Pro (mean 3.94, SD 0.19). In contrast, the 3 apps with the lowest scores in section A were Complete Anatomy 2024 (mean 3.34, SD 0.09), Anatomy–3D Atlas (mean 3.36, SD 0.05), and Visual Anatomy Lite (mean 3.44, SD 0.05).

For the "functionality" section (ie, section B), the mean (SD) was 4.36 (0.22). The top-rated apps were Organos internos 3D (anatomía) (mean 4.65, SD 0.19), Sistema óseo en 3D (Anatomía) (mean 4.63, SD 0.19), and VOKA Anatomy Pro (mean 4.60, SD 0.24). Conversely, the 3 apps with the lowest scores in this section were Anatomy–3D Atlas (mean 4.00, SD 0.08), Complete Anatomy 2024 (mean 4.05, SD 0.31), and Visual Anatomy Lite (mean 4.08, SD 0.35).

Regarding the "aesthetics" section (ie, section C), the mean (SD) was 4.14 (0.21). The highest-rated apps were Sistema óseo en 3D (Anatomía) (mean 4.47, SD 0.15), Organos internos 3D (anatomía) (mean 4.43, SD 0.23), and Teach Me Anatomy (mean 4.40, SD 0.20). In contrast, the lowest-scoring apps in this section were Anatomy–3D Atlas (mean 3.70, SD 0.30), Complete Anatomy 2024 (mean 3.93, SD 0.06), and Gray's Anatomy-Anatomy Atlas (mean 3.93, SD 0.06).

For the "information quality" section (ie, section D), the mean (SD) was 3.90 (0.23). The highest-rated apps were Organos internos 3D (anatomía) (mean 4.30, SD 0.13), VOKA Anatomy Pro (mean 4.23, SD 0.05), and Sistema óseo en 3D (Anatomía) (mean 4.22, SD 0.17). In contrast, the lowest-scoring apps in this section were Anatomy–3D Atlas (mean 3.57, SD 0.23), Complete Anatomy 2024 (mean 3.58, SD 0.08), and Anatomy by Muscle and Motion (mean 3.60, SD 0.13; Table 2).

Subjective Quality Evaluation (Section E) and Perceived Effectiveness (Section F)

The general mean (SD) for the "subjective quality" section (ie, section E) was 3.63 (0.22). The 3 top-rated mobile apps in this section were VOKA Anatomy Pro (mean 3.95, SD 0.10), Organos internos 3D (anatomía) (mean 3.93, SD 0.17), and Sistema óseo en 3D (Anatomía) (mean 3.88, SD 0.22). Conversely, the 3 apps with the lowest scores in this section were Anatomy–Atlas 3D (mean 3.25, SD 0.10), Complete Anatomy 2024 (mean 3.28, SD 0.15), and Esqueleto|Anatomía 3D (mean 3.35, SD 0.19). The average scores for section E are listed in Table 3.

Regarding the "perceived effectiveness" section (ie, section F), the recorded mean (SD) was 3.65 (0.18). The 3 top-rated apps with the highest scores were Organos internos 3D (anatomía) (mean 3.93, SD 0.10), VOKA Anatomy Pro (mean 3.90, SD 0.11), and Sistema óseo en 3D (Anatomía) (mean 3.87, SD 0.15). In contrast, the 3 apps with the lowest scores in this

section were Complete Anatomy 2024 (mean 3.37, SD 0.20), Anatomy–Atlas 3D (mean 3.40, SD 0.13), and Visual Anatomy Lite (mean 3.45, SD 0.15). The average scores for section F are listed in Table 4.

The section with the highest score was "functionality" (ie, section B), with a mean (SD) of 4.36 (0.22), followed by "aesthetics" (ie, section C), which scored a mean (SD) of 4.14 (0.21). In the third place was "information quality" (ie, section D), with a mean (SD) of 3.90 (0.22), followed by "engagement" (ie, section A), with a mean (SD) of 3.69 (0.20). The fifth position corresponded to "perceived effectiveness" (ie, section F), with a mean (SD) of 3.65 (0.18), while the sixth and final position was occupied by "subjective quality" (ie, section E), with a mean (SD) of 3.63 (0.22). It is notable that the app-specific score (ie, section F) was higher than the subjective quality score (ie, section E), although the latter was lower than the overall MARS quality score (mean 4.02, SD 0.20). This is demonstrated in Figure 2.

Table 3. Average score for "subjective quality" (section E).

App name	Section E—subjective quality (mean 3.63, SD 0.22), mean (SD)
VOKA 3d Anatomy and Physiology	3.95 (0.10)
Organos internos 3D (anatomía)	3.93 (0.17)
Sistema óseo en 3D (Anatomía)	3.88 (0.22)

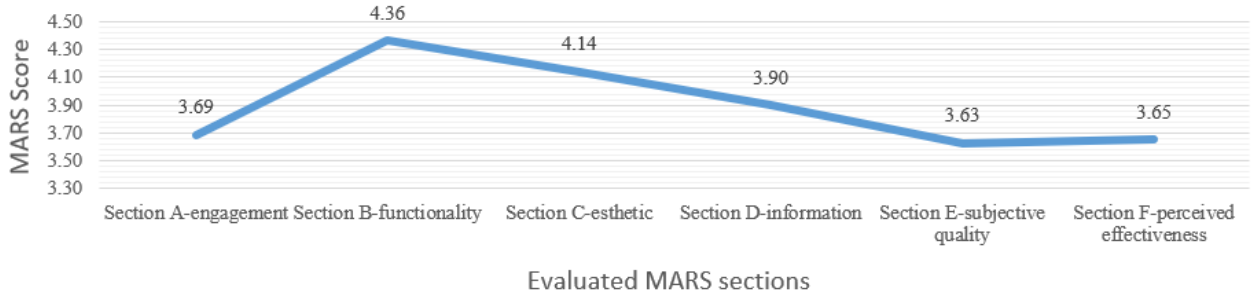
Figure 2. Average scores by the Mobile App Rating Scale (MARS) sections.



Average Scores by Section and Item

The following section details the items that received the highest and lowest scores in the various evaluated sections. In section A, item 5 concerning the target population received a mean score of 3.87 (SD 0.24), whereas item 4 related to interactivity scored a mean value of 3.52 (SD 0.20). In section B, item 6 on performance received the highest score with a mean value of 4.57 (0.14), followed by item 8 related to navigation with a mean score of 4.24 (SD 0.23). In section C, item 11 concerning graphics received a mean score of 4.37 (SD 0.28), and item 12 on visual appeal scored a mean value of 4.02 (SD 0.26). In section D, item 17 on the quality of visual information received a mean score of 3.98 (SD 0.24), whereas item 18 on credibility scored a mean value of 3.83 (SD 0.31). In section E, item 23 on overall quality received a mean score of 3.79 (SD 0.20), and item 22 on willingness to pay for the app scored a mean value of 3.52 (SD 0.24). Finally, in section F, the item with the highest overall mean score was "attitudes," with a mean value of 3.77 (SD 0.23), whereas the item "help seeking" received the lowest score (mean 3.54, SD 0.23). The mean scores with respect to the section and items are listed in Table 5.

Table 5. Mean scores by section and item.

Section and item	Scores, mean (SD)
Section A—engagement (mean 3.69, SD 0.20)	
Item 1. Entertainment	3.67 (0.35)
Item 2. Interests	3.78 (0.28)
Item 3. Customization	3.59 (0.20)
Item 4. Interactivity	3.52 (0.20)
Item 5. Target population	3.87 (0.24)
Section B—functionality (mean 4.36, SD 0.22)	
Item 6. Performance	4.57 (0.14)
Item 7. Ease of use	4.37 (0.37)
Item 8. Navigation	4.24 (0.23)
Item 9. Gestural design of the app	4.27 (0.23)
Section C—aesthetics (mean 4.14, SD 0.21)	
Item 10. Design	4.04 (0.19)
Item 11. Graphics	4,37 (0.28)
Item 12. Visual appeal	4.02 (0.26)
Section D—quality of information (mean 3.90, SD 0.23)

[a]No apps presented explicit scientific support in the descriptions and comments.

MARS Overall Quality Scores and Star Rating (Item 23)

The overall MARS quality scores were higher than the scores for item 23 (ie, subjective quality). Similarly, the overall MARS star ratings (ie, item 23) were lower than the star ratings in the Google Play store (Table 6).

Table 6. Overall MARSa quality scores, overall star ratings for item 23, and star ratings in the Google Play store.

App name	Health professionals		Users	
	MARS overall quality score (mean 4.02)	MARS (item 23; mean 3.79)	Star rating in the Google Play store (mean 4.63)	Downloads

[a]MARS: Mobile App Rating Scale.

Statistical Analysis

ICC (Assessment Reliability)

The average reliability measures of the evaluation ranged from "good" to "excellent." In the engagement section (ie, section A), an ICC of 0.892 (95% CI 0.807-0.952) was obtained. In the functionality section (ie, section B), the ICC was 0.901 (95% CI 0.822-0.956). In the aesthetics section (ie, section C), an ICC of 0.866 (95% CI 0.758-0.941) was recorded. In the information quality section (ie, section D), the ICC was 0.890 (95% CI 0.804-0.951). In the subjective quality section (ie, section E), an ICC of 0.862 (95% CI 0.751-0.939) was obtained. Finally, in the app specificity section (ie, section F), an ICC of 0.868 (95% CI 0.764-0.941) was recorded. Similarly, the reliability of the overall MARS quality evaluation (ie, average of sections A, B, C, and D) was classified as "excellent," with an ICC of 0.912 (95% CI 0.820-0.963).

Pearson Correlation

For the calculation of Pearson correlation coefficient, the average MARS quality scores and the scores for subjective item 23 from section E presented earlier in Table 6 were considered. The result showed an excellent correlation (r=0.989, P<.001; Table 7). Also, the 95% CI for this correlation was 0.971 to 0.996, based on the Fisher r-to-z transformation.

Table 7. Pearson correlation results.

Correlations	MARS overall quality score	MARS (item 23)
MARS overall quality score		
Pearson correlation	1	0.989[a]
P value (bilateral)	__[b]	<.001
N	19	19
MARS (item 23)		
Pearson correlation	0.989[a]	1
P value (bilateral)	<.001	—
N	19	19

[a]The correlation is significant at the .01 level (2 sided).

[b]Not applicable.

Discussion

Overview

The primary objective of this study was to identify and assess the quality of mobile apps related to human anatomy available on Google Play using the MARS. This scale focuses on the usability and accessibility of mobile health apps, considering aspects such as engagement, functionality, aesthetics, information quality, subjective quality, and app specificity. The MARS organizes the evaluations of the apps into 3 different dimensions. The first dimension includes sections A, B, C, and D and focuses on the evaluation of the objective technical items. The evaluations in the second and third dimensions are subjective and are divided into 2 sections: section E, which considers the evaluator's personal appreciation, and section F, which focuses on the perceived effectiveness. These 3 dimensions are crucial because, while mobile health apps must meet functionality and design standards, the evaluator's perception and the app's impact are determinants for its adoption. In addition, the MARS sections cannot be considered in isolation, as they are interrelated and influence each other.

Principal Findings

In the first dimension of the MARS, the best-rated section was "functionality" with a mean score of 4.36, followed by "aesthetics" with a mean score of 4.14, "information quality" with a mean score of 3.90, and, finally, "engagement" with a mean score of 3.69, which was the least valued. Although the apps generally received a good average score, it is crucial to examine the relatively low ratings in fundamental aspects such as engagement (mean score 3.69) and look for solutions. In order to strengthen the engagement section (ie, section A), which is made up of items 1 to 5 of the MARS (ie, entertainment, interest, personalization, interactivity, and target population), specific recommendations can be applied for each item. In item 1 (ie, entertainment), it is suggested to integrate elements such as gamification, challenges, achievements, rewards, or progressive levels and use good quality graphics, attractive colors, animations, and multimedia content (eg, videos and music) to make the user experience more attractive. In item 2 (ie, interest), it is recommended to include new content and personalized reminders. For item 3 (ie, personalization), it is recommended that users be able to adjust themes, difficulty levels, colors, or display modes according to their preferences, as well as the use of artificial intelligence to offer suggestions based on the user's preferences. Regarding item 4 (ie, interactivity), it is suggested to incorporate interactive content such as questionnaires and practical activities that require active participation, as well as real-time communication to forums, live chats, or social interactions to encourage collaboration between users and provide immediate feedback to correct errors or recognize achievements. Finally, in item 5 (ie, target population), it is recommended to carry out previous studies on the characteristics and needs of the target population, such as age, educational level, and cultural context, and ensuring that the content, graphics, and design are consistent with the population for which the app was designed.

The average general quality score according to the MARS (ie, sections A, B, C, and D) was good (mean score 4.02), supported by excellent reliability with an ICC of 0.912 and a 95% CI of 0.820 to 0.963. The mobile apps that excelled in overall quality according to the MARS (ie, sections A, B, C, and D) were Organos internos 3D (anatomía) with a mean score of 4.34, Sistema óseo en 3D (Anatomía) with a mean score of 4.32, and VOKA Anatomy Pro with a mean score of 4.29. These results indicate that these apps, having received high scores and offering high-quality content, can be recommended for users interested in learning human anatomy. In the second and third dimensions of the MARS, corresponding to sections E and F, where the impact on the user is more significant, the lowest average scores were recorded: subjective quality with a mean score of 3.63 and app specificity with a mean score of 3.65. These ratings were even lower than the general quality score of the MARS, which was 4.02.

These results underscore the importance of conducting a thorough analysis of all the 3 dimensions of the MARS; otherwise, apps that are technically well developed might be overvalued, whereas those that receive better subjective ratings from users could be overlooked. This indicates that developers of human anatomy mobile apps should not only address aspects of functionality, aesthetics, engagement, and information but also actively consider user perception and the impact of their

apps. There are various practical uses of the study's results, such as a more appropriate selection of mobile apps in the student context or in medical practice, where those that obtained a higher score in the MARS evaluation are chosen, which provide greater reliability and comfort in use.

Another relevant point of discussion is that the MARS, specifically item 19 (ie, section D), which addresses "information quality," assesses whether mobile apps have scientific foundations that support their usefulness. However, the apps evaluated in this study did not present explicit scientific support in the descriptions and comments provided by the developers, which is why they lack a rating in item 19 of the MARS evaluation.

Therefore, it is crucial that research centers and universities get involved in the development of mobile health apps so that they are supported by scientific research and can be hosted in app stores to make them accessible to the general public. Collaboration among software developers, health professionals, researchers, and academics in the creation and review of educational materials for a medical mobile app would generate greater confidence in its use. In addition, conducting validation studies in real learning environments also plays an important role in assessing the quality and effectiveness of apps through various methodologies, such as the MARS framework discussed in this study.

Limitations

The main limitations are the exclusion of paid apps, apps in languages other than English or Spanish, and apps with a star ratings less than 4.3. In addition, the search was limited to apps present in the Google Play store. Although these criteria may seem restrictive, English is the predominant language in global medical education, ensuring that the evaluated apps covered a substantial portion of the app market. However, the exclusions may limit the scope, particularly by omitting paid apps, which in certain cases may offer higher-quality content that could facilitate and enhance the learning of anatomy. To address these limitations in future research, inclusion criteria could be expanded to incorporate human anatomy mobile apps available in other languages or those that are paid, creating a broader repertoire for analysis. This approach would also enable comparative studies, such as exploring potential differences between free apps and those requiring a license or payment.

Conclusions

This study provides a comprehensive and detailed analysis of apps available for teaching human anatomy, aimed at health care professionals, medical students, and interested users. For example, students and health professionals can both use a human anatomy mobile app before orthopedic surgery to consult a 3D model of the leg of a patient with a femur fracture. This would allow them to more accurately understand the location of bones, blood vessels, and muscles in the affected region, contributing to greater success in the procedure.

Overall, the evaluated apps demonstrated high quality, particularly excelling in functionality and aesthetic design. However, some apps need to improve aspects such as user engagement (ie, section A) and the quality of the information provided (ie, section D). Among the highest-rated apps according to the MARS are Organos internos 3D (anatomía), Sistema óseo en 3D (Anatomía), and VOKA Anatomy Pro.

The subjective MARS score (ie, item 23) was 3.79, in contrast to the average rating of 4.63 given by users on the Google Play store. This suggests that evaluators provided lower ratings, whereas users tend to overrate the apps. This discrepancy may stem from the fact that evaluators typically adhere to more rigorous and objective criteria, systematically assessing technical, functional, and usability aspects. Professional evaluators are often more critical regarding technical implementation and practical utility.

In contrast, users base their ratings on personal and subjective experiences, scoring according to their expectations and the level of satisfaction experienced while using the app. Both perspectives offer valuable feedback: on the one hand, an objective evaluation of quality, and on the other hand, a subjective evaluation of user satisfaction. This difference in ratings does not negatively impact the overall MARS evaluation of the apps. Instead, it provides a perspective where both developers and potential users can identify strengths and areas for improvement from complementary approaches.

This study highlights the evolving role of mobile apps as transformative tools in medical education by offering innovative solutions for accessibility and interactivity in learning. Mobile apps use advanced features such as 3D models, simulations, and dynamic interfaces, and these tools overcome the limitations of traditional methods of teaching human anatomy, such as the scarcity of cadavers and high costs of dissection laboratories. In addition, they facilitate personalized learning of topics and selection of difficulty levels. They allow continuous access, allowing students to practice and reinforce their knowledge anytime, anywhere.

To maximize the impact of mobile apps in medical education, we suggest strategies focused on design and functionality, such as the incorporation of gamification elements, challenges, and rewards to increase user motivation, as well as strengthening interactivity through real-time feedback, collaborative learning tools, and interactive clinical cases. It is essential to align the content of the apps with medical education curricula to ensure their relevance and applicability. Similarly, we recommend combining their use with traditional methods, such as face-to-face classes and laboratory practice, to offer a comprehensive learning experience. Training teachers to integrate these tools into their teaching methodologies is also essential. Finally, to guarantee both the scientific rigor and the accessibility of these mobile apps, we propose collaboration with universities and research centers to develop content based on solid scientific evidence.

Abstract

Background: Gender is increasingly recognized as a crucial determinant of health and health care delivery. Integrating gender-sensitive content into medical education is essential for cultivating socially responsive, culturally competent, and clinically effective physicians of the future. However, limited research has examined how medical students conceptualize gender in clinical contexts, particularly through their own reflective narratives.

Objective: This study explores the thematic landscape of gender-related perceptions among first-year medical students in Israel following a mandatory course in gender medicine. Using latent semantic analysis (LSA), we examined how students reflected on gendered dimensions of health care and how these reflections varied by gender and ethnicity.

Methods: First-year medical students enrolled in the four-year path of medicine in Israel participated in a compulsory gender medicine course and were invited to submit anonymous written reflections. A total of 83 students (n=52, 63%, females; n=31, 37%, males; n=68, 82%, Jewish; and n=15, 18%, Arab) submitted responses, which were preprocessed and analyzed using LSA. The texts were lemmatized and vectorized to construct a term-document matrix, followed by singular value decomposition for dimensionality reduction. Ten latent topics were extracted, and thematic labels were assigned through an inductive, consensus-based coding procedure. Subgroup analyses were conducted by gender and ethnicity.

Results: LSA identified 10 distinct topics, accounting for 56.6% of the total variance in the overall sample. The most dominant theme was Gendered Patient-Doctor Interactions (eigenvalue=121.188; 28.1% variance; 527 terms; 75 documents), followed, in terms of variance, by Gender-Specific Diseases and Health Concerns (5.7%) and Cultural and Religious Influences on Health Care (4.3%). Reflections from female students introduced 3 unique themes: Gendered Help-Seeking and Familial Roles (2.8%), Gender and Health Education (2.5%), and Gendered Communication and Advocacy (2.2%). Male students uniquely discussed Perceived Gender Bias in Clinical and Research Settings (3.8%) and the Legal and Ethical Dimensions of Reproductive Health Care (3.3%). Among Jewish students, additional themes included Population-Level Framing of Gendered Conditions (3.7%) and Gendered Youth Expectations (2.1%). Arabic students contributed culturally specific themes, such as Modesty and Cultural Norms (8.6%), Paternal Authority and Structural Discrimination (6.3%), and Reproductive Vulnerability (3.6%).

Conclusions: Thematic patterns in student reflections suggest that gender medicine curricula are effective in fostering critical engagement with diverse gendered realities in clinical care. The emergence of culturally grounded and gender-specific themes underscores the importance of tailoring educational interventions to reflect student diversity.

Introduction

Sex and gender are distinct yet interrelated factors that shape health, health care access, and, ultimately, health outcomes in multiple and profound ways [1]. While sex refers to biological attributes such as chromosomes, hormones, and reproductive anatomy that typically categorize individuals as male or female, gender encompasses the socially constructed roles, behaviors, expressions, identities, and power relationships associated with being a man, woman, or gender-diverse person [2,3]. As a social determinant of health, gender intersects with biological factors as well as with other cultural, societal, and systemic constructs to influence the incidence, prevalence, and manifestation of diseases, diagnostic pathways, therapeutic decisions, clinical interactions, and patient experiences across the care *continuum* [4-6].

Despite increasing recognition of these dynamics and interwoven interplays, medical education has historically followed a reductionist biomedical model that often underrepresents or insufficiently integrates sex- and gender-sensitive perspectives [7]. In recent years, sex- and gender-based medicine has emerged as a multidisciplinary field aimed at addressing these gaps by incorporating the complexities of sex- and gender-specific differences into clinical education, research, and practice [8].

Embedding sex- and gender-based medicine into undergraduate medical curricula is essential for preparing future physicians to recognize and respond to sex- and gender-based disparities in health care delivery, enhance diagnostic accuracy, and foster more equitable patient care [9,10]. However, most medical schools do not offer a formal, integrated curriculum in sex- and gender-sensitive medicine; when included, content is often confined to reproductive health and rarely extends to other specialties such as cardiology, pharmacology, or psychiatry. Educators have expressed concerns about the lack of standardized materials, institutional support, and faculty preparedness, all of which hinder implementation. Students, while generally receptive, often report minimal exposure to these topics, and when presented, content is frequently framed in binary, biologically deterministic terms [11]. Despite these limitations, increasing evidence shows that structured educational interventions can raise awareness of implicit bias and promote more equitable clinical practice [12,13].

Yet little is known about how students internalize and reflect on sex- and gender-sensitive content when it is presented within a formal curriculum [14]. This gap underscores the need for qualitative and data-driven evaluations of student perspectives to better inform curriculum design and pedagogical strategies. Narrative reflection provides a window into students' evolving attitudes and cognitive engagement with sex and gender in clinical contexts [14,15]. It is a tool grounded in constructivist learning theory, which posits that learners actively construct knowledge through experience, reflection, and social interaction rather than passively absorbing facts [15]. Rooted in the work of Piaget, Vygotsky, and others, constructivism emphasizes that meaning-making is contextual and shaped by prior knowledge, cultural frameworks, and active engagement. In health professions education, constructivist approaches have gained traction as educators recognize the limitations of didactic instruction in preparing students for the complex, value-laden, and relational aspects of clinical care, such as those encountered in sex- and gender-based medicine. Reflective writing further enables learners to make sense of the social and ethical dimensions of medicine, including issues of power, identity, and equity [16].

By leveraging narrative reflection and a computational linguistic framework, this study aims to elucidate how students conceptualize sex and gender in medical practice and to identify thematic patterns that vary by gender and ethnicity within a diverse multicultural educational context. Through written reflections, students engage in metacognitive processing of sex- and gender-related content presented during the course. These narratives serve not only as evidence of individual meaning-making but also as artifacts that reveal the evolving cognitive, emotional, and ethical dimensions of learners' understanding. Within the constructivist paradigm, reflection functions as both a tool and a product of learning, enabling students to surface biases, grapple with complexity, and reconcile new information with existing worldviews.

Specifically, we asked (1) what thematic patterns emerge in first-year medical students' reflections following a formal course in sex- and gender-based medicine? and (2) how do these patterns differ by students' gender and ethnicity? Based on prior literature on sex and gender awareness in medical education [12,13,17,18], we hypothesized that the reflections would reveal themes capturing both clinical and sociocultural dimensions of sex and gender in medicine. These themes were expected to include recognition of sex- and gender-specific differences in disease incidence, prevalence, presentation, and outcomes; awareness of gender bias in clinical practice as presented during the course; and acknowledgment of the role of sociocultural norms in shaping health care experiences. Given the absence of prior extensive clinical exposure, we anticipated that students' narratives would primarily integrate knowledge gained from the structured curriculum with their preexisting personal,

cultural, and societal perspectives on sex, gender, and health. We further expected thematic emphases to vary by students' gender, with potential differences in the extent to which narratives addressed interpersonal, affective, and patient-centered aspects of care alongside structural, biomedical, or systems-level considerations. We also anticipated that students from different ethnic backgrounds would foreground culturally specific norms, values, and challenges in applying sex- and gender-based medicine principles. By articulating these differences, this study aims to provide medical educators with evidence to design more culturally responsive and pedagogically effective curricula in sex- and gender-sensitive medicine.

Methods

Study Population

The participants were first-year medical students enrolled in the 4-year medical program at the Azrieli Faculty of Medicine, Bar-Ilan University, Safed, Israel. They attended a mandatory sex- and gender-based medicine course as part of their curriculum. All students provided written reflections on their experiences and learning outcomes, which constituted the textual dataset for analysis.

Ethical Considerations

This study adhered to ethical guidelines for educational research. Written informed consent was obtained from all students before data collection. Institutional ethical approval was granted by the Human Subjects Institutional Review Board at Bar-Ilan University, Safed, Israel (approval number 040325496). Participation was entirely voluntary, and students' reflections were anonymized and used solely for academic and research purposes.

Course Syllabus

The course Sex- and Gender-Based Medicine was designed to introduce and deepen understanding of key concepts, theories, and practices in sex- and gender-sensitive medicine, emphasizing how sociocultural and institutional determinants shape health disparities.

Over 7 structured first-year sessions, each consisting of a 90-minute plenary lecture followed by a 90-minute small-group practice, students developed both conceptual and applied competencies for integrating a sex- and gender-aware perspective into clinical practice and medical research.

Using Bloom's taxonomy [19], the learning progression moved from remembering (defining sex and gender; describing biological, social, and cultural determinants) and understanding (explaining how sex and gender influence biological systems, disease manifestation, health-seeking behavior, and access to care) to applying (using a sex- and gender-sensitive lens to analyze case studies such as women with chest pain or men with breast cancer), analyzing (identifying bias in biomedical research design and interpretation), evaluating (assessing the impact of policy, feminist theories, and global perspectives on health care delivery), and creating (formulating strategies to address inequities and adapt medical innovations for diverse populations).

Learning activities combined plenary lectures with small-group sessions featuring case-based discussions, simulations with standardized patients, podcast analyses, and reflective exercises. The curriculum integrated national and global perspectives, traced the historical evolution of feminist thought and its influence on medicine, examined gender gaps in research, and critically analyzed the effects of bias on health care delivery and innovation.

Students were required to attend at least 80% of sessions and submit a written reflection, for instance, applying a sex- and gender-sensitive framework to a clinical scenario, thereby demonstrating mastery of course objectives across multiple levels of cognitive engagement.

Reflective Writing Assignment and Prompts

At the conclusion of the Sex- and Gender-Based Medicine course, students were required to submit a 1-page written reflection as a mandatory graded assignment. The prompt invited them to describe and critically analyze their learning experience, drawing on lectures, small-group discussions, case-based exercises, or personal experiences relevant to sex- and gender-sensitive medicine. Students were encouraged to focus either on a specific event or on their overall experience, integrating description, interpretation, and self-analysis.

The assignment was structured around the DIEP (Describe, Interpret, Evaluate, and Plan) model guiding students to (1) describe the chosen experience or case; (2) interpret the actions, motives, emotions, and contextual factors involved; (3) evaluate their own responses and the quality of their engagement; and (4) plan how to apply the insights gained to future academic, clinical, or research contexts. To support the reflective process, students were given stepwise guidance: identifying the experience, describing the learning process, engaging in introspection, recognizing shifts in perspective or values, and directing the reflection toward future practice. They were encouraged to write in the first person and connect their reflections to personal perspectives and professional aspirations. Model phrases were provided to help articulate reflective thinking (eg, "This experience made me aware of...", "Looking back at what happened..."). All submissions received individualized feedback aimed at deepening reflective skills.

Data Collection and Preprocessing

The dataset consisted of written responses submitted by students at the conclusion of the course. These reflections were collected electronically and compiled into a structured corpus for text mining. The responses varied in length and complexity, reflecting diverse perspectives on gender-related topics in medicine. Before analysis, all textual data underwent preprocessing to ensure the reliability of results. This included tokenization, stop-word removal, stemming, and lemmatization. Text was converted to lowercase, and punctuation and nonalphabetical characters were removed to standardize the dataset. Common medical terminology and gender-related terms were retained to preserve contextual relevance. Preprocessing was performed using the English stopword list and English-language stemming algorithms.

Statistical Analysis

This study used latent semantic analysis (LSA) to examine the perceptions and conceptualizations of gender medicine among Israeli first-year medical students. LSA is a computational information-processing method for humanlike, meaning-based cognitive tasks, including the extraction of conceptual meaning from large textual *corpora*. It addresses the question of "how word and passage meaning can be constructed from experience with language, that is, by what mechanisms—instinctive, learned, or both—this can be accomplished" [20]. In LSA, "words do not have meanings on their own..., words get their meanings from their mapping" [20], and it is "the underlying map (that) is (to say) the primitive substrate that gives words meaning, not vice versa" [20]. LSA recognizes that people rarely communicate using isolated words but typically speak and comprehend clusters of words, often extending beyond a single sentence. Such units of meaning are more accurately represented at the level of paragraph-length discourse.

More technically speaking, LSA relies on the "compositional constraint," which posits that "the representation of any meaningful passage must be composed as a function of the representations of the words it contains" [20]:

"LSA learns about the meaning of a word from every meeting with it and from the composition of all the passages in which it does not occur...Word meaning is latent in the evidence of experience and can be extracted from natural linguistic data" [20].

The LSA technique has been increasingly applied in health professions education to analyze reflective narratives and explore students' mental models [21,22]. By identifying patterns of word co-occurrence and reducing linguistic dimensionality, LSA detects latent themes that may not be readily apparent through manual coding alone. It thus offers a scalable, data-driven approach to evaluating the impact of educational interventions, particularly in areas involving subjective and contextually embedded content such as gender.

A term-document matrix was constructed using a bag-of-words representation with a minimum term frequency of 2 and a sparsity threshold of 0.975. Singular value decomposition was applied to reduce dimensionality and reveal key semantic relationships between words. The number of topics was determined using an optimal singular value selection approach to capture the most relevant themes without overfitting the data. LSA was first performed on the overall sample to identify global themes and semantic structures, followed by stratified analyses by gender and ethnicity.

Following LSA, the resulting topics were manually reviewed and labeled according to their most representative words. Two independent researchers (RKF and NLB) conducted the topic interpretation to ensure reliability, resolving discrepancies through discussion until consensus was reached. A hybrid coding approach was applied: an initial a priori codebook was developed based on the study's research questions and prior literature on sex- and gender-based medicine. This preliminary framework included categories expected to capture both clinical and sociocultural dimensions of student reflections. The codebook was then iteratively refined in a data-driven manner, consistent with constructivist theory, through manual review of the topic-modeling outputs and a subset of student narratives. This process allowed for the addition of new codes and the consolidation or clarification of existing ones. In doing so, the final set of codes reflected both theoretically informed expectations and emergent themes in the data, thereby enhancing the validity and reproducibility of the analysis.

The codebook, including a priori categories, their definitions, and emergent subcodes within each category, is presented in Table 1.

All LSA procedures were conducted using XLSTAT (Lumivero, LLC).

Table 1. Codebook for the thematic analysis.

A priori category	Definition	Emergent subcodes
Clinical Applications of Sex- and Gender-Based Medicine	Recognition of how sex and gender influence disease incidence and prevalence, presentation, outcomes, pharmacology, and decision-making in clinical contexts	Gender and Decision-Making in Medicine; Gender Differences in Pharmacology; Gender Differences in Pharmacology and Disease Education; Gender-Specific Diseases and Health Concerns; Reproductive Health and Feelings of Vulnerability
Sociocultural Influences on Health	Influence of cultural, religious, and social norms on health beliefs, access, and care delivery	Cultural and Religious Influences on Health Care; Cultural and Social Attitudes Toward Gender and Health; Cultural Norms in Clinical Settings; Gendered Help-Seeking and Familial Roles; Gendered Youth, Expectations, and Identity Formation; Intergenerational and Familial Perspectives on Gendered Health
Educational and Institutional Contexts	The role of medical education, institutional structures, and team dynamics in shaping awareness and practice of gender-sensitive medicine	Gender and Health Education; Gender Equality and Team Dynamics; Gender Roles in the Medical Profession; Institutional and Interpersonal Perspectives on Gender; Perceived Gender Bias in Clinical and Research Settings
Health Access and Equity Issues	Barriers and facilitators to equitable health care for diverse gender identities	Gender and Public Health Framing of Conditions; Health Care Access for Transgender Individuals; Legal and Ethical Dimensions of Gendered Health Care
Gendered Communication and Relationships	How gender influences patient-provider interactions, communication styles, and relational dynamics in care	Gendered Clinical Encounters; Gendered Communication and Assertion in Health Care Contexts; Gendered Patient-Doctor Interactions
Psychological and Emotional Dimensions of Gender and Health	Emotional, mental health, and psychosocial aspects linked to gender identity or experience	Paternal Authority and Structural Discrimination; Psychological and Emotional Dimensions of Gender and Health; Psychosocial Support and Gendered Distress

Results

Overview

All 83 students were recruited. Of these, 52 (63%) identified as female and 31 (37%) as male. In terms of ethnicity, 68 participants (82%) identified as Jewish and 15 (18%) as Arab.

In the overall sample analysis, LSA (Table 2) revealed a rich and multidimensional thematic structure, highlighting the broad spectrum of gender-related issues perceived by students in the context of medical education and clinical care.

In total, 10 distinct topics were identified. Topic 1 exhibited the highest eigenvalue (121.188), accounting for approximately 28.1% of the total variance, and demonstrated high lexical richness (527 terms) as well as strong document representation (75 documents). The primary terms within this topic indicate that students engaged critically with gendered dynamics in patient-doctor interactions, emphasizing gender as a determinant of health and its implications for clinical communication, empathy, and diagnostic equity. Beyond this dominant theme, topic 2, with an eigenvalue of 54.519 (5.68% of the explained variance), reflected students' awareness of gender-specific health concerns, particularly those disproportionately affecting women. This thematic axis reflects recognition of both the biological and social dimensions of illnesses such as breast cancer and their ramifications for patient care and support systems. Topic 3, with an eigenvalue of 47.175 and accounting for 4.26% of the overall variance, indicates that students considered how religious beliefs and cultural contexts intersect with gender identity and health care experiences, particularly for conditions such as endometriosis that are not only underdiagnosed but also socially stigmatized. This highlights the students' developing sensitivity to culturally competent care and the complexities of treating individuals within diverse socioreligious frameworks. The subsequent topics (topics 4-10) each accounted for between 3.49% and 1.90% of the variance, with eigenvalues ranging from 42.725 to 31.507. Topic 4 addressed the complex role of gender in shaping professional identities and hierarchies in medicine. This theme was further reflected in topics 7 and 8, which collectively examined gender-based dynamics in medical decision-making, team interactions, and perceived equality in clinical and academic settings. Topic 7 highlighted heightened student awareness of the gendered structures influencing teamwork, authority, and career progression within medicine, while topic 5 underscored students' growing recognition of transgender health concerns and the structural barriers to inclusive health care delivery. Topic 6 focused on gender pharmacology—particularly the often underappreciated physiological and hormonal differences that affect drug efficacy and therapeutic response. Topic 9 addressed students' reflections on interpersonal and institutional factors shaping gendered experiences within medical learning environments. Finally, topic 10 conveyed a nuanced consideration of the psychological and normative dimensions of gendered illness narratives, emphasizing students' awareness of how gender norms shape both the perception and lived experience of illness, as well as

the societal frameworks governing the provision of emotional support and care.

Table 2. Labeled topics identified through latent semantic analysis of student reflections following participation in a gender medicine course. Each topic is characterized by its corresponding eigenvalue, percentage of explained variability, key terms, and the thematically assigned label.

Topic	Label	Representative quotes	Eigenvalue	% Variability	Top words
Topic 1	Gendered Patient-Doctor Interactions	"For me, this was the first time I had to deal with questions of gender identity and the complex feelings of her and the team..." ". I intend to avoid pre-assumptions about gender identity and pay attention to how the environment may affect how patients feel..."	121.188	28.08	gender, patient, women, feel, doctor
Topic 2	Gender-Specific Diseases and Health Concerns	"We learned how much awareness is lacking about the disease among men, how male patients with breast cancer have to cope with coming to a ward where all the patients are women, and how their image is affected because the disease is perceived as a women's disease..." "In our world, the word "breast" or "breasts" is perceived as a feminine and maternal organ (for feeding a baby), and telling a man that he has breasts can be very difficult for him..."	54.519	5.68	diseas, breast, cancer, partner, didn
Topic 3	Cultural and Religious Influences on Health Care	"I spoke to my grandparents and tried to explain the situation to them in simple words, without medical terminology, I clarified that it would be documented in her medical record and that there would be no societal reason to look down on her, I reminded them that preventing treatment and causing harm to a person contradicts our religion..." "One particular issue that deeply resonated with me that was raised during the course is the prolonged time it often takes to diagnose endometriosis in women..."	47.175	4.26	peopl, comfort, religi, comprehens, endometriosi
Topic 4	Gender Roles in the Medical Profession	"I thought to myself why I was actually hurt by his behavior, maybe because I wanted to prove that I could fulfill the role no less than a male paramedic and I wanted to receive the treatment I deserved as a team leader, as a woman, as someone who spoke a different language..." "Dr. *** described to us how she participated in a discussion during one of the meetings of the heads of department, she was one of the few women, if not the only woman in such a senior and managerial role, surrounded by male colleagues..."	42.725	3.49	complex, role, profess, realiti, sick
Topic 5	Health Care Access for Transgender Individuals	"In our work as doctors, we may be required to address the unique issues of the transgender population..." "The case I chose to describe occurred several years ago and concerns my own and society's attitude toward a transgender soldier..."	40.302	3.11	base, transgend, servic, unit, serv
Topic 6	Gender Differences in Pharmacology	"I knew that drugs could affect women and men differently, but I was surprised to discover the extent of the difference..." "We were told that most drugs have been and are still being studied in men only..."	38.321	2.81	lectur, drug, dose, menstrual, gap
Topic 7	Gender and Decision-Making in Medicine	"This exposure pushed me to reflect on how gender-associated stigma influences my own life and decision-making..." "Returning to what happened in this case, it is clear that unconscious gender biases influenced medical decisions..."	36.769	2.59	student, woman, decis, separ, stori

Topic	Label	Representative quotes	Eigenvalue	% Variability	Top words
Topic 8	Gender Equality and Team Dynamics	"I had always treated all the women around me with respect and it was clear to me that men and women were equal..." "My values, based on human dignity and equality, pushed me to act in the girl's best interest..."	35.082	2.35	sister, equal, team, dr, incid
Topic 9	Institutional and Interpersonal Perspectives on Gender	"I feel that I have received significant tools for dealing with questions from patients, friends, and acquaintances on various topics..." "In addition, I learned from the case the importance and need for raising awareness of the issue and the great importance of training the staff to respect the identity of each person and allow them to receive the best medical care for them..."	34.349	2.26	subject, friend, biolog, staff, liber
Topic 10	Psychological and Emotional Dimensions of Gender and Health	"It was important to me that, during the meeting, she express herself to the doctor and raise the points that concerned her, so she could feel comfortable and overcome her fear and embarrassment..." "My choice of a gynecologist (rather than a doctor) was made mainly due to discomfort or fear of being examined by a male doctor, following unpleasant experiences and situations experienced by my friends and family..."	31.507	1.90	ill, fear, syndrom, norm, save

Subanalysis by Gender

The LSA of reflections from female medical students (Table 3) revealed that while several key topics were retained from the full-sample analysis, new themes also emerged, and some existing ones underwent lexical refinement and thematic expansion.

Topic 1 remained the most dominant, with topic 2 also consistent. Topic 3, however, demonstrated a partial thematic reorientation: while previously aligned with cultural and religious dimensions, it now emphasized communication and generational perceptions over doctrinal belief. Topic 4 incorporated a broader intersectional framing of gender complexity and patient autonomy. Similarly, topic 5 integrated educational and clinical discourse, with a particular focus on conditions such as breast cancer. Distinctively, several new themes emerged uniquely within the female-only dataset. Topic 6 introduced a previously unarticulated theme of Gendered Help-Seeking and Familial Roles, possibly reflecting caregiving norms and informal consultation practices. Topic 7 clarified the psychological and emotional dimensions of gender and health. Topic 8 suggested a pedagogical and developmental framing, while topic 9 reflected an intergenerational perspective on gendered health experiences. Finally, topic 10 revealed a discourse on self-expression, advocacy, and possible resistance to gendered dismissal or invalidation.

The LSA of reflections from male medical students (Table 4) showed that while most identified topics were retained, some exhibited lexical drift and partial thematic reorientation.

For instance, topic 6 indicated a shift toward a more biologically grounded understanding of gender. Topic 8 appeared to merge interpersonal reflections with the emotional and physical dimensions of team-based care, thereby becoming lexically broader in scope. Two new themes also emerged in the male-only analysis. Topic 9 reflected critical engagement with perceived gender bias in diagnostic processes and biomedical research. Finally, topic 10 introduced a novel legal and ethical discourse on reproductive health, suggesting that at least some male students approached gendered issues through a rights-based and normative framework.

Table 3. Labeled topics identified through latent semantic analysis of student reflections following participation in a gender medicine course in the female-only sample.

Topic	Label	Representative quotes	Eigenvalue	% Variability	Top words
Topic 1	Gendered Patient-Doctor Interactions	"The patient's actions and motivations stem from the enormous difficulty of dealing with rejection from her father and the lack of acceptance of the gender change she underwent..." "When I went to the doctors to find out the cause, they said it would pass, that I was a girl experiencing stress, or that it might be anxiety..."	101.038	31.89	patient, gender, doctor, women, medic
Topic 2	Gender-Specific Diseases and Health Concerns	"I learned a lot from my sister's case, I knew that I wanted to be a doctor even before the experience we went through as a family, but the aforementioned experience sharpened for me the importance of seeing the patient as a whole..." "At that time, I had been with my partner for about a year, I asked him to accompany me to the gynecologist due to pain I was experiencing..."	44.608	6.22	diseas, examin, sister, gynecologist, hospit
Topic 3	Cultural and Social Attitudes Toward Gender and Health	"From this experience, I realized that due to my gender and the doctor's prejudices, I received treatment that, in my opinion, was improper and disparaging..." "I think that there is at least some kind of shame and discomfort in society to talk about the subject, especially for a girl and even more challenging in an environment with boys..."	39.634	4.91	girl, peopl, opinion, talk, convers
Topic 4	Health Care Access for Transgender Individuals	"During my work as a nurse in the emergency room, I treated a patient who identified as a transgender woman..." "The patient had a psychiatric background and a past suicidal experience, which stemmed from the insults and bullying she experienced for being a transgender woman..."	36.700	4.21	respect, complex, menstrual, transgend, oper
Topic 5	Gender Differences in Pharmacology and Disease Education	"For example, we talked about breast cancer, which in most cases only affects women, and that is why most of the health system focuses on women..." "I realized that the patient experienced side effects following the dosage of the drug and that gender differences that may affect the pharmacokinetics and pharmacodynamics of the drug cannot be ignored..."	33.003	3.40	breast, cancer, lectur, student, drug
Topic 6	Gendered Help-Seeking and Familial Roles	"A few months ago, my aunt had a general check-up with her gynecologist, the results showed that she had a large polyp on her cervix..." "I felt anger toward both society and my grandparents because delaying the treatment would put my aunt's health and life at risk..."	30.062	2.82	aunt, help, step, consult, recommend
Topic 7	Psychological and Emotional Dimensions of Gender and Health	"I assume that this was due to the emotional difficulties that the syndrome brings with it..." "The doctor did not delve into the impact of the pain on my moods and did not refer me to further advice, but only gave me a prescription..."	28.420	2.52	discuss, mention, syndrom, save, delv
Topic 8	Gender and Health Education	"I plan to...continuously educate myself on gender and sex-specific health issues to improve my diagnostic skills..." "Medical education that emphasizes sex and gender medicine may improve awareness of many specific diseases, especially endometriosis, and lead to improved diagnosis and treatment..."	28.052	2.46	period, member, educ, boy, reach
Topic 9	Intergenerational and Familial Perspectives on Gendered Health	"Being nervous didn't make the exam any easier, and my mother, in her response, increased my concerns..." "This interested me because my mother had breast cancer and underwent a partial mastectomy and no doctor in the process talked about this issue..."	27.066	2.29	didn, mother, comprehens, comfort, age
Topic 10	Gendered Communication and Assertion in Health Care Contexts	"I remember trying to explain to the person in charge that I believed in that girl's pain, and that I thought it was better to leave her to rest in the room than to force her to travel while she was suffering..." "I feel like I didn't handle this situation very well because I let my emotions, the feeling that I felt attacked, manage my way of talking..."	26.382	2.17	group, explain, respond, don't, attack

Table 4. Labeled topics identified through latent semantic analysis of student reflections following participation in a gender medicine course in the male-only sample.

Topic	Label	Representative quotes	Eigenvalue	% Variability	Top words
Topic 1	Gendered Patient-Doctor Interactions	"It is possible that this was caused by unconscious gender stereotypes, as although the symptoms were typical of a heart attack, the doctors initially attributed them to stress or anxiety, delaying the correct diagnosis and appropriate treatment..." "In the course I had the experience of getting exposed to gender-based challenges in the health system..."	72.569	25.97	gender, feel, women, men, medic
Topic 2	Gender-Specific Diseases and Health Concerns	"During the Gender Medicine course we were presented with a scenario that highlighted the unique challenges faced by men who have been diagnosed with breast cancer, a condition primarily associated with women..." "For men dealing with diseases that are perceived as feminine, such as breast cancer, the lack of appropriate gender support can lead to feelings of not belonging and even avoidance of receiving essential care..."	41.085	8.32	breast, cancer, incid, –, moment
Topic 3	Health Care Access for Transgender Individuals	"The incident I chose to describe happened a few years ago and deals with the attitudes of myself and society towards a transgender soldier, the incident highlights challenges in military service..." "Indeed, the soldier arrived at my unit for a professional evaluation, while the HR personnel explained to me the complex living and service conditions that must be provided to a transgender soldier and how difficult it would be to arrange these conditions in my unit and therefore, they suggested it was not advisable for me to "deal" with such a soldier..."	39.584	7.73	base, transgend, servic, unit, train
Topic 4	Cultural and Religious Influences on Health Care	"This case highlighted the need to find a balance between respecting religious beliefs and maintaining equality and inclusion..." "This experience made me change my perspective on respecting religion and beliefs..."	34.938	6.02	student, decis, separ, belief, religi
Topic 5	Gender Equality and Team Dynamics	"There is an inconsiderate and unequal view of a woman's abilities just because she is a woman..." "The society [should] advocate for social equality without discrimination of sex and gender..."	34.212	5.77	equal, dr, manag, sister, role
Topic 6	Institutional and Interpersonal Perspectives on Gender	"The two-day course in sex and gender medicine was for me a small taste of the turbulent world of reality in our small country, which is at the heart of a clash between East and West, between religion and liberalism, between boundless freedom and compulsive conservatism..." "It also connects to Israeli reality, particularly the case of Alice Miller, who applied to become a pilot and the President of Israel, who was himself a former pilot, responded to her by saying "Just as women were meant to knit socks, flying planes is the domain of men, and one cannot change the order of the world"..."	32.122	5.09	subject, sex, realiti, world, biolog
Topic 7	Psychological and Emotional Dimensions of Gender and Health	"I connected with my partner's feelings; we both felt the disdain from the doctor and were very hurt by him..." "In general, the issue of treating a patient's body with sensitivity in front of us as medical professionals is something that is very important to me, for example, not long ago, when a woman about my age in my community called me because of chest pain that required an EKG..."	30.317	4.53	partner, topic, pain, question, long

Topic	Label	Representative quotes	Eigenvalue	% Variability	Top words
Topic 8	Gender and Decision-Making in Medicine	"During the treatment of the incident, which took place at the entrance to her home, the driver on my team, who is a paramedic by medical authority, lifted the woman's shirt to look for any other areas of rash besides what we saw..." "This incident stayed with me even later, on the next shifts I worked, and I literally promised myself that next time I would not let something like this happen when I was the team leader, and that even if I had unpleasantness in front of another team member, it was better than allowing something like this to happen..."	29.472	4.28	friend, hurt, team, bodi, high
Topic 9	Perceived Gender Bias in Clinical and Research Settings	"Meanwhile, Dr. ***'s presentation on the higher prevalence of autoimmune diseases in women and the lack of gender-oriented research in this field was eye-opening..." "Interpreting these lectures together, I see a pattern of systemic bias in health care and medical research that has long neglected women's specific needs and experiences..."	27.908	3.84	symptom, research, level, bias, underestim
Topic 10	Legal and Ethical Dimensions of Gendered Health Care	"After I got home, I searched for more information on Google and found that the law grants the woman the almost exclusive right to decide [whether to terminate or continue a pregnancy], while men, on the other hand, are not entitled to decide the issue except in very specific cases..." "The comparison to Iran, a country known for its restrictive laws toward women, expressed her feelings of oppression and coercion..."	25.898	3.31	convers, side, pregnanc, right, law

Subanalysis by Ethnicity

The LSA of reflections from Jewish medical students (Table 5) revealed that the dominant theme, topic 1, accounted for 28.06% of the variance and reinforced the central, cross-cutting theme of Gendered Patient-Doctor Interactions, which consistently emerged as the core axis across all subgroups. Other key full-sample themes—such as gender-specific diseases, transgender health care, gender differences in pharmacology, gender and decision-making, and psychosocial dimensions—were retained in both lexical structure and conceptual scope. However, 2 new themes emerged in the Jewish-only analysis. Topic 5 suggested a discourse on population-level gendered conditions, possibly linking epidemiological thinking to gendered illness patterns, while topic 10 revealed a narrative centered on early socialization, gendered expectation formation, and informal educational settings.

The LSA of reflections from Arabic medical students (Table 6) explained 92.2% of the total variance, indicating a semantically rich and cohesive thematic structure.

Topic 1, which accounted for 35.95% of the total variance (eigenvalue=58.017), reaffirmed the central theme of Gendered Patient-Doctor Interactions. Topic 2 (13.31% variance) was likewise retained. Topic 3 represented a new theme, characterized by culturally specific terms that suggested heightened sensitivity to modesty, gendered exposure, and familial expectations in clinical contexts. Similarly, topic 5 introduced a novel discourse on paternal authority and structural discrimination, with terms pointing to familial and systemic influences on gender roles and health care access—elements particularly salient in Arabic sociocultural settings. Two other themes were reoriented from their original full-sample conceptualizations. Topic 4 captured procedural aspects of care and implicitly gendered experiences during physical examination and consultation. Topic 7 aligned with the previously defined theme of gendered communication but introduced a spatial and emotional safety dimension, with cultural reframing. Additional new themes were identified in topics 9 and 10. Topic 9 pointed to concerns around reproductive health and perceived vulnerability. Finally, topic 10 captured emotional burden and coping dynamics.

Table 5. Labeled topics identified through latent semantic analysis of student reflections following participation in a gender medicine course in the Jewish-only sample.

Topic	Label	Representative quotes	Eigenvalue	% Variability	Top words
Topic 1	Gendered Patient-Doctor Interactions	"I feel that as a professional expanding my knowledge in the field of medicine in general and in ECGs specifically, I underestimated the patient due to a lack of knowledge and the routine of daily life, the treating doctor did as well, as did her husband based on his understanding..." "I think and feel that as a professional and a future doctor we must listen to our patients..."	109.760	28.06	gender, patient, feel, women, doctor
Topic 2	Gender-Specific Diseases and Health Concerns	"I was surprised, because I thought that precisely because they have little breast tissue, the diagnosis would be earlier, but most of the time they do not check for changes in the breast at all..." "During the weight loss process, my brother had fatty tissue on his chest that bothered him and looked like female breasts..."	51.474	6.17	breast, cancer, partner, didn, hurt
Topic 3	Gender and Decision-Making in Medicine	"It is clear to me that a woman's individual rights and freedom in making decisions about her own body are fundamental principles that must be protected..." "It is important to recognize that the weight of the final decisions lies with the woman, but also to be sensitive to the needs and feelings of men in these situations..."	43.140	4.34	student, opinion, sister, decis, separ
Topic 4	Health Care Access for Transgender Individuals	"This was the first time I had interviewed a transgender person..." "I chose this topic because I believe it is a complex and important issue in the field of sex and gender-aware medicine. The complexity of treating transgender patients concerns not only medical aspects, but also behavioral and psychological ones, and I think it is very important to raise awareness of the issue, create a more supportive and respectful medical environment, and improve the quality of care and life of patients who have undergone this procedure..."	41.514	4.01	base, transgend, servic, unit, train
Topic 5	Gender and Public Health Framing of Conditions	"We are required to learn about the needs of [all] populations, regardless of religion, race, gender, or age, while providing comfort and a pleasant experience to every patient..." "Everyone was shocked, as there isn't enough awareness of these conditions and the numbers, especially in this population!..."	39.559	3.65	condit, popul, month, arriv, week
Topic 6	Gender Differences in Pharmacology	"In a lecture, I learned about a drug that has a stronger effect on women, to the point that the dose needed is half that needed by men..." "It is clear that women, even if you take into account their body weight, often receive drugs in doses that are not suitable for them..."	35.990	3.02	lectur, drug, dose, menstrual, communiti
Topic 7	Gender Equality and Team Dynamics	"I always taught my paramedic trainees and colleagues along the way to listen to the patient, not to diminish their value or their feelings, to rule out and take things seriously-it's life!..." "A specific event that I remember was a shift in which I was the team leader and worked with another male paramedic from the Arab sector..."	35.558	2.95	woman, team, incid, leader, paramed
Topic 8	Institutional and Interpersonal Perspectives on Gender	"Although my mother and friends told me a little about the subject [i.e., menstruation], they never went into depth, so I didn't exactly understand what it was about until it happened to me..." "Recently, at a regular gathering among friends, I was present at a conversation, on the subject of discrimination against men in unwanted pregnancies, a topic that has come up in the past..."	33.649	2.64	subject, studi, friend, realiti, biolog
Topic 9	Psychological and Emotional Dimensions of Gender and Health	"This may have been caused by a lack of understanding of the emotional and mental effects of the syndrome..." "I assume that this was due to the emotional difficulties that the syndrome brings with it..."	31.049	2.25	social, save, syndrom, attack, mention
Topic 10	Gendered Youth, Expectations, and Identity Formation	"It prompted a deeper examination of how societal expectations around gender impact not only health care but also various aspects of daily life, from career choices to personal relationships..." "I think we have to find the power in the decisions we want to make as independent, and not as something that society expects us to do..."	29.704	2.06	girl, meet, expect, don't, camp

Table 6. Labeled topics identified through latent semantic analysis of student reflections following participation in a gender medicine course in the Arabic-only sample.

Topic	Label	Representative quotes	Eigenvalue	% Variability	Top words
Topic 1	Gendered Patient-Doctor Interactions	"Her doctor referred her to a specialist at the hospital in order to begin the treatment steps as early as possible..." "I understood that there is a price for mistakes and lack of adequate response to gender issues as an important part of the treatment..."	58.017	35.95	gender, women, medic, treatment, import
Topic 2	Gender Equality and Team Dynamics	"This incident taught me a lot about myself: I learned how hard it is for me to skip things that go against my values and don't fit my worldview, I learned how much I care about the health of the people around me and how important it is for them to feel good..." "My values, based on human dignity and equality, pushed me to act in the girl's best interest..."	35.304	13.31	dr, equal, manag, sister, valu
Topic 3	Cultural Norms in Clinical Settings	"At the time, she felt embarrassed by his reaction in front of the rest of the family and was hurt, which led to an argument between the two of them..." "After a long conversation, I was able to understand from her that she was afraid and did not know how to break the news to her parents due to embarrassment..."	28.317	8.56	aunt, society, situation, surgery, embarrass
Topic 4	Gendered Clinical Encounters	"I suggested that she postpone this step until after her consultation with the specialist, and at the end of the conversation, she asked me to accompany her to the hospital on that day..." "In my eyes, this is where the hardest part of the treatment began, because one of the steps of the surgery involved breaking the hymen to reach the polyp located on the cervix..."	25.686	7.05	pain, exam, step, consult, result
Topic 5	Paternal Authority and Structural Discrimination	"She claimed that her father and brothers did not believe her and supported her father's wife; her mother, who lived in Rahat after a divorce, did not object to the father returning her daughter home..." "Personally, the event strengthened my understanding of the importance of supporting and assisting people in distress, especially women who experience violence and discrimination..."	24.217	6.26	felt, father, explain, driver, discrimin
Topic 6	Psychological and Emotional Dimensions of Gender and Health	"This experience reinforced my understanding that mental and physical health are interconnected, and that comprehensive care must address the whole person..." "During her hospitalization, we worked to understand her experiences, her special needs as a new mother, and the impact of her mental state on her functioning as a mother..."	22.917	5.61	dose, mental, impact, clinic, provid
Topic 7	Gendered Communication and Assertion in Health Care Contexts	"The new doctor's approach was completely different, she addressed not only the physical aspects of the pain but also its emotional and social effects..." "I tried to talk to him sensitively at that moment because it was a family matter..."	20.968	4.70	emot, address, sens, room, start
Topic 8	Intergenerational and Familial Perspectives on Gendered Health	"The case ended with a compromise, in which the girl would move in with her mother..." "Following what happened, I think back to my own distant childhood and remember my mother, who is now a retired teacher and her education for me and my sister, who were the youngest children and how she educated us for equality, that whatever is fair for my sister is also fair for me..."	19.533	4.08	mother, disease, topic, face, factor
Topic 9	Reproductive Health and Feelings of Vulnerability	"First, I realized how much a lack of listening on the part of medical professionals can lead to a feeling of helplessness and loneliness in the patient..." "I chose to present this topic because it is an extremely important topic in psychiatry and medicine in general [i.e., postpartum depression], as it requires a special understanding of the physiological and emotional changes that women go through after childbirth..."	18.314	3.58	birth, touch, question, helpless, correct

Topic	Label	Representative quotes	Eigenvalue	% Variability	Top words
Topic 10	Psychosocial Support and Gendered Distress	"I learned to appreciate the importance of social and psychological support and develop a more inclusive and understanding approach towards people in complex situations..." "This includes recognizing the emotional effects of illness on a patient's life and understanding the importance of emotional support alongside medical care..."	16.941	3.07	support, girl, complex, distress, act

Discussion

Principal Findings

The findings of this study highlight the complex and multidimensional ways in which first-year medical students in Israel engage with the concept of gender in both educational and clinical contexts. LSA of student reflections revealed a dominant recurring theme—Gendered Patient-Doctor Interactions—across all analyses. This convergence aligns with prior scholarship underscoring the critical role of gender in shaping clinical communication, empathy, and trust [23]. The centrality of this theme suggests that even early exposure to gender medicine can prompt students to critically reflect on the influence of gender on therapeutic relationships and clinical outcomes [24,25]. In line with the World Health Organization's assertion that gender is a fundamental social determinant of health [5], students in this study demonstrated an emerging awareness of how gender shapes illness narratives, health care access, and diagnostic pathways. Their reflections also echoed the "gender mainstreaming" approach promoted in international medical education policy, which advocates for integrating gender considerations at all levels of health care delivery and education [5,26,27]. Notably, themes related to transgender health care, gender-specific diseases, and pharmacological differences paralleled the growing literature that underscores the need to dismantle androcentric biases in medical curricula [28,29]. These insights suggest that when given structured opportunities for reflection, learners are capable of recognizing and critically interrogating structural inequities embedded within biomedical discourse and practice.

Rather than merely acknowledging the existence of inequities, participants were challenged to examine critically the structural foundations of medical knowledge production, clinical practice, and professional formation. Many expressed dismay at the historical exclusion of female bodies from clinical research and the persistent privileging of male physiology as the normative reference point. As one student succinctly articulated: "We were presented with the historical neglect of female subjects in clinical trials in various fields, and an approach that perpetuated biased medical treatments that favor male physiology as the default standard." This statement reflected not only an awareness of bias but also a structural critique of the biomedical canon, echoing feminist analyses of knowledge systems that render women invisible or anomalous within clinical reasoning. Importantly, the student's reference to "perpetuated biased medical treatments" underscored an understanding that these are not merely vestiges of the past but ongoing epistemic and clinical injustices. The course further encouraged students to reevaluate their professional identity and the ethics of care through a gender-responsive lens. Many participants described how the training reshaped their conception of good medical practice—shifting from a mechanistic, one-size-fits-all model to a more nuanced, context-sensitive, and individualized approach. One student reflected: "I learned about the importance of listening to patients and the need to treat them as individuals, and not just as representatives of a particular gender." This shift marks a clear departure from biomedical reductionism, highlighting the importance of relational ethics and embodied listening—practices central to feminist clinical pedagogy. Importantly, the course also created space for critical emotional and identity work, particularly among male students. While some initially reacted with defensiveness or discomfort, perceiving gender-sensitive discourse as accusatory or polarizing, dialogical engagement and pedagogical scaffolding helped transform these affective responses into opportunities for deeper, transformative learning. As one male student candidly recounted: "At the beginning of the 'Sex and Gender-Aware Medicine' course, I felt, as a man, uncomfortable and even indirectly attacked...However, in small group exercises, the learning experience changed. The instructors helped me understand that the goal is not to blame, but to train us to be better doctors." This reflection illustrates how pedagogical designs grounded in openness and dialogic learning can transmute resistance into productive introspection. The student's movement from a sense of personal indictment toward professional growth signals a successful pedagogical intervention—one that shifts affective orientations while fostering ethical self-positioning. Crucially, the course did not stop at generating cognitive insights; it also catalyzed concrete commitments to behavioral change. Several students described actionable strategies for integrating sex- and gender-aware practices into their future patient encounters. One such example reads: "Following the course, I intend to ask more focused questions about the medical history of my patients, taking gender differences into account. I also intend to continue to stay up-to-date with research and literature in the field of gender medicine, in order to provide my patients with the best possible care." Here, we witness the internalization of gender mainstreaming not as an abstract principle but as a guiding framework for everyday clinical decision-making and professional formation. Some students even extended their reflections beyond the medical *curriculum*, engaging with the broader sociocultural implications of gendered behavior and ethics. One student, for example, recounted a personal experience in which a pregnant woman was ignored on public transport, using this incident as a lens to interrogate gendered expectations, moral responsibility, and social awareness. While not strictly clinical, such reflections highlight the pervasiveness of gendered norms and underscore the importance of cultivating ethical responsiveness that transcends disciplinary boundaries.

The gender-stratified analysis revealed meaningful differences in both the conceptual emphasis and emotional tone of student reflections. Female students more frequently highlighted relational and affective dimensions of gender, including intergenerational caregiving roles, informal consultation, and communicative dynamics in health care. These findings align with prior research indicating that female medical students often adopt a relational epistemology and are more inclined to reflect on their positionality and ethical responsibilities in clinical practice [30]. By contrast, male students tended to engage more with the biomedical, legal, and structural dimensions of gender, raising issues such as diagnostic bias and reproductive rights. This pattern reflects what prior literature has described as a more abstract and normative framing of social issues among male learners [30].

Moreover, this study reveals that students construct divergent understandings of gender medicine through identity lenses deeply shaped by religion, ethnicity, ideology, and sociopolitical context. One particularly compelling reflection came from a student who described the course as exposing "the tumultuous reality in our small country, which is caught in the middle of a clash between East and West, between religion and liberalism." The student reflected on the tension between their conservative upbringing and the realities of contemporary clinical practice, asking: "Is there room for the religious beliefs upon which my upbringing is based, or do I need to re-examine or abandon my personal beliefs and open up to secularism and liberalism?" These questions encapsulate the internal negotiation learners face when confronted with dissonant ideas that challenge their foundational schemas. Similarly, ethnic subgroup analyses highlighted the intersection of gender and cultural identity. Reflections from Jewish students revealed a tendency to extrapolate personal experiences to broader public health framings, often invoking themes such as epidemiological patterns and gendered health behaviors. This ability to connect micro-level experiences with macro-level perspectives aligns with what Cruess et al [31] describe as the development of the physician's "professional identity." Meanwhile, reflections from Arabic students revealed a deeper engagement with culturally embedded norms surrounding modesty, familial authority, and structural barriers to health care access—patterns consistent with scholarship on the intersection of gender, religion, and medicine in collectivist cultures [32]. Notably, these students also voiced affectively charged concerns related to reproductive health, vulnerability, and emotional burden, underscoring the cultural and emotional labor involved in reconciling conflicting expectations within clinical spaces [33,34]. Taken together, these reflections—shaped by diverse positionalities—illustrate how pedagogical encounters with gender can elicit complex and, at times, conflicting epistemic trajectories.

Overall, this study adds to the growing body of scholarship calling for the integration of gender and cultural competence into medical education. The themes identified suggest that structured gender curricula, when paired with reflective pedagogy and systematic evaluation, can cultivate critical consciousness and social responsiveness in future physicians [35].

Reflection—especially when systematically analyzed through computational methods—can serve as both a pedagogical and evaluative tool, enabling the assessment of not only cognitive but also affective and ethical dimensions of learning [36].

Implications of Findings

The findings of this study carry important implications for the design and implementation of gender medicine curricula, particularly in culturally and identity-diverse contexts. The subgroup differences observed—for instance, female students' greater emphasis on relational and affective dimensions, or Arabic students' focus on culturally embedded norms and structural constraints—demonstrate that learners do not uniformly assimilate gender medicine content. Rather than passively absorbing knowledge, students actively interpret and reframe new information through the lens of prior experiences, sociocultural background, and identity. This process reflects constructivist learning theory, which emphasizes that learning is active, situated, and coconstructed. Gender and ethnic identity often function as interpretive filters, amplifying certain issues while diminishing others. Such identity-based perspectives can enrich the learning environment by contributing diverse viewpoints, yet they may also generate tensions when personal or cultural values conflict with curricular content. From a pedagogical perspective, these findings underscore the importance of embedding structured opportunities for students to articulate and critically examine their own perspectives. Dialogical learning spaces, culturally responsive facilitation, and peer-to-peer engagement can help learners navigate potentially dissonant concepts and integrate them into their emerging professional identity. Such strategies may bridge the gap between abstract knowledge of gender medicine and its practical application across diverse clinical contexts. At the institutional level, embedding gender medicine within an explicitly intersectional framework ensures that the interwoven effects of gender, ethnicity, religion, and other social determinants are systematically addressed. This approach can strengthen both cultural competence and the ability to provide equitable, patient-centered care to heterogeneous populations.

Strengths and Limitations

Nonetheless, while the results are promising, caution is warranted. The interpretability of LSA findings is contingent on robust preprocessing, linguistic clarity within the student corpus, and careful topic labeling. Although this study benefited from certain strengths, including stratification by gender and ethnicity, the limited sample size precluded a comprehensive intersectional analysis. Furthermore, the reflections were collected at a single time point and situated within a specific institutional and sociocultural context, which may constrain the transferability of findings. Longitudinal studies are needed to assess whether these conceptual gains translate into sustained behavioral change and improved clinical competence in gender-sensitive care. In addition, comparative research across medical schools and national contexts could illuminate how curricular design, institutional culture, and sociopolitical environments shape the uptake and integration of gender medicine.

Conclusions

This study underscores the importance of embedding gender-sensitive content within medical education and demonstrates the utility of LSA as an analytic tool for examining how learners engage with complex sociomedical themes. The findings highlight the need for an intersectional, contextually attuned approach to curriculum design that actively considers students' diverse identities and lived experiences. By fostering reflexivity, empathy, and critical literacy, gender medicine education holds the potential to shape future physicians who are better equipped to provide equitable, inclusive, and socially responsive health care.

Abstract

Background: Clinical competency is essential for oncology students to deliver high-quality patient care. However, traditional teaching methods may not fully support the development of critical skills such as communication, empathy, and clinical judgment. Peer role-play has emerged as a promising approach to bridge these gaps by enhancing interpersonal and diagnostic competencies within clinical settings.

Objective: This study aims to evaluate the effectiveness of peer role-play in developing clinical competencies among oncology graduate students during their clinical rotation.

Methods: This study involves 70 first-year oncology graduate students from Affiliated Cancer Guangzhou Medical University Cancer Hospital in a 3-month clinical rotation within the department of oncology from January 2022 to December 2023. Participants were randomly assigned to either a peer role-play group (n=35) or a traditional teaching group (n=35), ensuring balanced gender and baseline competencies. The role-play group engaged in a structured curriculum that included case presentation, classroom instruction, and weekly role-play sessions, with debriefing and feedback sessions following each role-play. The traditional teaching group adhered to a standard curriculum without role-play exercises. Assessments included a baseline oncology theory exam, Mini-Clinical Evaluation Exercise for clinical competency evaluation, and a satisfaction survey for the role-play group.

Results: Baseline theory exam scores were comparable between the 2 groups (P=.08). However, the peer role-play group demonstrated significant improvements in doctor-patient communication, medical history taking, clinical judgment, and overall clinical competence compared to the traditional teaching group (P<.05). Furthermore, students in the role-play group reported high levels of satisfaction, citing scenario realism, communication practice opportunities, and feedback quality as key benefits.

Conclusions: This study indicates that peer role-play is an effective educational approach for developing clinical competencies in oncology graduate students, particularly in communication, empathy, and clinical reasoning. Role-play provides an engaging and practical learning experience, making it a valuable addition to clinical training programs aimed at enhancing patient-centered care skills in students.

peer role-play; Mini-Clinical Evaluation Exercise; clinical competencies; oncology; physician-patient communication

Introduction

The Need for Effective Communication in Oncology Education

The rapid advancements in medical knowledge and technology have reshaped oncology practice, increasing the demand for oncology graduate students to develop clinical competencies and patient-centered communication skills [1,2]. In oncology, where patients face emotionally and physically challenging conditions, the ability to communicate with empathy, clarity, and sensitivity is essential. Discussions involving complex diagnoses, treatment options, and prognoses have a profound

impact on patients and their families, requiring clinicians to balance clinical accuracy with emotional awareness. However, mastering these communication skills can be challenging for students newly entering clinical settings. Many lack the experience to navigate oncology's intense emotional landscapes, making it difficult to build rapport, demonstrate compassion, and manage challenging conversations [3].

Traditional medical education, largely based on lectures and observational learning, often falls short in fostering the interpersonal skills necessary for these interactions. There is a critical need for training approaches that provide early, practical opportunities for realistic patient engagement. Role-play, an active learning methodology, offers a promising solution by enabling students to assume both practitioner and patient roles within controlled simulations [4]. This technique allows students to practice essential clinical skills in a low-risk setting and helps them develop effective, empathetic communication with patients. By simulating real-life interactions, role-play encourages students to develop the confidence and sensitivity required to manage emotionally complex oncology conversations before they enter clinical practice [5].

Despite the recognized importance of communication in oncology, few studies have examined the specific impact of role-play on preparing students for these complex interactions. Most research on role-play in medical education focuses on general skill development or communication in less specialized fields [6], leaving a gap in understanding its potential in comprehensive oncology training. This study sought to bridge this gap by investigating the effectiveness of role-play in enhancing oncology graduate students' clinical competencies, especially in patient communication, diagnostic reasoning, and emotional intelligence.

Role-Play as a Tool for Enhancing Patient-Centered Communication

Role-play can be situated within an experiential learning and deliberate practice framework, allowing learners to iteratively rehearse complex communicative and diagnostic tasks with targeted feedback in a psychologically safe environment. In medical education, role-play has been used both informally and within structured curricula to improve communication, empathy, and professionalism, with guidance on task design, briefing, and debriefing to maximize learning [7]. Peer role-play specifically offers a low-cost, scalable alternative to standardized patients (SPs) and high-fidelity simulation while retaining core pedagogical features such as scenario authenticity, role clarity, and structured feedback [8]. Our study extends this literature by testing a systematic, oncology-specific peer role-play curriculum during a real clinical rotation.

In oncology, communication frequently involves serious illness conversations, including breaking bad news and discussing goals of care—domains supported by established frameworks such as SPIKES (setting, perception, invitation, knowledge, empathy, and strategy) and the Calgary-Cambridge guide [9,10]. Embedding these frameworks into role-play scenarios can promote patient-centered communication, empathy, and ethical clinical judgment before students encounter such conversations in the real world. While high-fidelity and SP-based simulations are valuable and increasingly used, particularly for palliative and end-of-life communication, resource-sensitive peer role-play can serve as an effective stepping stone that is feasible for routine integration in busy oncology rotations.

Through this research, we aimed to illuminate the potential of role-play to strengthen the practical and interpersonal skills necessary in oncology. By assessing student outcomes in clinical skills and communication confidence, this study sought to contribute valuable insights to the development of interactive training models that better equip future oncologists to meet the complex demands of their profession.

Methods

Study Design and Participants

This study involved 70 graduate students majoring in oncology from Guangzhou Medical University Cancer Hospital who were in their first clinical rotation in the department of oncology from January 2022 to December 2023. The participants' ages ranged from 22 to 24 years. Of these 70 graduate students, 36 (51%) were males and 34 (49%) were females. Using a simple randomization method, students were assigned to either a peer role-play group (n=35, 50%) or a traditional teaching group (n=35, 50%), ensuring an even distribution of gender, age, and baseline competencies.

Participants were randomized in a 1:1 ratio to the peer role-play or traditional teaching group using a computer-generated sequence with permuted blocks (sizes 4 and 6) stratified by gender and baseline oncology theory exam tertiles to promote balance on key variables. The randomization list was prepared by a statistician independent of the teaching and assessment teams. Allocation was concealed using sequentially numbered, opaque, sealed envelopes that were opened only after enrollment. This process yielded comparable distributions of gender, age, and baseline knowledge across groups.

Sample size was calculated based on a power analysis, which determined that a minimum of 32 students per group would be required to detect a moderate effect size (Cohen d=0.5) with 80% power and a 5% significance level. Both groups participated in a 3-month clinical rotation.

Study Setting and Curricular Context

This study was conducted at Guangzhou Medical University Cancer Hospital, a tertiary cancer center in southern China. *Oncology graduate students* refer to first-year postgraduate trainees in a 3-year Master of Medicine program who undertake supervised clinical rotations alongside coursework. Both groups participated in the standard 12-week medical oncology rotation comprising didactic lectures, case presentations and tumor boards, ward-based care, and outpatient clinics under faculty supervision. To accommodate the intervention while preserving clinical exposure, 1 weekly case discussion hour was replaced with a 60-minute peer role-play session plus structured debriefing in the role-play group; all other learning activities (lectures, case presentations, and patient care) were identical between the groups.

Before this study, structured simulation was not embedded within the oncology rotation. SPs are available at the university's skill center primarily for preclinical communication courses; however, SP-based sessions had not been routinely implemented in the oncology rotation due to timetable and cost constraints. To introduce an accessible form of simulation, we integrated peer role-play into the existing schedule by replacing 1 weekly case discussion hour with a structured role-play session followed by debriefing and feedback. This approach preserved clinical exposure while creating protected time for deliberate practice of communication, clinical reasoning, and professionalism.

Participant Characteristics and Learning Context

All participants were first-year postgraduate students in oncology who had completed a 5-year undergraduate medical degree and were beginning their initial clinical oncology rotation; none had completed specialty residency training. Instruction and clinical care were delivered primarily in Mandarin Chinese, with Cantonese used as appropriate in-patient interactions. On the basis of institutional records, students had not received formal, oncology-specific role-play or simulation training before this rotation, although all had previous exposure to lecture-based teaching and bedside observation.

Consistent with the common features of local medical education, students were accustomed to lecture-centric learning, summative written assessments, and faculty-led bedside teaching. Formative feedback opportunities existed but were less structured. Introducing weekly peer role-play with facilitated debriefing was intended to provide regular, structured opportunities for practice, feedback, and reflection aligned with experiential learning principles.

Intervention

Peer Role-Play Group Implementation

The peer role-play group participated in a structured role-play curriculum designed to enhance clinical skills and communication in oncology. The implementation of the role-play sessions involved several key steps.

Case Presentation

At the beginning of each week, the instructor conducted a case presentation session for the role-play group. During this session, the instructor introduced a real patient case, detailing the patient's medical history, physical examination findings, diagnostic results, and the clinical reasoning behind the diagnosis. This foundation enabled students to familiarize themselves with real-life oncology cases and understand the complexities involved in patient interactions.

Classroom Teaching and Role-Play Instruction

Following the case presentation session, the students attended a classroom session in which the instructor introduced the principles and significance of role-play in clinical education. The instructor explained the objectives of role-play in enhancing empathy, communication skills, and diagnostic reasoning. The instructor then demonstrated how role-play scenarios would be structured, detailing each step of the role-playing process.

Role-Play Scenario Execution

Each week, students engaged in a 60-minute role-play session. Students were divided into small groups, with each group member assigned a specific role within the scenario: health care provider, patient, or observer. The health care provider role required students to undertake patient interactions, including history taking, explanation of diagnosis, treatment planning, and handling patient emotions. Students in the patient role were given background information to simulate the patient's condition and emotional state, whereas observers provided feedback and noted areas for improvement.

Debriefing and Feedback

After each role-play session, students and instructors gathered for a structured debriefing. Instructors facilitated reflective discussions, allowing students to share their experiences and insights. Feedback was provided on communication style, empathy, clarity, and clinical decision-making. The debriefing emphasized areas in which students excelled and identified specific skills for improvement, thereby promoting a safe environment for learning and growth.

Traditional Teaching Group

The traditional teaching group followed the standard clinical rotation curriculum, which included lectures, case presentations, and observational learning. Students in this group participated in routine patient care activities supervised by attending physicians without structured role-play exercises.

Assessment and Data Collection

To evaluate the effectiveness of the intervention, assessments were conducted for both groups before and after the rotation using 3 primary measures.

Oncology Theory Exam

A standardized written test covering key oncology knowledge areas, including diagnosis, treatment protocols, and patient management principles, was used to evaluate each student's theoretical knowledge. The exam was administered only at the beginning of the clinical rotation (before the intervention) to assess students' baseline knowledge in oncology. This examination was not repeated at the end of the rotation.

Mini-Clinical Evaluation Exercise

The Mini-Clinical Evaluation Exercise (Mini-CEX), a well-recognized tool for evaluating clinical skills [11,12], was used to assess practical competencies. The Mini-CEX was conducted only at the end of the clinical rotation, after the intervention, to evaluate the practical competencies and clinical skills of the students. Students obtained medical histories from patients and conducted physical examinations. The Mini-CEX assessed students across 7 criteria using a 9-point scale:

1. History taking: accuracy in gathering patient history, responding to nonverbal cues, and demonstrating empathy
2. Physical examination: competence in conducting examinations in an organized manner, maintaining patient privacy, and managing discomfort
3. Professionalism: respect, compassion, ethical standards, and confidentiality

4. Clinical judgment: students' ability to select and execute appropriate diagnostic tests and weigh the risks and benefits of various treatment options
5. Physician-patient communication: clarity in explaining medical tests, obtaining consent, and educating patients
6. Organizational efficiency: skill in prioritizing patient care and effectively using resources
7. Overall competence: integration of clinical knowledge and overall patient care effectiveness

The Mini-CEX scoring encompassed "below expectations" (1-3 points), "meeting expectations" (4-6 points), and exceeding expectations (7-9 points). All assessments were conducted by a single evaluator who was blinded to the study condition of the students and was unaware of whether the assessment was before or after the intervention. This evaluator was not involved in other aspects of the study to avoid any potential bias and ensure consistency in the assessments.

Satisfaction Survey for the Role-Play Group

At the end of the rotation, students in the peer role-play group completed a satisfaction questionnaire. This survey measured their perceived value of the role-play activities, including aspects of engagement, realism, feedback quality, communication skill improvement, empathy development, and overall satisfaction with role-play as a learning method. The satisfaction survey comprised the following six items, each rated on a 5-point Likert scale (1="strongly disagree"; 5="strongly agree"): (1) "The role-play activities made me more involved in the learning process" (engagement), (2) "The scenarios in role-play felt realistic, helping me experience a clinical environment" (realism), (3) "I am satisfied with the quality of feedback received during the role-play activities" (feedback quality), (4) "I feel more confident in communicating with patients due to the role-play sessions" (communication skill improvement), (5) "The role-play exercises helped me better understand patients' emotions and needs" (empathy development), and (6) "I am generally satisfied with the overall effectiveness of the role-play teaching method" (overall satisfaction).

To improve the validity of the satisfaction survey, it was pilot-tested with a similar cohort to refine question clarity and response consistency.

Data Analysis

Data were analyzed to compare outcomes between the peer role-play and traditional teaching groups. Paired 2-tailed *t* tests assessed within-group improvements, and independent *t* tests compared between-group performance on the oncology theory exam and Mini-CEX. The satisfaction survey results were analyzed using descriptive statistics to summarize the feedback from the role-play group. Statistical significance was defined as $P<.05$.

Ethical Considerations

This study was conducted in accordance with the principles of the Declaration of Helsinki. Ethics approval was obtained from the ethics committee of the Affiliated Cancer Hospital of Guangzhou Medical University (number 11/01/22). 70 first-year oncology graduate students were asked to participate in the study. All of them had signed informed consent prior to participation. All data were pseudonymized before being subjected to statistical analysis. Participants did not receive any financial compensation. As an incentive, the 5 best-performing students in each group were awarded a book prize.

Results

Baseline Theory Exam Scores

At baseline, the average theory exam scores were comparable between the 2 groups. The peer role-play group achieved a mean score of 91.12 (SD 2.15), whereas the traditional teaching group scored an average of 91.33 (SD 2.16). Statistical analysis indicated no statistically significant difference between the groups' baseline theoretical knowledge ($P>.05$), confirming a similar level of theoretical understanding at the start of the rotation.

Mini-CEX Assessment

All trainees completed the Mini-CEX evaluation within an average of 36 (SD 0.5) minutes, and post-evaluation feedback required approximately 6.6 (SD 0.4) minutes per student. After the rotation, the peer role-play group performed significantly better than the traditional teaching group on the Mini-CEX domains of physician-patient communication, history taking, clinical judgment, and overall clinical competence ($P<.05$ in all cases). Detailed Mini-CEX scores for both groups are provided in Table 1.

Table 1. The distribution of the scale scores on the Mini-Clinical Evaluation Exercise assessment in the 2 groups.

Item	Peer role-play group (n=35), n (%)	Traditional teaching group (n=35), n (%)	*P* value
Medical history taking			.03
Meets expectations	13 (37)	23 (66)	
Exceeds expectations	22 (63)	12 (34)	
Clinical judgment			.02
Below expectations	0 (0)	2 (6)	
Meets expectations	15 (43)	24 (69)	
Exceeds expectations	20 (57)	9 (26)	
Physician-patient communication			.004
Meets expectations	12 (34)	25 (71)	
Exceeds expectations	23 (66)	10 (29)	
Professionalism			.03
Meets expectations	14 (40)	24 (69)	
Exceeds expectations	21 (60)	11 (31)	
Physical examination			.81
Meets expectations	18 (51)	16 (46)	
Exceeds expectations	17 (49)	19 (54)	
Organizational effectiveness			.34
Meets expectations	16 (46)	21 (60)	
Exceeds expectations	19 (54)	14 (40)	
Overall capabilities			.03
Meets expectations	12 (34)	22 (63)	
Exceeds expectations	23 (66)	13 (37)	

Satisfaction Survey Results for the Role-Play Group

At the end of the study, students in the peer role-play group completed a satisfaction survey to assess their perceptions of the role-play experience (Table 2). Results indicated high satisfaction levels, with most students agreeing that role-play was a valuable and engaging learning tool. Key areas of positive feedback included engagement (32/35, 91% agreement and "strongly agree"), the realism of the scenarios (29/35, 83% agreement and "strongly agree"), the quality of the feedback received (32/35, 91% agreement and "strongly agree"), and overall satisfaction (33/35, 94% agreement and "strongly agree").

Table 2. Students' satisfaction evaluation in the role-play group (n=35)[a].

	Strongly disagree, n (%)	Disagree, n (%)	Neutral, n (%)	Agree, n (%)	Strongly agree, n (%)
Engagement	1 (3)	0 (0)	2 (6)	25 (71)	7 (20)
Realism	2 (6)	2 (6)	2 (6)	24 (69)	5 (14)
Communication skill improvement	1 (3)	0 (0)	1 (3)	24 (69)	8 (23)
Feedback quality	0 (0)	1 (3)	1 (3)	28 (80)	4 (11)
Empathy development	0(0)	1(3)	2(6)	29(83)	3(8)
Overall satisfaction	1 (3)	1 (3)	0 (0)	26 (74)	7 (20)

[a]1=strongly disagree, 2=disagree, 3=neutral, 4=agree, and 5=strongly agree.

Discussion

This study examined the effectiveness of peer role-play versus traditional teaching methods in enhancing the clinical competencies among oncology graduate students. The findings offer valuable insights into the role of interactive learning methods, particularly in fostering communication skills and clinical decision-making.

The results indicate that, while both groups had similar theoretical knowledge at baseline, the peer role-play group

exhibited significantly higher scores in practical skills, including physician-patient communication, medical history taking, and overall clinical competence as assessed using the Mini-CEX (P<.05). This aligns with previous studies suggesting that role-play is an effective tool for enhancing soft skills in medical education, especially communication and empathy [13,14]. These improvements are crucial for oncology care, where patient interactions often involve delivering complex news and managing emotional responses.

Moreover, the peer role-play group demonstrated superior clinical decision-making skills, suggesting that role-play scenarios may foster critical thinking and integrative skills by actively engaging students in problem-solving rather than passive observation [15]. This active learning approach likely provides students with a deeper understanding of clinical workflows, which is essential for patient-centered care in high-stakes oncology settings.

The high levels of satisfaction reported by students in the role-play group underscore its acceptability and perceived value in clinical education. Students valued the realism of the scenarios and the opportunity for constructive feedback, contributing to the observed improvements in communication and clinical skills. These positive feedback results suggest that role-play was well received by students, particularly in terms of engagement and the quality of feedback. However, the results do not directly suggest an enhancement of learning outcomes or motivation, which would require further investigation.

Our scenarios deliberately targeted competencies central to oncology and palliative care communication—eliciting patient values and concerns, conveying difficult information, and negotiating shared decision-making—guided by the SPIKES framework and principles from the Calgary-Cambridge guide [9,10]. Prior work has shown that structured role-play and simulation can improve learners' confidence and observable communication behaviors in serious illness conversations, whereas ongoing feedback and deliberate practice are critical to maintaining gains. In settings in which SP programs and high-fidelity simulations are not yet routinely available in oncology rotations, peer role-play provides a pragmatic, low-cost modality that can be delivered regularly, reinforced by structured debriefing. Future work at our institution will extend scenario content to explicitly include dialogues on end of life and goals of care and compare peer role-play with SP-based approaches on performance and transfer to clinical practice.

Despite promising findings, several limitations should be acknowledged. First, this study was conducted at a single institution and focused solely on oncology graduate students, which may limit its generalizability to other medical fields. Additionally, the short rotation duration raises questions about the long-term retention of skills acquired through role-play. Another limitation is the potential for evaluator bias in Mini-CEX assessments, although the evaluator was blinded to group assignments.

This single-center study used a posttest-only design for the Mini-CEX and administered the theory exam only at baseline. Consequently, we cannot estimate within-group change or link knowledge gains to observed performance. We also relied on a single blinded assessor for Mini-CEX ratings, which may limit the generalizability of judgments. Satisfaction data were self-reported and limited to the role-play group. Finally, we did not include a dedicated empathy instrument or teamwork measure.

Future research could address these limitations by expanding sample sizes, including multiple institutions, and assessing long-term skill retention. Incorporating objective measures of patient outcomes could help assess the real-world impact of role-play on patient care quality. Additionally, comparing role-play with other interactive learning methods such as simulation-based training could deepen understanding of the most effective approaches for teaching clinical skills.

In conclusion, this study demonstrates that peer role-play is an effective and well-received method for enhancing clinical competencies in oncology education. By engaging students in realistic scenarios, role-play fosters key skills in communication, decision-making, and teamwork, which are all crucial for patient-centered care. These findings support the integration of role-play into clinical curricula as a valuable complement to traditional teaching methods, especially in fields that demand strong interpersonal and decision-making skills.

Data Availability

All datasets generated for this study were included in the manuscript.

Authors' Contributions

JL and HB conceived and designed the study. YW, FW, GL, and YL participated in data collection and processing. JL was the major contributor in organizing records and drafting the manuscript. Abstract

Background: Research capacity building (RCB) among health care professionals remains limited, particularly for those working outside academic institutions. Japan is experiencing a decline in original clinical research due to insufficient RCB infrastructure. Our previous hospital-based workshops were effective but faced geographical and sustainability constraints. We developed a fully online Scientific Research Works Peer Support Group (SRWS-PSG) model that addresses geographical and time-bound constraints and establishes a sustainable economic model. Mentees use online materials, receive support from mentors via a communication platform after formulating their research question, and transition into mentors upon publication.

Objective: We evaluated whether our model's theoretical benefits translated into actual program effectiveness in RCB among health care professionals.

Methods: We conducted a retrospective cohort study of health care professionals who participated in the SRWS-PSG program between September 2019 and January 2025. Mentees progressed through a structured modular curriculum covering systematic review methodology, from protocol development to manuscript preparation, with personalized mentoring support. We evaluated manuscript submission, program discontinuation, promotion to a mentor status, and mentor response time. We collected data from program records and chat logs. Manuscript submission was defined as mentor-confirmed submission of a systematic review manuscript to a peer-reviewed journal. Program discontinuation referred to formal withdrawal before manuscript submission. Mentor promotion was defined as acceptance of an invitation to serve as a junior mentor after manuscript submission. Mentor response time was the elapsed time from a mentee's question in the chat to the first reply by an assigned mentor.

Results: Of 85 mentees analyzed, 31 (36.5%) held academic degrees (PhD or MPH), and 68 (80%) were medical doctors. During a median follow-up of 10 months, 51 (60%) submitted manuscripts and 46 (90%) became mentors. Ten mentees (12%) discontinued the program. The median mentor response time was 0.8 hours, with 90% responding within 24 hours.

Conclusions: A majority of participants of SRWS-PSG submitted manuscripts. This fully online RCB program might address geographical barriers and provides an adaptable approach for RCB across diverse health care contexts.

Introduction

Research capacity building (RCB) among health care professionals is essential for addressing clinical challenges and improving health care quality. Cooke's RCB framework [1] comprises four structural levels (individual, team, organizational, and network/supra-organizational) and six principles (developing skills and confidence, supporting linkages and partnerships, ensuring research close to practice, enabling appropriate dissemination, investing in infrastructure, and building sustainability and continuity). A systematic review showed that RCB strategies are interlinked and interdependent, requiring implementation through an integrated "whole of system" approach with commitment and support from all levels of leadership and management [2]. Similarly, a scoping review found that these programs are typically multifaceted, often incorporating experiential learning and mentoring, but evaluations predominantly focus on lower levels of Kirkpatrick's educational outcomes typology (eg, participant satisfaction, improved knowledge, and confidence), with few assessing objective milestones (eg, protocol completion or manuscript preparation) or broader organizational and practice impacts. The authors conclude that rigorous evaluations are needed, considering long-term outcomes and translation into clinical practice, to better bridge the research-practice gap [3].

RCB programs for practicing health care professionals outside academic institutions remain limited [2]. In Japan, the decline in original clinical research is a recognized issue [4,5]. This is largely due to insufficient RCB infrastructure, a problem that affects both academic and non-academic settings [6,7]. Like in other countries, there are often no clear expectations or structured incentives for clinicians to engage in research [8]. The situation is worsened by systemic funding shortages in academia [9]. Many Japanese clinicians are therefore motivated not by the prospect of academic promotion, but by a sense of professional responsibility—or "rectitude," a concept deeply rooted in the traditional Japanese code of conduct [10]—to address clinical questions that arise from their practice. Our program was developed to support these grass-roots community healthcare professionals, who are motivated to address their research questions [11]. The program aimed to build research capacity from the bottom up. Between 2014 and 2017, we conducted a structured in-person scholarly productive model workshop for hospital-based health care professionals. This workshop developed a curriculum and achieved academic publications from participants through team-based systematic review projects. However, this hospital-based implementation faced two constraints: limited dissemination capacity and unsustainable dependence on voluntary mentor work. In 2019, we transformed the workshop into a fully online peer support program (Scientific Research Works Peer Support Group [SRWS-PSG]) with participant fees supporting mentor compensation. This redesign addressed geographical and time-bound barriers, strengthened cross-institutional partnerships, and established a sustainable economic model for ongoing RCB activities. The program features a comprehensive curriculum with over 140 modules covering all aspects of systematic review methodology. Mentees progress through self-paced online materials and receive feedback from mentors on their protocols, manuscripts, and any questions about the systematic review process via an internet communication platform, eventually transitioning into mentors upon publication.

We previously developed a structured, in-person scholarly productive model workshop for hospital-based health care staff between 2014 and 2017 [11]. This workshop developed a curriculum and achieved academic publications from participants through team-based systematic review projects. However, this hospital-based implementation faced two constraints: limited dissemination capacity and unsustainable dependence on voluntary mentor work. In 2019, we transformed the workshop into a fully online peer support program (SRWS-PSG) with participant fees supporting mentor compensation. This redesign addressed geographical and time-bound barriers, strengthened cross-institutional partnerships, and established a sustainable economic model for ongoing RCB activities. The program features a comprehensive curriculum with over 140 modules covering all aspects of systematic review methodology. Mentees progress through self-paced online materials and receive feedback from mentors on their protocols, manuscripts, and any questions about the systematic review process via an internet communication platform, eventually transitioning into mentors upon publication.

While the need for RCB for health care professionals is clear, scalable and sustainable programs remain scarce, particularly for those outside academic institutions in Japan. This study, therefore, aimed to evaluate the effectiveness of our fully online and economically self-sustaining SRWS-PSG model. Our research question was "How effective is this program in enabling health care professionals to complete and submit systematic reviews?" To address this, we conducted a retrospective cohort study analyzing data from participants enrolled between 2019 and 2025. We hypothesized that this peer-supported, online model would demonstrate a high proportion of manuscript submission and program continuation, validating its utility as a scalable RCB solution. The findings are intended to inform medical educators, hospital administrators, and health policymakers seeking to develop and implement effective RCB programs.

Methods

Study Design

We conducted a retrospective cohort study of health care professionals who participated in the SRWS-PSG program between September 2019 and January 2025. The SRWS-PSG is designed specifically to support health care professionals from any discipline in conducting systematic reviews as their primary research output. The SRWS-PSG program is now

operated by the SRWS-PSG, a non-profit general incorporated association registered in Japan (corporate Number: 6120005024588). The mission is to increase clinical research in Japan. The members consist of health care professionals, and it is funded through membership and mentorship fees. The program provides a structured, modular curriculum covering the entire systematic review process, from protocol development to manuscript submission. Learning is facilitated through self-paced online materials and personalized, responsive mentorship via a communication platform. We applied Cooke's RCB framework [1] for the methodology and structured our findings. To report this article, we followed the Strengthening the Reporting of Observational Studies in Epidemiology (STROBE) statement [12].

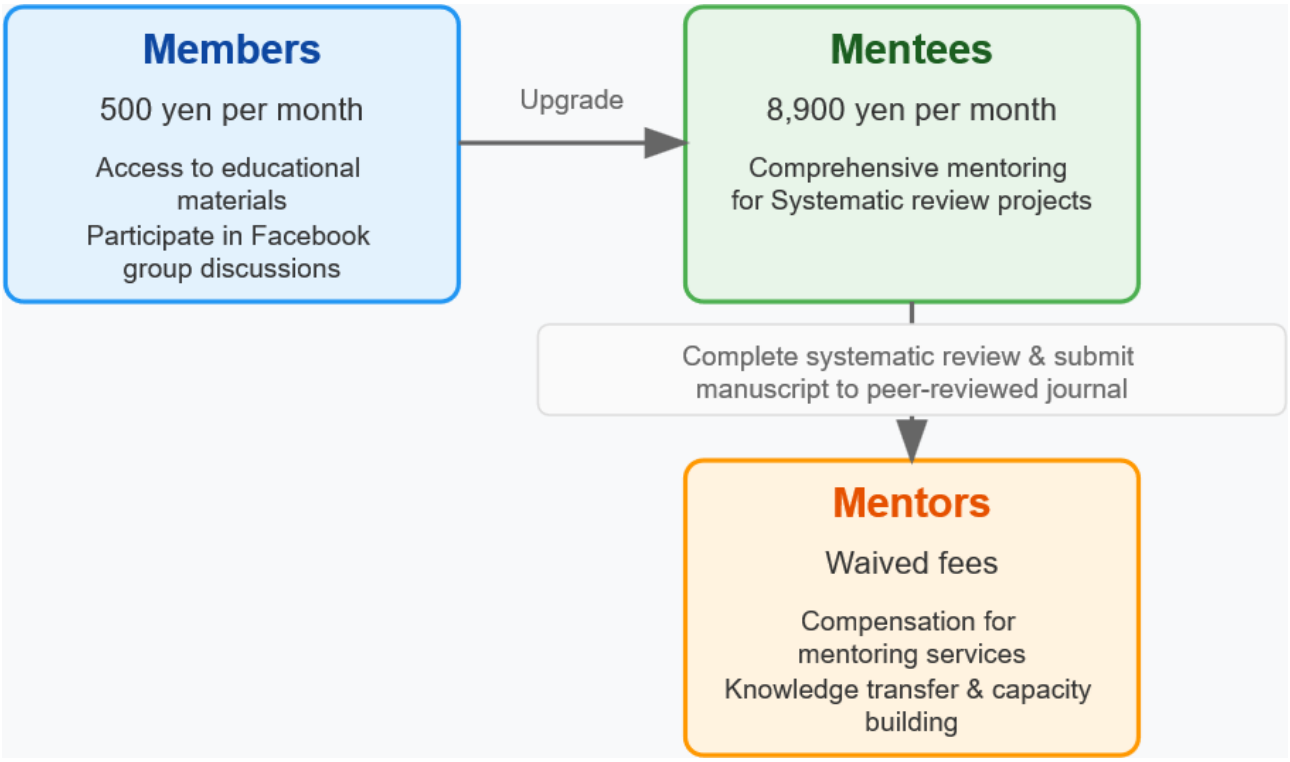
Setting

This study was conducted in a fully online environment. We recruited participants through social media, websites, academic conferences, and referrals from previous participants. The primary registration portal was CAMPFIRE, a Japanese crowdfunding platform [13]. We collected data from Slack chat logs, program participation records, and manuscript submission status. Occupations and academic degrees came from registration forms. The data cut-off was February 2025.

Participants

As of 2025, the SRWS-PSG uses a tiered membership structure with different levels of engagement and fee schedules. Entry-level "members" pay 500 yen (3 - 4 US$) per month to access educational materials and participate in research-related discussions through a Facebook group. "Mentees" pay 8900 yen (around 60 US$) per month for comprehensive mentoring support throughout their systematic review projects. Mentees who submit their manuscript to a peer-reviewed journal are invited to become mentors—with waived fees and compensation—if their two assigned mentors assess them as suitable for the role based on their aptitude for chat-based communication (Figure 1).

Figure 1. The Scientific Research Works Peer Support Group (SRWS-PSG) membership structure.



In this study, we analyzed mentees who were health care professionals from various disciplines including physicians, nurses, pharmacists, physical therapists, clinical psychologists, and registered dietitians. All mentees could communicate online, had research questions suitable for systematic review topics, and agreed to participate. None had conducted a systematic review as the lead author. We excluded those withdrew before program initiation or did not complete initial training. The cumulative incidences of manuscript submission and discontinuation of the program, stratified by university affiliation, are plotted with 95% CIs. Shaded areas represent the 95% CIs.

Curriculum

The SRWS-PSG curriculum uses outcome-based learning objectives to enable health care professionals to conduct systematic reviews and publish in peer-reviewed journals [14]. Objectives include formulating research questions, developing literature search strategies, performing critical appraisal, synthesizing evidence, evaluating certainty of evidence, and producing academic manuscripts meeting international publication standards. The curriculum follows a modular progression aligned with the systematic review process, from orientation modules through protocol development, execution, analysis, and manuscript preparation (Multimedia Appendix 1). Training materials are in Japanese. To become familiar with English academic writing, mentees without English writing

experience critically appraised an article and submitted a letter to the editor before formulating their research question. The program incorporates methodological updates including the latest Cochrane Handbook [15] and Risk of Bias 2 tool [16] to ensure current best practices.

The instructional methodology combines asynchronous self-paced learning with responsive mentoring support. Mentees first view 10 to 30 minutes of video content explaining systematic review concepts and methodologies. Mentees then draft specific sections of their research protocols—structured tasks with concrete deliverables. Each mentee receives personalized feedback from two assigned mentors—a junior and a senior mentor—through Slack, a business-oriented chat application [17]. Mentors serve as co-authors on the mentee's systematic review project. Junior mentors are recent program graduates, who are promoted to senior status after guiding three mentees to publication. Mentors respond within 24 hours, while mentees follow a "15-minute rule" (a structured guideline that requires mentees to attempt solving methodological or procedural challenges independently for at least 15 min before posting questions to mentors, designed to promote self-reliance, enhance problem-solving skills, and ensure efficient use of mentoring resources). Optional synchronous online meetings occur upon mentee request.

To enhance learning through practical application, members actively contribute to other mentees' projects. This approach leverages the systematic review methodology's requirement for independent dual assessment of article screening, data extraction, and risk of bias evaluation [18]. This collaborative structure enhances learning through practical application.

Outcomes

Overview

We selected four outcomes based on data available from our existing program records. These outcomes partially reflect key dimensions of Cooke's RCB framework [1]. Manuscript submission was chosen as an indicator of skill development and confidence building, representing participants' ability to complete a systematic review project. Program discontinuation was measured to assess individual-level sustainability and continuity. Promotion to mentor status following manuscript submission was evaluated as a marker of organizational-level sustainability and continuity. Mentor response time was analyzed as a proxy for infrastructure investment and team support quality. The outcomes were described as given below.

Manuscript Submission

Manuscript submission was defined as the time from mentor approval of the mentee's research question to start the protocol to the submission of systematic review manuscripts to academic journals. Mentees self-reported manuscript submission with mentor confirmation.

Program Discontinuation

Discontinuation was defined as when a mentee formally notified the program of their withdrawal, leading to the cessation of monthly program fee payments prior to manuscript submission.

Promotion to a Mentor

Promotion to mentor status was evaluated by determining the proportion of manuscript-submitting mentees who accepted the invitation to become a junior mentor after being assessed as suitable by their assigned mentors. This transition was documented in program administration records.

Mentor Response Time

The mentor response time was defined as the time from a mentee posting a question in a designated Slack channel to the first response from any assigned mentor in the same channel. Data were extracted from Slack chat logs.

Study Size

We included all mentees during the program operation period, without formal sample size calculation. This size was similar to that in other research capacity development program evaluation studies [19,20].

Statistical Analysis

We used descriptive statistics to summarize participant characteristics, continuation rate, and mentor response time. Manuscript submission and publication were analyzed as time-to-event outcomes. We estimated the cumulative incidence functions for both submission and publication using the Aalen-Johansen estimator [21]. Discontinuation from the program was a competing risk. Competing risk occurs when an event (manuscript submission) cannot occur because another event (discontinuation) happens first. We censored participants still active without an event at data cut-off. For subgroup analyses, we performed univariable Fine-Gray subdistribution hazard models to calculate subdistribution hazard ratios (sdHR) with 95% CIs for academic degree, profession, and university affiliation. We performed analyses using Python (version 3.11.4; Python Software Foundation) and R (version 4.3.2; R Foundation for Statistical Computing). Python packages included *lifelines* (version 0.30.0) and *scikit-survival* (version 0.24.1). R packages included *cmprsk* (version 2.2.12).

Ethical Considerations

The Ethics Committee of Kyoto Min-iren Asukai Hospital approved the study protocol (Approval number: 202502 - 3) and waived the need for individual informed consent. The waiver was granted because this retrospective study analyzed routinely collected clinical data without any direct contact or intervention, posed no more than minimal risk to participants, and obtaining consent from all eligible patients would have been impracticable. All procedures complied with the institutional ethics standards and the Declaration of Helsinki. To protect privacy and confidentiality, the analytic dataset was deidentified before analysis: direct identifiers were removed. Study data were kept on access-controlled servers.

Results

Participants

During the study period, 118 individuals registered. After excluding 33 participants (30 who failed initial training for formulating research questions, and 3 who did not start), 85

mentees entered the final analysis. Of 85 mentees, 31 (36.5%) held academic degrees (PhD: 27, MPH: 2, PhD and MPH: 2), and 44 (51.8%) were working at university-affiliated hospitals. Sixty-eight (80%) were medical doctors, and 17 (20%) represented other health care professions: physical therapists (n=8), pharmacists (n=3), clinical psychologists (n=2), nurses (n=1), registered dietitians (n=1), dentists (n=1), and unspecified (n=1). No mentees had missing follow-up data.

Outcomes

During a median follow-up of 10 months (range, 0 - 54 months), 51 mentees (60%) submitted manuscripts. Forty-six (90%) became mentors. Ten (12%) discontinued. Discontinuation reasons included work commitments (n=4), workplace change (n=2), unclear (n=2), personal reasons (n=1), and competing systematic review publication (n=1). Twenty-four mentees continue projects. Cumulative manuscript submission reached 75.2% (95% CI 62.1% - 84.3%), and cumulative discontinuation was 18% (95% CI 9.3% - 28.9%) at the end of follow-up (Figure 2). At 12 months, manuscript submission was 42.9% (95% CI 31.4% - 53.9%) and discontinuation was 2.7% (95% CI 0.5% - 8.5%). At 24 months, manuscript submission was 63.3% (95% CI 50.6% - 73.6%) and discontinuation was 5.8% (95% CI 1.9% - 13.1%). In univariable analyses, the sdHR for manuscript submission was 0.78 (95% CI 0.43 - 1.43) for academic degree, 1.00 (95% CI 0.53 - 1.86) for profession, and 1.31 (95% CI 0.77 - 2.24) for university affiliation (Figures 3-5). Of 51 submissions, 50 appeared in English peer-reviewed journals. One submission remains under peer review. Submissions included 32 pairwise meta-analyses, 7 scoping reviews, 4 network meta-analyses, 2 prognostic studies, 2 diagnostic test accuracy studies, and 3 other study types (Multimedia Appendix 2). All published articles were indexed in the Web of Science at the time of publication. Journal impact factors were available for all except *The Annals of Translational Medicine*, which was indexed in the Web of Science and PubMed at submission but later excluded from the Web of Science. Citation counts, disregarding time since publication, had a median of 6 (range 0 - 60) as of Aug 1, 2025. Twelve articles (24%) appeared in journals requiring article processing charges. Analysis of 58,952 messages showed a median mentor response time of 0.8 hours (IQR 0.1 - 6.1), with 90% responding within 24 hours.

Figure 2. Cumulative incidence of manuscript submission and discontinuation of the program are plotted with 95% CIs. Shaded areas represent the 95% CIs.

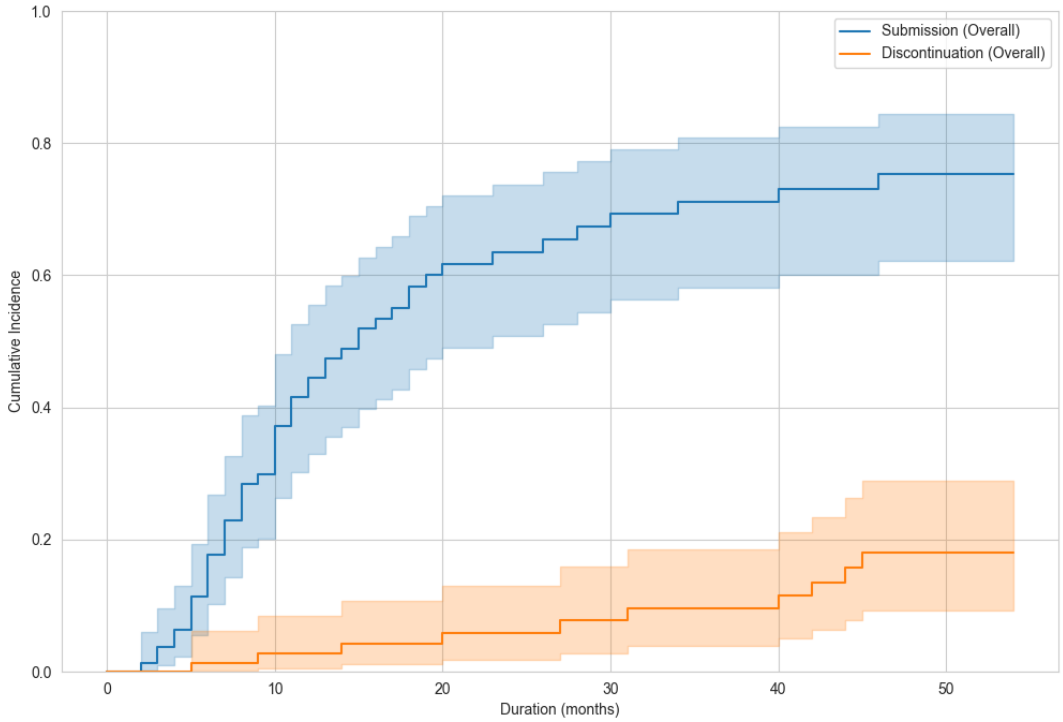


Figure 3. Cumulative incidence of manuscript submission and discontinuation of the program, stratified by the presence or absence of an academic degree (PhD or MPH), are plotted with 95% CIs. Shaded areas represent the 95% CIs.

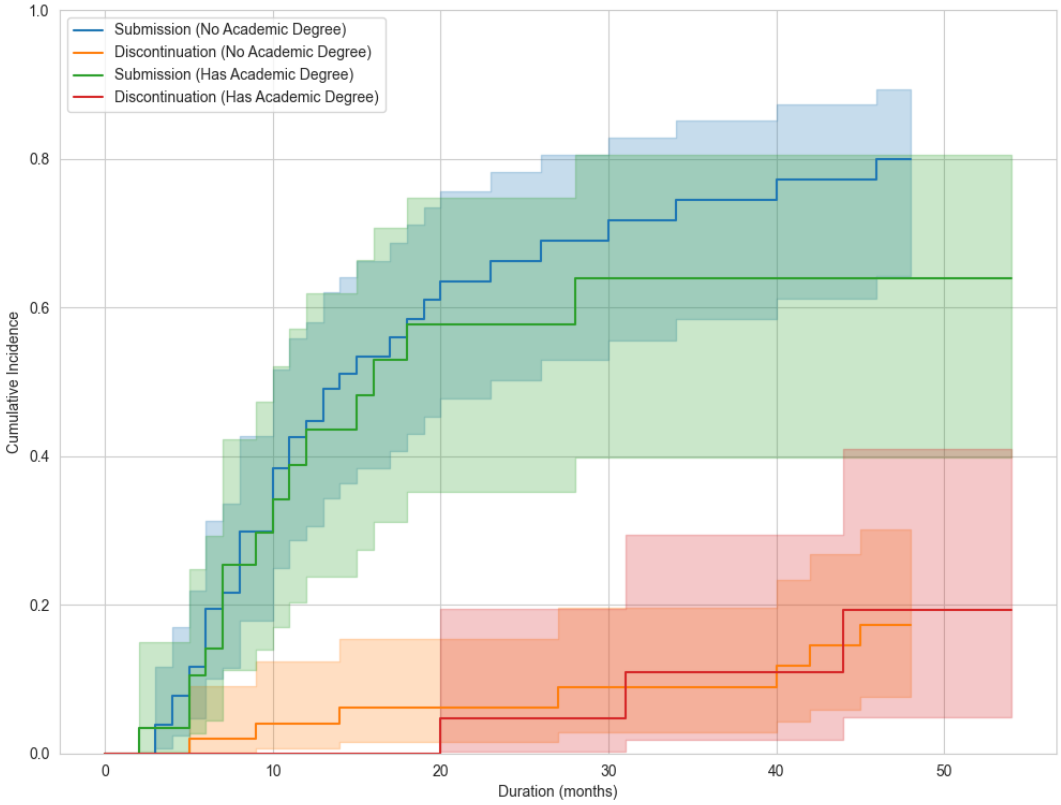

Figure 4. Cumulative incidences of manuscript submission and discontinuation of the program, stratified by profession (medical doctor or non-medical doctor), are plotted with 95% CIs. Shaded areas represent the 95% CIs.

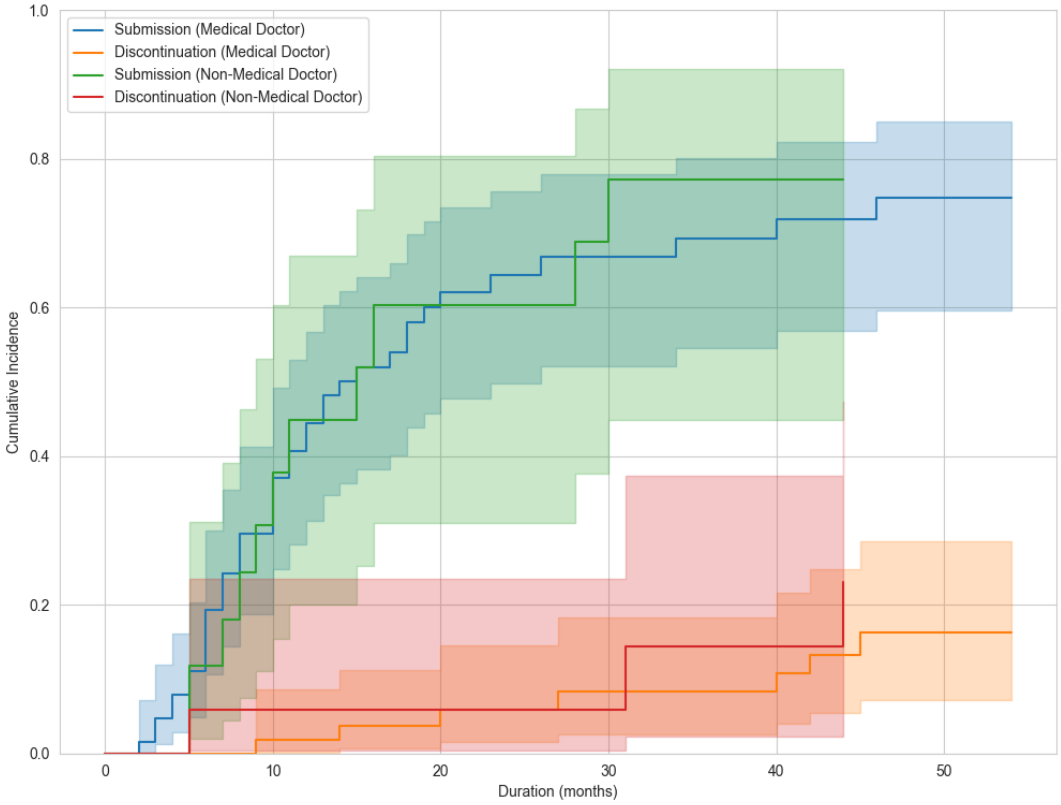

Figure 5. Cumulative incidences of manuscript submission and discontinuation of the program, stratified by university affiliation, are plotted with 95% CIs. Shaded areas represent the 95% CIs.

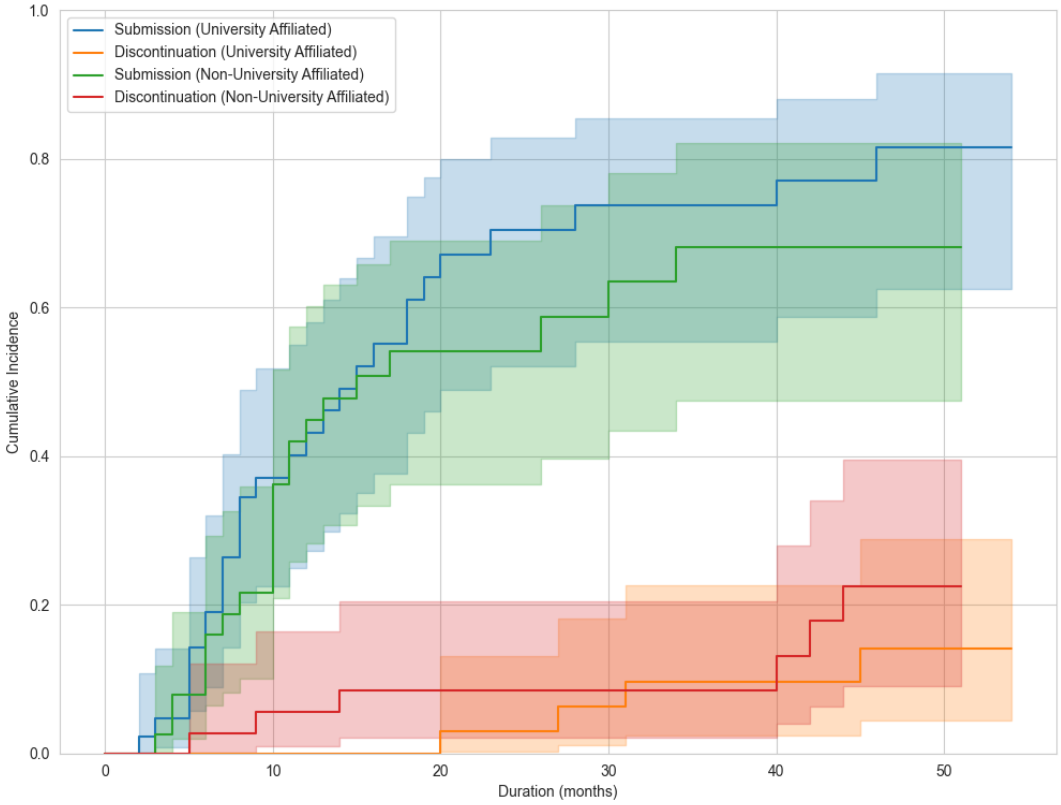

Discussion

Principal Results

The principal finding is that our fully online, peer-supported RCB model might contribute to actual research outputs for health care professionals. Specifically, cumulative manuscript submission reached 75.2% at the end of follow-up, while cumulative discontinuation remained at 18%. The publications appeared in journals indexed in the Web of Science, with a median citation count of 6 (range 0 - 60), indicating initial uptake. The rapid mentor responsiveness (median 0.8 hours) further contributed to program effectiveness. Ninety percent of mentees who submitted manuscripts transitioned to mentors. These quantitative outcomes provide a foundation for the subsequent discussion of the program's effectiveness through the lens of Cooke's RCB framework [1].

While we did not set specific a priori cut-offs for outcomes, we consider the observed outcomes meaningful. Of note, we view discontinuation as a particularly critical metric because it directly reflects program adequacy—participants who leave the program cannot achieve the primary outcome of manuscript submission. The reasons for discontinuation (work commitments, workplace changes, personal reasons, and competing publications) were all external factors beyond the scope of SRWS-PSG's organizational support, suggesting that the program's support structure itself was adequate.

Implications of Findings

Research-novice medical professionals were able to participate in the SRWS-PSG program. Our subgroup analyses demonstrated that manuscript submission rates were similar regardless of participants' academic degrees, professional backgrounds, or institutional affiliations. The program's fully online format addresses geographical and temporal constraints, enabling flexible participation around clinical duties. Rapid mentor feedback provides continuous support for novices navigating the systematic review process. This accessibility suggests that the SRWS-PSG model might expand RCB opportunities beyond traditional academic boundaries.

Hospital administrators seeking to foster their medical professionals' research competency could provide protected time for SRWS-PSG participation. The primary reasons for program discontinuation were external factors such as work commitments and workplace changes rather than program inadequacy. Institutional support through protected time could address these barriers and enhance completion rates [6]. The program's modest monthly fee represents a cost-effective investment for institutions.

The SRWS-PSG model's features suggest broad applicability across diverse global contexts, including low- and middle-income countries. The fully online format eliminates geographical barriers and infrastructure requirements, while the focus on systematic reviews—requiring only internet access without expensive equipment or data collection costs—makes research accessible in resource-limited settings. The self-sustaining economic model through participant fees offers an alternative to scarce grant funding. While implementation would require translation and fee adjustment to local contexts, the core elements—peer support, standardized methodology following international guidelines, and progression from mentee to mentor—address universal challenges in RCB regardless of economic or cultural setting.

Comparison to the Literature

Our findings extend previous RCB evaluations in several ways. The SRWS-PSG model's continuous feedback approach shares elements with intensive programs like writing boot camps [22] but delivers them in a sustained, online format throughout the entire systematic review process. This contrasts traditional time-limited workshops. Our approach shares goals with the Rural Research Capacity Building Program in Australia [20] but operates entirely online.

Mentees formulated research questions directly relevant to their clinical environments, bridging research and practice in ways that promote Boyer's scholarship concept of "integration" and "application" [23]. This contrasts with academic programs where research topics may be driven by funding or institutional priorities rather than clinical needs.

The self-supporting economic model offers a sustainable alternative to grant-dependent programs. Mentee fees fund mentor compensation and administrative costs. This enables 5 years of operation without external funding. Many RCB programs require institutional or funding support [2]. This approach echoes Japan's Edo period tradition of community-based education. Community mathematics teachers ("Wasan-ka") sustained themselves through teaching fees. This grass-roots system enabled people from all social classes to publish their mathematical problems at shrines as open access articles ("Sangaku") [24]. SRWS-PSG functions as a traditional citizen science model, maintaining economic sustainability through community participation rather than institutional supports.

Limitations and Future Directions

This study has several limitations. First, this retrospective observational study without a control group cannot establish causality. Although continuous program improvements pose a challenge for evaluation, a rigorously designed well-powered randomized controlled trial is the necessary next step to definitively assess the efficacy. Second, our metrics emphasized outputs such as submission but did not directly evaluate some dimensions of Cooke's framework. Specifically, we did not assess changes in individual research skills (including systematic review methodology competency beyond evidence-based medicine competency [25]), self-reported confidence, or participant motivation levels. We also could not evaluate the quality of mentor-mentee relationships, organizational-level support, and infrastructure investments, or the dynamics of online community participation and peer interactions that illuminate collaborative learning. Future studies should incorporate comprehensive assessments including skills evaluation, qualitative analyses of mentoring relationships, surveys of institutional support structures, and quantitative measures of online engagement to elucidate how these collaborative learning dynamics influence program outcomes. Third, our analysis of participant affiliation was limited to a binary variable (university-affiliated or not), which is an imperfect proxy for the actual research environment. In Japan, university affiliation does not guarantee a supportive research environment [6]. Future studies should collect more granular data on the institutional support environment. Fourth, a challenge remains in the formal assessment of mentees for mentorship roles and the structured faculty development for new mentors. While we provide web-based training on mentoring, a comprehensive evaluation system for these skills is not yet fully established and represents a key area for future development. Fifth, while we provided summary data on publication venues and citations, we did not conduct a formal analysis of article quality metrics beyond indexing status. Future evaluations should include more detailed assessments, such as independent article quality ratings, to better characterize program outputs.

Looking forward, we are exploring large language models as a "third mentor" [26,27] to improve mentor feedback speed and quality while reducing workload. We are investigating the application of large language models in the systematic review process to accelerate research timelines [28,29]. While being mindful of the potential for hallucinations in large language models [30], SRWS-PSG will improve the efficiency of medical scientific endeavors.

Conclusion

A majority of health care professionals who participated in the SRWS-PSG program submitted manuscripts with low discontinuation rates. This model might address geographical barriers and create a self-sustaining financial structure, providing an adaptable approach for RCB across health care contexts. Future research should incorporate a more comprehensive evaluation of program mechanisms and outcomes.

Acknowledgments

We would like to express our gratitude to all SRWS-PSG participants and mentors who contributed to this program over the years. Special thanks to Chisato Fujiwara for her invaluable secretarial assistance. We used Claude 4.0 Opus for English Editing. All authors reviewed the final manuscript.

Open Access publication supported by Tohoku University FY2025 APC Support Program.

Abstract

Background: Electronic medical records (EMRs) are a potentially rich source of information on an individual's health care providers' clinical activities. These data provide an opportunity to tailor web-based learning for health care providers to align closely with their practice. There is increasing interest in the use of EMR data to understand performance and support continuous and targeted education for health care providers.

Objective: This study aims to understand the feasibility and acceptability of harnessing EMR data to adaptively deliver a web-based learning program to early-career physicians.

Methods: The intervention consisted of a microlearning program where content was adaptively delivered using an algorithm input with EMR data. The microlearning program content consisted of a library of questions covering topics related to best practice management of common emergency department presentations. Study participants were early-career physicians undergoing training in emergency care. The study design involved 3 design cycles, which iteratively changed aspects of the adaptive algorithm based on an end-of-cycle evaluation to optimize the intervention. At the end of each cycle, an online survey and analysis of learning platform metrics were used to evaluate the feasibility and acceptability of the program. Within each cycle, participants were recruited and enrolled in the adaptive program for 6 weeks, with new cohorts of participants in each cycle.

Results: Across each cycle, all 75 participants triggered at least 1 question from their EMR data, with the majority triggering 1 question per week. The majority of participants in the study indicated that the online program was engaging and the content felt aligned with clinical practice.

Conclusions: The use of EMR data to deliver an adaptive online learning program for emergency trainees is both feasible and acceptable. However, further research is required on the optimal design of such adaptive solutions to ensure training is closely aligned with clinical practice.

Introduction

Background

Medical practitioners engage in a variety of formal and informal training activities to stay up to date on best practices for delivering patient care. Activities undertaken by medical practitioners in the context of professional training can take many forms, including mentorship and consultation with peers, attendance at local seminars and international conferences, journal clubs, and other activities [1]. It has also been observed that medical practitioners dedicate considerable time to undertaking education and training activities. An observational study of physicians on hospital wards found that around 7% of observed tasks involved engaging in education or supervision [2]. Another study found that medical practitioners early in their careers spend close to 2 hours every day engaging in training activities [3].

Digital technologies are increasingly being used to share knowledge and evidence between medical practitioners in the workplace [4]. Online learning as a mechanism for delivering training to the medical profession is also increasingly widespread [5]. Benefits of online learning include making training available when and where individuals would like to access it, potentially enabling more innovative approaches to teaching and making information more easily accessible [6]. In the context of training medical practitioners, flexibility or adaptivity has been emphasized as a major advantage of online education [7]. However, online learning can also have disadvantages, and there is disagreement in the literature as to whether delivering training to medical practitioners online impacts learning outcomes [5]. Another potential issue is that online learning can require more self-discipline and greater time management skills to complete than face-to-face training [8]. This phenomenon may be why online learning has been noted to have high completion rates, with 60% being a high completion rate for many online courses [9].

One strategy for strengthening online learning for medical practitioners could be to align it more closely with clinical practice. It has been noted in the literature that current approaches to medical education disconnect learning activities from practice and care delivery [10]. To date, there is limited research into how online learning could be personalized to align it more strongly with clinical practice. A recent scoping review of secondary use of data from all health information technologies (HITs) identified education as one of 4 key domains for this purpose, but data were used in this way in only 1% of the identified studies [11]. Another scoping review exploring the design of dashboards presenting data from HITs to support reflective practice found that these types of visualization tools were often designed to present data to individual medical practitioners to allow them to reflect on their practice, but such platforms rarely incorporated scaffolds that would support learning or other improvement activities [12].

The field of learning analytics has also explored the significant potential of data collected about learners in online programs for enhancing learning. Learning analytics broadly describes the collection, analysis, and reporting of data about learners and their contexts for the purpose of understanding and optimizing learning and the environments in which it occurs [13]. A recent review of the literature identified personalization as a major focus of learning analytics, particularly in the context of online learning environments where large amounts of data about the learning process are routinely collected [14]. Research into learning analytics in medical education has identified several barriers in this space, including implementation challenges, such as how to collect data to use in learning analytics; data management issues, such as governance and access to appropriate data; and outcomes challenges, such as how data can be used to assess learners, programs, and systems [15]. Furthermore, it has been noted in the wider literature on medical education that when training is delivered digitally, analytics collected about learning progress are a potentially rich source of information for informing evidence-based instruction [7].

In the context of online learning for medical practitioner education, routinely collected electronic health data such as that in electronic medical records (EMRs) may have value for aligning learning with clinical practice. While there is a wide range of HITs used in clinical practice, EMRs are a core technology that have been widely adopted in many health care organizations [16,17]. Data from EMRs have been identified as being useful for understanding the practice patterns of medical practitioners [18] and for supporting formative assessment of early-career physicians in the workplace [19]. There is also literature suggesting that health care providers across a range of disciplines are interested in EMR data being harnessed to inform learning and training activities [20]. To date, there has been limited research undertaken into the use of EMR data to support workplace learning for medical practitioners.

There is a small but growing body of research exploring the intersection between EMR data and health professional learning. A recent study investigated the use of EMR data to support medical practitioners undertaking a learning needs assessment, which was subsequently used as the basis for delivering a customized continuing medical education program for the next year [18]. In this study, medical practitioners were provided an EMR report showing their data compared to other participating practitioners, which they then used to identify personalized learning goals. Another study of this type used data from electronic prescribing systems has also been used to personalize the delivery of letters to prescribers advising them of their compliance with antimicrobial prescribing policy [21]. Researchers have also investigated the use of EMR reports to populate dashboards to educate medical practitioners about their performance. In one such study, a dashboard visualizing EHR reports was made available to medical practitioners for 6 months with the goal of reducing overprescribing of antibiotics [22], though this study was not able to demonstrate a change in practice.

Although interest is increasing in the use of EMR to support training for medical practitioners aligned with clinical practice, the data have some limitations for this application. A considerable limitation is that there can be gaps in the data and that the data are not captured for the primary purpose of education [23], and there are limitations on how these data can be used to understand performance [19]. As has already been highlighted, a further limitation is the relatively few examples in the literature demonstrating how to use EMR data to design this type of personalized education [18,22]. Furthermore, current popular approaches for presenting EMR data to medical practitioners to support reflection lack scaffolds such as self-reflection tools, goal-setting options, or learning plans that could be used to support professional learning [12].

Problem Statement

Despite the plethora of electronic data being collected by the health system and growing interest in their use to support health professional education, there is a dearth of knowledge on how to design data-driven learning interventions for professional learning. This study aimed to address that gap by investigating the feasibility and acceptability of using EMR data to adaptively deliver an online learning program. In the context of this study, feasibility included answering the following research questions:

- Could data be routinely extracted from an EMR to support data-driven learning?
- Could EMR data be linked to microlearning questions to trigger adaptive delivery to different learners?
- How engaging did learners find the data-driven learning program?

A secondary aim was to understand how to design such a program so that learners felt the content was well aligned with their clinical practice. The study investigated EMR data specifically due to the widespread adoption of this HIT in health care organizations [17] and the recognized use of EMR data for understanding clinical practice patterns [18].

Methods

Study Design

The study used 3 design cycles to iterate on the design of the adaptive online learning program. The approach was based on a design-based research approach that has been used in research education contexts to provide a systematic but flexible approach to improv practice through iterative cycles of design, development, and implementation [24]. At the end of each cycle, a mixed methodology was used to evaluate the feasibility and acceptability of the program and refine it in response to learner feedback. Within each cycle, learners were enrolled in the adaptive program for 6 weeks, with new cohorts of learners in each cycle.

Participants and Study Setting

The study was undertaken within the emergency department at 2 public metropolitan hospitals in Sydney, Australia. The 3 design cycles were run over a 12-month period between December 2018 and December 2019.

Potential participants were early-career physicians who were undergoing postgraduate training. Early-career physicians in Australia are those who have graduated from medical school and have provisional registration to practice but have not undergone enough training to be qualified to be independent practitioners. The first step of the training pathway, typically completed within 2 years of postgraduation from a medical degree, is working as an intern for 12 months. As an intern, early-career physicians undertake 10-week terms to expose them to different clinical environments. A rotation in emergency medical care is always included in this training. After working as an intern, early-career physicians may become residents for an additional year, potentially followed by being a registrar to undertake training for a specialized medical pathway [25].

Inclusion criteria for the study required participants to be interns undergoing their emergency medical care term at the study sites during the recruitment period. Participants were excluded from the study if they were not interns at the study sites or were not undertaking an emergency medical term while the study was recruiting.

All interns at the participating study sites were invited to participate in the study. Participants were recruited via flyers and an online notice with a link to sign up for the study. In design cycle 1, 22 physicians consented to participate; in design cycle 2, 36 physicians consented to participate; and in design cycle 3, 18 physicians consented to participate in the study. No physicians formally withdrew from the study.

Study Procedures

Intervention Design

The online program was delivered using the Qstream microlearning platform [26]. This is an off-the-shelf platform that sends multiple-choice questions to learners via email or a smartphone app. To reinforce a single take-home message, multiple-choice questions provided learners with detailed feedback on why the response they had entered was correct or incorrect. By default, the platform delivered learners a small bundle of 2 to 3 questions at a time, so that it only took a few minutes to respond to the bundle. The platform would then repeat questions a set number of times depending on whether the learner answered incorrectly or correctly. In the intervention, the microlearning platform was modified to alter the way questions were selected for individual learners and the frequency at which they were delivered. The modified functionality was an adaptive algorithm using data extracted from the EMR. Data were extracted from the EMR via a report that was run 2 times each week the adaptive program was running. The adaptive algorithm ingested EMR data related to the cohorts of patients an individual participant had encountered in the previous few days. The algorithm would subsequently tailor the delivery of microlearning questions for each learner based on the patients they had encountered in the reporting period. For example, if a participant had seen a patient with a heart condition, they would be sent a question on best practice for managing this patient group. If a peer of the participant had not seen a patient with a heart condition but had seen a patient presenting with shortness of breath, they would receive a question on best practice for managing patients with this condition. Multimedia Appendix 1 shows an example of the Qstream app interface and one of the cases for this intervention.

Questions were developed by a team of domain experts in emergency care and educational designers. The domain experts developed a curriculum that covered common clinical scenarios encountered in the emergency department that were considered opportunities to improve knowledge and behavior related to the best practice of potential participants. The curriculum and the questions that were built within it were developed based on the domain experts' understanding of common knowledge gaps of the potential participants. The educational designers undertook a structured review of EMR reports to understand the data that were available to trigger the delivery of curriculum content in a manner that would adapt to an individual participant's clinical encounters during the intervention. The curriculum and question set were designed to be relevant to improve clinical practice of participants as well as feasible to personalize through accessing EMR data and were developed using an evidence-based approach to developing microlearning questions [27]. The final curriculum consisted of cases on the management of care for patients presenting with the following symptoms: (1) chest pain, (2) abdominal pain (triggered by clustering 2 presenting problem codes), (3) breathlessness, (4) syncope (triggered by clustering 2 presenting problem codes), (5) headache, and (6) fever. A

seventh category was added to the curriculum for the third cohort of learners: mental health (triggered by clustering 10 presenting problem codes). A total of 45 questions were developed for the original 6 program categories. Five additional questions were developed for the mental health category made available for the third cohort of learners. Questions were not pilot-tested with representatives from the cohort they were developed for prior to use in the intervention. Table 1 presents an overview of the microlearning program curriculum and questions.

Table . Overview of the microlearning program, including the topics, the question names, and take-home messages, and the cohort that had access to the library.

Topic and question ID	Take-home message	Cohort
Abdominal pain		Cohorts 1-3
1	In females of childbearing age, ectopic pregnancy should always be the first consideration and a diagnosis of exclusion regardless of the menstrual and conception history reported.	
2	General supportive measures remain consistent in all resuscitation scenarios, especially in the bleeding patient. Warming patients may help prevent worsening coagulopathy and further bleeding.	
3	Abdominal pain in older people can be a challenging presentation. In contrast to younger patients, a broad range of life-threatening differentials should be considered.	
4	In high-stress settings, cognitive readiness may be enhanced using simple techniques that minimize autonomic hyperarousal.	
5	It is important to explore and investigate the causes of bloody or prolonged diarrhea which in this case could be due colitis. Night time defecation is suggestive of an underlying pathological cause.	
6	Pancreatitis is inflammation of the pancreas and involves activation of proteolytic enzymes that may progress to hemorrhagic necrosis of the pancreatic parenchyma. Different geographic locations may report different incidences of aetiologies but universally ethanol and gallstones are common causes.	
7	Intrarenal calculi are not, on their own, an indication for referral to urology.	
8	Examination of the testes is an essential part of the abdominal examination in young males, even if they do not report testicular pain. Torsion is the diagnosis of exclusion.	
Shortness of breath		Cohorts 1-3
1	A structured approach to x-ray interpretation is required when reviewing in the ED[a] because we do not normally have the benefit of a *formal* report from a radiologist. Subtle pneumothorax is an easily missed diagnosis.	

Topic and question ID	Take-home message	Cohort
2	BiPAP[b] NIV[c] therapy is indicated in a patient with an acute exacerbation of COPD[d] with a persistent respiratory acidosis despite appropriate initial treatment. A low level of consciousness is not an absolute contraindication to the use of NIV.	
3	The treatment of anaphylaxis requires a dose of intramuscular adrenaline. The EpiPen dose is 0.3 mg. Typically, 0.3 mg to 0.5 mg (1:1000=0.3 - 0.5 mLs) is the dose for an adult patient with anaphylaxis.	
4	In a patient with hypoxia and known COPD at risk of CO_2 retention, apply titrated oxygen first until target saturations are achieved. Positioning the patient is also an important management step.	
5	Patients with underlying cancer are at higher risk of life-threatening sepsis (associated with chemotherapy), pericardial effusions, and PE[e].	
6	A plain CXR[f] is practical, easily accessible, and universally indicated for a patient with acute shortness of breath in the ED.	
7	It is important to remember that there are noncardiorespiratory differentials to shortness of breath. Patients with a metabolic acidosis will often present with tachypnoea (Kussmaul respiration).	
Chest pain		Cohorts 1-3
1	Early diagnosis of AD[g] requires a high index of suspicion. Blood pressure treatment should target control of both heart rate and the pressure itself.	
2	Chest pain “PLUS” another symptom should trigger the thought, “Could this be a diagnosis of Aortic Dissection?” AD may mimic acute MI[h] (including ECG[i] findings).	
3	No one factor can reliably rule out ACS[j] in the ED setting. Pain radiating to the right shoulder or arm is considered more specific for ACS than pain radiating to the left arm.	
4	An ECG should be performed in anyone presenting with chest pain. While well known, S1Q3T3 is uncommon in the setting of PE. Sinus tachycardia and anterior *T* wave inversions are more common.	

Topic and question ID	Take-home message	Cohort
5	It is important to consider PE as a differential in patients with cancer. There are scoring tools available to assist you (Wells and PERC being the most commonly used in the ED).	
6	A CXR should be part of your workup for chest pain and shortness of breath. Special care should be paid to looking for pneumothorax and consolidation.	
7	MI, PE, and AD are 3 critical conditions to consider with any patient presenting with chest pain.	
8	AD should be considered in any patient with chest pain with risk factors (eg, hypertension), or chest pain with a concurrent symptom such as neurological deficits.	
Fever		Cohorts 1-3
1	The presence of severe pain (pain out of proportion to the clinical findings) in an at-risk patient should raise concerns about the diagnosis of necrotising fasciitis.	
2	It is important to note the patient's allergy to penicillin. Tazocin (piperacillin or tazobactam) is a penicillin, therefore is relatively contraindicated for febrile neutropenia, though it remains first line in guidelines.	
3	Early recognition of sepsis is paramount (new concept of qSOFA[k] rather than use of nonspecific or sensitive "SIRS[l]" criteria).	
4	Patient is MRSA[m] colonized so we should consider vancomycin as additional cover (with expert advice). Antibiotics choice should always be judiciously guided by guidelines and ID team support	
5	You must cleanse your hands before and after any patient interaction. Alcohol is generally preferable over soap and water unless the hands are soiled or if *Clostridium difficile* infection is an issue (ie, spores are not necessarily killed by alcohol rub).	
Headache		Cohorts 1-3
1	In the event of a late (>6 h) presentation with a typical SAH[n] story, further investigations are required to excluded the diagnosis. All headache cases should be discussed with a senior physician prior to discharge.	

Topic and question ID	Take-home message	Cohort
2	If a patient presents with an acute severe headache plus fever and if the CT[o] is normal, consider a lumbar puncture to exclude meningitis. Consider giving early intravenous antibiotics and antivirals.	
3	If a patient with no history of headaches presents with a sudden onset headache and classic features of SAH, and the CT scan comes back *'normal'* consider further testing. MRI[p] or MRA[q] and specialist review may be warranted under these circumstances.	
4	When a patient presents with a headache, be sure to prescribe analgesia. Patients with papilledema require ED evaluation with referral to both ophthalmology and neurology following neuroimaging.	
5	Over analgesia (especially with paracetamol, codeine, and aspirin) is associated with a paradoxical increase in headache in some patients. While analgesia in the acute setting is a mainstay of our ED management, we should discuss refractory cases with a neurologist and arrange follow-up.	
6	Typically, the CSF[r] glucose concentration is two-thirds that of the serum glucose concentration.	
7	Temporal arteritis is a sight-threatening condition that is also known as GCA[s]. Jaw claudication is a classic symptom.	
8	Low CSF headache is a distinct and familiar syndrome that is seen most frequently following lumbar puncture. Typically, the headache is orthostatic and significantly improves by lying flat.	
Syncope		Cohorts 1-3
1	Patients presenting with syncope should be risk-stratified based on their overall history, examination, and a period of observation. Risk scores (eg, San Francisco or the Rose Criteria) may have some use as an adjuvant to your thorough clinical assessment.	
2	An ECG is a very important test in a patient with syncope. It is a mandatory test in the ED for a patient with syncope.	

Topic and question ID	Take-home message	Cohort
3	Dosing of NOACs[t] can be confusing and factors such as age, weight, renal function, and indication may affect dosage. Consultation with hematology and a pharmacist regarding dosing is pertinent.	
4	Vertigo is a common ED presentation. The history given is concerning for a "*central*" cause of vertigo. Age is an independent risk factor for stroke.	
5	Early defibrillation and commencement of high-quality BLS[u] are critical to outcomes in cardiac arrest. While not contraindicated, checking for a pulse is no longer specifically recommended in assessing for signs of life or confirming arrest.	
6	Metoclopramide and prochlorperazine both worsen Parkinson disease symptoms, and therefore are contraindicated in those with Parkinson disease. Domperidone is more appropriate for these patients.	
7	If in doubt with a case of "wide complex tachycardia," call for help and assume the diagnosis is VT[v] until proven otherwise.	
8	If in doubt with a case of "wide complex tachycardia," call for help and assume the diagnosis is VT until proven otherwise.	
Mental health		Cohort 3
1	This is a possible first presentation of schizophrenia with paranoid delusions. The importance of a mental state examination and collateral history is highlighted in this case.	
2	Although there are some variations in practice, current guidelines for parental sedation have droperidol as the most appropriate first-line agent. This should be done with care not to cause further harm to the patient, both through physical and medical means. Droperidol is a commonly used agent in the ED at Westmead Hospital.	
3	Alcohol withdrawal can often present in unusual circumstances such as a change of environment limiting someone's access to alcohol. The presence of visual hallucinations, confusion, and physical complaints make a purely psychiatric diagnosis less likely.	

Topic and question ID	Take-home message	Cohort
4	A person may be treated without consent under two conditions: (1) life-threatening emergencies when a patient lacks "capacity"; and (2) under the Mental Health Act (but only for psychiatric treatments).	
5	There is no such thing as "low risk" in assessing the patient with suicidal tendencies. All patients with mental health issues in the ED have a significantly higher long-term risk of suicide than the general population.	

[a]ED: emergency department.
[b]BiPAP: bilevel positive airway pressure.
[c]NIV: noninvasive ventilation.
[d]COPD: chronic obstructive pulmonary disease.
[ee]PE: pulmonary embolism.

[s]GCA: giant cell arteritis.
[t]NOAC: nonvitamin K antagonist oral anticoagulant.
[u]BLS: basic life support
[v]VT: ventricular tachycardia.

Intervention Delivery

During the 6-week intervention period for the online program, a report was manually extracted 2 times each week (Tuesdays and Fridays) from the EMR and fully deidentified patient information. The frequency of extraction was chosen for feasibility reasons as the extraction process was manual and we could not continually extract the data. Only structured data were included in the report as EMR data were only being used to trigger the delivery of questions, not to tailor the content in individual cases received by learners. The deidentified report was then provided to the researchers in .csv format. The EMR report was used to identify if participants had interacted with the relevant patients to populate the adaptive algorithm in the microlearning program. If the EMR data indicated a participant had encountered patient presentations related to the microlearning program, they would "trigger" a question related to managing that type of patient presentation. "Triggering" a question meant that a participant would be allocated a relevant question in the microlearning platform, and it would subsequently be pushed to them via email or the smartphone app to complete. If a participant did not see any clinical presentations that could trigger a question in the reporting period, they did not receive any questions. If participants had seen clinical presentations that could trigger a question, they were enrolled in the relevant question. Questions were pushed to each participant on the same day they were generated, so they received the case within 3 days of seeing the patient that triggered it.

The number of questions participants could receive and the topics in the program were iterated on each cycle in response to analysis of data evaluating that cycle. Participants could be re-enrolled in a question at a later point in the intervention period if they had not previously attempted to respond to it, and the EMR data indicated they had triggered it again. Modifications were made to the delivery of the algorithm for the cases in each cycle. Table 2 summarizes the iterations across all the design cycles.

Table . Summary of iterations made across the design cycles and explanation of why those modifications were made.

Summary of quantitative data	Design cycle 1	Design cycle 2	Design cycle 3
Iterations undertaken	• Cases delivered across 6 presenting problem domains. • Participants were assigned up to 3 questions each for each EMR[a] reporting period. • If only 1 patient presentation was encountered by a participant during the EMR reporting period, 3 questions related to that patient presentation would be delivered. • If no patient presentations that could trigger a question were encountered during the EMR reporting period, then no questions would be assigned.	• Cases delivered across 6 presenting problem domains. • Participants were assigned up to 3 questions each for each EMR reporting period. • If only 1 patient presentation was encountered by a participant during the EMR reporting period, only 1 question related to that patient presentation would be delivered.	• Cases delivered across 7 presenting problem domains. Mental health was added as a new presenting problem.
Justification for iterations	• N/A[b]	• Reduce the number of questions participants had to respond to in a single bundle to increase course engagement	• Increase the perceived alignment of the course content with clinical practice by using a less common, but still frequent patient presentation

[a]EMR: electronic medical record.

[b]N/A: not applicable.

During design cycle 1, each participant was assigned 3 questions chosen using the personalization algorithm based on the cases they had attended during the EMR reporting period. If only 1 clinical presentation that could trigger a question was seen by a participant, they would receive 3 different questions on that topic from the question library. For example, in a single EMR report, if a participant had seen only patients with chest pain, they would receive 3 chest pain questions; if that participant had seen 1 patient with chest pain, 1 patient with abdominal pain, and 1 patient with syncope, they would receive 1 question on each topic; if a participant had seen nonrelevant patients, they would receive zero questions.

During design cycle 2, participants who saw relevant clinical presentations in each reporting period were assigned up to 3 questions chosen using the personalization algorithm. They only received 1 question per topic triggered by the EMR data, rather than multiple questions as was the case in design cycle 1. This change was made to reduce the number of questions the participants had to respond to in a single bundle, as analysis of temporal data collected in design cycle 1 indicated some participants were completing all cases in a single bundle at the end of each week. For example, in a single EMR report, if a participant had seen only a patient with chest pain, they would receive 1 question on chest pain; if that participant had seen 1 patient with chest pain and 1 patient with syncope, they would receive 1 question on chest pain and 1 question on syncope; if that participant had seen 1 patient with chest pain, 1 patient with abdominal pain, and 1 patient with syncope, they would receive 1 question on each topic; if a participant had seen no relevant patients, they would receive zero questions.

During the final design cycle, the delivery of questions was the same as in design cycle 2; however, questions related to the topic of mental health were added to the program. Mental health cases were added to see if a less common patient presentation would increase the sense of alignment between the intervention and clinical practice.

Regardless of the design cycle, at the end of each week during an intervention period, all participants in that cycle were unenrolled from any questions they had not responded to. This was done to ensure a large backlog of questions did not accumulate for participants to answer, also to ensure participants were not receiving questions that were not aligned with their recent clinical practice. Participants could also be enrolled in the same question multiple times during the design cycle if they had not attempted it on a previous enrollment and had subsequently been unenrolled. There were two situations in which participants would not be enrolled in a new question even if they had triggered it in the EMR report. The first reason a participant was not enrolled in new questions was if they already had questions they had been enrolled in and had not finished answering. The second reason was because a participant had answered all the questions on that topic correctly and had not triggered any other topics based on the EMR report.

Intervention Evaluation

To evaluate the program, a number of data points were collected. EMR reports were used to trigger the delivery of questions during the intervention, as well as to determine the time that had elapsed between seeing a clinical scenario and completing a question. Coupled with metrics from the EMR, metrics captured by the online learning platform were extracted to understand participant engagement with the intervention, participant progress during the program, the number of questions participants were enrolled in that they completed, the accuracy of their responses, and the time that elapsed between being

allocated a question and answering it. Finally, a bespoke online survey created by the researchers was disseminated at the end of each design cycle to capture participant feedback on the program. Survey responses were anonymous. The survey consisted of a combination of Likert responses and free-text comments. Structured questions explored how participants accessed the program, the value of clinical data for learning, the relevance of the program content, the course format, and overall experience with the course. Free-text responses allowed participants to provide general comments and feedback on changes to the course. The survey questions were not pilot-tested prior to use in the study.

Data Analysis

Metrics captured by the online learning platform on participant progress during the program were descriptively analyzed to understand how adaptations to the algorithm influenced participant behaviors. These data, combined with EMR reports, were also analyzed to understand how temporal factors related to the alignment of questions with the participant's clinical practice influenced engagement with content. Reports extracted from the EMR were analyzed to understand the link between participant test ordering and allocation of questions in the online learning platform.

Structured data from the survey were descriptively analyzed. Unstructured data from free-text survey comments were analyzed to understand participant engagement with the content of the intervention, the online learning platform, and the adaptive component. The content analysis was undertaken by one researcher (AJ) who read all the comments to get a sense of the data. Additional read-throughs of the data were undertaken to code the data and subsequently classify it into categories based on the similarity of themes discussed.

Ethical Considerations

The study received ethical approval from the Western Sydney Local Health District Human Research Ethics Committee (protocol: 2019/ETH02509). All participants provided written informed consent before agreeing to participate in the study. The researchers complied with informed consent guidelines when necessary and have adhered to local, national, regional, and international law and regulations regarding the protection of personal information, privacy, and human rights. Study data was de-identified prior to analysis. Participants did not receive any compensation for participating in the study.

Results

Overview

The following sections present a description of data from each design cycle of the intervention. Table 3 shows an overview of key quantitative data compared across each design cycle, and Table 4 shows an overview of the responses to the online survey across all 3 design cycles. There was a library of 37 questions across 5 topics during design cycles 1 and 2. There was a library of 43 questions covering 6 topics in design cycle 3. If a participant encountered a patient related to one of the topics in the biweekly EMR report (2 times a week) during a design cycle, it would trigger the delivery of a question. Figure 1 shows the question topics in the program and the percentage of participants who correctly, incorrectly, or did not respond to each topic for design cycles 1-3. Figure 2 visualizes the top 20 presenting problems encountered by participants during the intervention period for design cycles 1-3.

Table . Comparison of key quantitative data points across design cycles 1-3 of the intervention.

Summary of quantitative data	Design cycle 1 (n=21)	Design cycle 2 (n=36)	Design cycle 3 (n=18)
Unique questions in cohort, mean (SD; range)	9.72 (4.62; 3-20)	9.69 (5.79; 1-22)	6.27 (4.93; 1-17)
Range of unique questions in cohort, mean (SD; range)	3 - 20 (4.62)	1 - 22 (5.79)	1 - 17 (4.93)
Participants attempting more than 50% of the questions, n (%)	18 (86)	23 (66)	7 (37)
Total patient presentations (including duplicates) for participant cohort that could have triggered a question, n	1931	4918	2961
Three most common presenting problems encountered by all participants in a cohort that could trigger a case, n	• Abdominal pain: 649 presentations • Chest pain: 484 presentations • Shortness of breath: 215 presentations	• Chest pain: 600 presentations, • Abdominal pain: 573 presentations • Shortness of breath: 335 presentations	• Abdominal pain: 357 presentations • Mental health: 159 presentations • Shortness of breath: 156 presentations
Survey responses, n	9	15	1

Table . Comparison of survey responses across design cycles 1-3 of the intervention.

Summary of survey responses	Design cycle 1 (n=9), n (%)	Design cycle 2 (n=15), n (%)	Design cycle 3 (n=1), n (%)
Participants who agreed or strongly agreed with the statement that the duration of the course suited their needs	6 (67)	12 (80)	1 (100)
Participants who agreed with the statement they would have like to have received more cases each week.	4 (44)	11 (73)	0 (0)
Participants who agreed or strongly agreed with the statement they found the online program engaging	6 (67)	12 (80)	1 (100)
Participants who agreed or strongly agreed they would recommend the course to a colleague	7 (78)	12 (80)	0 (0)
Participants who agreed or strongly agreed with the statement the program content was realistic	8 (89)	8 (89)	0 (0)
Participants who agreed or strongly agreed with the statement that the content felt aligned with clinical practice.	8 (89)	14 (93)	0 (0)
Participants who agreed or strongly agreed with the statement that the questions in the program felt aligned or linked to their clinical practice.	8 (89)	14 (93)	1 (100)
Participants who agreed or strongly agreed with the statement the program felt engaging because it used clinical data relevant to their practice.	6 (67)	10 (67)	0 (0)
Participants who agreed or strongly agreed with the statement that they would like to see clinical data used to deliver personalized professional development in future.	5 (56)	15 (100)	1 (100)

Figure 1. Questions in the program, and the percentage of participants that correctly, incorrectly, or did not respond to for design cycles 1-3.

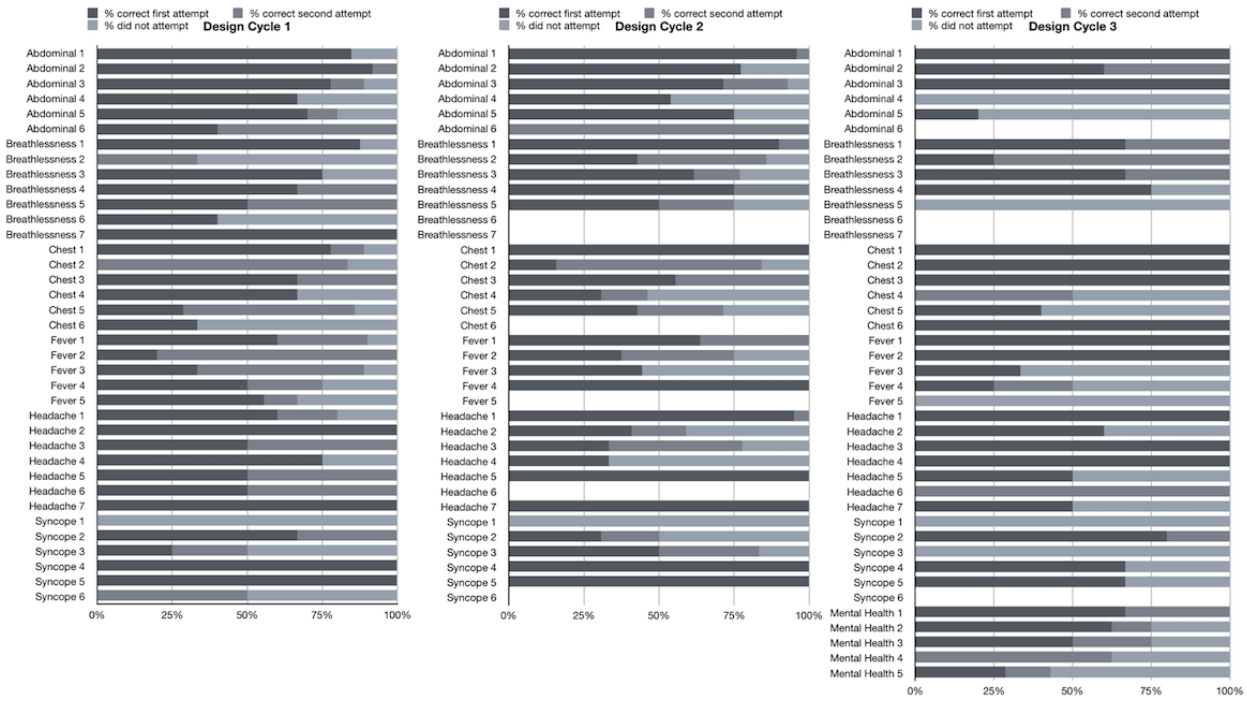

Figure 2. Visualization of the top 20 presenting problems encountered by participants during the intervention period for design cycles 1-3. (A-C) The presentations in design cycles 1-3. The presenting problems that could trigger a question in the online program are highlighted in red.

Design Cycle 1

There were 21 participants in cohort 1. Over the 6-week intervention period, the average number of unique questions participants were enrolled in was 9.72 (SD 4.62; range 3-20). A total of 9 participants in design cycle 1 responded to the postprogram survey (Table 4). The majority of respondents, 6 (67%), indicated that they completed the cases during personal time, after work, or on weekends; 2 (22%) respondents indicated they completed the cases when they had time during the workday; and the remaining 1 (11%) participant completed the program while commuting.

Design Cycle 2

There were 36 participants in cohort 2. Over the 6-week intervention period, the average number of unique questions participants were enrolled in was 9.69 (SD 5.79; range 1-22). A total of 15 participants in cohort 2 responded to the postprogram survey, but only 10 responded to the whole survey (Table 4). Of the 14 respondents who provided feedback on when they completed the program, the majority of respondents, 9 (64%), indicated they completed the cases during personal time, after work, or on weekends. In addition, 3 (21%) respondents indicated they responded to a question as soon as they received an alert, 11 (7%) respondents indicated they completed the cases when they had time during the workday, and the remaining 11 (7%) participants completed the program while commuting.

Design Cycle 3

There were 18 participants in cohort 3. Over the intervention period, the average number of unique questions participants were enrolled in was 6.27 (SD 4.93; range 1-17). One participant responded to the postprogram survey for cohort 3 (Table 4). The respondent indicated they had responded to the questions during personal time, after work, or on weekends.

Problems Encountered by Participants That Could Trigger a Question

Over the intervention period, EMR data indicated participants had a total of 2961 patient presentations that could have triggered a question. This number included duplicate instances of a participant seeing the patient presentation categories that could trigger a case. Of these, the most common presenting problem encountered by participants was abdominal pain (357 presentations), followed by mental health (159 presentations), and shortness of breath (156 presentations). Of the top 20 presenting problems participants encountered during the intervention period, all 7 presenting problem clusters that could have triggered a question in the online program were present (Figure 2).

Discussion

Principal Findings

Findings from this study indicate that EMR data can be used to personalize an online program for early-career physicians on management of common emergency presentations and link clinical practice directly with education in a timely manner. The researchers were able to extract EMR data at regular intervals during the intervention and use it to populate the adaptive algorithm that delivered personalized questions for individual participants. Regarding acceptability, findings suggested most participants found the program engaging and felt there was a level of alignment with their clinical practice. In addition, study findings indicated that early-career physicians undertaking intern training in emergency departments would like to see online programs personalized using electronic data in the future. This finding aligns with the literature, which has shown that health care providers across a range of professions are interested in seeing EMR data used in education and training [20].

Insights on EMR Data for Enabling Adaptive Learning

The potential value of using analytics related to interactions with training programs to personalize learning has been well researched in the context of learning analytics [14]. In the context of medical education, harnessing practice data about learners in digital and online education has been noted as a means to improve evidence-based instruction [7], but there are still significant gaps in our understanding of how to do this. This study presents one of the first studies demonstrating how routinely collected EMR data can be used to personalize learning. This study demonstrated that in the context of medical practitioner education, there are unique opportunities to strengthen training using analytics of data from clinical sources such as EMRs, not just learner data generated by undertaking educational interventions [15].

In the context of this study, the course curriculum was developed by first working with domain experts to identify common clinical presentations that were challenging for participants, and then refining it based on what was feasible to extract from the EMR during the intervention. Retrospective analysis of EMR data extracted during the intervention highlighted that participants had commonly encountered a number of presenting problems that were not included in the curriculum (falls, back pain, and cough). An alternative approach involving data mining of EMR data to generate a preliminary curriculum, followed by domain expert review, may have strengthened the intervention. EMR data mining has not been used in this way to date, though the approach has been shown to have some use to identify areas where medical practitioners are deviating from best practice and may benefit from undertaking specific training [28].

Furthermore, findings from this study indicated that, while data can be used to personalize training, the quantity of data collected by EMR datasets is substantial, and choosing which data to use to prompt learning can be complex. A confounding factor is that while there is an upward rise for EMR adoption in health care globally [17], real-world adoption varies considerably across countries and health care settings. This may limit the availability of EMR data for supporting the type of intervention, but there are many other clinical information systems in use in the health system [29]. Data from different clinical information has been shown to have value for understanding aspects of practitioner performance [30] and may be able to be used for this type of adaptive intervention.

Data-Driven Learning and Learner Engagement

Although it is feasible to adaptively deliver training using EMR data, findings from this study do not resolve how such an approach improves engagement with educational offerings. While study participants reported generally positive experiences with the program, there was also a notable decline in participation between the first and third cohorts. It is not clear why this decline occurred, but one explanation is that it aligned with the progression of the year. It is possible that participants undertaking the study were experiencing more exhaustion and had less capacity to engage with the intervention further along in their training year. There is some evidence to suggest that internship burnout is higher later in the year when completing postgraduate training [31].

The majority of learners in the personalized program attempted at least 50% of the program, which demonstrates a retention rate on the higher end for an online program [9]. Findings further indicated that many participants felt the intervention seemed aligned with their clinical practice. Aligning training with clinical practice may have a range of benefits for learners including increased engagement with training, better alignment with clinical practice, and more efficient delivery. Improving efficiency is important in medical practitioner education because learners are time-limited and have many competing obligations in their workloads beyond undertaking training, including completing core clinical responsibilities and administrative tasks [2,3].

Strengths, Limitations, and Future Research

A limitation of this study is that the survey response rate across all three cycles was fairly low, particularly for the third cycle. This limits our overall understanding of the intervention and its generalizability. The lack of data on the final cycle limits understanding of how changing the content may have altered the learner experience with the program in the last cycle. Although we can only speculate as to why the response rate was low, one speculation is that the evaluation was done very late in the participants' clinical term, and in some instances when they had started a new term. At this point in the term, participants had particularly busy clinical loads and may have had less capacity to provide feedback on the intervention.

Future researchers should consider further exploring how to design medical practitioner learning to be pedagogically sound and well-aligned with clinical practice. Design considerations that remain to be explored include developing a process for automated extraction of data to more closely link delivery of learning with the clinical encounter, identifying where in workflows adaptive training is optimally delivered (at point of care and after hours), and customizing content of the learning not just delivery using EMR data. It would be valuable to undertake studies that evaluate whether personalization of training using EMR data and the timing of content delivery affect learner retention rates, as well as improve the processes and outcomes of care. Beyond this, questions remain about the scalability and cost-effectiveness of adaptive learning interventions of this nature.

Conclusions

This study demonstrates that personalizing an online learning program for emergency trainees using EMR data is feasible for this group of medical practitioners, and most also found it to be an acceptable approach to align learning with workplace interactions. This opens up considerable opportunity to tailor and personalize learning for health professionals that is aligned with their practice activities and performance. However, more research is needed to understand how to deliver these types of adaptive learning interventions in a scalable and sustainable way. To do this, there is a need to develop a better understanding of how routinely collected data can be used to understand performance, as well as its suitability enabling health professionals to reflect on their performance and practice to support continuous learning. Relatedly, on the solution design side, there is a need to develop platforms that can automate the extraction, analysis, and feedback of these data to support health professional education and practice reflection in a way that is streamlined for use by health professionals. Considerable focus to date has been placed on the value of aggregating large data sets into single repositories, which represents a significant infrastructure achievement. However, moving forward, it is as important to understand why data are being collected and how they will be collected to ensure that the right information is available to provide benefits to the health system and support people's health and well-being.

Acknowledgments

AJ was undertaking a postdoctoral research fellowship funded through the Digital Health Cooperative Research Center when this research was undertaken. The Digital Health Cooperative Research Center was established and supported under the Australian Government's Cooperative Research Centres Program. The authors wish to acknowledge the support of Shannon Joyce and Shima Ghassem Pour in supporting access to fully deidentified electronic medical record reports to enable delivery of the adaptive program.

Abstract

Background: Early exposure to research methodology is essential in medical education, yet many students show limited motivation to engage with nonclinical content. Gamified strategies such as educational escape rooms may help improve engagement, but few studies have explored their feasibility at scale or evaluated their impact beyond student satisfaction.

Objective: This study aimed to assess the feasibility, engagement, and perceived educational value of a large-scale escape room specifically designed to introduce third-year medical students to the principles of diagnostic test evaluation.

Methods: We developed a low-cost immersive escape room based on a fictional diagnostic accuracy study with 6 puzzles mapped to five predefined learning objectives: (1) identifying key components of a diagnostic study protocol, (2) selecting an appropriate gold standard test, (3) defining a relevant study population, (4) building and interpreting a contingency table, and (5) critically appraising diagnostic metrics in context. The intervention was deployed to an entire class of third-year medical students across 12 sessions between March 2023 and April 2023. Each session included 60 minutes of gameplay and a 45-minute debriefing. Students completed pre- and postintervention questionnaires assessing their knowledge of diagnostic test evaluation and perceptions of research training. Descriptive statistics and 2-tailed paired *t* tests were used to evaluate score changes; univariate linear regressions assessed associations with demographics. Free-text comments were analyzed using the hierarchical classification by Reinert.

Results: Of the 530 participants, 490 (92.5%) completed the full evaluation. Many participants had had limited previous exposure to escape rooms (206/490, 42% had never participated in one), and most (253/490, 51.6%) reported low initial confidence with critical appraisal of scientific articles. Mean overall knowledge scores increased from 62 of 100 (SD 1) before to 82 of 100 (SD 2) after the activity (+32%; $P<.001$). Gains were observed across all learning objectives and were not influenced by age, sex, or previous experience. Students rated the educational escape room as highly entertaining (mean score 9.1/10, SD 1.1) and educational (mean score 8.2/10, SD 1.5). Following the intervention, 86.9% (393/452) felt more comfortable with critical appraisal of diagnostic test studies, and 79% (357/452) considered the escape room format highly appropriate for an introductory session.

Conclusions: This study demonstrates the feasibility and enthusiastic reception of a large-scale, reusable escape room aimed at teaching the fundamental principles of diagnostic test evaluation to undergraduate medical students. This approach may serve

as a valuable entry point to engage students with evidence-based reasoning and pave the way for deeper exploration of medical research methodology.

Introduction

Evidence supports the need for early exposure of medical students to research and critical appraisal of scientific articles. According to the World Federation for Medical Education 2020 standards, medical curricula must include the principles of the scientific method, cover analytical and critical thinking, medical research methodology, and evidence-based medicine [1]. The ability to interpret and apply evidence-based medicine is now widely regarded as a core competency for graduating medical students, as emphasized by both the Association of American Medical Colleges and the UK Clinical Reasoning in Medical Education group [2,3]. By developing critical appraisal skills, early exposure to research in medical education favors abilities valuable for future clinical practice (analytical reasoning and communication skills).

In particular, diagnostic test studies involve key elements of Bayesian reasoning [4], such as pretest probability, likelihood ratios, and the process of updating diagnostic probabilities based on test results—all of which are central to clinical decision-making [5]. However, evidence shows that medical professionals struggle with these concepts [6]. In addition, integration of such nonclinical skills into medical curricula is arduous, especially with undergraduate students [7,8]. In particular, generating and maintaining student interest is highly challenging [9]. In France, for example, critical appraisal of scientific articles, despite its inclusion in the final undergraduate national matching exam since 2009, varies in terms of course load and content across universities, and medical students lack motivation to invest time in nonclinical skills [10]. However, as observed with the recent expansion of biomedical literature related to the COVID-19 pandemic, physicians are at the center of both scientific and societal discussions involving critical appraisal of medical literature [11]. Thus, innovative strategies are needed to engage medical students with research training and critical appraisal of scientific articles early in their curriculum [7].

Educational escape rooms (EERs) have recently garnered growing interest in health professional education [12-15]. These gamified, immersive scenarios typically involve a series of puzzles that participants solve collaboratively, each aligned with a specific learning objective. While most published studies have focused on fostering clinical reasoning or teamwork, only a few have examined the potential of EERs for teaching research methodology [16,17]. Existing evidence remains limited, often based on small-scale initiatives with variable outcomes [12,18-20]. This gap underscores the need to explore their applicability in large cohorts and in domains beyond clinical knowledge.

This study evaluated the feasibility and perceived educational value of a large-scale EER designed to introduce medical students to key aspects of scientific methodology. The pedagogical content focused specifically on the evaluation and interpretation of diagnostic test studies while also aiming to foster teamwork and engage students with a nonclinical topic early in their training.

Methods

Escape Room Design and Learning Objectives

Using guidelines from Davis et al [14], we developed an EER for third-year medical students with three main goals: (1) to introduce fundamental principles of research methodology and terminology, (2) to promote collaborative problem-solving through teamwork, and (3) to foster more positive attitudes toward research training. The design team included 4 medical doctors, 1 pharmacist, and 1 medical resident, drawing on interdisciplinary expertise in clinical medicine, public health, and pedagogy.

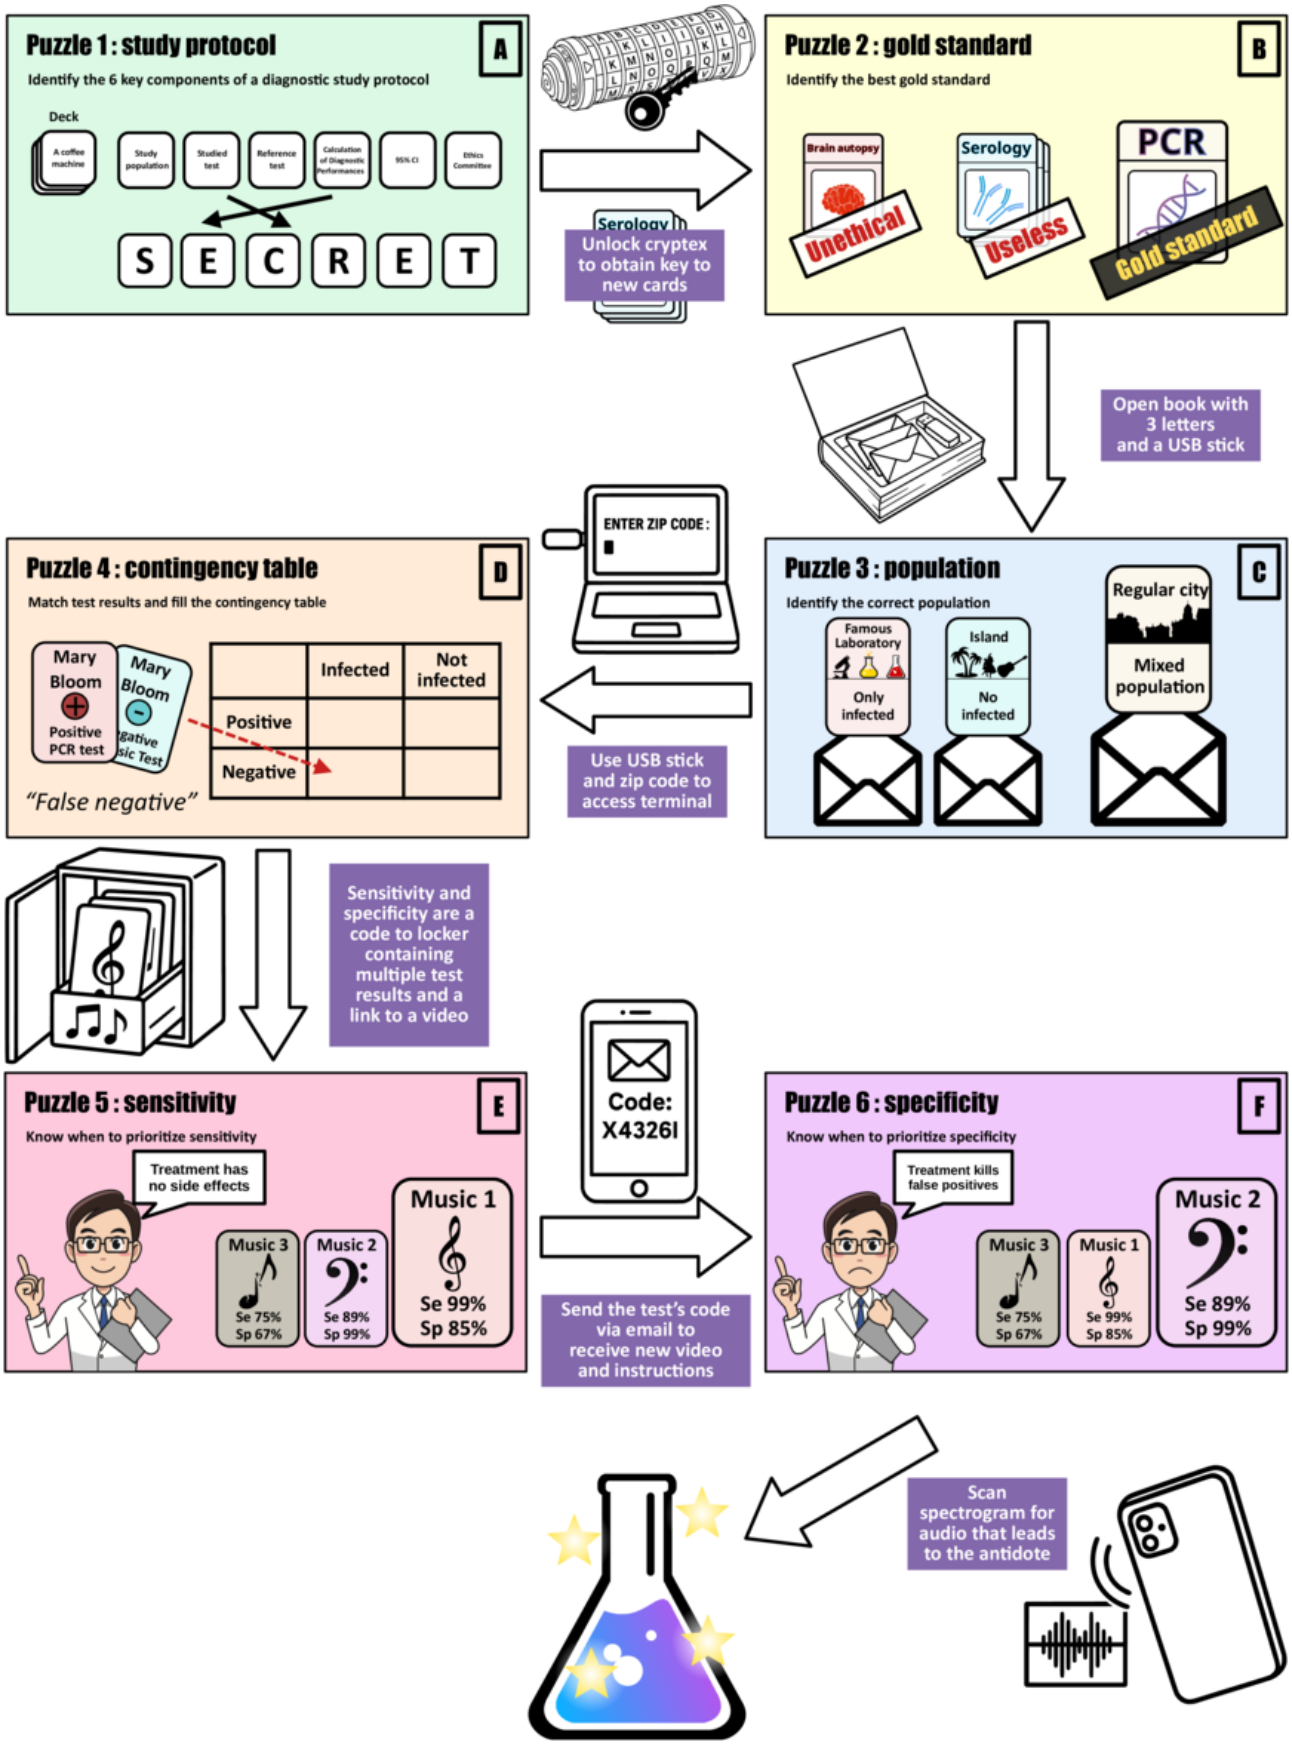
A diagnostic accuracy study was deliberately chosen as the pedagogical framework as this type of research offers an accessible and clinically meaningful entry point for undergraduate students without previous exposure to research methods. It aligns closely with diagnostic reasoning processes familiar to most learners while also serving as a structured introduction to key methodological concepts—such as reference standards, population selection, and diagnostic performance metrics (eg, sensitivity and specificity)—that remain challenging even for many practicing clinicians [5,6]. By anchoring the learning objectives in a framework that is both practical and conceptually rich, this approach facilitates early engagement with evidence-based thinking without requiring advanced statistical background.

Learning objectives were defined a priori based on recurrent misconceptions observed in upper-year students and the collective teaching experience of the faculty involved. By the end of the session and debriefing, students were expected to (1) identify the key components of a diagnostic accuracy study protocol, including relevant methodological tools; (2) recognize the characteristics of an ideal reference standard, including performance, cost, invasiveness, and availability; (3) understand the structure of a study population that includes both individuals with and without the condition of interest; (4) construct and interpret a contingency table from diagnostic test and gold standard results; and (5) critically assess the strengths and limitations of a diagnostic test based on its performance metrics and intended clinical use.

Escape Room Scenario

The escape room scenario centered on a fictional outbreak of a zombie virus disease. Students were tasked with identifying an effective diagnostic test to detect infected individuals and locate an antidote. Working in teams, they had 60 minutes to examine the research notes of a mysterious scientist who had nearly discovered a high-performing test. To succeed, students needed to solve 6 sequential puzzles, each aligned with one of the predefined learning objectives (Figure 1).

Figure 1. Narrative sequence and pedagogical content of the 6 puzzles composing the educational escape room. (A) Puzzle 1—study protocol. Participants select the 6 key components required to design a diagnostic accuracy study from a deck of 24 color-coded sticky notes. Each correct sticky note reveals 1 letter; when combined, they form a password that unlocks a cryptex. (B) Puzzle 2—gold standard. Inside the cryptex, participants find a key granting access to a new set of test cards. They must identify the most appropriate reference test. Although brain autopsy provides definitive results, it is excluded as unethical and impractical. Serology is dismissed due to poor diagnostic value. Polymerase chain reaction (PCR) is correctly selected as a feasible and valid gold standard. A clue hidden in invisible ink on the back of the PCR card leads them to the next step. (C) Puzzle 3—study population. Inside a hollow book designed as a lockable book safe, participants find a USB stick and 3 fictional letters each proposing a different study population: only infected individuals (famous laboratory), only uninfected individuals (isolated island), and a mixed population (regular municipality). Despite the laboratory's prestige, they must reject biased populations and select the mixed group to ensure valid assessment of diagnostic performance. (D) Puzzle 4—test results and matching. Using the zip code from the city letter and the USB stick, participants access a computer terminal. They learn that the studied test involves a music-based rhythm activity. They receive patient test results, one card per test per patient, and must match each pair. Recognizing that both the studied test and reference test are needed for each patient, they correctly populate the contingency table to proceed. They calculate sensitivity (Se) and specificity (Sp), which together form the code to open a locker. (E) Puzzle 5—sensitivity. Inside the locker, they find test cards associated with musical rhythms, each labeled with sensitivity and specificity values. A QR code on one card links to a researcher's video revealing that the treatment has no side effects. Participants must deduce that false positives are acceptable and, therefore, select the test with the highest sensitivity. They email the chosen test's code to proceed. (F) Puzzle 6—specificity. A second video reveals a crucial update: the treatment is actually harmful to false positives. Participants must now prioritize specificity to avoid treating uninfected individuals. They scan a spectrogram printed on the back of each card using a mobile app. The correct choice plays a final audio message and leads to the antidote and a reward.



The six puzzles included (1) classifying keywords relevant to diagnostic study protocols (*study protocol*), (2) selecting the most appropriate gold standard test from a series of candidates (*gold standard*), (3) identifying a valid study population using fictional application letters (*study population*), (4) analyzing mock laboratory test results to construct a contingency table (*contingency table*), (5) calculating diagnostic accuracy metrics based on the table (*test metrics*), and (6) interpreting these

metrics to choose the best test in context (*metric appraisal*). The terms in parentheses will be used throughout the manuscript for clarity.

Each completed puzzle provided a clue, object, or code that allowed progression to the next stage of the game. A team succeeded when they completed all 6 puzzles within the allotted time, thereby unlocking the location of the antidote. The scenario was fully autonomous: game masters were available only to provide hints or intervene in case of technical difficulties upon request. The immersive experience included props such as a cryptex, mock test description cards, a book safe, invisible ink, a digital lockbox, a custom-designed computer program, role-play videos, QR codes, a spectrogram decryption smartphone app, and purpose-built board game–style cards (Figure 2). All materials were original creations funded by the Faculty of Medicine at the University of Lille, with a total cost of €1800 (approximately US $1925) for approximately 600 students.

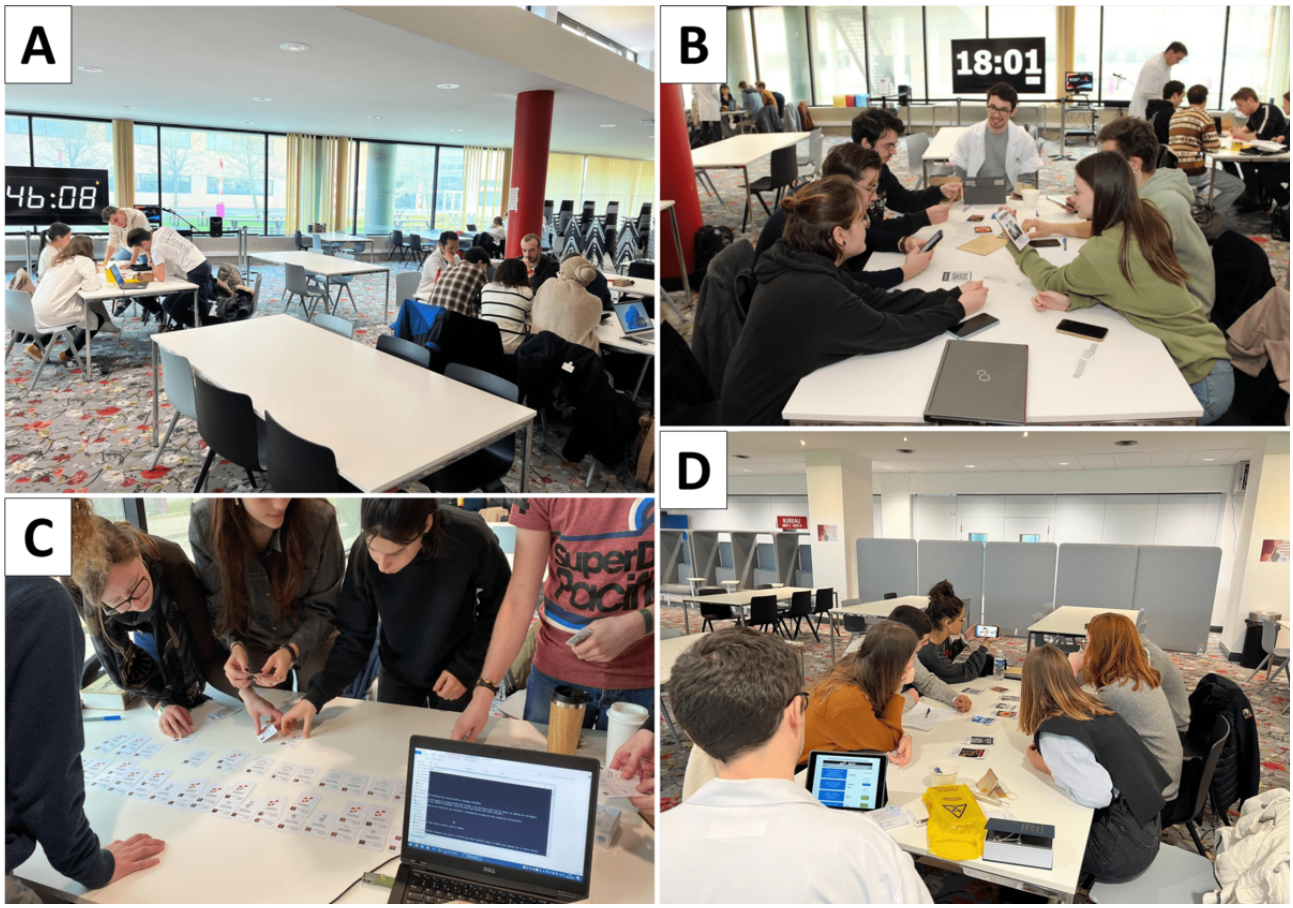
Figure 2. Accessories used throughout the educational escape room. (A) All materials are stored in a single portable bag to ensure easy deployment. (B) Keyword cards used to reconstruct the components of a diagnostic accuracy study (puzzle 1, *study protocol*). (C) Candidate reference tests from which participants must identify the most appropriate gold standard (puzzle 2, *gold standard*). (D) Fictional letters describing different populations, among which students must select the most suitable study population (puzzle 3, *study population*). (E) Decks of index and reference test result cards used to reconstitute patient data pairs (puzzle 4, *contingency table*). (F) USB flash drive containing an automated program through which students must input their reconstructed contingency table (puzzle 5, *test metrics*). (G) Test cards with various diagnostic performance metrics from which students must select the most appropriate test depending on the clinical scenario (puzzle 6, *metric appraisal*).

Setting, Materials, and Staffing

Twelve 120-minute sessions were conducted over the course of the program. Each session included a 15-minute introductory briefing, 60 minutes of gameplay, and 45 minutes of structured debriefing. Sessions were held in a large open space of approximately 150 m^2, accommodating up to 45 students per session (Figure 3). Upon arrival, students were randomly

assigned to teams of 4 to 6 using an algorithm triggered by swiping their university ID card.

Figure 3. Scenes from the educational escape room illustrating the gameplay environment and student engagement. (A) Students collaborate in real time to solve puzzles under time pressure, with a visible countdown clock reinforcing immersion. (B) Small groups work simultaneously in the same session space, each supported by a facilitator in a white coat, simulating a clinical research environment. (C) Participants match test result cards to reconstruct the correct index and reference test pairs before entering the data into a contingency table via a terminal. (D) A team discusses the interpretation of diagnostic performance metrics from QR-coded test cards guided by the game's unfolding narrative under the supervision of a dedicated faculty facilitator who performs real-time formative assessment using a tablet-based checklist. All individuals appearing in the photos provided written consent for their images to be used and published for educational and research dissemination purposes.



Eight teams participated simultaneously in each session seated at individual tables spaced apart to allow for parallel problem-solving without interference. Although certain immersive elements were shared—such as a bookshelf, storage lockers with digital codes, a whiteboard, and a wall-mounted countdown timer—each team engaged independently with dedicated materials and instructions. All essential components were either prepacked in portable game bags (Figure 2) or duplicated in 8 identical sets to ensure autonomous progression. The briefing began with a short immersive video introducing the fictional mission and setting the narrative tone, aiming to engage students from the outset and foster a collaborative atmosphere (Multimedia Appendix 1).

Each session involved 9 facilitators: 1 game master assigned to each team and a session coordinator overseeing the entire room. Facilitators ensured smooth progression and conducted real-time formative assessments. After each puzzle, they rated the team's clinical reasoning and collaborative dynamics using a tablet-based checklist with Likert scale items. This structure allowed students to work independently while maintaining consistent pedagogical oversight and documentation of performance. In total, 20 facilitators contributed across the sessions, representing a broad range of specialties including public health, radiology, nephrology, biology, biostatistics, pharmacology, pharmacy, pathology, family medicine, pediatrics, anesthesiology, and intensive care. All facilitators completed the escape room before student sessions to ensure fluency with the scenario and educational objectives.

To support scalability, all materials were designed for reuse. Game bags were reorganized after each session to allow for immediate reset. One month before implementation, the scenario was pilot-tested by 30 fourth-year medical students and 6 instructors whose feedback informed refinements to both content and logistics.

Study Setting and Design

This monocentric prospective study was conducted between March 2023 and April 2023 at the Faculty of Medicine at the University of Lille All third-year medical students enrolled in the 2022 - 2023 cohort were eligible to participate. The escape room was integrated into the mandatory curriculum as part of a course on research and critical appraisal and was a graded educational activity. Participation was required, and any student

who missed a scheduled session was expected to provide a formal justification.

Before the session, participants provided demographic information (age range and sex) and reported previous experience with recreational escape games ("How many times have you participated in a recreational Escape Game?"). They also rated their comfort with critical appraisal of scientific articles using a 5-point Likert scale ("What is your level of comfort with critical appraisal of scientific articles?") and submitted a free-text response identifying 3 words that best reflected their perception of critical appraisal ("Tell us the first three words that come to mind to describe your perception about critical appraisal of scientific articles").

They then individually completed a knowledge questionnaire covering the 5 predefined learning objectives of the session. All questions were answered using "true" or "false" and grouped by objective. The same 5 learning objectives were reassessed during the debriefing immediately after the intervention using a different but equivalent set of "true"-or-"false" questions. A score out of 100 was calculated for each objective, and relative gain was defined as the absolute change between pre- and posttest scores divided by the pretest score. The complete list of questions is available in Multimedia Appendix 2. During the debriefing, students also completed an individual postintervention survey. They were asked to provide 3 words summarizing their perception of the escape room experience and to rate both the entertainment value and the pedagogical interest of the session on a scale from 0 to 10. They were again asked to rate their comfort with critical appraisal using the same 5-point Likert scale. In addition, they were asked the following: "Do you think an escape room is a suitable format for an introductory course on the critical appraisal of scientific articles?" Responses were collected using a 5-point Likert scale ranging from "Not at all suitable" to "Absolutely suitable." Although "suitable" was not formally defined, the proximity of this question to those assessing the activity's educational and entertainment value likely guided students to interpret it in terms of relevance, clarity, and pedagogical appropriateness. Finally, students were invited to leave open-ended comments about the session, including organizational aspects, perceived strengths, limitations, and suggestions for improvement.

This monocentric prospective study was conducted between March 2023 and April 2023 at the Faculty of Medicine at the University of Lille All third-year medical students enrolled in the 2022 - 2023 cohort were eligible to participate. The escape room was integrated into the mandatory curriculum as part of a course on research and critical appraisal and was a graded educational activity. Participation was required, and any student who missed a scheduled session was expected to provide a formal justification.

Ethical Considerations

The study protocol was reviewed and approved by the Institutional Review Board of the University of Lille in February 2023. The IRB determined that formal ethical approval was not required due to the pedagogical nature of the intervention and the exclusive use of anonymized data.

All procedures were conducted in accordance with the ethical standards of the institutional and national research committees and with the 1964 Helsinki Declaration and its later amendments or comparable ethical standards.

Upon registration on the study platform, students completed a short presession questionnaire and provided individual informed consent, including authorization to analyze their anonymized responses for research purposes. The study also ensured the privacy and confidentiality of all participants. Data were collected and stored on a secure, password-protected server, and identifying details, such as names and email addresses, were immediately deidentified and replaced with unique participant IDs to protect anonymity. No personal health information was collected.

Participants were not compensated for their involvement in the study (Multimedia Appendix 2).

Statistical Analysis

Descriptive statistics were used to summarize participant characteristics and questionnaire responses. Quantitative variables were reported as means and SDs or medians and IQRs depending on their distribution. Categorical variables were expressed as counts and percentages. To assess knowledge gains, pre- and postintervention scores were compared using paired *t* tests. Associations between participant characteristics (age, sex, previous experience with escape rooms, and self-reported ease with critical appraisal) and relative score improvement were explored using univariate linear regression models. All statistical tests were 2-sided, and a P value of $<.05$ was considered statistically significant. All analyses were conducted using the R software (version 4.3.1; R Foundation for Statistical Computing).

Qualitative Analysis of Free-Text Feedback

Students' postintervention free-text comments were analyzed using the hierarchical classification method by Reinert [21], a lexical clustering approach based on word co-occurrence patterns. The analysis was conducted using the R Interface for Multidimensional Analysis of Texts and Questionnaires [22]. Comments were anonymized and preprocessed to remove low-frequency and noninformative words. The text corpus was segmented, and descending hierarchical classification was conducted to identify stable clusters of vocabulary. Factorial correspondence analysis was used to visualize the associations between lexical classes. The number of clusters retained was selected based on thematic coherence and interpretability. Two researchers (BLG and AH) independently reviewed and labeled each cluster using representative keywords and excerpts. Discrepancies were resolved through consensus. For reporting, all illustrative quotes were translated from French into English by the authors.

Results

Study Population

Of the 560 eligible third-year medical students, 530 (94.6%) participated in the escape room activity. Students who did not attend the escape room sessions were absent for justified

personal or medical reasons. Of the 530 students who participated, 490 (92.5%) completed the preintervention questionnaire. Among them, 66.3% (325/490) were women, and 83.5% (409/490) were aged between 20 and 22 years. Most students reported limited or no previous experience with recreational escape rooms: 42% (206/490) had never participated in one, and 45.9% (225/490) had only done so once or twice. A substantial proportion expressed discomfort with critical appraisal of scientific literature: 18.8% (92/490) reported being "absolutely not comfortable," and 33% (161/490) reported being "rather not comfortable" with the task (Table 1).

Table . Description of the study population (N=490).

Characteristic	Participants, n (%)
Female sex	325 (66.3)
Age group (y)	
<20	22 (4.5)
20 - 22	409 (83.5)
22 - 25	41 (8.4)
>25	18 (3.7)
Previous experience with recreational escape rooms	
None	206 (42)
1 - 2 times	225 (45.9)
3 - 4 times	52 (10.6)
≥5 times	7 (1.4)
Reported ease with critical appraisal of scientific articles	
Absolutely not comfortable	92 (18.8)
Rather not comfortable	161 (32.9)
Neither comfortable nor uncomfortable	201 (41)
Rather comfortable	31 (6.3)
Absolutely comfortable	5 (1)

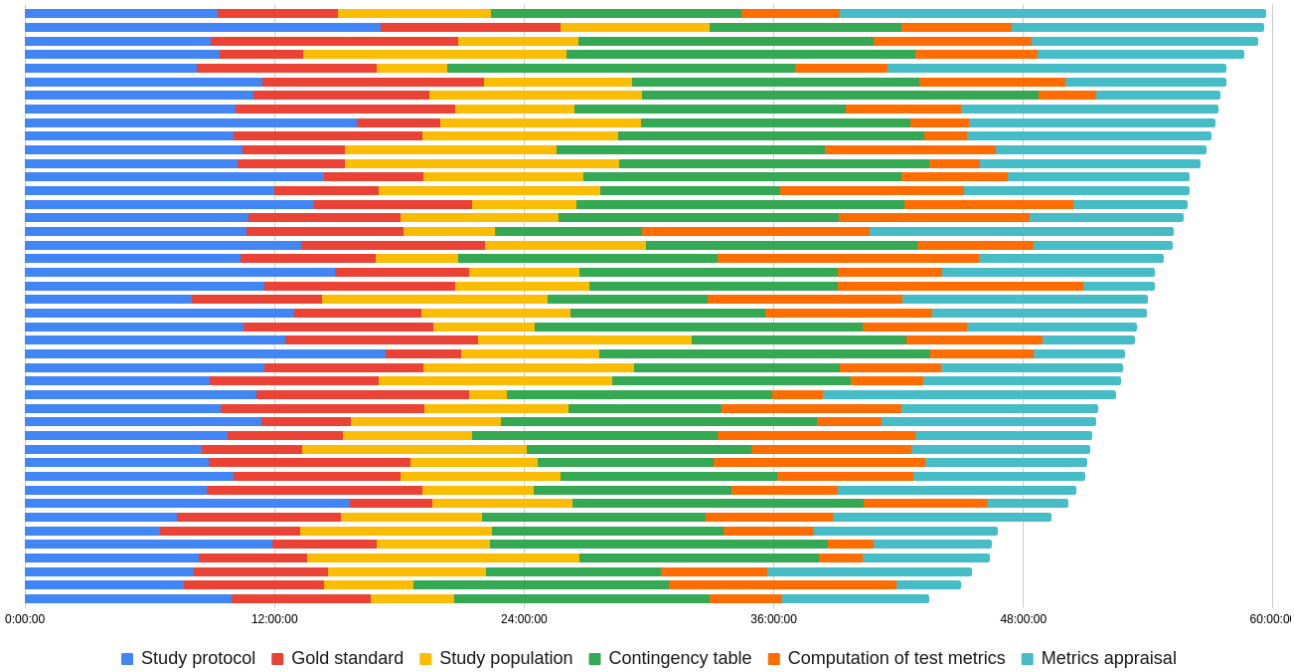
Escape Room Progression

Divided into 96 teams across 12 sessions, students advanced through the escape room with a high degree of consistency. All teams completed the mission within the allotted time, with a mean duration of 53 (SD 4) minutes. Each of the 6 puzzles required approximately 10 minutes to solve. The fastest puzzle, focused on test metrics, was completed in an average of 6 minutes and 12 seconds (SD 2 min, 49 s), whereas the most time-consuming one, involving the construction of a contingency table, took 12 minutes and 21 seconds on average (SD 2 min, 51 s; (Table 2). Team progression was largely synchronous, with most groups working on the same puzzle simultaneously (Figure 4).

Table . Table 2. Completion time of puzzles.

Puzzle	Mean completion time (Minutes:seconds)	SD of mean completion time (Minutes:seconds)
Study protocol	10:52	2:35
Gold standard	7:11	2:09
Study population	7:31	2:41
Contingency table	12:21	2:49
Computation of test metrics	6:10	2:48
Metrics appraisal	9:15	3:24

Figure 4. Puzzle progression timeline for a sample of 43 teams. Each horizontal line represents 1 team, and colors indicate the specific puzzle being solved at each moment during the session.



Pre- and Posttest Evaluations

A total of 85.3% (452/530) of the students completed the postintervention questionnaire. Student performance improved markedly following the intervention. The average score increased from 62/100 (SD 1) before the session to 82/100 (SD 2) afterward, representing a 32% gain (SD 5%; P<.001). Average subscores improved across all 5 learning objectives: from 58 (SD 3) to 71 (SD 3) for *study protocol*, from 74 (SD 2) to 89 (SD 4) for *gold standard*, from 43 (SD 1) to 83 (SD 3) for *study population*, from 71 (SD 2) to 88 (SD 5) for *contingency table*, and from 72 (SD 2) to 79 (SD 5) for *metric appraisal* (P<.001 in all cases; Figure 5). No significant associations were observed between score improvement and student characteristics (sex, age, previous escape room experience, or initial self-reported ease with critical appraisal), as shown in Table 3.

Figure 5. Pre- and posttest scores across learning objectives. Violin plots showing the distribution of student scores before and after the intervention for each of the 5 predefined learning objectives (top panels) and the overall mean score (bottom right panel). Asterisks indicate statistical significance. ***P<.001; EER: educational escape room.

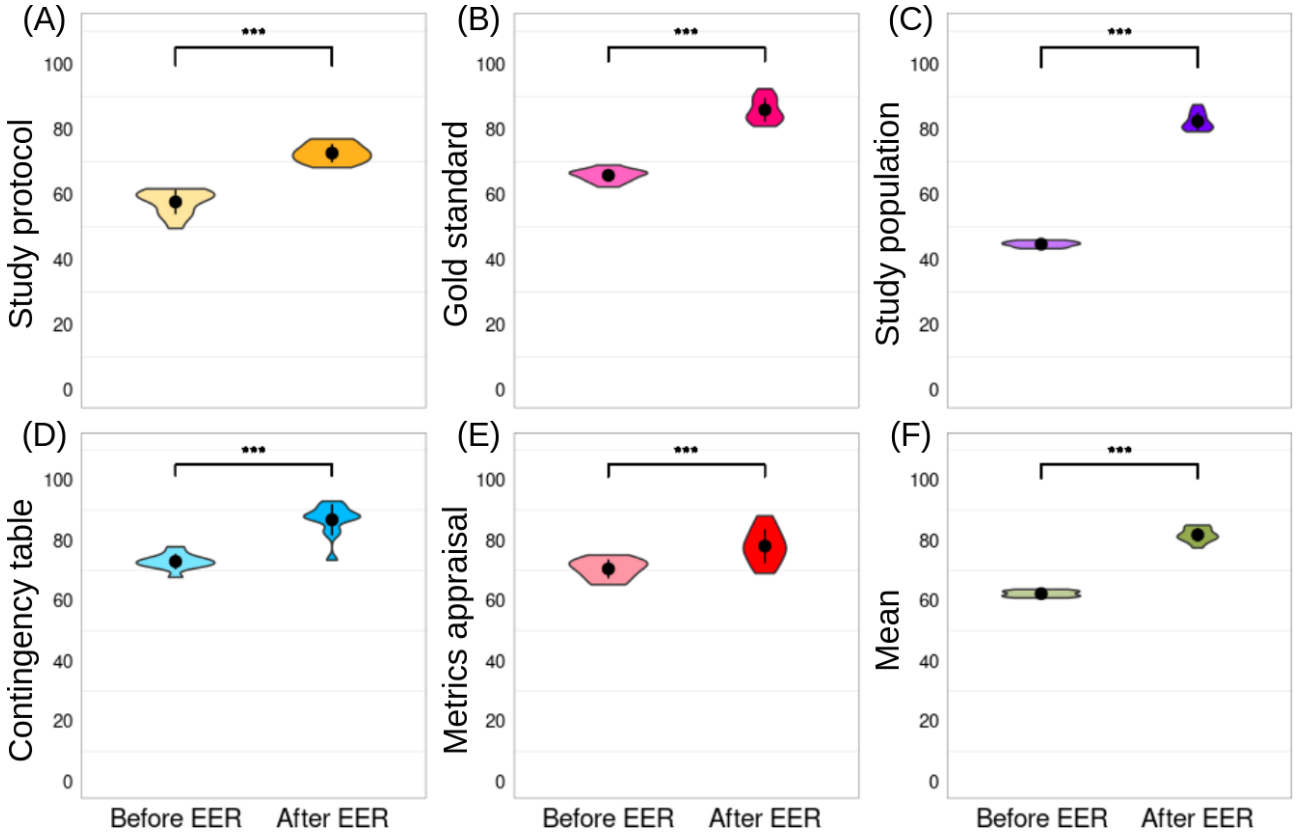


Table . Association between student characteristics and relative score improvement (univariate linear regressions).

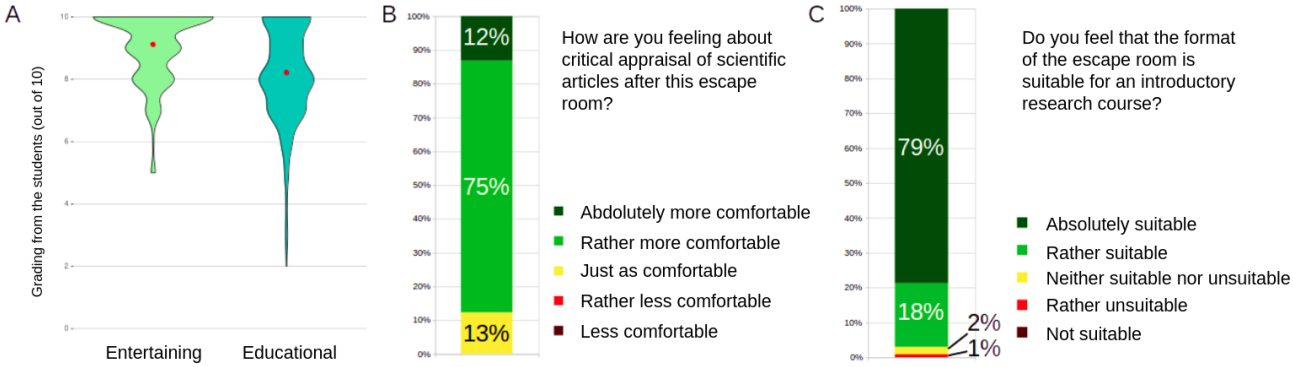
Characteristic	β (95% CI)	*P* value
Sex (female vs male)	−2.5 (−6.8 to 1.9)	.26
Age category (ordinal scale)	1.7 (−2.1 to 5.4)	.38
Previous experience with ERs[a] (ordinal scale)	0.9 (−2.8 to 4.6)	.63
Reported ease with critical appraisal of scientific articles (ordinal scale)	−0.6 (−3.3 to 2.1)	.69

[a]ER: escape room.

Students' Feedback

Feedback was strongly favorable. Students rated the session highly in terms of enjoyment (mean 9.1/10, SD 1.1) and educational value (mean 8.2/10, SD 1.5). Most participants (393/452, 86.9%) reported feeling more comfortable with the appraisal of diagnostic accuracy studies after the session. Regarding the overall suitability of escape rooms for introducing research training, 79% (357/452) rated the format as "absolutely suitable" on a 5-point Likert scale (Figure 6). The term "suitable" was not explicitly defined but followed questions about entertainment and educational value, likely guiding interpretation in terms of relevance and clarity.

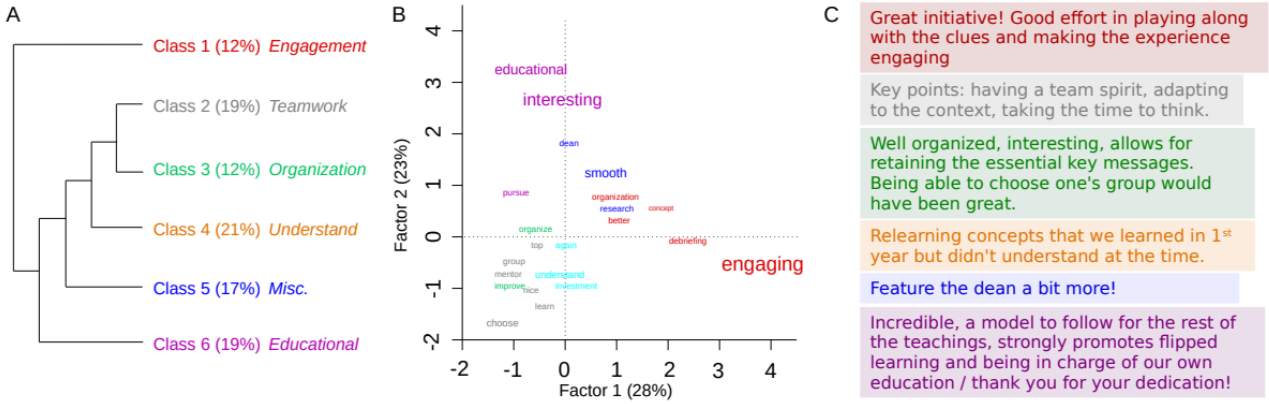
Figure 6. Students' perceptions of the educational escape room (EER). (A) Student ratings of the EER's entertainment and educational value (scale from 0 - 10); red dots indicate mean scores. (B) Proportion of students reporting increased comfort with critical appraisal of scientific articles. (C) Students' perception of the suitability of the escape room format as an introductory approach to research training.



Students' 3-word perceptions of research training shifted notably. Before the session, most descriptors were negative or reflected uncertainty (eg, "difficult," "tedious," "unknown," or "complicated"). Afterward, the most frequent terms were markedly more positive—"engaging," "entertaining," "original," and "educational" (Multimedia Appendix 3).

Thematic analysis of students' free-text comments using the hierarchical classification by Reinert [21] identified 6 primary thematic clusters, reflecting engagement, teamwork, pedagogical value, conceptual understanding, and overall organization (Figure 7 [21]).

Figure 7. Classification and thematic mapping of students' written feedback on the educational escape room. (A) The 6 semantic classes generated from a Reinert hierarchical clustering of students' open-ended comments (translated from French by the authors). Each class reflects a distinct theme: engagement, teamwork, organization, understanding, educational value, and miscellaneous remarks. (B) The factorial correspondence analysis map of the vocabulary used across classes, with words spatially projected according to their association with the underlying dimensions (factor 1: 28%; factor 2: 23%). (C) Representative anonymized student quotes from each class highlighting the diversity of perspectives on the format, group dynamics, and perceived learning outcomes.



Discussion

Our study demonstrates the feasibility of implementing a large-scale EER focused on introducing undergraduate medical students to core principles of diagnostic test evaluation as an entry point into research training. Student feedback echoed the 3 central aims of the intervention: to familiarize participants with key research concepts, foster teamwork, and improve perceptions of research-oriented courses. Pre- and postintervention assessments revealed significant immediate gains across all 5 targeted learning objectives. The activity was met with strong enthusiasm, in sharp contrast to students' initial reservations about research training.

EERs have been scarcely used in recent years for medical students, mostly to teach various clinical disciplines such as emergency medicine [23,24], radiology [25,26], surgery [16], dermatology [18], pulmonology [27], pediatrics [28], internal medicine [29], general medicine [30], infectious diseases [31], physiology [32], and patient safety [33-35] (Table 4). In this paper, we report an introductory course designed for a transversal, nonclinical skill and with no expected prerequisite among undergraduate medical students. Another study designed an EER as an introductory course involving research articles with great success, although the aim of that study was to introduce a small group of participants to technical skills in surgery [16]. A recent study by Mirshahi et al [17] described a self-developed escape room designed to assess and reinforce research competencies across a multidisciplinary group of undergraduate and postgraduate health profession students, including medical students; while promising, this initiative involved a limited number of participants and did not focus specifically on diagnostic reasoning. Most studies published to date have involved relatively small cohorts of students (Table 4) (up to 245 students over 3 years). However, to consider real-life implementation of EERs within medical curricula, it is crucial to demonstrate their compatibility with the current growing size of medical classes, often comprising hundreds of

students [36,37]. By using a parallelizable and repeatable gaming protocol, we showed the feasibility of delivering an innovative course to over 500 students while maintaining an entertaining and engaging environment. Another crucial challenge in implementing innovative pedagogic tools is the need to keep financial and human costs reasonable [38]. In our case, the allocated financial resources were constrained relative to the student count—€3.40 (US $3.95) per student. Through reusable material, this intervention can be replicated annually, refined, and adapted and enables the smoothing of the initial limited investment over the years [33]. As of July 2025, the EER has been repeated for 3 consecutive years (approximately 1800 students) without any additional financial cost. On the other hand, the human resources required for our intervention were substantial, with a total of 20 supervisors involved across the 12 sessions.

[a]REI: reproductive endocrinology and infertility.

Whether EERs meaningfully improve learning outcomes remains uncertain [12,15,19,20]. Previous studies have reported mixed results, with some suggesting potential benefits [32] and others, such as a recent controlled study by Fedorcsak [20], finding only modest improvements in declarative knowledge after a single EER session (Cohen d=0.22). In our study, we observed an immediate gain across 5 targeted learning objectives. However, in the absence of a control group and long-term follow-up, these findings should be interpreted cautiously. The structured, sequential format of the EER, aligned with the logic of a diagnostic study, may have supported knowledge acquisition, but the true impact on learning remains difficult to disentangle from engagement effects or short-term memory recall. Importantly, the intervention appeared accessible across subgroups, with no influence of previous escape room experience or self-perceived ease with critical appraisal. Beyond performance, the ability to foster interest in research methodology among a large cohort of students may in itself constitute a valuable educational outcome [12,15,19].

Our findings suggest a strong alignment between student feedback and our initial pedagogical intentions: namely, to introduce foundational research skills, foster collaborative teamwork, and demystify research training through an engaging and enjoyable format. Motivating undergraduate medical students to engage with research remains a recognized challenge [7,8,10]. In our study, students reported a marked shift in perception, from predominantly negative views on research training to positive reflections on the escape room experience. Free-text responses frequently emphasized the value of teamwork, a dimension often underrepresented in their curriculum, as well as the quality of facilitation and meaningful interactions with faculty. As observed in other EER-based interventions, we noted a high level of student cooperation and an intrinsic drive to complete the challenge within the allotted time [16,18,25,29,31]. This positive, collaborative atmosphere appeared to promote rich student-mentor interactions, an important benefit for a generation of learners shaped by recent experiences of social distancing and remote education [39].

This study has several limitations. As a pilot implementation, it was not designed to isolate the specific effects of the escape room format compared to traditional pedagogical approaches. The absence of a control group precludes any definitive conclusions about the causal impact of the intervention on student performance or attitudes. All outcome measures relied on self-reported or short-term evaluations, with no assessment of knowledge retention over time. Moreover, the educational content focused exclusively on diagnostic accuracy studies. While this choice was pedagogically motivated, it limits the generalizability of the findings to other types of research designs. This study was also conducted in a single institution, which may affect broader applicability. Future research should explore the added value of EERs in research training using comparative designs—such as cluster randomized trials—and include a broader range of research topics and longer-term follow-up to assess sustained learning outcomes. Despite these limitations, this study benefits from a high participation rate, detailed process documentation, and rich qualitative feedback, which collectively provide meaningful insights into the feasibility, perceived value, and immediate educational impact of this innovative teaching format.

In conclusion, this study demonstrates the feasibility of a large-scale, low-cost, and replicable EER to introduce undergraduate medical students to key concepts of diagnostic test evaluation. The format was well received and may offer a promising entry point into research training provided that its targeted scope and pedagogical objectives are clearly defined.

Acknowledgments

The authors would like to thank all of the faculty's services for their support in setting up the escape room experiment, from the academic services (Mrs Mathilde Moreno Garcia and Mrs Magali Lance) to the multimedia service (Mr Pierre Verquin, Mr Karim Bouadjla, and Mr Christian Delsol) and the IT department (Mr Arnaud Lecoq and Mr Jean-Christophe Alexandre) of the Faculty of Medicine at the University of Lille. They would also like to thank all the supervisors who agreed to participate in the different sessions (Dr Benoît Brassart, Dr Eole Nyangwile, Dr Gabrielle Lisembart, Dr Jean-Baptiste Gibier, Dr Julien Chapuis, Dr Mehdi Maanaoui, Dr Michaël Génin, Dr Pierre Dourlen, Dr Thavarak Ouk, Dr Victor Fages, Dr Victor Leblanc, Dr Victor Lestrade, and Professor Sébastien Aubert). This work was supported by internal educational funds from the Faculty of Medicine at the University of Lille. No external funding was received for this study.

Data Availability

The datasets generated or analyzed during this study are available from the corresponding author on reasonable request. In addition, all materials necessary to reproduce the educational escape room—including the full scenario, puzzles, facilitator instructions, and evaluation forms—are freely available upon request to the corresponding author for noncommercial academic use.

Conflicts of Interest

None declared.

Multimedia Appendix 1

Immersive mission briefing shown before the start of the escape room. This introductory video was designed to immerse students in a fictional investigation scenario. It presented the mission's narrative context, introduced the main characters and storyline, and created a suspenseful atmosphere to enhance student engagement from the outset. The video served solely to set the scene and did not provide any instructions or clues related to the upcoming puzzles.
[MP4 File, 36320 KB - mededu_v11i1e71339_app1.mp4]

Multimedia Appendix 2

Content of the "true"-or-"false" questionnaire administered immediately before and after the escape room intervention. Items are grouped by learning objective (*study protocol*, *study population*, *gold standard*, *contingency table*, and *metric appraisal*). For each pretest item, the expected correct answer and the proportion of students who responded correctly at baseline are reported; identical or conceptually equivalent items were presented at the posttest time point to assess immediate knowledge gain.
[DOCX File, 36 KB - mededu_v11i1e71339_app2.docx]

Multimedia Appendix 3

Word clouds illustrating students' perceptions before and after the educational escape room (EER). The left panel reflects students' initial impressions of critical appraisal of scientific articles before the intervention, whereas the right panel captures their reactions to the EER format afterward. Comments were originally written in French and translated by the authors.

Abstract

Background: Emergency radiology is essential for future doctors, who will face urgent cases requiring radiologic diagnosis. Using virtual simulations, gamified clinical scenarios, and case-based learning enhances practical understanding, develops technical and communication skills, and fosters educational innovation.

Objective: This study aimed to assess the feasibility of learning emergency radiology in the virtual world Second Life (Linden Lab) through a gamified experience by evaluating team performance in clinical case resolution, individual performance on seminar assessments, and students' perceptions of the activity.

Methods: Teams of 3 - 4 final-year medical students, during a 2-week radiology clerkship, had access to 7 clinical cases in virtual clinical stations and were randomly assigned 2 to solve and submit. They later discussed the cases in a synchronous virtual meeting and attended an emergency radiology seminar. The experience was repeated over 2 consecutive years to assess reproducibility through comparison of learning outcomes and students' perceptions. Learning outcomes were evaluated through team-based case resolution and individual seminar assessments. Students' perceptions were gathered via a voluntary questionnaire including 5-point Likert scale items, cognitive load ratings, 10-point evaluations, and open-ended comments.

Results: In total, 182 students participated in 2020 - 2021 and 170 in 2021 - 2022, demonstrating strong team-based case resolution skills with mean scores of 7.36 (SD 1.35) and 8.41 (SD 0.99), respectively (P<.001). The perception questionnaire had a 90.6% response rate. The highest cognitive load was observed in avatar editing (median 7, 95% CI 6.56 - 6.96). Case-solving cognitive load was significantly lower in 2021 - 2022 compared with 2020 - 2021 (median 6, 95% CI 5.69 - 6.21 vs 5.10 - 5.66; P<.001). The students rated the experience highly, with average scores exceeding 8.0 out of 10 across various aspects. Notably, the highest-rated aspects were the teaching staff (9.13, SD 1.15), cases (8.60, SD 1.31), project organization (8.42, SD 1.67), and virtual rooms (8.36, SD 1.62). The lowest-rated aspect was internet connectivity (6.68, SD 2.53). Despite the positive scores, all aspects were rated significantly lower in 2021 - 2022 compared with 2020 - 2021. These year-to-year comparisons in performance and perception support the reproducibility of the experience.

Conclusions: This study demonstrates that a game-based learning experience in the Second Life virtual world, combining virtual clinical scenarios and team-based tasks, is feasible and reproducible within a radiology clerkship. Students showed strong performance in case resolution and rated the experience highly, within a playful context that integrated asynchronous and synchronous activities. Lower ratings in the second year may reflect contextual differences, such as changes in COVID-19 pandemic restrictions.

Introduction

Gamification is the use of game elements in nongame environments, such as in education. This alternative educational approach promotes student motivation and active participation in the learning process [1]. Its implementation has been shown to enhance engagement, increase motivation, improve knowledge retention, and develop problem-solving skills [2-4].

The effectiveness of gamification is rooted in the fulfillment of 3 basic psychological needs [2]: (1) autonomy—the need to feel in control of one's actions; (2) competence—the desire to achieve goals and experience success [5]; and (3) relatedness—the need to feel connected to others and be part of a group [6]. Through game-based tasks, students are encouraged to experiment, interact, and collaborate with peers [7]. However, gamification alone is not sufficient to ensure meaningful learning outcomes. Its effectiveness depends on thoughtful design and alignment with the specific skills students are expected to acquire [8]. To support knowledge acquisition and consolidation, game elements must be carefully selected based on academic goals, student needs, and a pedagogically sound teaching methodology [9]. In this context, gamification proves to be a viable strategy at the university level—particularly in undergraduate programs—as a means to fulfill the educational goals outlined in academic curricula [10]. Studies have reported positive academic outcomes, high levels of student engagement, and strong adherence to gamified activities [11-14]. At the postgraduate level, gamification has also found applications in health care education. It has been used with surgical residents through the Da Vinci simulator to enhance surgical skills [15], with internal medicine residents—both individually and in teams—via online platforms to update clinical knowledge [16], with radiology residents through virtual tools for interpreting chest x-rays [17], and with otorhinolaryngology residents to assess and train new laryngoplasty techniques [18].

Game-based learning, often referred to as digital games [19,20], supports students in achieving learning objectives through immersive and engaging learning experiences. These activities have shown promising results with medical students, especially when implemented in immersive digital platforms [21,22], and their use in undergraduate education is worth exploring. These immersive platforms, known as virtual worlds, are computer-generated 3D spaces where people interact remotely through representations of themselves called avatars. The concept of virtual worlds, along with others such as virtual reality, mirror worlds, and augmented reality, fits within the broader notion of the metaverse [23], a collective virtual shared space expressed through digital media and the internet. Clinical simulation environments in such settings have been developed to train various skills, including taking anamnesis from virtual patients [24], resolving clinical situations in a pneumology ward [21], training cardiopulmonary resuscitation [25], or developing communication skills with patients [26,27].

One of the most widely used virtual worlds for health professional education is Second Life (SL; Linden Lab) [28]. Its advantages include remote access, a strong sense of presence, ease of access, user anonymity, opportunities to develop communication skills, promotion of active learning, and being free of charge. SL allows educators to design and recreate clinical training scenarios [29], including those based on the Objective Structured Clinical Examination (OSCE) format, in which specific "stations" simulate clinical cases in a standardized, reliable, and objective way [30]. It has already proven to be a valuable tool for teaching radiology in both synchronous and asynchronous online formats [31], and it has supported interactive learning focused on radiological anatomy and imaging signs [22]. However, to our knowledge, no experiences have yet incorporated radiology OSCE-like scenarios using gamified approaches in SL or similar environments.

Emergency radiology is essential for medical students, as future doctors will inevitably encounter urgent clinical scenarios requiring timely and accurate radiologic diagnosis. The ability to interpret commonly used x-ray examinations in the primary assessment of acutely unwell patients, and to recognize basic findings on emergency computed tomography (CT) scans, is considered a core competency in undergraduate medical training [32]. The European Society of Radiology highlights the importance of educating medical students in emergency radiology to ensure they understand imaging's critical role in acute care and can contribute effectively in managing clinical emergencies [33]. Furthermore, teaching emergency radiology to medical students has been shown to enhance their knowledge, promote appropriate imaging usage, support evidence-based decision-making, and increase awareness of the potential downstream effects of incidental findings [34].

This study aimed to assess the feasibility of learning emergency radiology in the virtual world SL through a gamified experience by evaluating team performance in clinical case resolution, individual performance on seminar assessments, and students' perceptions of the activity. The educational activity combined case-based problem-solving in OSCE-style stations with virtual online seminars. The activity was developed for sixth-year medical students (in their final year of medical school in our country) as part of a formal radiology clerkship.

Methods

Overview

This was a quasi-experimental study conducted over 2 academic years to evaluate a virtual, gamified radiology learning experience.

Background and Project Design

Sixth-year medical students at our university complete a 2-week radiology clerkship, consisting of 4 days of hospital practice, ten 2-hour seminars on clinical radiology, and online learning activities. Each year, 7 groups of 24 - 28 students successively complete the radiology clerkship between mid-October and early February. Eligibility criteria included enrollment in this clerkship during the 2020 - 2021 or 2021 - 2022 academic years. All students met these criteria, and no exclusions were applied. The educational purpose of the activity in this study, called "Rainbow-Game," was to provide students with reflective training on clinical situations involving medical emergencies mediated by the corresponding radiological procedures, in a playful and collaborative context, as part of the activities of the clerkship.

Each group was randomly divided into 7 teams of 3 - 4 students named with the colors of the rainbow. On the first day of the clerkship, students were briefed on the details of this experience. They had to dress their avatar in shirts of their team's color and had 9 days to visit, on demand, a virtual space with 7 OSCE

stations, each containing an emergency radiology case. Students had unrestricted access to all stations throughout this period, encouraging self-directed learning and flexibility in how they engaged with the cases. Although they were encouraged to review all 7 cases, only 2 were randomly assigned to each team on the eighth day for formal written resolution and submission via SL's internal messaging system (notecard). To support them, they received a short orientation on how to use SL and step-by-step mini-tutorials to assist with independent navigation, creating and sending notecards, and customizing their avatars with the team T-shirts. Although students used their own devices, they were advised to ensure basic technical compatibility and stable internet access. As part of the game, teams also had to send the professor original and imaginative SL screenshots showing their avatars dressed in the corresponding color. On the tenth day, there was a 2-hour meeting with the whole group in SL. First, the teams had to orally present the results of the assigned cases and discuss them with their peers. Subsequently, they received a 1-hour seminar on emergency radiology, in which the professor presented 15 clinical cases, distributed equally among head, chest, and abdominal emergencies. At the end of the seminar, 3 exam cases were arranged to be answered individually using a notecard. A 24-item checklist was used to correct answers uniformly (see Multimedia Appendix 1). This activity was repeated during 2 academic years (2020 - 2021 and 2021 - 2022) with the same contents and organization. The TREND (Transparent Reporting of Evaluations with Nonrandomized Designs) statement [35] was followed to ensure transparent and comprehensive reporting.

Outcomes and Assessment

The study evaluated three categories of outcomes: (1) team performance in clinical case resolution, (2) individual performance on seminar assessments, and (3) students' perceptions of the activity. Team performance was scored using a structured checklist (0 - 10 points per case), and individual seminar responses were graded using a 24-item checklist (Multimedia Appendix 1). In both cases, higher scores indicated better performance.

Students' perceptions were captured through a questionnaire adapted from a previously validated instrument [22] (Multimedia Appendix 2) including 5-point Likert items (ordinal), 9-point cognitive load ratings (ordinal), 10-point satisfaction ratings (continuous), and open-ended comments. Higher Likert scores reflected more positive perceptions, higher cognitive load scores indicated greater perceived mental effort, and higher satisfaction ratings indicated greater satisfaction.

Virtual Scenarios

This study was conducted at the SL location named "The Medical Master Island," designed with various academic buildings surrounded by trees and plants (Figure 1A). Seven OSCE stations were designed with access from the same distributor, imitating a real OSCE. Each station had: (1) an access door; (2) a panel on the wall describing the clinical situation and the questions to be answered; (3) a table with one or 2 monitors, showing the images of the case; and (4) x-ray or CT equipment to contextualize the place as a radiology room (Figure 1B). To minimize repetitions, 16 cases were used (Table 1), which were rotated for the 7 groups (Table 2). An example case is shown in Figure 2. The clinical situation presented to the students is that of a 65-year-old woman who went to the emergency department due to progressive dyspnea occurring with minimal effort, reporting weight loss over the last month. Her personal history includes smoking and dyslipidemia. On examination, she is conscious, oriented, and cooperative, with mild respiratory retractions. Global hypoventilation in the left lung is noted. Oxygen saturation is 85%. She is afebrile. An imaging test is performed. Tasks to be carried out included describing as accurately as possible the imaging technique used and the pathological findings, establishing a differential diagnosis, and outlining the clinical approach to the suspected condition. Indicate what other tests would be required and why. The group meeting was held in the main building's aula magna, which had monitors with images to discuss the cases and a panel of slides to present the seminar (Figure 1C). Students submitted screenshots of their teams as part of the competition (Figure 1D).

Figure 1. Various scenes during the Second Life virtual world experience. (A) Aerial view of Medical Master Island with a flying avatar in the foreground. In the background, the main building, where the synchronous seminars were held, can be seen. (B) Example of an Objective Structured Clinical Examination station set up as a radiology room, with a team of students reviewing a head computed tomography case. The description of the clinical situation and the tasks to be performed are displayed on the wall. (C) Scene during a synchronous meeting with a student group, reviewing one of the Objective Structured Clinical Examination cases. (D) Screenshot submitted by a team of students as part of the competition.

Table . Description of the 16 cases used in the Rainbow-Game.

Case	Image modality shown	Case description
1	Brain CT[a] without IV[b] contrast: 18 axial slices.	52-year-old man. Spontaneous intraparenchymal hemorrhage with a subarachnoid component.
2	Abdominal CT with IV contrast: 18 axial slices and 18 coronal slices.	39-year-old woman. Multiple renal lacerations with hemoperitoneum.
3	Chest x-ray: posteroanterior.	65-year-old woman. Complete opacification of the left hemithorax: atelectasis of left lung due to a bronchial carcinoma.
4	Brain CT without IV contrast: 18 axial slices.	79-year-old man. Acute ischemic lesion in the left cerebral hemisphere: MCA stroke with subfalcine herniation.
5	Abdominal radiography: oblique.	73-year-old man. Large bowel dilatation with coffee bean sign: Acute sigmoid volvulus with pneumoperitoneum.
6	Abdominal CT with IV contrast: 18 axial slices.	55-year-old woman. Gallbladder distention, wall thickening, mucosal hyperenhancement, and pericholecystic fat stranding: Acute cholecystitis.
7	Brain CT without IV contrast: 18 axial slices plus 18 in bone window.	40-year-old man. Parietal acute epidural hematoma with associated bone fracture.
8	Chest x-ray: posteroanterior.	59-year-old woman. Widening of the mediastinum, wide aortic contour, tracheal deviation, aortic kinking: Acute aortic dissection.
9	Abdominal CT with IV contrast: 18 axial slices.	55-year-old man. Ruptured abdominal aortic aneurysm with hemoperitoneum.
10	Brain CT without IV contrast: 18 axial slices plus 18 in bone window.	58-year-old man. Frontal intraparenchymal hemorrhage, subdural hemorrhage, and occipital skull fracture.
11	Chest x-ray: posteroanterior.	65-year-old man. Pulmonary consolidation without volume loss, air bronchogram, and silhouette sign: Lobar pneumonia.
12	Abdominal CT with IV contrast: 18 axial slices.	60-year-old man. Colonic wall thickening, pericolic fat stranding in an area of sigmoid diverticulosis: Acute diverticulitis.
13	Chest x-ray: posteroanterior.	62-year-old man. Consolidations and ground-glass opacities bilateral, peripheral, and located in the lower fields: COVID-19 pneumonia.
14	Brain CT with and without IV contrast: 2 sets of 18 axial slices.	55-year-old woman. Single cortical lesion, round, well-demarcated with enhancement and perilesional vasogenic edema: Metastatic lesion.
15	Abdominal CT with IV contrast: 18 axial slices and 18 coronal slices.	49-year-old man. Large soft-tissue mass, with internal heterogeneity: Retroperitoneal sarcoma.
16	Chest x-ray: posteroanterior and lateral.	76-year-old man. Bone osteoblastic lesions: Metastasis due to prostate carcinoma.

[a]CT: computed tomography

[b]IV: intravenous.

Table . Assignment of cases to the Objective Structured Clinical Examination stations across different groups.

Groups[a]	Station 1	Station 2	Station 3	Station 4	Station 5	Station 6	Station 7
Group 1	Case 1	Case 2	Case 3	Case 4	Case 5	Case 6	Case 7
Group 2	Case 8	Case 9	Case 10	Case 11	Case 12	Case 13	Case 14
Group 3	Case 15	Case 16	Case 1	Case 2	Case 3	Case 4	Case 5
Group 4	Case 6	Case 7	Case 8	Case 9	Case 10	Case 11	Case 12
Group 5	Case 13	Case 14	Case 15	Case 16	Case 1	Case 2	Case 3
Group 6	Case 4	Case 5	Case 6	Case 7	Case 8	Case 9	Case 10
Group 7	Case 11	Case 12	Case 13	Case 14	Case 15	Case 16	Case 1

[a] The same cases were used for the 7 consecutive groups of students in both the 2020–2021 and 2021–2022 academic years.

Figure 2. A chest x-ray corresponding to case number 3 shows complete opacification of the left hemithorax due to atelectasis of the left lung caused by bronchial carcinoma.

Qualification of the Participants

Each team was qualified based on 3 parameters, normalized to 10 points each: (1) the written response to the 2 assigned cases, using a checklist for each case (40%); (2) the originality and quality of the best screenshot submitted (20%); and (3) the average of the individual points of the team to the 3 seminar questions (40%). Students were informed that their team's score on this compulsory online activity would have no impact on their clerkship grades. However, as extrinsic motivation, the team with the highest score in each group received a bonus of one extra point in the final grade, up to 10 points.

Perception of the Experience by the Students

After the seminar, the students were asked to complete a questionnaire about the experience (see Multimedia Appendix 2), which included: (1) a dichotomous question about whether they knew SL before the experience; (2) an assessment of 13

aspects of the game with a Likert scale of 1 - 5 (from totally disagree to totally agree); (3) an assessment of the cognitive load of 6 aspects of the game, following the 9-point scale proposed by Paas and Merriënboer [36]; (4) a rating of up to 10 points on 9 aspects of the game; and (5) a space for open comments asking "anything else to add." The questionnaire contained questions constructed, worded, and validated in previous studies [22,31].

Data Analysis

Descriptive statistics were performed using Microsoft Excel 2021 to characterize the population and subpopulations of participants, and the SPSS statistical package v24 (IBM Corporation) was used for statistical analysis. The normality of the data was assessed using the Shapiro–Wilk test. Based on the distribution of each variable, unpaired 2-sample *t* tests were used for continuous variables that met the normality assumption, while Mann–Whitney *U* tests were applied to compare ordinal or nonnormally distributed variables. Statistical significance was accepted at a probability of error of $P<.05$. Reproducibility was assessed by comparing student performance (project scores and seminar results) and perception data (questionnaire responses) across the 2 academic years.

Open comments were analyzed using the systematic collaborative consensus coding by committee [37]. Comments related to aspects of the clerkship other than the Rainbow-Game were not considered. During 2 consensus meetings, a 2-layer hierarchical coding was established, with 3 codes in the first layer (advantages, disadvantages, and suggestions) and different subcodes in the second layer.

Ethical Considerations

This study received approval from the Institutional Ethics Committee for Experimentation at the University of Malaga (decision number 141 - 2022-H; approval date: January 18, 2023). Questionnaire participation was voluntary, and participants gave their explicit informed consent at the time of submission. All data collected were anonymized before analysis to ensure the privacy and confidentiality of participants. Students were informed that their participation would not affect their academic evaluation and had the opportunity to opt out without any consequences. No monetary or material compensation was provided for participation in the study.

Results

Outcome of the Rainbow-Game

Three hundred and fifty-two students participated in this project, 182 in 2020 - 2021 and 170 in 2021 - 2022. Of the 352 students, 227 (64.5%) were women and 125 (35.5%) were men. The mean age was 23.7 (SD 2.8) years, with a median of 23 and a range from 22 to 51 years.

The normality of the distributions was assessed using the Shapiro–Wilk test. OSCE case scores (2020: W=0.934, $P=.009$; 2021: W=0.891, $P<.001$) and the final experience score (2020: W=0.874, $P<.001$; 2021: W=0.944, $P=.02$) did not follow a normal distribution and were compared using the Mann–Whitney *U* test. In contrast, the results of the seminar questions (2020: W=0.966, $P=.17$; 2021: W=0.981, $P=.59$) and academic clerkship grades (2020: W=0.968, $P=.20$; 2021: W=0.967, $P=.18$) followed a normal distribution and were compared using unpaired 2-sample *t* tests. The average rating up to 10 points of the teams in 2020 - 2021 versus 2021 - 2022 was as follows: in OSCE cases, 7.36 (SD 1.35) versus 8.41 (SD 0.99*;* $P<.001$); screenshots taken in SL, 7.31 (SD 1.65) versus 7.04 (SD 1.73; $P=.35$); the seminar questions 4.98 (SD 0.83) versus 4.41 (SD 1.07; $P=.004$); and the final score of the experience, 6.40 (SD 0.86) versus 6.54 (SD 0.77; $P=.40$). Figure 3 shows the average score of the 7 groups for each year in chronological order. There was no difference in the academic grade of the clerkship between the students of both years (7.68, SD 0.44 vs 7.79, SD 0.43; $P=.19$).

In Figure 3, the final scores were obtained by considering the percentage contribution of the OSCE cases (40%), the SL screenshots (20%), and the seminar test (40%). The points represent the mean values of the 7 teams in each group. The solid line corresponds to the 2020 - 2021 academic year, and the dashed line to 2021 - 2022. The average score obtained in the 16 OSCE cases is shown in Figure 4. In 5 cases, the score obtained in 2021 - 2022 was significantly higher than in 2020 - 2021; there were no other significant differences. Considering both years, the easiest case was number 9, a ruptured abdominal aortic aneurysm with hemoperitoneum on CT (mean score 9.58, SD 0.79), and the most difficult was number 16, osteoblastic bone metastases from prostate carcinoma in a chest x-ray (5.83, SD 2.25).

Figure 3. Scoring of the different components of the Rainbow-Game educational experience. OSCE: Objective Structured Clinical Examination; SL pics: Second Life pictures.

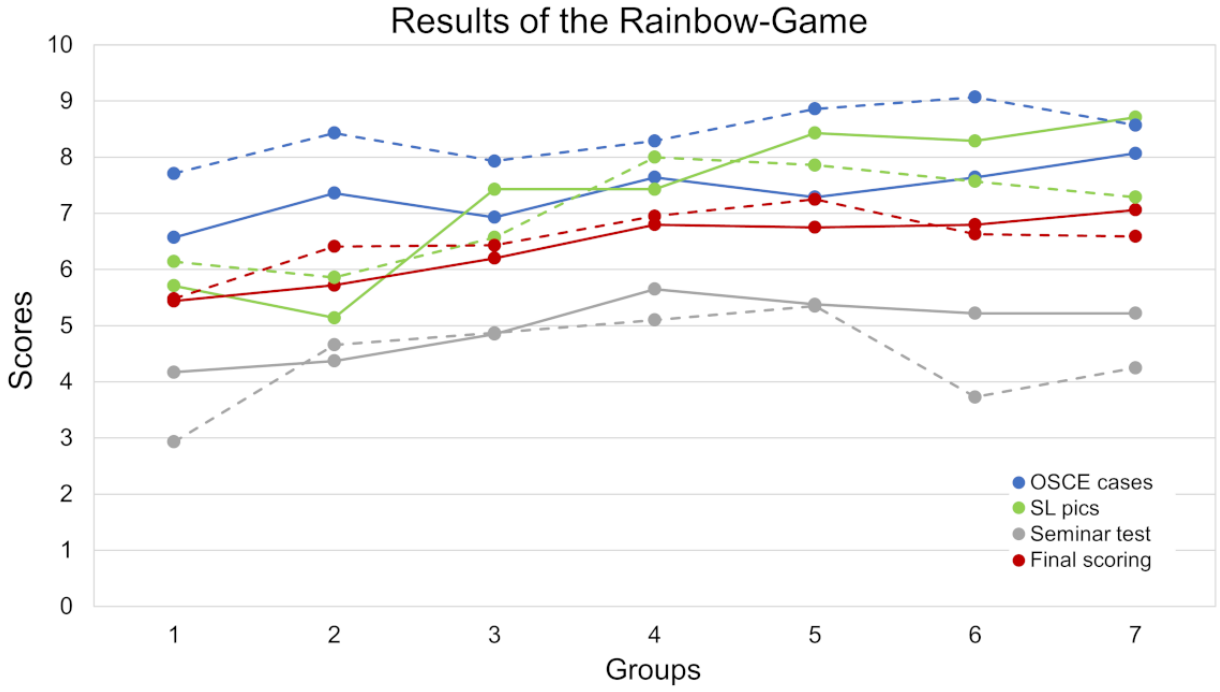

Figure 4. Bar chart with the average score obtained for each case over 2 consecutive years. Each year, 6 teams evaluated the cases, except for case 1, which was evaluated by 8 teams. Error bars represent the SD. Statistically significant differences, with $P<.05$, are identified with the letter "a." OSCE: Objective Structured Clinical Examination;

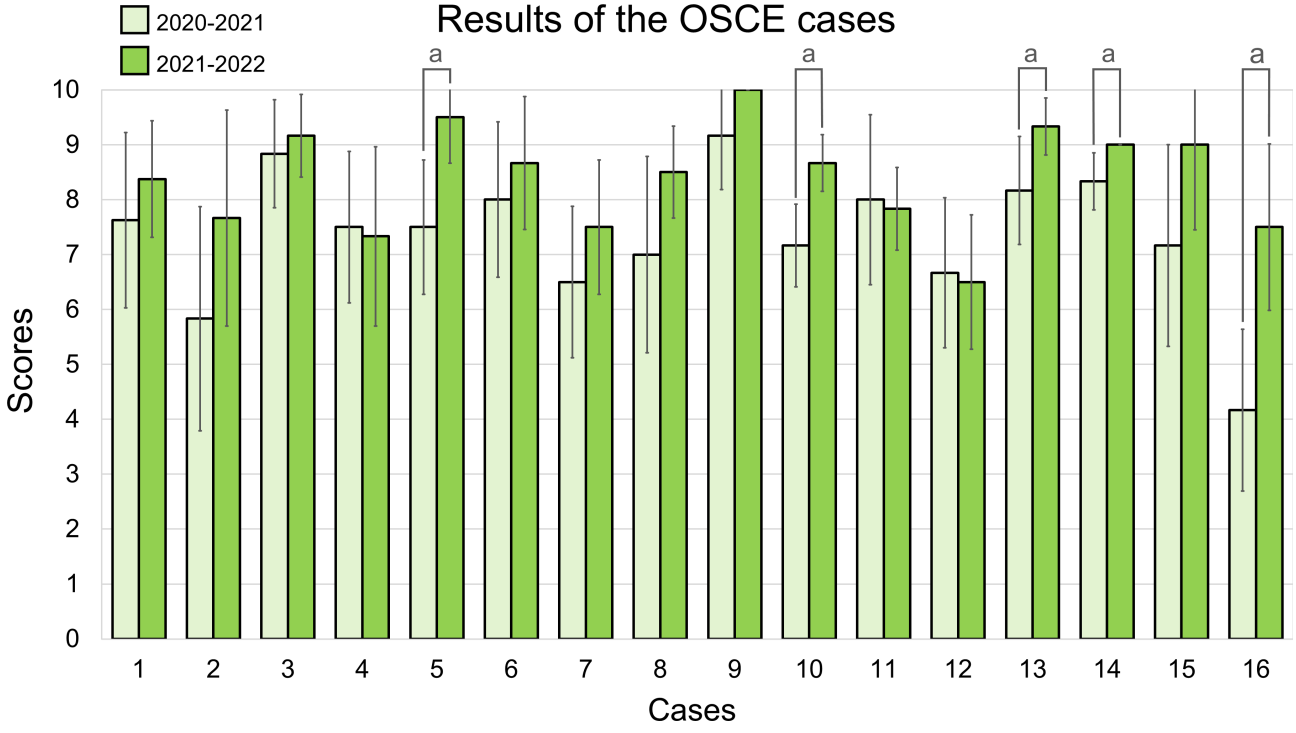

Students' Perception

Three hundred and nineteen students (90.6%) submitted the perception questionnaire, 167 (91.8%) in 2020 - 2021 and 152 (89.4%) in 2021 - 2022. Only 38 (11.9%) stated that they did not know SL previously, the rest had participated in educational activities in SL during their third year. All items from the questionnaire showed significant deviation from normality, with Shapiro–Wilk tests yielding $P<.001$ in both cohorts. Consequently, all comparisons were performed using the Mann–Whitney *U* test.

The results regarding cognitive load are summarized in Table 3. The task that required the greatest mental effort was editing and dressing the avatar, with an average score between rather high and high mental effort (median 7, 95% CI 6.56 - 6.96),

followed by solving the cases proposed in the OSCE stations, with an average score between no mental effort and rather high mental effort (median 6, 95% CI 5.48 - 5.86). The rest of the tasks required from rather low to very low mental effort. There were no significant differences in cognitive load between the 2 years except for the tasks of dressing the avatar, which required greater mental effort in 2021 - 2022, and the resolution of OSCE cases, which required less mental effort in 2021 - 2022.

Table . Results of the questionnaire about the cognitive load.

How much mental effort does it cost you to develop the following tasks?[a]	2020 - 2021		2021 - 2022		*P* value[b]	Both years	
	Mean (SD)	Median (95% CI)	Mean (SD)	Median (95% CI)		Mean (SD)	Median (95% CI)
Moving around in Second Life	3.85 (2.25)	4 (3.51 - 4.19)	3.93 (2.25)	3 (3.57 - 4.29)	.59	3.89 (2.25)	3 (3.64 - 4.14)
Communicate by written chat	2.07 (1.52)	2 (1.84 - 2.30)	2.23 (1.69)	2 (1.96 - 2.50)	.50	2.15 (1.60)	2 (1.97 - 2.33)
Communicate by voice	2.67 (2.14)	2 (2.34 - 3.00)	2.99 (2.34)	2 (2.62 - 3.36)	.19	2.83 (2.24)	2 (2.58 - 3.08)
Edit and dress your avatar	6.62 (1.81)	7 (6.34 - 6.90)	6.90 (1.85)	7 (6.61 - 7.19)	.08	6.76 (1.83)	7 (6.56 - 6.96)
Solve the proposed cases in the OSCE-RX[c] room	5.95 (1.71)	6 (5.69 - 6.21)	5.38 (1.73)	6 (5.10 - 5.66)	<.001	5.67 (1.74)	6 (5.48 - 5.86)
Follow the development of the seminar in Second Life	4.54 (2.26)	5 (4.19 - 4.89)	4.44 (1.92)	5 (4.14 - 4.74)	.33	4.49 (2.10)	5 (4.26 - 4.72)

[a]Likert scale from 1 to 9 according to: (1) Very, very low mental effort; (2) Very low mental effort; (3) Low mental effort; (4) Rather low mental effort; (5) Neither high nor low mental effort; (6) Rather high mental effort; (7) High mental effort; (8) Very high mental effort; and (9) Very, very high mental effort.

[b]*P* is the probability of error of the Mann Whitney *U* test. Statisitical significance set at $P<.05$.

[c]OSCE-RX: Objective Structured Clinical Examination: Radiology.

Overall, more than 95% of the respondents agreed or strongly agreed that the OSCE case selection was suitable for their training, the contents were appropriate, and that they worked as a team. In addition, more than 79% found the environment of the OSCE rooms attractive, the competition design appropriate, and the information provided adequate (Figure 5). Between 49% and 56% agreed that learning radiology in SL is interesting and that playing and competing is a better way to learn. Twenty-two percent of students disagreed with the suitability of their computers, and 9% disagreed with the adequacy of their internet connection for working in SL. Fifty-four percent of the 2021 - 2022 students agreed that they had fun during the experience. There was significantly lower agreement in 2021 - 2022 on 8 of the 5-point Likert scale statements.

The participants rated the experience up to 10 points, with mean scores higher than 8 points in 7 of 9 items (Table 4). The lowest rating was given for connectivity to SL. All mean scores in 2021 - 2022 were significantly lower than those in 2020 - 2021. One hundred and forty-three questionnaires (44.8%) included open comments: 82 (49.1%) in 2020 - 2021, and 61 (40.1%) in 2021 - 2022. After the initial first-layer coding, 12 second-layer subcodes were found among the advantages, 8 among the disadvantages, and 9 among the suggestions, as shown in Table 5, along with the thematic description and frequency.

Figure 5. Diagram showing the degree of agreement, expressed as a percentage, reached each year in the responses to the experience evaluation questionnaire, which used a 1 - 5 Likert scale. OSCE: Objective Structured Clinical Examination;

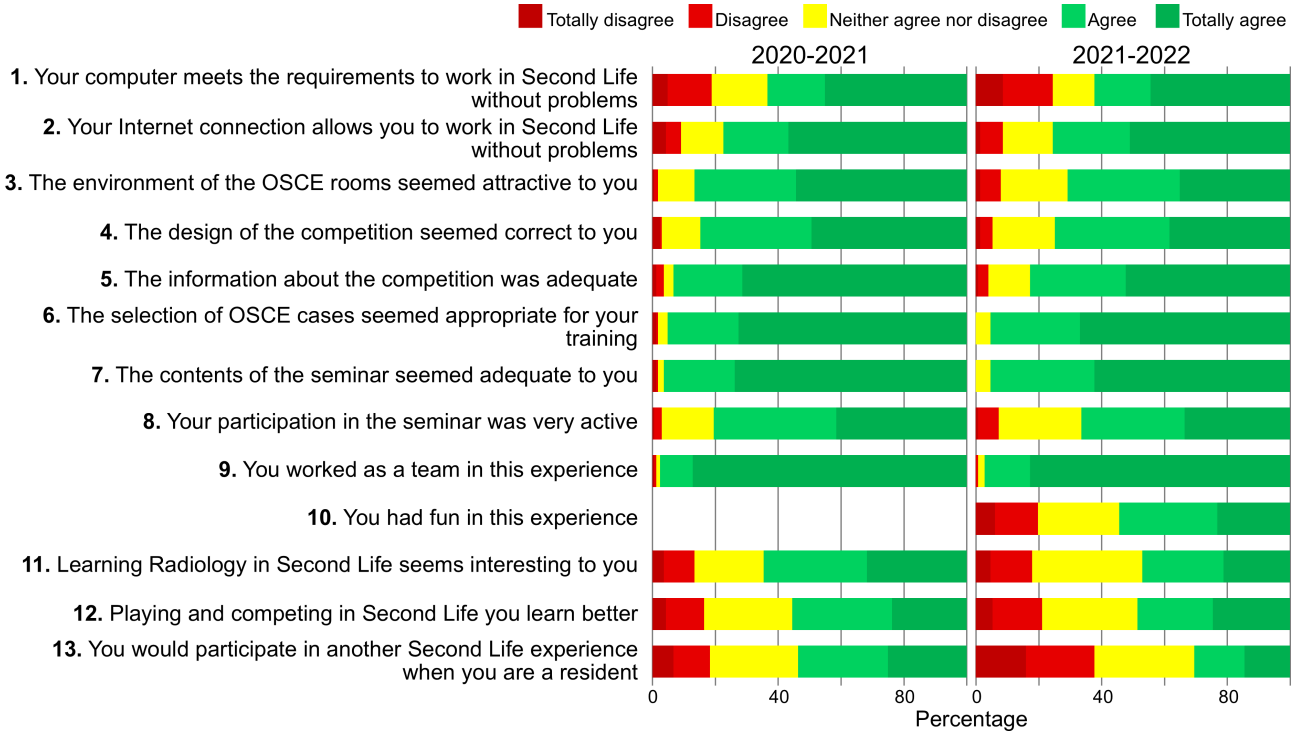

Table . Rating in a 0 - 10 points scale of various aspects of the experience.

Items	2020 - 2021, mean (SD)	2021 - 2022, mean (SD)	*P* value[a]	Both years, mean (SD)
Overall experience	7.81 (1.70)	7.07 (1.72)	<.001	7.46 (1.75)
Organization of the project	8,88 (1.45)	7.92 (1.75)	<.001	8.42 (1.67)
Environment of the OSCE[b] rooms	8.66 (1.44)	8.03 (1.74)	<.001	8.36 (1.62)
OSCE cases	8.75 (1.35)	8.43 (1.25)	.007	8.60 (1.31)
The virtual seminar	8.63 (1.66)	7.62 (2.03)	<.001	8.15 (1.91)
The teachers	9.30 (1.17)	8.93 (1.10)	<.001	9.13 (1.15)
The utility for your training	8.52 (1.59)	7.56 (1.98)	<.001	8.06 (1.85)
Interaction with peers	8.55 (1.65)	7.73 (1.99)	<.001	8.16 (1.86)
Connectivity to Second Life	7.22 (2.37)	6.09 (2.57)	<.001	6.68 (2.53)

[b]OSCE: Objective Structured Clinical Examination

Table . Thematic codification of the open comments included in the questionnaire.

Codes and subcodes	2020 - 2021	2021 - 2022	Both
Advantages			
Appreciation: with terms like I liked, interesting, attractive, gratifying, enjoyable, positive, very cool, fantastic.	30	19	49
Acknowledgment: recognition, thanks to teachers for the effort, design, and organization.	20	9	29
Didactic: indicating that the experience is useful for learning, profitable, helpful, formative.	14	11	25
Playful: fun, entertaining, expressing that you learn by playing.	18	9	27
Innovative: also expressed with terms such as new, original, unusual, surprising, creative, different.	13	8	21
Teamwork: highlighting its importance, social contact, collaboration, coworking.	14	4	18
Cases: finding them interesting, of balanced difficulty, useful or of didactic value for active learning.	6	9	17
Seminar: emphasizing the interest in medical training, the educational value or the feeling of presence and dynamics as in the classroom.	11	4	15
COVID: a good solution or adequate for the pandemic situation, which allows them to maintain social contact.	7	3	10
T-shirt: together with the picture contest, expressing that they liked it, thought it was a creative idea, or that it favors a good atmosphere.	3	1	4
Guidelines: highlighting that they were good, useful, or detailed.	4	0	4
2D Platforms: preference over 2D platform platforms such as Zoom, Google Meet, Microsoft Teams, etc.	0	2	2
Disadvantages			
Technical problems: due to the computer or the Internet connection, the program does not run well.	22	20	42
Mild or occasional	15	15	30
Serious (prevents executing SL)[a]	7	5	12
Of them, resolved	6	4	10
Second Life (SL): running SL is complicated, even stressful. They feel that they are not used to it or that they do not handle the interface well. A learning curve is necessary	13	11	24
Dressing up: the tasks of dressing the avatar are difficult, complicated, time-consuming, or not important to them.	8	9	17
Time: this activity becomes more complicated in the last year of the degree, in which there is a lot of occupation with other activities and tasks.	1	15	16
Face-to-face: preference for face-to-face seminars in the real world.	5	6	11
Camera: problems using the camera (avatar vision) and seeing the images properly.	6	4	10
Notecards: problems sending notecards	0	2	2
2D Platforms: preference for 2D online platforms, such as Zoom, Google Meet, Microsoft Teams, etc.	1	1	2
Suggestions			

Codes and subcodes	2020 - 2021	2021 - 2022	Both
Voluntary: proposal that these activities be voluntary, even on vacation.	0	7	7
Other platforms: to be used as a resource when Second Life fails or there are connection problems.	3	1	4
More cases: include more cases, with more modalities, such as ultrasound, breast imaging, etc.	2	1	3
Training SL: provide training on handling SL in medical school, including tricks, handling avatars, etc.	2	2	4
Modifications: slight modifications to the current experience related to scheduling, team building, or information	2	2	4
SL proposals: new gamification proposals, learning strategies, and radiology repositories. Even do all the clerkship seminars in SL.	4	0	4
Patients: add virtual patients to OSCE stations	1	0	1
Computers SL: enable computers with the SL viewer in the Faculty of Medicine.	0	1	1
Ubiquity: carry out the experience with professors and students from other universities.	0	1	1

[a]SL: Second Life

Discussion

Principal Findings

Today's radiology students have different learning styles compared with previous generations, preferring to shift from the traditional lecture-based approach to more active learning methods that engage them more effectively [38]. This study presents a new educational experience for sixth-year medical students, conducted in SL during a 2-week radiology clerkship and replicated over 2 academic years. This educational experience is grounded in a constructivist and experiential learning approach [39], integrating several complementary pedagogical strategies. These include game-based learning to foster engagement and motivation [40]; case-based learning to stimulate clinical reasoning [38]; and team-based learning to promote collaboration and peer discussion [41]. The design also combines asynchronous and synchronous components to support flexibility and self-regulated learning. Simulation-based activities in a virtual world (SL) provide a safe, immersive environment for clinical skill development [42,43]. In addition, the experience draws on Self-Determination Theory [44], addressing both intrinsic motivation (interest and enjoyment) and extrinsic motivation (competition and rewards). Further pedagogical framing may be informed by Bers' Coding as Another Language approach [45], which conceptualizes digital environments as spaces for exploration, communication, and meaning-making—aligning with our use of SL for collaborative and immersive clinical learning.

Case-based learning connects theoretical knowledge with the clinical environment and encourages students to think like doctors. By reflecting on radiological images through clinical cases, students can appreciate the role of radiology in patient care [38]. The 24/7 availability of the content in SL enables the organization of asynchronous tasks, such as the 9-day period for evaluating OSCE cases in this study, adapting to students' study schedules, an essential factor for reflection and self-regulated learning [46]. Team-based learning is particularly suitable for visual topics like radiology, as it promotes and facilitates group discussion of complex, real-life radiological cases [47]. Teamwork dynamics are vital in undergraduate medical training, as they foster collaboration among students with varying levels of knowledge and experience [4,48].

Virtual world technologies, such as SL, make avatar-mediated student assessment in simulated 3D scenarios technically feasible to set up and run. This has been demonstrated in home accident scenarios in geriatric medicine [49], as well as in office or hospital settings [27], but has never been used to replicate scenarios for learning radiology. In this study, 7 OSCE stations were developed to simulate clinical scenarios involving medical emergencies, providing students with a variety of cases. The environment created allowed students to work in groups remotely at significantly lower cost than a similar scenario in the real world.

The educational activity in this study includes a significant component of competitive team gamification, a cooperative learning technique that enhances students' motivation and focus on learning tasks [48], combining group rewards with individual responsibility [50]. According to self-determination theory, motivation has 2 components [51,52]: intrinsic motivation, defined as participation in an activity because it is found to be inherently interesting and enjoyable, and extrinsic motivation, where participation is driven by external factors such as rewards, promotions, or the avoidance of academic failure. Competition is a powerful extrinsic motivator; however, it is criticized for creating high-pressure environments that reduce intrinsic motivation and hinder optimal learning [53]. Previous studies have shown that multi-user competitive games developed in SL through asynchronous activities can enhance medical students' learning of basic radiological content, such as anatomy and semiology, and that students find these games highly beneficial

for their training as physicians, both when competing individually [25,54] and in teams [55]. This study proposes a different approach to learning games, incorporating clinical content commonly found in medical practice, centered on case resolution through teamwork and supplemented by synchronous discussion and debate activities. In both courses, students recognized and appreciated the educational value of the Rainbow-Game experience.

SL is an appropriate environment to develop oral communication skills in clinical radiology through the presentation and discussion of content [56]. In this study, effective communication was fostered through group discussion and reflection on the cases. The experience concluded with a seminar on emergency radiology to reinforce students' knowledge and clinical reasoning. Seminars conducted in SL provide a strong sense of co-presence and have an educational impact comparable to those held in person, as long as the same objectives, content, and script are maintained [57].

Emergency radiology is an essential part of the undergraduate medical curriculum, ensuring that students can recognize major radiological emergencies [58]. In this study, students delved into clinical reasoning on cases commonly found in hospital emergency settings, achieving good results on the cases assigned to each team, with differences mainly related to the difficulty of the cases (Figure 4). This provides a measure of student performance on clinical cases in the final year of medical school. In contrast, the seminar exam questions were scored poorly due to limited response time and possibly an excessive number of items on the assessment checklist (see Multimedia Appendix 1). Students in 2021 - 2022 performed better on the cases than those in 2020 - 2021 and reported a lower cognitive load to solve them. This could indicate that they were better prepared for this type of tasks; however, they performed worse on the seminar questions, and there were no significant differences in the academic grades for the clerkship, so some leakage of results from one year to another cannot be ruled out. Although no traditional learning group was included, similar clerkship grades across both years suggest that the SL-based activity maintained academic performance while adding value through engagement and teamwork.

In general, the students perceived the experience as innovative and appropriate for their training. They valued the selected cases, the design and organization of the project, and the opportunity to work collaboratively in teams. In their open comments, they frequently described the activity as "fun," "interesting," and "useful for learning," highlighting its originality and the engaging nature of solving clinical cases in a virtual world. Several students also appreciated the social interaction and teamwork it encouraged, particularly under pandemic restrictions. However, some disadvantages were noted, particularly technical issues related to SL, such as interface difficulties or connectivity problems. Although students received technical support, using personal devices may have contributed to differences in their experiences. These issues may be related to the technical requirements of the platform, which must be installed locally and require specific hardware and internet conditions [59]. One student suggested enabling access to university computers with the SL viewer. The task of customizing avatars was often described as time-consuming and lacking clear educational purpose. A number of students, particularly in 2021 - 2022, felt the activity required too much time, and some suggested it should be optional or scheduled during a less demanding academic period.

These differences in perception may be attributed to the timing of both experiences during different phases of the COVID-19 pandemic. In the first semester of 2020 - 2021, students faced a stressful situation with restricted in-person academic activities, where online solutions were seen as essential for teaching. One year later, teaching had partially normalized, with some precautions still in place, but there was a certain sense of fatigue from the overuse of online activities [60]. This may have contributed to a greater perception of workload among the students and, consequently, a lower appreciation of the learning experience. Despite lower satisfaction scores in 2021 - 2022, students performed better on case resolution tasks and reported lower cognitive load. This suggests that learning outcomes do not always align with perceived satisfaction. Improved performance may reflect greater digital familiarity and self-regulation skills developed through previous remote learning. In contrast, lower ratings may have been influenced by reduced novelty, increased academic pressure, or persistent fatigue from extended online education, rather than the activity's educational value.

Comparison With Previous Work

This type of learning experience may be less appealing to those who are not drawn to gamification and technology. In fact, it has been shown that mandatory participation in gamification activities in SL can lead to a lower perception and acceptance of the game by a proportion of students [54]. Mandatory activities contribute to the extrinsic motivation of medical students, but "imposed" gamification has a counterproductive effect, described as "mandatory fun" [61]. User acceptance of 3D virtual world technology is positively influenced by their perception of the ease of use, usefulness, enjoyment, and visual appeal of a virtual learning environment, which significantly impacts student satisfaction, learning outcomes, and retention [62,63]. Most participants in the Rainbow-Game found the experience interesting and suitable for learning, and more than half found it fun. However, some students may not have perceived sufficient reward in a compulsory learning game. Therefore, the option for the best team in each group to earn an additional point on their academic grade compensates for this by providing an extrinsic motivation.

This study demonstrates how a mandatory game-based learning experience in SL can be added to the formal teaching organization of a radiology clerkship. Training in case resolution, peer discussion, and attending a seminar on emergency radiology provides added value to the educational objectives of this clerkship in the final year of the degree. The design of the cases and OSCE stations, along with the positive perception of students, is another added value. The immediate continuation of this project, which has already been completed and is pending publication, involved the development of individual, synchronous radiology OSCEs conducted over a restricted period of several minutes per station, emulating

face-to-face OSCEs, like those carried out at the end of the degree [64]. Future developments will focus on comparing the virtual world activity with a control group performing identical tasks either in real-world settings or in 2D virtual environments. This will allow for a more comprehensive evaluation of the added value of immersive 3D learning environments in radiology education.

Limitations

The main limitation of this experience, consistent with previous studies [31,57], was the presence of technical problems with the computers and the online connection needed to run SL correctly, as recognized in the open comments of 13% of the questionnaires. However, two-thirds of these issues were minor or occasional problems, and a third were resolved through simple solutions, such as borrowing a computer or using a cable connection. Since SL is developed as computer software, it requires suitable hardware that meets minimum requirements. In addition, SL is an internet-based technology with a client/server structure, which relies on stable internet connectivity. Despite the significant increase in internet access for higher education students, many still face restricted connectivity [63]. Another limitation to consider is that this study was conducted at a single institution. Although the experience has been replicated over 2 academic years, it would be valuable to see if it could be implemented elsewhere, which would require the cooperation of professors from other institutions and the inclusion of the project in the teaching guide for the corresponding courses.

Conclusions

This study presents a game-based radiology learning experience conducted in the SL virtual world, integrating simulated case-based learning in virtual OSCE stations, team-based competitive learning, and synchronous group sessions. The experience, adapted to a radiology clerkship, is feasible and reproducible, promoting clinical reasoning and teamwork among students in a playful context that they recognize and value highly. In addition, it is worth exploring the educational potential of OSCEs in 3D virtual environments for radiology and other medical disciplines.

Acknowledgments

This work was partially supported by the Educational Innovation Projects of the University of Malaga PIE19-217 and PIE22-045. Funding for open access charge was provided by Universidad de Málaga / CBUA. The funders had no role in study design, data collection and analysis, decision to publish, or preparation of the manuscript. The authors also want to acknowledge the students who participated in this study and voluntarily sent the project assessment questionnaires.

Abstract

Background: Applying functional anatomy to clinical examination techniques in shoulder examination is challenging for physicians at all learning stages. Anatomy teaching has shifted toward a more function-oriented approach and has increasingly incorporated e-learning. There is limited evidence on whether the integrated teaching of professionalism, clinical examination technique, and functional anatomy via e-learning is effective.

Objective: This study aimed to investigate the impact of an integrated blended learning course on the ability of first-year medical students to perform a shoulder examination on healthy volunteers.

Methods: Based on Kolb's experiential learning theory, we designed a course on shoulder anatomy and clinical examination techniques that integrates preclinical and clinical content across all 4 stages of Kolb's learning cycle. The study is a randomized, observer-blinded controlled trial involving first-year medical students who are assigned to one of two groups. Both groups participated in blended learning courses; however, the intervention group's course combined clinical examination, anatomy, and professional behavior and included a peer-assisted practice session as well as a flipped classroom seminar. The control group's course combined an online lecture with self-study and self-examination. After completing the course, participants uploaded a video of their shoulder examination. The videos were scored by 2 blinded raters using a standardized examination checklist with a total score of 40.

Results: Thirty-eight medical students were included from the 80 participants needed based on the power calculation. Seventeen intervention and 14 control students completed the 3-week study. The intervention group students scored a mean of 34.71 (SD 1.99). The control students scored a mean of 29.43 (SD 5.13). The difference of means was 5.3 points and proved to be statistically significant (P<.001; 2-sided Mann-Whitney U test).

Conclusions: The study shows that anatomy, professional behavior, and clinical examination skills can also be taught in an integrated blended learning approach. For first-year medical students, this approach proved more effective than online lectures and self-study.

Introduction

Although clinical guidelines recommend that imaging diagnostics be based on a structured clinical examination, primary care physicians frequently rely on imaging modalities such as magnetic resonance imaging when managing shoulder complaints [1-4]. This raises the broader issue of how well clinical anatomy and musculoskeletal examination skills are integrated and emphasized during medical education and training. In fact, both residents and medical students report substantial learning needs in musculoskeletal examination

techniques, except among those with a preexisting interest in musculoskeletal specialties [5-11].

Learning clinical competencies is a complex process that can be better understood through the application of a theoretical framework [12-14]. Kolb's experiential learning theory provides such a framework. It conceptualizes learning as a continuous cycle involving concrete experience, reflective observation, abstract conceptualization, and active experimentation [15]. This model is particularly relevant in traditional Flexnerian curricula, where preclinical and clinical training are distinctly delineated, with the cultivation of clinical competencies unfolding over the course of several semesters. It encompasses various dimensions—such as interpreting pathology, applying appropriate examination techniques, and demonstrating professional behavior—achieved through diverse instructional methods, all within a stressful learning environment [3,11,16-20].

Due to the fragmented way students encounter clinical skills and related knowledge, anatomy education has increasingly moved toward region- and function-based integration—though this shift remains incomplete [21-25].

The advent of the COVID-19 pandemic, along with its associated restrictions on in-person interaction, accelerated the adoption of digital teaching formats in medical education. This shift aligned with a general trend toward expanding e-learning in both clinical and anatomical instruction [26-36]. Specifically, shoulder examination techniques can be taught either face-to-face or digitally through synchronous and asynchronous methods, with face-to-face formats demonstrating superior outcomes and higher learner acceptance [9,13,14,27,37]. Blended learning approaches, such as the flipped classroom, which combine digital and in-person elements, have gained increased traction since the pandemic by effectively linking clinical and anatomical content [11,25-27,32,33,38-41]. In addition, peer teaching has been shown to enhance students' confidence in clinical examination skills and facilitate the transfer of anatomical knowledge into clinical practice [42-44].

The optimal timing for introducing clinical skills within anatomy education and how best to align these skills with examination formats remain subjects of debate [11,45-47]. Clinical skills are predominantly assessed through objective structured clinical examinations (OSCEs), which can also be conducted using video recordings [14,16,48,49].

In summary, Flexnerian curricula typically teach and assess anatomical knowledge, clinical skills, and professional behavior separately, using fragmented instructional methods that include both digital and face-to-face formats. These components correspond to distinct stages of Kolb's experiential learning cycle—for instance, peer teaching facilitates reflective observation and abstract conceptualization [42], while clinical training fosters concrete experience and active experimentation [9,37]. However, Kolb emphasizes that meaningful and deep learning requires progression through all stages of the cycle [15]. This suggests that educational approaches intentionally integrating these phases may lead to improved learning outcomes.

Although previous studies have demonstrated that anatomy and clinical skills can be taught through both face-to-face and digital modalities [36-38,50], there remains a lack of robust empirical evidence supporting integrated teaching approaches that unify preclinical and clinical domains. Our intervention was therefore designed not only to bridge preclinical and clinical content but also to combine multiple instructional methods, aligning with Kolb's model to support an effective learning process.

This study aimed to assess the effect of this integrated blended-learning course on first-year medical students' clinical performance, professionalism, and anatomical knowledge.

Methods

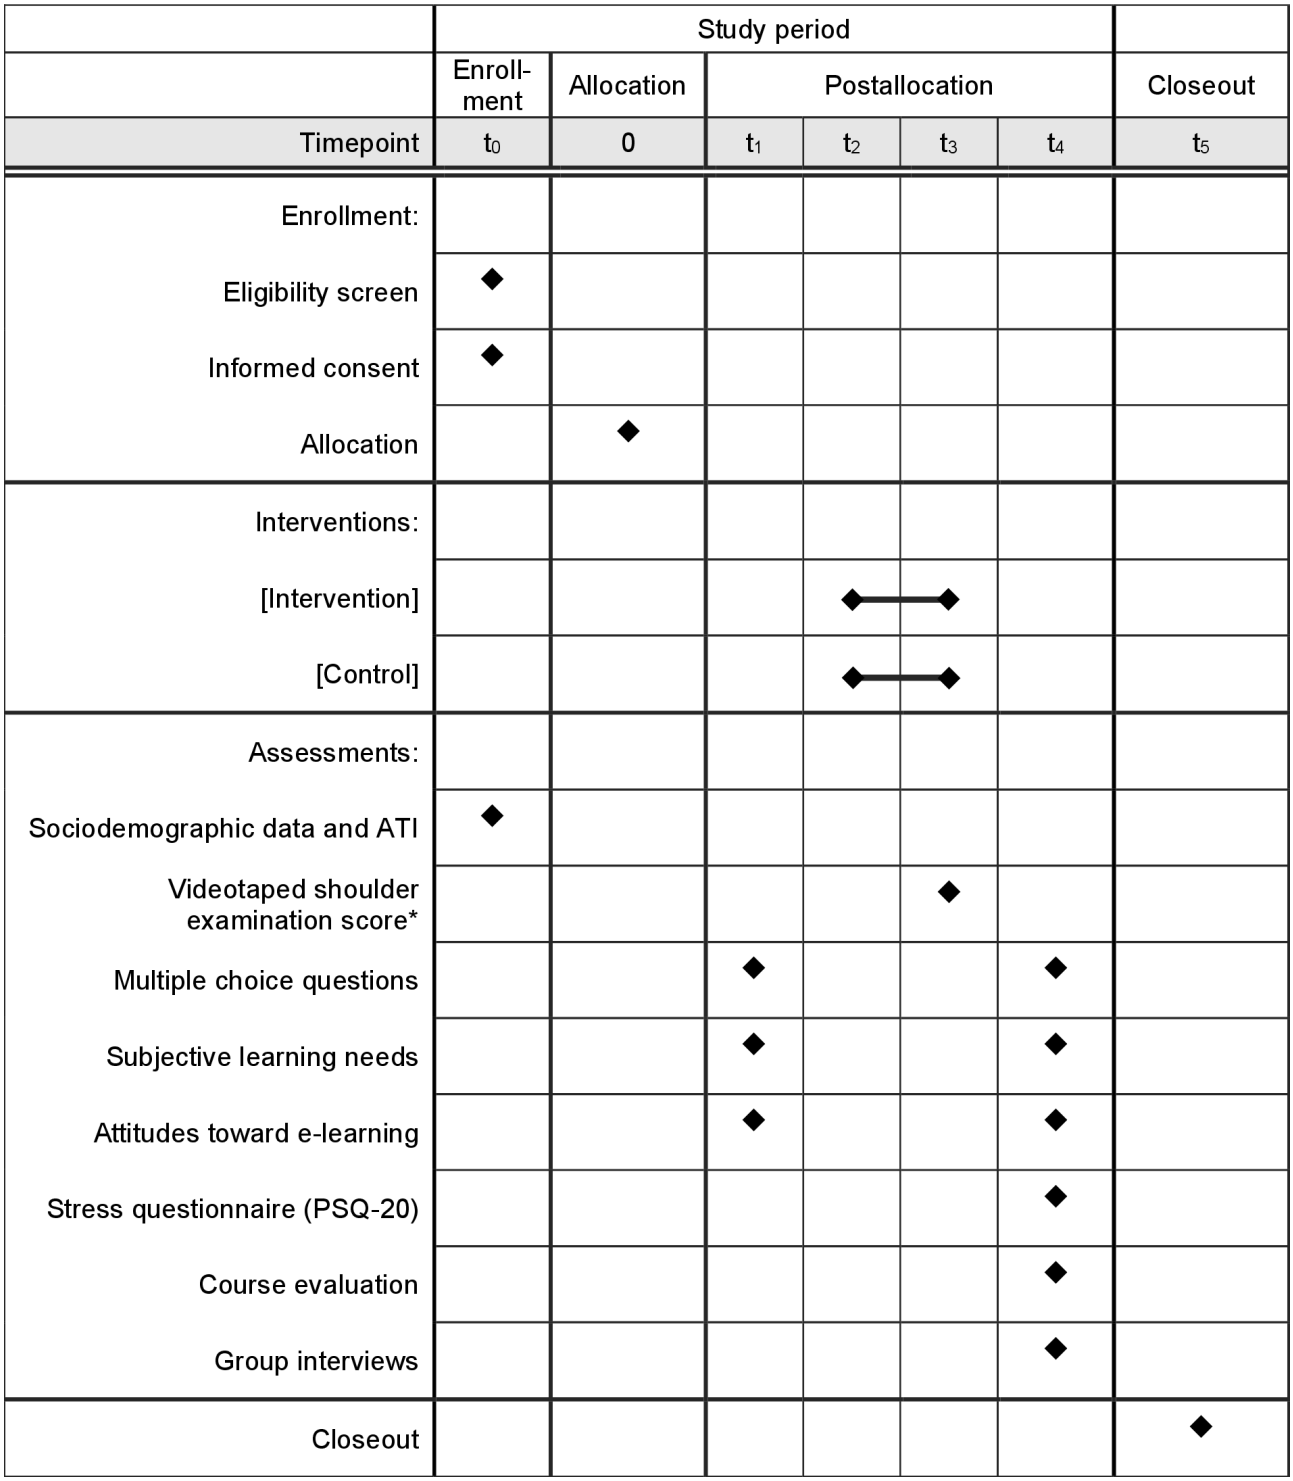
This paper follows the CONSORT (Consolidated Standards of Reporting Trials) guidelines [51].

Study Design

The study was conducted as a 2-arm, randomized, observer-blinded intervention. The study's acronym, TraceX, is derived from "TRansfer of AnatomiCal knowledge in the EXamination situation for preclinical medical students." It was conducted as part of a curricular development project with the same name. The project was funded by the Medical Faculty of Tübingen University Hospital (Universitätsklinikum Tübingen [UKT]). The study protocol underwent an external peer-review process by reviewers not involved in the project. The dean of the faculty and the faculty commission approved the project in 2020.

Its protocol is illustrated in Figure 1, based on the SPIRIT (Standard Protocol Items: Recommendations for Interventional Trials) figure template [52]. The study compared students' performance in a videotaped shoulder examination after a 3-week blended-learning course. The intervention and control groups received 2 different blended-learning modules.

Figure 1. Transfer of anatomical knowledge in the examination situation for preclinical medical students (TraceX) study design protocol. The asterisk indicates the primary outcome. ATI: affinity for technology interaction; PSQ-20: Perceived Stress Questionnaire.



Study Population and Setting

The study took place at the Medical Faculty of Eberhard Karls University Tübingen in southern Germany. It was conducted between October 2021 and March 2022 by the Institute for General Practice and Interprofessional Health Care in cooperation with the Institute of Clinical Anatomy and Cell Analysis. In Tübingen, online courses are provided using the Integrated Learning, Information, and Work Cooperation System (ILIAS) online-learning platform, which is a commonly used learning management system among German universities (ILIAS open source e-Learning e.V). It allows log-in via authenticated student email accounts.

Pilot Study

Several instruments used in the study were piloted in 2020 with 18 first-year medical students. The primary purpose of the pilot study was to check interrater reliability for the primary outcome measurement instrument and to calculate the internal reliability of the self-developed questionnaire items. The results of these checks and their impact on the development of the items are listed below for each respective instrument.

In addition, participants of the pilot study were asked to assess the online learning modules. Based on their feedback, the course content was adapted. Two of the pilot study participants provided valuable comments on course benefits and weaknesses in an additional voluntary online interview. The interview served as an extended evaluation. Furthermore, LG (who later conducted the group interviews in the main study) piloted interview guidelines and received interviewer training based on the participants' feedback.

Recruitment

Recruitment for the main study started in May 2021. First-year medical students were approached via email and in 2 online lectures. Interested students were invited to contact the Institute for General Practice's office to receive additional information (eg, type of study, goal, significance, and participant rights). Study participation was voluntary and did not impact other courses in the curriculum. For students who did not wish to participate in the study, regular curriculum activities proceeded. The teaching coordinator (responsible for course and lecture coordination at the Institute) communicated with students but did not participate in the study design or execution. Eligibility criteria included being a first-year medical student, having provided informed consent to use ILIAS, and feeling healthy enough to participate in the study.

Intervention and Control

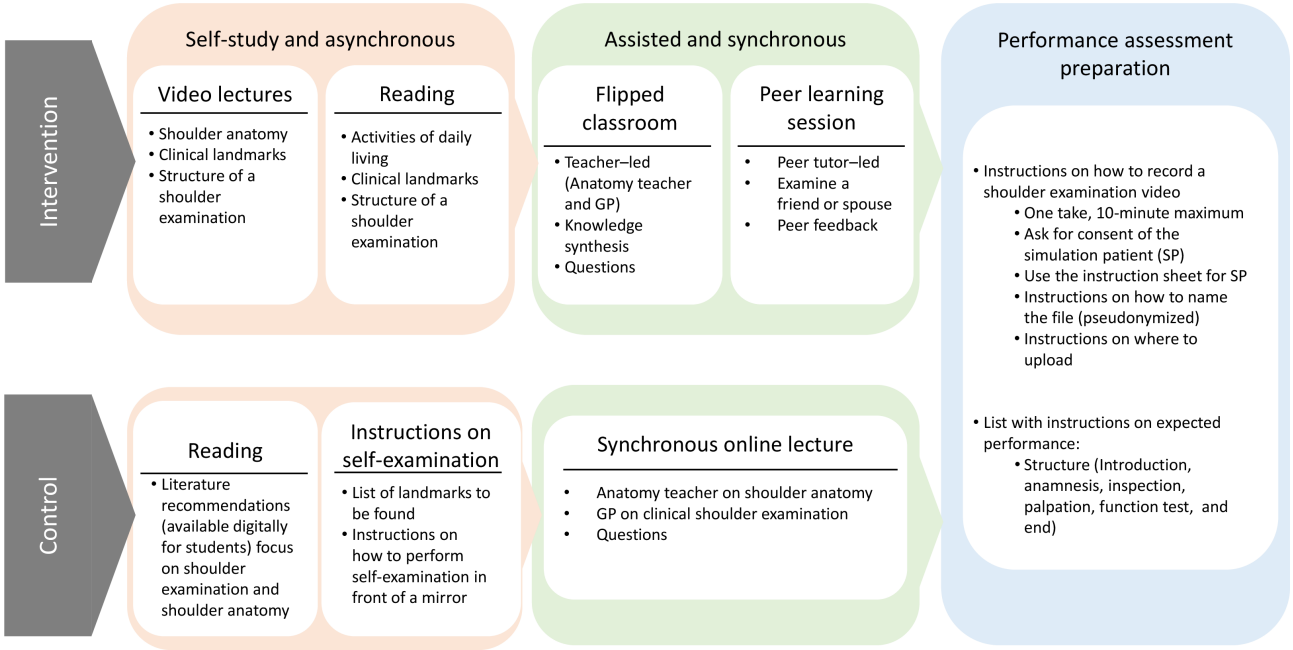
Intervention and control courses were developed collaboratively in interdisciplinary workshops involving general practitioners (GPs), a medical didactics expert, an orthopedic surgeon, a psychotherapist, medical students, a physiotherapist, and a medical psychologist.

Common learning objectives were developed first and then applied to both groups, which differed in instructional design and learning format. The intervention group received access to structured online modules, including physiotherapist-led examination videos, functional and topographic anatomy videos performed by an anatomy lecturer, and modules on daily life impact and professional conduct. Content was integrated across preclinical and clinical domains. After self-study, students joined a 90-minute flipped-classroom seminar (taught by the same anatomy lecturer and a GP), which included preparation for a peer-training session. Due to COVID-19 restrictions, this 90-minute peer-training session was held in decentralized student pairs or moderated small groups on Zoom (Zoom Communications Inc), with trained peer tutors facilitating feedback.

The control group followed a more traditional format with lectures and self-study. Students received literature for self-study and instructions for self-examination (eg, palpation in front of a mirror). In addition, they attended 2 distinct synchronous online lectures: one on anatomy (anatomy lecturer) and one on clinical examination (GP), based on the same content as the intervention videos but presented with still images, self-demonstration by the lecturers, and a greater separation of clinical and preclinical content.

In summary, the intervention emphasized integrated, interactive learning with structured feedback and more practice time, providing a learning process with all 4 steps of Kolb's learning cycle [15], while the control group reflected conventional, lecture-based learning with limited interaction and a more fragmented learning process. Please refer to Figure 2 for an overview.

Figure 2. Intervention and control design. GP: general practitioner.



Randomization and Allocation

From those students who signed a written informed consent to participate in the study, basic sociodemographic data were obtained at t0 to enable stratified randomization. Randomization was undertaken in a 1:1 ratio using lists generated with the R programming package (The R Core Team, R Foundation, and R Consortium). Randomization was stratified for gender and

occupational experience and used block sizes of 2 and 4. Individualized identification codes were generated by the participants in the surveys (t1 and t4) to allow for linking of presurvey and postsurvey data without compromising participant anonymity or disclosing group affiliation. All other data that could reveal group affiliation were concealed until grading of the final examinations and statistical analysis was completed. Participants were not blinded to their own group affiliation. Randomization and group allocation were performed by 2 researchers not involved in the assessment and development of course content.

The groups received the same instructions for exam performance and grading criteria. Finally, a postcourse questionnaire was distributed to both groups, and voluntary postcourse online group interviews were conducted (t4). After study completion, members of the control group were provided full access to all e-learning resources to preclude disadvantage.

Primary Outcome

This study hypothesizes that an integrated course based on Kolb's learning theory would improve first-year medical students' performance in a standardized, complex OSCE shoulder station requiring structured clinical examination, anatomical knowledge, and professional conduct. Students in the intervention group attended the integrated course and were expected to outperform those in the control group. The primary outcome was OSCE performance at t3, assessed through a structured examination focusing on inspection, palpation, and functional movement assessment, with emphasis on identifying anatomical landmarks rather than detecting pathology.

Because contact restrictions prevented a face-to-face OSCE setting, participants recorded videos of their shoulder examinations and uploaded them to ILIAS. Video length was limited to 10 minutes and included a volunteer (peer, spouse, or family member) acting as a simulation patient. Students were instructed to ensure their volunteers had no preexisting shoulder pain or functional impairments and to obtain consent before recording. Simulation patients were asked to follow the students' instructions and cooperate during the examination, creating a controlled environment intended to minimize bias introduced by the simulation patients.

The uploaded videos were assessed independently by a pair of blinded raters (GP and a medical student) using an examination checklist. The checklist comprised a total of 40 items, including 12 items on anatomical knowledge, such as topography and functional anatomy, 17 items on structured clinical examination skills, and 9 items on medical professionalism. It was developed in multidisciplinary workshops based on existing literature [14] and items from the OSCE used at UKT [53]. It was piloted in the pilot study. In that study, the pair of most congruent raters (a medical student and a GP) achieved an interrater validity of κ=0.573 (Cohen κ). Due to this moderate agreement, several items were operationalized for better standardization of examiners [54]. The final version of the examination score used in this study is included as Multimedia Appendix 1.

Secondary Outcomes

Participants' subjective learning needs were assessed across three domains—anatomical knowledge, clinical examination skills, and professionalism—at time points t1 and t4 using a questionnaire. This questionnaire was developed during an interdisciplinary workshop and subsequently piloted in the initial study phase. The sample of 18 pilot study participants showed a Cronbach α of 0.92. The domain "anatomical knowledge" contained 5 items (ie, visible landmarks, anatomical structure of the shoulder, function, range of motion, and association of function with activities of daily living). The domain "clinical examination" also consisted of 5 items (ie, structured examination steps, history taking, shoulder inspection, shoulder palpation, and test of function). Finally, the domain "professionalism" was covered with 4 items (ie, use of patient-centered language, autonomous handling of the examination situation, perceptiveness toward patient feedback, and addressing patient feedback during the examination). All items were operationalized on a 4-point Likert scale. This yielded sum scores on a 5- to 20-point range and a 4- to 16-point range, respectively.

Theoretical anatomical knowledge was assessed before and after the course (at t1 and t4) using the same set of 10 randomized multiple-choice questions (MCQs). Each question had 5 answer options, with only 1 correct answer, resulting in a knowledge score ranging from 0 to 10. These MCQs reflect the current standard used in the written state medical examination in Germany.

Using Likert scale rating questions, we used 4 items of the standardized Affinity for Technology Interaction Short Scale (ATI-S), rendering a sum score on a 4- to 24-point scale. The ATI-S is a reliable (Cronbach α 0.88-0.92) and validated instrument [55].

The course evaluation included 5 items adapted from the standard evaluation used by the Medical Faculty of Tübingen, covering overall assessment, contribution to personal learning, curriculum alignment, course structure, and clarity of learning goals. Cronbach α for these items was 0.741 based on pilot study data. The evaluation was conducted online via ILIAS at time point t4. In addition, several items assessing blended learning formats were incorporated at t1 and t4, aiming to assess attitudes toward blended learning before and after the intervention. Students were asked to rate whether blended learning promotes self-directed learning, encourages lesson preparation and review, supports exam readiness, enhances curricular value, enables flexible learning, and increases study satisfaction.

Participants were additionally invited to online group interviews at t4. The interviews were analyzed with thematic analysis [56]. An in-depth mixed methods evaluation that includes the interviews will be published separately.

To evaluate the possible impact of the intervention on perceived stress, the validated and standardized 20-item Perceived Stress Questionnaire (PSQ-20) was applied at t4. It contains 20 items with 4 subscales: worries, tension, joy, and demands. Cronbach α is 0.80-0.86 [57].

Statistical Analysis

General

Data were analyzed using SPSS (version 27; IBM Corp). Summary statistics on participants' demographic characteristics, baseline information, course evaluation, and primary outcome were computed using means, SDs, and proportions.

The following statistical tests were used to assess group differences in primary and secondary outcomes. For the primary outcome and exploratory analysis of subscores, 2-sided Mann-Whitney *U* tests were performed to account for nonparametric data distributions. For comparison between groups for nominal scales, chi-square (χ^2) tests were performed or, if cell size was less than 5, Fisher exact test. For the secondary outcomes on longitudinal effects preintervention and postintervention, Wilcoxon rank tests were performed.

Concerning the internal reliability of questionnaires and evaluation based on the pilot study data, Cronbach α was calculated. We also calculated κ statistics underlying the primary outcome for assessment of interrater reliability in examination grading.

The study's intention-to-treat approach considers possible contamination effects by between-group communication or student account misuse between groups.

Power

Power analysis suggested a sample size of 62 subjects to detect intergroup differences in examination scores of 16% with a SD of 20% and an estimated effect size of 0.71 when using 2-sided *t* tests for independent samples at a 5% significance level [58]. Adding a 25% buffer for dropouts, a total of 80 participants were aimed for as the total sample size.

Ethical Considerations

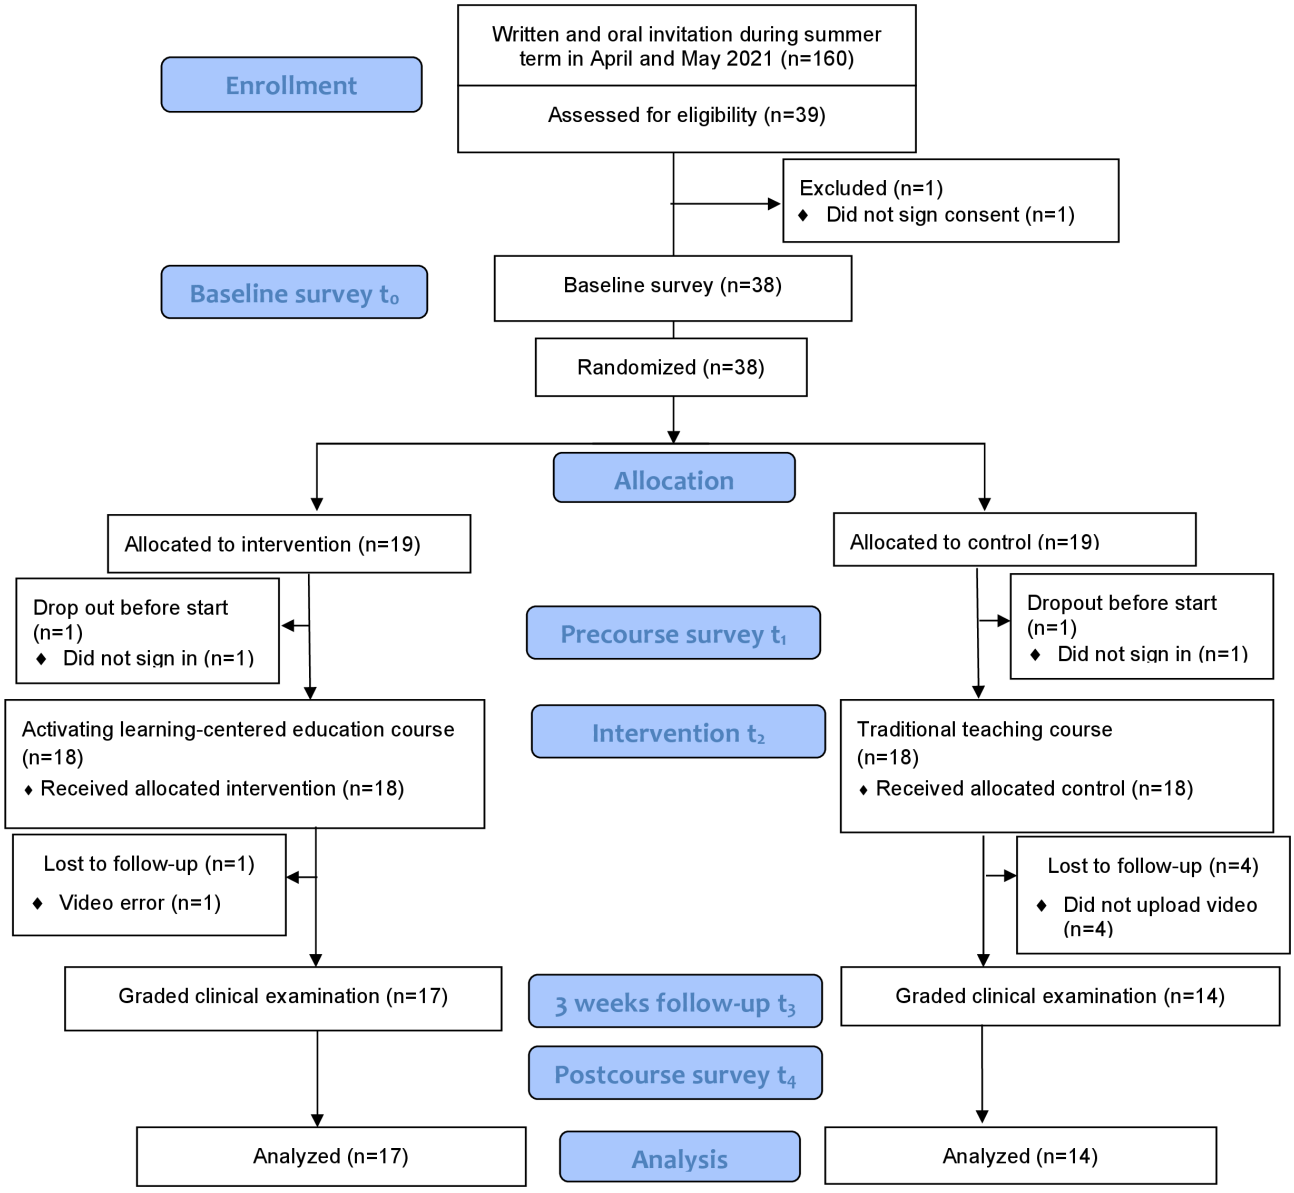
The study was assessed by the Ethics Committee of the Medical Faculty of Tübingen University on May 4, 2020, (231/2020BO1) and did not require ethical approval. Study participation was voluntary and students provided informed consent to participate in the study and access the respective course material in ILIAS. No financial inducement was given for study participation. However, all participating students received a bookstore voucher to compensate for their time commitment. Furthermore, participants who completed the study requirements were eligible to enter a lottery drawing for one iPad. Data were stored on ISO 27001–certified servers at UKT. The trial protocol is available from the authors upon request.

Results

Study Flow

Of 39 enrolled students, 38 were allocated to the intervention and control groups. In both groups, one participant, who, despite having signed informed consent, did not sign in to ILIAS. In the intervention group, one student dropped out before analysis due to an unresolvable video error. The control group had 4 dropouts who did not upload a video. In total, analyzable data from 31 study participants were obtained. Figure 3 below shows the study flow (CONSORT chart).

Figure 3. CONSORT (Consolidated Standards of Reporting Trials) study flowchart.



Sociodemographic and Occupational Characteristics

The majority of participants had no current employment. The intervention group had 2 more participants currently employed in the medical sector. Statistically, neither current nor past employment differed significantly between groups. Participant characteristics at baseline (t1) are presented in Table 1.

Table . Participant characteristics (N=18).

Characteristic	Intervention	Control	*P* value
Age (years), mean (SD)	21.78 (3.56)	21.94 (5.68)	.92[a]
Female[b], n (%)	13 (72)	14 (78)	≥.99[c]

[b]No participant identified as nonbinary.

[c]Fisher exact test.

[d]Chi-square test.

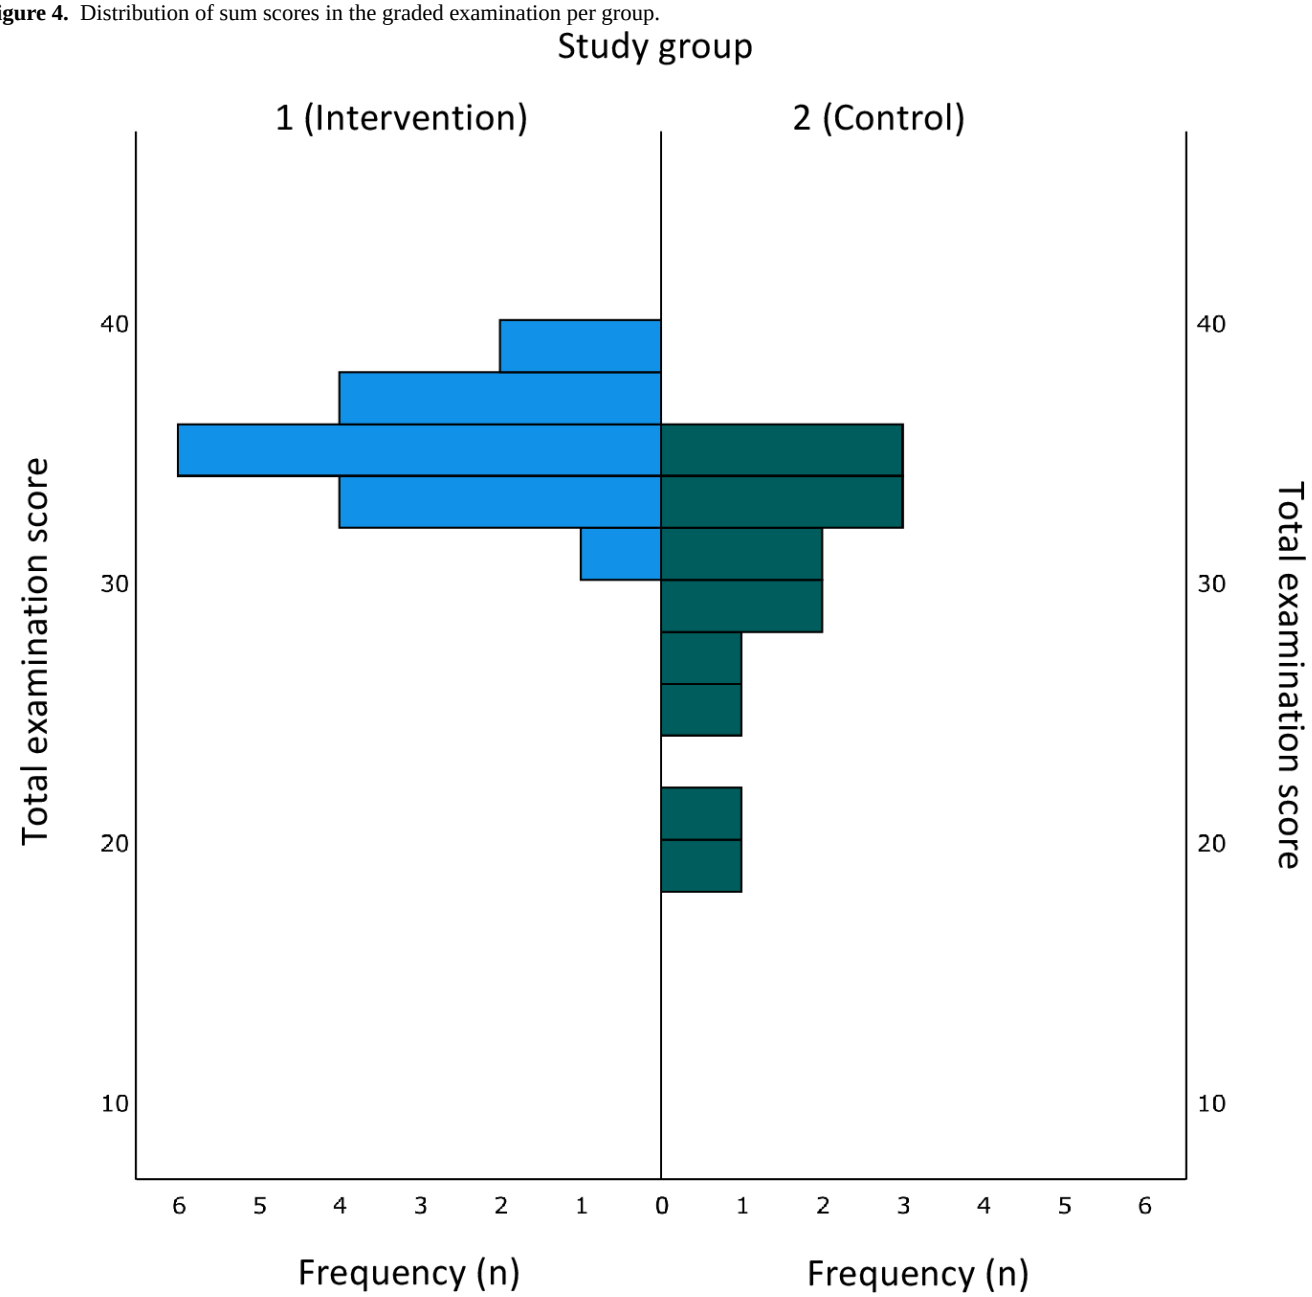
[e]Not applicable.

Primary Outcome

Overview

Intervention group participants reached higher mean performance scores compared to those in the control group (mean 34.71, SD 1.99 vs mean 29.43, SD 5.13), with differences being statistically significant at $P<.001$. Score distributions are shown in Figure 4. Interrater reliability for the shoulder examination checklist score between the two blinded raters was 0.763.

Figure 4. Distribution of sum scores in the graded examination per group.



Exploratory Analysis of Primary Outcome Subscores

We conducted a post hoc exploratory analysis of the primary outcome subscores: anatomical knowledge, clinical examination skills, and professionalism. In the anatomy subscore, the intervention group performed slightly better than the control group, with the difference reaching statistical significance. For clinical examination skills, the difference between groups was less pronounced but remained statistically significant. Table 2 summarizes the results of this analysis.

Table . Exploratory analysis of primary outcome subscores.

Variable	Intervention, mean (SD)	Control, mean (SD)	*P* value[a]
Total performance score (40 items, primary outcome)	34.71 (1.99)	29.43 (5.13)	<.001
Anatomical knowledge (12-item subscore)	9.88 (1.73)	8.21 (1.93)	.02
Clinical examination (17-item subscore)	17.88 (0.86)	15.14 (3.92)	.05
Medical professionalism (9-item subscore)	6.94 (0.90)	6.07 (1.44)	.15

[a]Mann-Whitney *U* test, exact significance.

Secondary Outcomes

Both groups showed a significant reduction in self-reported learning needs in anatomy and clinical examination. MCQ performance improved significantly in both groups after the course, with no significant differences between groups. Participants in the intervention group spent, on average, 2 hours more in the learning module than those in the control group, a statistically significant difference. No relevant group differences were found in attitudes toward blended learning. In the course evaluation, the intervention group rated the blended learning experience and overall course evaluation less favorably but gave higher ratings for the achievement of learning goals and curricular alignment compared to the control group.

Table 3 provides an overview of the secondary outcomes. Group differences at t1 were not significant and are not included.

Table . Secondary outcomes.

Discussion

Principal Findings

Overview

This randomized, observer-blinded trial tested whether an integrated course based on Kolb's learning theory would improve first-year medical students' OSCE performance. Students in the intervention group outperformed the control group after a 3-week course. Both groups showed reduced learning needs, though intervention students spent approximately 2 hours more in the course. The study confirmed the hypothesis but had limitations to consider.

Clinical Examination Skills

The observed difference in clinical examination performance between the 2 groups corresponded to a significant reduction in learning needs related to examination skills. These findings align with previous studies. Brewer et al [37] found that second-year students who received face-to-face instruction in clinical examination skills performed better than those in asynchronous e-learning or self-study groups, with the self-study group achieving the lowest scores. Brewer's study used simulated patients without pathology and included a broader range of clinical tests. Both Brewer et al [37] and Vivekananda-Schmidt et al [13] reported high effect sizes for OSCE shoulder performance when students supplemented regular studies with asynchronous computer-assisted learning. Vivekananda-Schmidt also noted improved student confidence with computer-assisted learning, though our study did not assess confidence due to its limited relevance to performance [7,12].

Anatomical Knowledge

Participants in the intervention group demonstrated improved clinical examination performance without a negative impact on their theoretical anatomical knowledge, as measured by MCQs. We believe that the exclusion of advanced clinical examination tasks such as the Jobe test or Hawkins sign from the learning goals contributed to the increase in anatomical knowledge demonstrated in the exam and the more pronounced reduction of anatomical learning needs in the intervention group. According to the participating preclinical and clinical teachers in the multidisciplinary workshop, these tests require extensive knowledge of clinical pathology and might confuse first-year medical students. This notion is in line with existing research that advises careful didactic planning of anatomical content [2,3,11].

Although the online instruction in our study offered only basic anatomical content—focusing on muscles, bones, and function while underrepresenting coverage of nerves and vessels—both groups had recently attended curricular lectures designed to provide deeper anatomical knowledge. After the course, participants in both groups could identify anatomical structures and assess normal findings in a structured way. The key difference was that the intervention group had the chance to apply their theoretical knowledge in practice and receive structured feedback during the peer tutoring session [11,42]. Our findings suggest that early integration of practical experience does not hinder but may, in fact, support deeper anatomical and clinical learning if implemented appropriately [3,11,25].

Professional Conduct

Neither the professional subscore in the shoulder examination nor learning needs showed significant differences between groups. Professional conduct might represent a subjective feeling of confidence rather than a measurable outcome. It may not have been adequately operationalized in this study; for example, the relative passive role of the standardized patients posed no real challenges for professionalism. In addition, too little time was allocated to student-teacher interaction and exchange about professional conduct—a common shortcoming of blended learning [32]. This shows that some aspects of learning should be performed face-to-face and that time must be allocated for this interaction [26,30,32]. Also, professional conduct is difficult to teach explicitly and is often learned from various sources over a long period of time [13,18,19,27]. Social learning elements play a crucial role in fostering professionalism even

in a predominantly remote learning environment [32]. It thrives through direct interaction between instructors and learners. This insight will inform the curricular integration of our learning module.

In summary, this study shows that clinical examination skills can successfully be taught early in the curriculum using a blended learning approach. The reduction in learning needs was not dependent on current or past employment or different levels of preexisting anatomical knowledge. We controlled for differences in gender and preoccupation through randomization. A baseline performance check using a structured examination before the study would perhaps have shown a clearer dependence on preexisting examination skills [59].

Dropout Analysis

The 5 dropouts had higher subjective learning needs at t1, scored lower in the MCQ knowledge test, and had a slightly lower technical affinity. Their attitudes toward blended learning differed from those of the other study participants. While they believed that blended learning provided added value to learning, they were less confident that it helped them prepare for exams or increase personal satisfaction with their studies. The dropout sample was too small for statistical analyses. However, there are 2 ways to interpret this: there might be a subgroup of students with such low expectations of blended learning that they might not use the method if given the choice [60], or the small study population could reflect a selection bias of motivated, stress-resilient, technology-affine, high-performing students who would do well in any learning environment [32].

Other Secondary Outcomes

The intervention group required, on average, 2 additional hours to complete the course compared to the control group. This was due to engagement with video lectures and demonstrations, as well as participation in the peer-assisted synchronous learning session, all of which required learners to allocate additional time, even though they had greater flexibility to choose when and where to engage with most of the content than the control group. Similar increases in workload have been observed in other studies on blended learning formats [36].

This interpretation is further supported by the intervention group's high ratings of course structure, clarity of learning objectives, and perceived alignment with the curriculum.

Although overall stress levels were high in both groups at t4, they were comparable to those of other medical student cohorts [20]. We therefore infer that the increased workload did not result in a heightened perception of stress among intervention group participants.

Technical affinity was equally high across both groups, consistent with findings that current medical student cohorts are generally digitally literate [27]. For our sample, this suggests that time invested in studying, rather than digital affinity, was more strongly associated with learning success [46,47].

Implications for Curricular Development

When Should Clinical Aspects in Anatomy Learning Be Integrated?

Our study supports the integration of anatomy teaching and clinical examination early in the curriculum. Both study groups, exposed to clinical examination content during the first year, reported reduced learning needs and demonstrated measurable skill acquisition without compromising anatomical knowledge. These findings suggest that early competency development is feasible and particularly effective when teaching content and assessment formats are well aligned [10,14,21-25,45].

What is the Role of Blended Learning in Integrated Clinical and Anatomy Learning?

Our study demonstrated that an intervention using synchronous peer-assisted clinical training paired with asynchronous training videos in a flipped-classroom seminar improved student outcomes compared to self-study and synchronous online lectures, aligning with previous studies [30,37]. However, despite improved performance, students reported a less satisfactory blended learning experience, highlighting the challenge of effectively implementing such approaches [27,29]. Based on our findings, key factors for successful blended learning include clear learning goals, structured delivery, and theory-guided integration of content and teaching methods, which may be more influential than the delivery format itself on student evaluation [32,33]. In addition, effective implementation must account for contextual factors such as the COVID-19 pandemic, which may have influenced student perceptions in our study [26]. These findings highlight that while blended learning can enhance outcomes, its effectiveness depends on thoughtful design, clear objectives, and contextual factors—underscoring the need for nuanced, context-aware research in this field [41].

Limitations

This study is limited by its small sample size, although a power analysis indicated a need for 80 participants; only 38 were recruited, and 31 completed the trial. While randomization controlled for gender and professional experience, the small sample size limits generalizability and prevents definitive conclusions about causality.

Recruitment was difficult despite incentives, likely due to increased student workload during the COVID-19 pandemic [26,27]. Although results were promising, the recruitment shortfall and end of funding prevented a second cohort. In addition, curriculum changes during the later stages of the pandemic affected the study environment, leading us to conclude the trial and prioritize efforts to integrate the intervention into the curriculum.

Concerning the main outcome, the intervention course provided learners with tailored modular learning material and feedback opportunities, in contrast to the control group. Importantly, both groups received teaching on shoulder anatomy and clinical skills—a more integrated approach than the regular curriculum—and identical guidance on the performance assessment. This substantially reduces the study's ability to

isolate the effect of blended versus traditional learning. However, both groups showed knowledge gains, suggesting that early integration of clinical content is effective overall. The superior performance in the intervention group likely reflects not only the learning format but also the stronger alignment between the instructional design and the assessment tasks—consistent with our hypothesis that an integrated, theory-based course would improve clinical competency [47].

A reconnaissance effect on anatomical knowledge cannot be excluded, as the same MCQs were repeated at t4. However, student performance and learning needs indicated stable or improved knowledge. Peer learning sessions and exams were intended to be conducted face-to-face but were instead held via videoconferencing due to COVID-19. Although this deviated from the protocol, comparable learning outcomes have been reported in other studies. Video-recorded OSCEs are an established method [16], with only one upload failure. Interobserver reliability was substantial and consistent with other studies [9,14,37].

Conclusions

First-year medical students' clinical performance on shoulder examinations can objectively be improved by an integrated blended-learning course in anatomy, professional conduct, and clinical examination skills. The results encourage early integration of clinical examination skills in preclinical medical education. Didactically, early clinical examination courses should focus on functional anatomy, a structured examination approach, and healthy subjects. Methodologically, the content can be delivered using blended learning that considers social aspects of learning and aligns the content to a standardized shoulder examination simulating a single OSCE station. If a face-to-face exam is not possible, videotaped examinations are a viable alternative. This study does not provide information about the sustainability of the learning. A cohort study that follows the progression through surface and deep learning phases to the transfer phase in this integrative approach is warranted [11].

Acknowledgments

We thank Anna-Jasmin Wetzel and Nadine Nicole Koch for their support in the randomization process. We also thank all participants of the pilot study and our medical student tutors who moderated the online training sessions. The generative artificial intelligence tool ChatGPT (OpenAI) was used to revise the language and style of the manuscript, which were further reviewed and revised by the study group. The authors acknowledge support from the Open Access Publication fund of the University of Tübingen. The project received intramural funds from UKT (Profil Plus funds for curricular development).

Data Availability

The datasets generated or analyzed during this study are not publicly available due to data protection regulations but are available from the corresponding author on reasonable request.

Authors' Contributions

TS and RK contributed to the conceptualization of the study, with additional input from LG and TFW. Data curation and formal analysis were performed by NG, LG, and RK. TS and RK were responsible for funding acquisition. LG, NG, and RK conducted the investigation. Methodology was developed by NG, LG, RK, and TFW. Project administration was carried out by NG, LG, and RK. SJ, BH, and TS provided resources, while RK and NG developed the software. Supervision was provided by SJ, BH, and TS. Validation was carried out by SJ, BH, and TS. RK, NG, and LG were responsible for visualization. RK, LG, and NG prepared the original draft, and BH, TS, TFW, and SJ reviewed and edited the manuscript.

Conflicts of Interest

Abstract

Background: Status epilepticus (SE) represents a critical pediatric emergency necessitating prompt treatment and monitoring. The diagnosis of nonconvulsive SE and the monitoring of convulsive SE require electroencephalogram (EEG) recordings. The integration of simplified point-of-care EEG may improve care in pediatric emergency departments.

Objective: This study aims to assess the efficacy of an electronic EEG self-learning module for improving the interpretation of normal cortical activity, artifacts, and seizure patterns in point-of-care EEG by pediatric emergency medicine (PEM) providers.

Methods: This prospective cohort study was conducted in a tertiary academic pediatric emergency department and primarily targeted senior medical staff while also engaging junior medical staff and registered nurses. A novel EEG e-learning module trained participants to identify normal cortical activity, artifacts, and seizure patterns. The study comprised pretest, posttest, and 3-month retention assessments to evaluate the EEG total score as its primary outcome and basic EEG knowledge and confidence measures as secondary outcomes. Outcomes were analyzed using mixed-effects proportional odds logistic regression models.

Results: Of 102 PEM providers invited, 61 individuals participated (25 senior medical staff, 15 junior medical staff, and 21 registered nurses), and 29 finished the 3-tiered study. In finishers, the EEG total score (max=12 points), indicative of accurate EEG classification, increased substantially between pretest and posttest from a median of 7 (IQR 5 - 8) to 10 (IQR 7 - 11) points, corresponding with an increase in the odds of achieving higher EEG total scores at the posttest (odds ratio 24.18, 95% CI 7.398-79.043, *P*<.001). At the retention test, the EEG total score remained elevated, although to a lesser extent (median 8 points [IQR 6 - 9]). Similar trends were observed in secondary outcomes.

Conclusions: The implementation of an e-learning EEG module improved the ability of PEM providers to interpret EEGs. This study highlights the feasibility of imparting basic EEG skills to nonexperts through targeted educational interventions. However, the sustained retention of such skills requires improvement, emphasizing the necessity for ongoing refresher training.

Introduction

Acute central nervous system disorders are common childhood emergencies [1]. These disorders are very frequent among highly acute presentations in pediatric emergency departments (PEDs) and are the most frequent type of presentation in pediatric resuscitation bays [2-4]. Status epilepticus (SE) is a paramount medical emergency in pediatric neurology. Early identification of SE in PEDs is crucial for prompt initiation of treatment and thus for improving patient outcomes [5]. However, nonconvulsive SE (NCSE) often eludes detection, particularly in patients with altered mental status (AMS) or seemingly

controlled convulsive SE [6,7]. Standard electroencephalogram (EEG) is the gold standard for monitoring SE treatment and detecting NCSE due to its high sensitivity in identifying electrographic-only seizure activity [8].

Although electroencephalograms (EEGs) in PEDs provide valuable diagnostic information and aid in decision-making [9,10], immediate access to standard EEG may be challenging in many settings [10]. Low standard EEG availability poses a challenge, both during and after standard working hours, because standard EEG requires significant time, equipment, and specialized personnel [11]. A simplified, reduced-lead EEG, also termed point-of-care EEG (pocEEG), has emerged as a feasible option [12] to aid diagnostics [13-15] and facilitate the management of AMS, the treatment and monitoring of SE, and the detection of NCSE [15,16]. However, the interpretation of pocEEG by nonexpert PED staff in the absence of or with delayed access to EEG experts, such as pediatric neurologists, is challenging, undermining the applicability of this novel approach in the PED setting [17].

Previous research has explored efforts to train nonexperts in EEG interpretation in both adult and neonatal and pediatric acute care settings [18,19], with most studies focusing on processed EEG, such as amplitude integrated EEG or continuous EEG in intensive care units [18]. Yet, only one study has investigated the acquisition of standard EEG interpretation skills in adult emergency department (ED) physicians [20]. To date, data are lacking on the feasibility and efficacy of teaching basic EEG skills to pediatric emergency medicine (PEM) providers, even though here this approach could significantly improve patient care by facilitating AMS evaluation and expediting NCSE diagnosis and treatment [17,21]. To address this gap, we designed a novel pocEEG e-learning module to transfer basic EEG knowledge of montages, EEG signal generation, and EEG reading and interpretation skills to PEM providers. The module focuses on identifying normal cortical activity, artifacts, and seizure patterns. These 3 domains are important for distinguishing between true neurological events and artifacts, and thus for identifying and managing seizures.

Therefore, the primary aim of this study was to determine the impact of our EEG e-learning module on EEG skill acquisition by nonexpert PED staff through a 3-tiered longitudinal assessment. Secondary aims were to assess whether training led to measurable improvement in recognizing specific EEG patterns, self-assessment, and confidence among PEM providers over time.

Methods

Study Design and Setting

This study was conducted at the tertiary academic PED of the University Children's Hospital Zurich, Switzerland, which treats 50,000 patients annually. The department is staffed by diverse professional groups, including senior medical staff (SMS) such as PEM attendings and PEM fellows, junior medical staff (JMS) such as pediatric residents and pediatric surgery residents, registered nurses (RNs), and medical practice assistants.

In this prospective cohort study, we tested an e-learning module as an intervention primarily targeting the SMS, who have the final responsibility for patient evaluations. However, all PEM providers were invited to participate in a 3-visit program consisting of a baseline pretest followed by a posttest and a 3-month retention test.

Study Population

For enrollment, 102 PEM providers were invited via email using the REDCap (Research Electronic Data Capture; Vanderbilt University) survey tool [22]. We extended invitations for anonymous participation in this e-learning module to all SMS, JMS, and RNs within our PED. Our primary goal was to actively engage the majority of SMS while also providing access to EEG training and promoting the use of pocEEG in the PED by JMS and RNs. After completion of the pretest, participants were provided with a passcode to access the learning module. One hour after pretest completion, participants were provided with another survey link and prompted to complete the posttest by entering a passcode provided on module completion. The retention test was automatically scheduled 3 months following posttest completion. Up to 4 automated reminders were sent to encourage participation between 88 and 120 days after pretest. Pretest participants who failed to complete the learning module were invited to join a control group by completing the 3-month retention test.

Study Protocol

In a collaborative effort, a PEM expert and a neurophysiologist (LS and BKB) devised an innovative e-learning module aimed at facilitating the use and interpretation of pocEEG. Drawing on insights from a previous adult study [20], this module incorporates audio-guided PowerPoint (Microsoft Corp) presentations. The content covers fundamental EEG principles, including electrode placement according to the 10‐20 system, a standardized method of electrode placement, and insights into standard EEG and pocEEG findings. The module focuses on identifying normal EEG waveforms, artifacts, and seizure patterns in accordance with the American Clinical Neurophysiology Society 2021 guidelines [23].

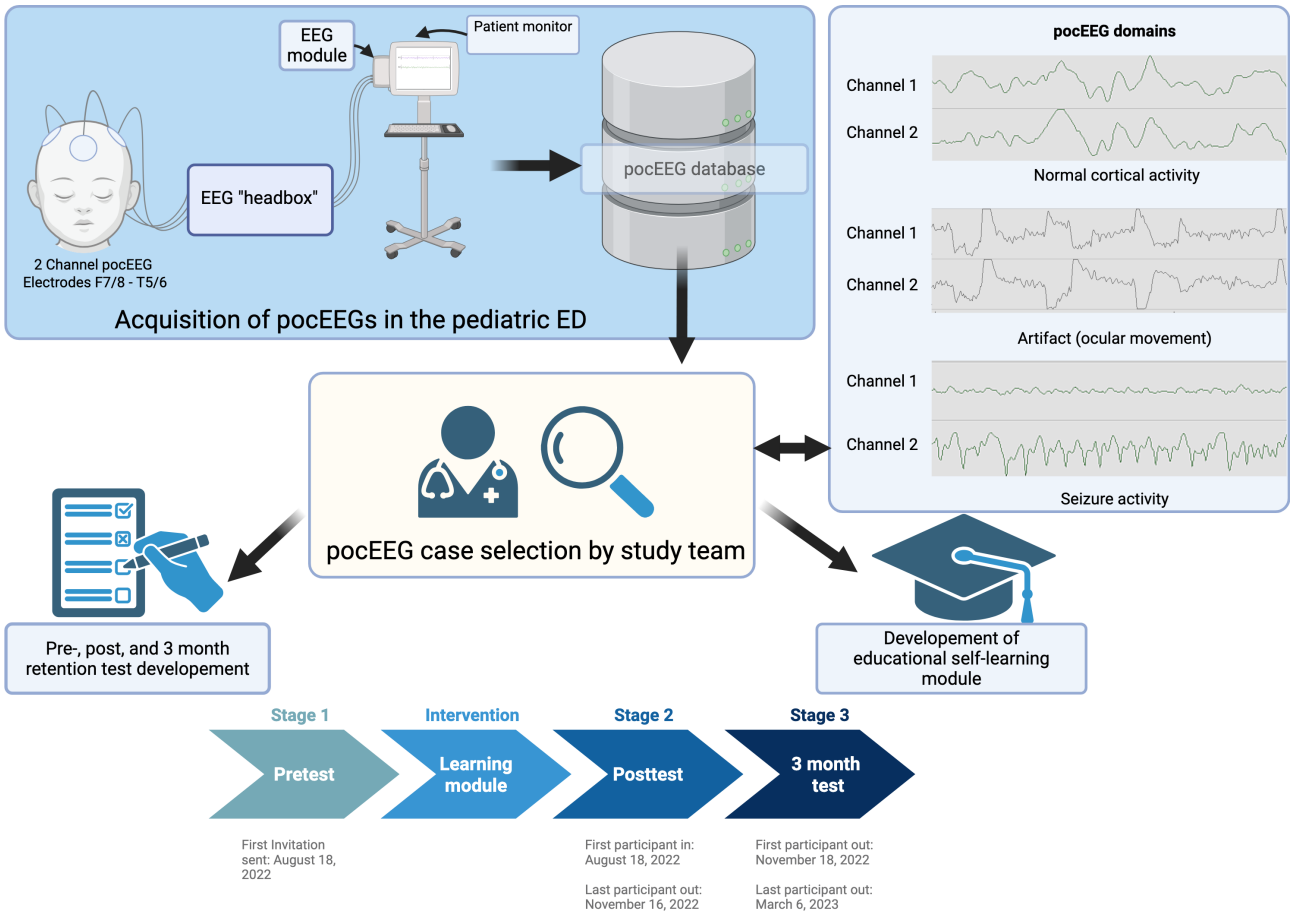
The main segment of the module, spanning about 60 minutes, is dedicated to two primary objectives: (1) providing a systematic framework for assessing cortical activity by familiarizing participants with normal EEG waveforms, and (2) educating participants about critical EEG findings such as seizure patterns in pocEEGs. Additionally, a 20-minute chapter offers technical instructions for pocEEG covering electrode placement, EEG, and optionally video recording, and troubleshooting techniques. Although this technical knowledge is not tested, it enhances participants' understanding of pocEEG procedures.

Measurements and Test Materials

Participants were assessed on their ability to distinguish normal cortical activity, artifacts, and seizure patterns by reviewing 12 anonymized pocEEGs. These pocEEGs were acquired via patient monitors from patients presenting to the PED during the introduction phase of this modality [24] and consisted of 2-channel pocEEG recordings (channels F7/8 and T5/6; 10‐20

system) as described elsewhere [24]. These recordings were processed with Vitalrecorder (version 1.8.16.4) [25], and educationally valuable EEGs were carefully selected from the pocEEG database by PEM and neurophysiology experts (LS and BKB; Figure 1).

Figure 1. pocEEG acquisition, learning module, and test development (created with BioRender.com). EEG: electroencephalogram; pocEEG: point-of-care electroencephalogram.



Each test session included basic demographic data on the participants' profession, seniority, and post board certification experience; a self-assessment of confidence; and basic EEG knowledge. The 12 EEG interpretation tasks comprised 7 pocEEG trace snapshots (10 s duration) and 5 pocEEGs with video segments lasting up to 60 seconds each. Each of the 3 domains, normal cortical activity, artifacts, and seizure patterns, was assessed with 4 pocEEGs. EEG interpretation knowledge was tested with single-choice questions, each with 5 answer options. Each answer included a statement about background symmetry, dominant activity, and whether the pocEEG included an artifact or indicated seizure activity. Additionally, participants were asked to disclose which of their answers they had guessed [26]. To minimize bias, question sequences varied across all 3 tests. A pediatric neurology fellow who was not involved in the study piloted the test material. Feedback was used to adjust item difficulty and ensure technical feasibility. Study data were collected and managed using the REDCap electronic data capture tool hosted at the University Children's Hospital Zurich [22]. We report this survey data in accordance with the CHERRIES (Checklist for Reporting Results of Internet E-Surveys) guidelines [27], and a detailed CHERRIES checklist is provided in Checklist 1.

Outcome Measures

We assessed both the theoretical knowledge and practical skills of participants in pocEEG interpretation through a series of 3 tests, which yielded these outcomes:

- Primary Outcome
  - EEG total score: This score is calculated from the accurate classification of 12 pocEEG recordings into categories of normal cortical activity, artifacts, or seizure patterns. Scores range from 0 (no correct answers) to 12 (all correctly answered).
- Secondary Outcomes
  - EEG basic knowledge score: This score reflects the accuracy of answers to 5 basic EEG knowledge questions (single choice, each with 4 answer options) evaluated across 3 tests. Scores range from 0 (no correct answer) to 5 (all answered correctly).
  - Classification accuracy per domain: The 12 EEG recordings are categorized into 3 domains: normal activity, artifacts, and seizure patterns, each represented by 4 EEGs. The classification of each EEG recording is evaluated with a binary outcome (correct/incorrect).
  - Assurance level: This includes the total number of answers guessed per test, ranging from 0 (no guesses)

to 12 (all guessed), and the number of correct, deliberate answers per test, ranging from 0 to 12.
- Self-assessment and confidence measures: Five items measured on a Likert scale from 1 (completely agree) to 5 (completely disagree).
- Estimation of an intervention effect: To measure the effect of the e-learning module, we compare the EEG total scores of finishers and the control group in the 3-month retention test.

Statistical Analysis

Descriptive statistics of study participants were tabulated overall, by professional group, and by group depending on test completion (see below). We report frequency and percentage for categorical variables.

The ordinal primary outcome EEG total score was analyzed by mixed-effects proportional odds logistic regression (PolrME) and mixed-effects enhanced proportional odds logistic regression (ePolrME) with the PolrME and ColrME functions in the R package tramME [28]. For simplicity, we report only the ePolrME results. To account for repeated measurements, random intercepts per study participant were included in the models. To investigate changes in the EEG total score between tests in participants who completed all tests, models were fitted with test (pre-, post-, and 3 mo retention) and professional group (SMS, JMS, and RNs) as explanatory variables. The analysis primarily focused on SMS, the largest professional group. To test whether changes in EEG total score across all tests differed between professional groups, we included an interaction between test and professional group in the models and used likelihood ratio tests to assess whether interaction terms improved model fit.

Similar models were fitted for the secondary outcome EEG basic knowledge score. To investigate the effect of completing the e-learning module as an intervention on EEG total score, we fitted an ordinary proportional odds logistic regression model to participants who completed all components of the study and to a control group who only completed the pretest and retention test without engaging with the e-learning module or posttest. The EEG total score at the pretest and completion of the e-learning module (yes/no) was used as explanatory variables.

The PolrME models (and proportional odds logistic regression model) estimate odds ratios (ORs) for falling into a higher EEG total score category, comparing a given level of the explanatory variables to the reference group (eg, posttest vs pretest or e-learning module completed vs not completed) for a given study participant. Similarly, ePolrME models estimate ORs for higher EEG total scores. The interpretation remains consistent when the models are applied to the secondary outcome, EEG basic knowledge. To assess differences in recognizing seizure patterns, artifacts, and normal cortical activity, a binomial general linear mixed effects model with logit link function was fitted to the correct EEG rating (binary outcome, 1=correct, 0=false). The data set was prepared to contain a row for each rating of an EEG by a participant (12 EEG recordings in each test and participant). The model included a random intercept for test nested within study participant and the type of EEG (normal cortical activity, artifact, or seizure pattern) and test as explanatory variables, and estimated ORs for correct rating of EEG recordings. All analyses were performed using R (version 4.1.2; R Foundation for Statistical Computing) [29].

Ethical Considerations

This study involves human participants but does not fall within the scope of the Swiss Human Research Act, and the responsible ethics committee (Cantonal Ethics Committee, Zürich, Switzerland) exempted this study (Req-2024 - 00833). All participants were volunteers and gave electronic consent to participate in the study.

Results

Overview

In all, 102 PEM providers were invited to participate in the study, and 61 consented to take the pretest (Figure 2), including 25 SMS, 15 JMS, and 21 RNs (Table 1). A total of 53 (86.9%) participants were female, 25 (41.0%) participants were SMS, 15 (24.6%) participants were JMS, and 21 (34.4%) participants were RNs. Participants had minimal or no prior experience in implementing and interpreting EEGs.

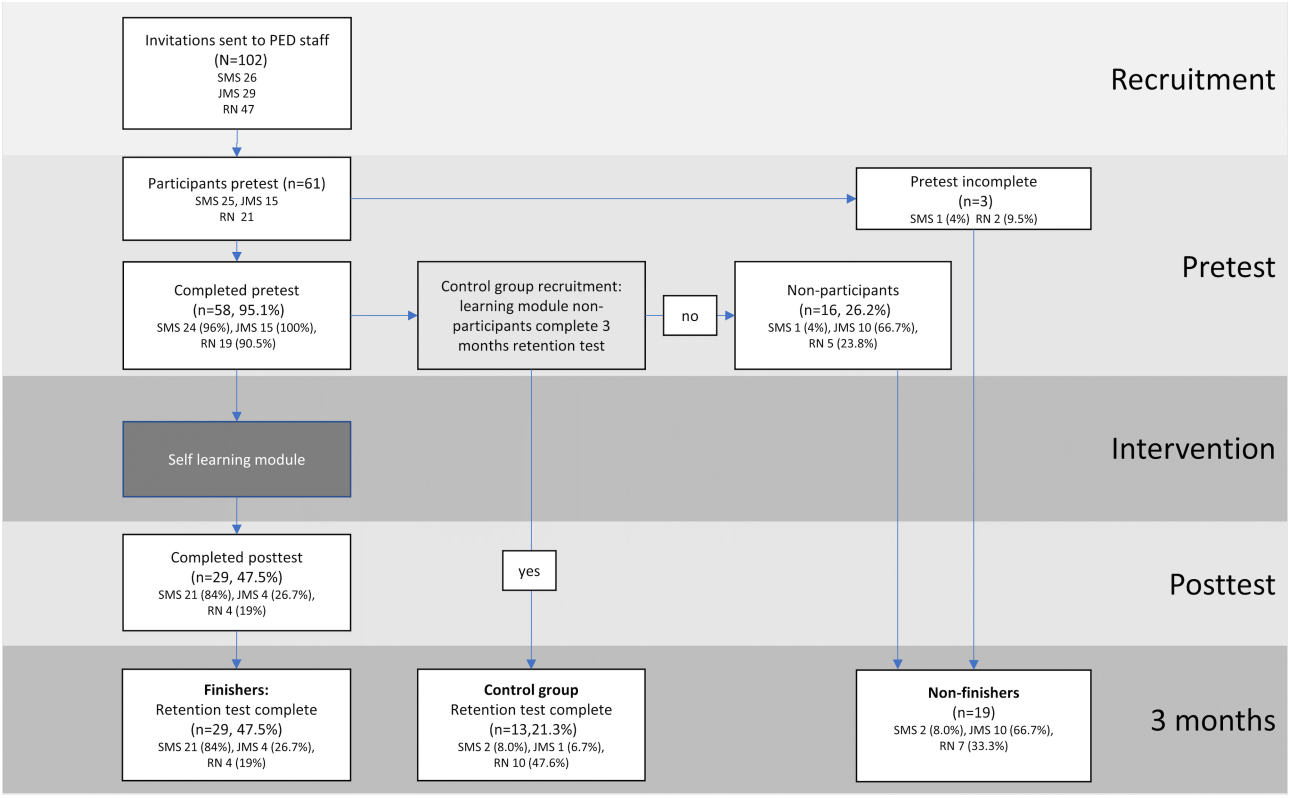
[c]EEG: electroencephalogram.

[d]aEEG: amplitude integrated electroencephalogram.

Figure 2. Flowchart of the study's stages from recruitment to pretest, intervention, posttest, and study conclusion. Percentages are calculated relative to the initial participant pool who took the pretest (n=61). Subgroup percentages always refer to the respective subgroup sample. JMS: junior medical staff (residents); RN: registered nurse; SMS: senior medical staff (attendings/consultants; fellows).



Of the 61 participants who took the pretest, 58 completed it and subsequently gained access to the e-learning module. Among these, 29 completed the e-learning module, posttest, and retention test and were designated as finishers (Table 1). Participants who only completed the pretest (n=29) and did not interact with the e-learning module formed a control group and were invited to take the 3-month test, resulting in 13 controls with a pretest and a 3-month test. The group of nonfinishers (n=19) consisted of 3/61 without and 16/61 with a complete pretest. The finisher rate among SMS, the primary focus group of our e-learning module, was 84% (21/25), while it was 26.7% (4/15) in JMS, and 19.0% (4/21) in RNs. The distribution of the various participants is shown in Figure 2.

Primary Outcome EEG Total Score

The primary outcome, EEG total score, increased considerably on average following completion of the e-learning module among all finishers. However, it subsequently decreased between the posttest and the retention test, although it remained higher than at the pretest (Figures 3A and 3B, Table 2, Figure S1 in Multimedia Appendix 1).

Figure 3. (A) Line plot for the progression of EEG total scores over pretest, posttest, and 3-month retention test of finishers: top panel senior medical staff (SMS, n=21), middle panel junior medical staff (JMS, n=4), and bottom panel registered nurses (RN, n=4). (B) Barplots for number of correct answers on pretest, posttest, and 3-month retention tests and per EEG domain artifacts (Artif), normal cortical activity (Norm), and seizure patterns (Path). (C) Lineplot showing the progression of scores in basic EEG knowledge; staff groups are shown in 3 separate panels. (D) Lineplot for progression of nonguessed correct responses (EEG total score) across the 3 tests with top panel SMS, middle panel JMS, and bottom panel RNs. EEG: electroencephalogram; JMS: junior medical staff; RN: registered nurse; SMS: senior medical staff.

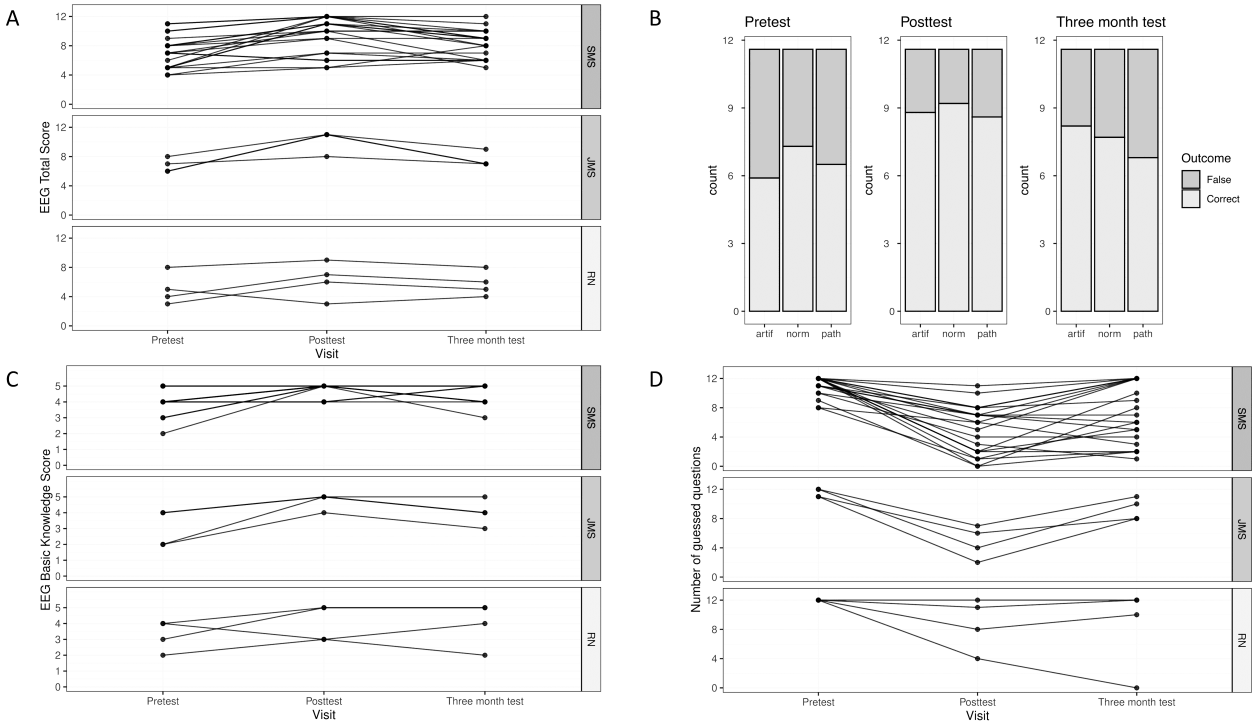


Table . Primary outcome electroencephalogram (EEG) total scores of finishers, finisher subgroups, control group, and nonfinishers at all 3 tests (maximum score=12). Results are summarized as median and IQR (1st and 3rd quartile).

	Finishers total (n=29)	Finisher SMS[a] (n=21)	Finisher JMS[b] (n=4)	Finisher RNs[c] (n=4)	Control group (n=13)	Nonfinisher (n=19)
EEG (total scores pretest), median (IQR)	7.00 (5.00-8.00)	7.00 (5.00-8.00)	6.50 (6.00-7.25)	4.50 (3.75-5.75)	5.00 (3.00-7.00)	6.00 (5.00-7.00)
EEG (total scores posttest), median (IQR)	10.00 (7.00-11.00)	10.00 (7.00-12.00)	11.00 (10.25-11.00)	6.50 (5.25-7.50)	0.00 (0.00-0.00)	0.00 (0.00-0.00)
EEG (total scores 3m[d] test), median (IQR)	8.00 (6.00-9.00)	9.00 (6.00-10.00)	7.00 (7.00-7.50)	5.50 (4.75-6.50)	4.00 (3.00-7.00)	0.00 (0.00-0.00)

[a]SMS: senior medical staff.

[d]3m: 3 months.

Results from the ePOLR model provide evidence for an increase in the odds of achieving higher EEG total scores at the posttest compared with the pretest (OR 24.18, 95% Wald CI 7.398-79.043; *P*<.001). Similarly, the odds of achieving higher EEG total scores at the retention test compared with the pretest increased by a factor of 3.7 (OR 3.7, 95% Wald CI 1.406-9.741; *P*=.008). Furthermore, differences emerged in EEG total scores among professional groups, with SMS achieving the highest scores, followed by JMS and RNs (OR compared with SMS of 0.79, 95% Wald CI 0.08-8.06; *P*=.84; and 0.03, 95% Wald CI 0.00-0.33; *P*=.005, respectively; Table 3).

Table . Odds ratio (OR) estimates with 95% Wald CIs from the enhanced proportional odds logistic regression model on the primary outcome, electroencephalogram total score. The model included 87 observations from 29 participants.

	OR (95% CI)	*P* value
JMS[a] versus SMS[c]	0.79 (0.08-8.06)	.84
RNs[b] versus SMS	0.03 (0.00-0.33)	.005
Posttest versus pretest	24.18 (7.40-79.05)	<.001
3 mo retention test versus pretest	3.70 (1.41-9.74)	.008

[a]JMS: junior medical staff.

[b]RN: registered nurse.

[c]SMS: senior medical staff.

Secondary Outcomes

Among SMS, we observed that EEG basic knowledge generally increased after the intervention, with a less pronounced decline at the retention test than at the EEG total score. This pattern was also seen in JMS and RNs, albeit with some individual variations (Figure 3C). In the ePolrME model, SMS odds for a higher score in basic EEG knowledge after the module increased significantly for the posttest (OR 32.89, 95% Wald CI 7.137-151.569; *P*<.001) and for the retention test (OR 12.96, 95% Wald CI 3.421-49.122; *P*<.001). JMS and RNs showed a decrease in odds for a higher score compared with SMS (OR 0.09 Wald CI 0.01-0.79, *P*=.03; and OR 0.06, Wald CI 0.01-0.52, *P*=.01; respectively).

In the secondary outcome analysis of EEG domains, the number of correct answers for normal cortical activity (norm), artifacts (artif), and seizure patterns (path) is shown in Figure 3B. Overall, the number of correct answers increased markedly in the posttest and remained higher in the retention test compared with baseline (Table 4). We observed minor variations among the 3 domains across these tests.

Table . Odds ratio (OR) estimates with 95% Wald CIs from the binomial generalized linear mixed-effects model on classification accuracy (binary outcome for correctness of answer). The model was fitted with a logit link function and a random intercept for visit nested within participant and included 1044 observations from 29 participants.

	OR (95% CI)	*P* value
Intercept	1.16 (0.78-1.73)	.47
Artifact versus pathological	1.15 (0.83-1.61)	.40
Normal cortical activity versus pathological	1.40 (1.00-1.96)	.049
Posttest versus pretest	2.75 (1.95-3.87)	<.001
Three-month retention test versus pretest	1.50 (1.09-2.07)	.014

To assess the participants' assurance level, we analyzed the guess rates for 12 EEG recording questions across professional groups (Figure 3D). The pretest revealed high guess rates across all groups, with SMS guessing between 8 and 12 questions, and many participants guessing all. Completion of the e-learning module was followed by a notable reduction in guess rates across all groups, with some senior staff not guessing any. However, at the 3-month retention test, guess rates increased again for all groups compared with posttest.

We evaluated the confidence levels of finishers in their interpretation of pocEEG by focusing on overall pocEEG skills, ability to detect pocEEG signals correctly, knowledge about potential artifacts, and proficiency in identifying artifacts on a Likert scale (Figures S2-S6 in Multimedia Appendix 1). During the pretest, responses regarding overall pocEEG skills varied widely across all groups, indicating a significant disparity in confidence levels. However, an improvement in confidence was observed across all occupational groups during the posttest. This increased confidence largely remained at the retention test, albeit with some variations among groups. Notably, SMS consistently exhibited higher confidence in overall skills throughout the study compared with JMS and RNs. Confidence in detecting pocEEG signals varied widely across occupational groups during the pretest but improved significantly after the completion of the e-learning module. This increased confidence remained high in the retention test, although JMS and RNs showed lower confidence levels than SMS. Likewise, confidence in identifying EEG artifacts was initially low across all occupational groups but improved notably after the e-learning module. This increased confidence generally remained in the retention test, with some variations observed among groups. Throughout the study, confidence in interpreting pocEEG recordings remained relatively low across all occupational groups, with only slight increases observed in certain subgroups and a general trend of continued uncertainty or disagreement.

Effect of the E-Learning Module: Finishers Versus Control Group

Comparing finishers with the control group revealed that the e-learning module led to increased EEG total scores at the retention test after 3 months.

The odds of achieving higher EEG total scores in the retention test were significantly increased by a factor of 9 for the finishers compared with the controls (OR 9.075, 95% CI 2.181-37.763;

P=.002). Furthermore, adjusting for initial EEG knowledge at pretest was important because participants with better pretest performance also performed better at the 3-month retention test (OR 2.053, 95% CI 1.505-2.800; *P*<.001).

Discussion

Principal Findings

This study evaluated the effectiveness of a novel e-learning EEG module in improving pocEEG interpretation skills among SMS, JMS, and RNs in the PED. Our findings indicate a notable improvement in EEG knowledge and interpretation skills across all participant groups following the module, which was particularly evident in the EEG total score, our primary outcome. These results are consistent with the literature emphasizing the importance of targeted educational interventions for nonexperts in interpreting EEGs in critical care settings [18]. To our knowledge, this study represents the first attempt to evaluate knowledge transfer of basic EEG skills to EEG nonexperts in the PED and the first investigation into training for reduced lead EEG and pocEEG skills. A recent review has also identified this topic as a research priority [17].

The primary outcome, the EEG total score, showed a substantial increase in correct classifications of EEG recordings immediately after module completion and, to a lesser extent, at the 3-month follow-up. This finding is encouraging because it demonstrates both the immediate impact and the lasting effect of the educational module, albeit with a decline over time. The increase in EEG total scores was particularly pronounced among the primary target group, SMS.

However, due to our limited sample size for JMS and RNs, we did not assess whether the increase in EEG total scores or EEG knowledge in general differed from SMS. Overall, finishers were significantly more likely to achieve higher EEG total scores at the 3-month retention test compared with the control group, with the caveat that the control group had a divergent composition (Figure 2 and Table 1).

The finisher rate among SMS was 84%, considerably higher than among JMS and RNs. This discrepancy can be attributed to several factors: JMS typically rotate through our PED for 3 to 6 months, and both JMS and most RNs lack nonclinical time in the PED and remote access to the hospital's computer system, thus preventing their participation from home. This underscores the need for tailored educational approaches that consider the specific needs, time constraints, and baseline competencies of various health care professionals.

Seizure pattern recognition appeared to be a slightly more challenging task for participants (Figure 3B) in our set of test EEGs. Extrapolating from our experience with point-of-care ultrasound, we had previously hypothesized that identifying seizure patterns would be more straightforward than discerning normal activity [30] or artifacts, but findings may differ with a larger set of EEGs.

Nevertheless, the improvement observed in identifying artifacts and normal cortical activity is encouraging and indicates a fundamental enhancement in EEG interpretation skills. The 3 domains of normal signal, artifact, and seizure pattern form the foundational pillars of continuous EEG teaching [31]. They are crucial for improving neurocritical care in the PED, where timely and accurate EEG interpretation can significantly impact patient management and outcomes.

Our additional observations, focusing on self-assessment and confidence measures, indicated a notable increase in confidence levels among participants. The initial high rate of guesses, which decreased significantly post training, highlights the initial uncertainty among staff members in interpreting EEGs. However, the resurgence in guess rates at the 3-month follow-up suggests that periodic refresher modules or ongoing training might be necessary to maintain confidence and competence levels. This retention challenge, as with any critical care skill, is particularly pronounced in ED settings [32,33].

A recent review by Taran et al [18] outlined numerous studies conducted in critical care settings involving nurses and physicians as participants and focusing on EEG educational initiatives. These studies often evaluated the use of processed EEGs, such as amplitude-integrated EEGs, with raw EEGs being less common [18]. Only one study in the adult ED context improved the abilities of emergency physicians to identify seizure patterns; that study used a learning module with full montage standard EEG examples [20]. Studies investigating long-term retention of EEG knowledge reported better scores [19], predominantly in intensive care units, where trainees had frequent exposure to continuous EEG.

One of the key strengths of our study is its high participation rate among SMS, our primary focus group. The 3-tiered longitudinal assessment helps to gauge knowledge retention over time and assess the long-term impact of the intervention. The involvement of diverse occupational groups in the study also provides a broader understanding of educational needs across different levels of PEM providers. By assessing guess rates, we also examined participants' confidence in their answers.

However, our study also has limitations. Its participants are all from a single pediatric academic tertiary center, which limits generalizability. The sample size of finishers other than SMS was small and limited the statistical analysis of differences between professional groups. In addition, the disparity in subgroup sizes contributed to substantial uncertainty in OR estimates, particularly for the EEG total score and EEG basic knowledge score. The reliance on self-assessment measures for confidence may introduce bias and may be influenced by local cultural factors. The composition of the control group was suboptimal due to the finite availability of study participants at the study site, which precluded the recruitment of matched controls. Selective participation and initial participant attrition limit the generalizability of our findings to broader interdisciplinary teams. In addition, the test instrument in this study was tailored for the local educational context and was not formally validated. It is unclear whether any participants engaged in interpreting pocEEGs on clinical shifts during the interval prior to the retention test, which could have influenced their knowledge retention. Finally, the decline in knowledge

retention over time suggests the need for ongoing training and support.

Conclusions

Our study demonstrates that a targeted educational module can improve EEG knowledge and interpretation skills among PED staff. This finding has important implications for enhancing neurocritical care in pediatric emergency settings, where rapid and accurate diagnosis is crucial for patient outcomes. Moreover, the decline in skill retention over time underscores the critical need for continuous education and ongoing training to ensure that these vital skills are maintained.

Acknowledgments

This study would not have been possible without the help of the nursing and medical staff in the Pediatric Emergency Department of the University Children's Hospital Zurich. We would like to thank Prof Geetha Chari (Department of Neurology, SUNY Downstate Medical Center, Brooklyn, NY, US) for sharing the teaching material that she used in her study [20]. Simon Milligan helped with editorial assistance. LS received grant money for investigator-initiated research from the Anna Mueller Grocholski Foundation, Zurich, Switzerland; and the Children's Research Center, University Children's Hospital Zurich, University of Zurich, Zurich, Switzerland.

Data Availability

The data sets used and analyzed in this study are in Multimedia Appendix 2.

Authors' Contributions

LS was responsible for conceptualization, methodology, software development, investigation, resource provision, data curation, drafting the original manuscript, reviewing and editing the manuscript, and creating visualizations. MHS contributed to formal analysis, visualization, and manuscript review and editing. SVF was involved in methodology, formal analysis, visualization, and manuscript review and editing. MS contributed to conceptualization, methodology, investigation, and manuscript review and editing. GR was responsible for validation and reviewing and editing the manuscript. BKB contributed to conceptualization, methodology, software development, validation, investigation, supervision, and reviewing and editing the manuscript. All authors read and approved the final manuscript.

Abstract

Background: Health care professionals seldom receive training on neurodevelopmental conditions such as attention-deficit/hyperactivity disorder (ADHD). An online training was co-developed to address some of the gaps in knowledge and understanding in primary care. A randomized controlled trial demonstrated that the training increased knowledge and confidence and improved practice.

Objective: This report highlights the implementation of the training in practice and follow-up 4 years post evaluation.

Methods: The online ADHD training comprises 2 modules: "Understanding ADHD" and "The Role of the GP," each taking approximately 45 minutes to complete. The training targets general practitioners primarily but is open to other health care professionals and parents. Feedback was collected through a survey at the end of the training, and the training has been widely adopted by various organizations internationally and nationally.

Results: Between December 2019 and January 2024, the "Understanding ADHD" module was accessed more than 13,486 times, while the "Role of the GP" module was accessed 7018 times, primarily by users from the United States and the United Kingdom. Survey results from both modules showed positive feedback with high ratings for usefulness, likelihood to inform practice, and recommendation to colleagues. Some suggestions for improvement included reducing the negative focus on ADHD consequences and incorporating more positive aspects of ADHD.

Conclusions: This ADHD online training program, despite facing implementation challenges, has seen positive outcomes, including international translation and high user ratings. Suggestions for improvement were received, but some were not feasible due to regional variations in ADHD pathways. The training's impact extended beyond GPs to other health care professionals, although the COVID-19 pandemic posed obstacles to dissemination efforts. Nonetheless, ongoing plans aim to expand the training's implementation globally.

Introduction

Background

Attention-Deficit Hyperactivity Disorder (ADHD) is a neurodevelopmental condition characterized by symptoms of persistent inattention or hyperactivity-impulsivity, which causes clinical impairment in academic and social functioning [1] affecting approximately 5% of children [2] and 2.5% of adults [3]. Having ADHD carries many additional risks [4], and these are worsened when unsupported and undiagnosed [5], often leading to an increase in access to primary care services [6].

In the United Kingdom, access to care for children and adults with attention-deficit hyperactivity disorder (ADHD) is complex, starting from general practitioners (GPs) in primary care or schools who refer on to specialist services for diagnosis and treatment (psychiatry, Children and Adolescent Mental Health Services, etc). Health care professionals, including GPs, receive little or no training on ADHD. This significantly impacts access to care for many children and adults as GPs are the main

gatekeepers for specialist services [7,8]. To fill this gap in ADHD training, an online training was coproduced with GPs to improve GPs' knowledge about ADHD [9]. The stepwise, coproduction approach toward developing this online ADHD training for GPs began with a preparatory workshop in order to highlight the relevant topics to be included in the intervention, from which educational videos were then developed, as well as the content and format for the training. Two workshops were then conducted with GPs, leading to further refinement of the video content and subsequently the final intervention. A pilot usability study (N=10 GPs) was conducted to assess the intervention's acceptability, feasibility, and accessibility. The online training included interactive psychoeducation elements reinforced with activities and videos lasting a total of 45 minutes. The content included enough information for GPs to identify ADHD and better understand the condition. The resulting intervention was then evaluated through a randomized controlled trial (RCT) [10] in GP practices based in England where 221 GPs took part. The evaluation of this training demonstrated that GPs' knowledge and confidence significantly improved, misconceptions decreased, and attitudes and reported practice changed [10]. The unique aspect of this training lies in the strong coproduction element, with GPs being involved throughout the development and review process and within the evaluation through an RCT, which is rarely done for education packages. The coproduction element, reviews, and evaluation aspect of the original project took over 2 years from January 2018 to March 2020. To our knowledge, no other online training package has been developed and evaluated for ADHD in primary care in the United Kingdom.

The original evaluation of this training terminated in March 2020. Since then, we have spent time implementing the training in GP practices, in alignment with the British National Institute for Healthcare Research (NIHR) priority settings in digital support for primary care [11].

This publication describes the impact, engagement, and implementation of the original ADHD training program, 4 years beyond completion of data collection.

Aims and Objectives

This project aimed to implement and evaluate the ADHD online training into practice, beyond the scope of the original project. The implementation and impact of the training are measured through website access analytics and responses to survey questions.

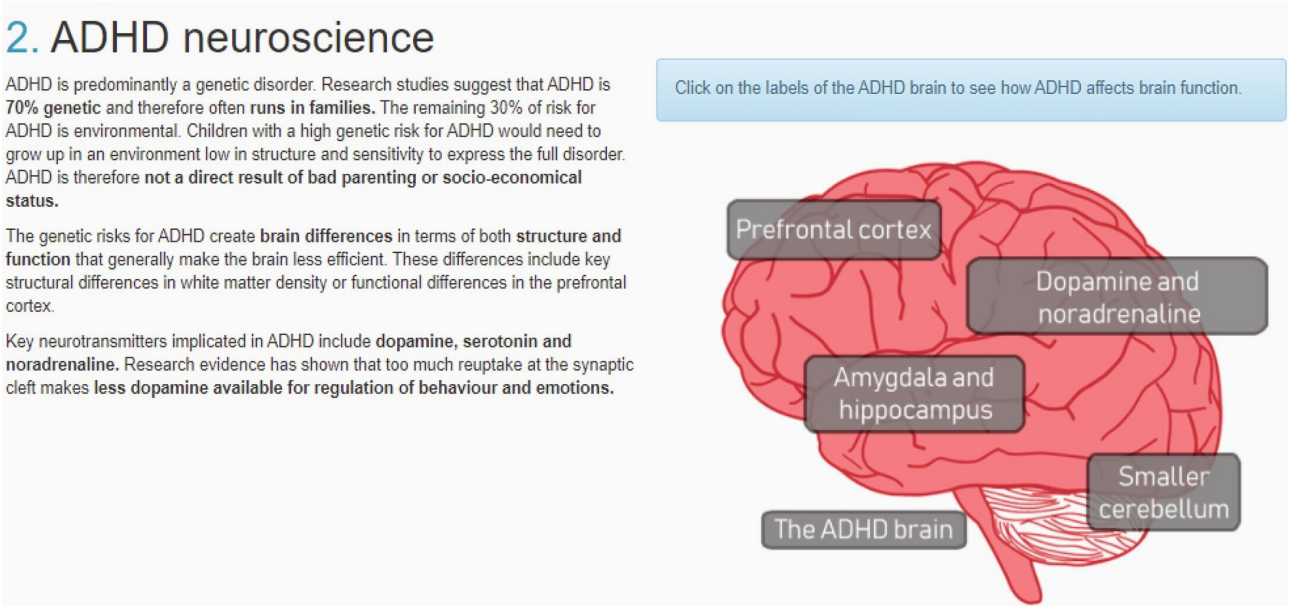
Methods

Blueprint Summary and Technical Design

The online ADHD training is a psychoeducation program consisting of 2 modules, one on "Understanding ADHD" and one on "the role of the GP in the care pathway." The training takes approximately 45 minutes to complete and can be accessed freely online (link in [12]; example of an education module page in Figure 1).

The training is hosted on a secure platform within the University of Nottingham Health E-learning and Media team (HELM). It has been developed to be easily accessible on a computer or a mobile device. Further details on the original project can be found online [13].

Figure 1. Example of educational module page from the training. ADHD: attention-deficit/hyperactivity disorder.



Target

The training is principally aimed at general practitioners or other medical doctors. However, while the module "Role of the GP" in the care pathway focuses on primary care, the module "Understanding ADHD" can be useful for anyone including other health care professionals, education professionals, and parents. Additionally, although the training has elements of the care pathway that are specific to the United Kingdom, a large proportion of the training is relevant to other countries and settings as well (psychoeducation on ADHD, effect of medication, types of interventions, etc) and therefore was found to be useful in different contexts. The original RCT had specific inclusion criteria, but for this aspect of implementation, no

restrictions were implemented on either module. The online training is freely available and hosted on a university server that is widely secure and accessible, including from health care servers (eg, SystmOne). This was essential as a lot of health care servers can block external links.

Survey

The survey was developed by the lead researchers. Following a pragmatic approach prioritizing quick time response, only 4 questions were presented to participants in the training. As the training is freely available and no longer part of a study, the questions were optional and presented upon completion of each module. Not all participants took part in both modules, and we wanted to capture the values of each. While the survey is aimed primarily at GPs, anyone could take part in the module, and we anticipated that many other health care professionals would take part in this training. Therefore, the questions were targeted to capture clinical impact on practice with health care, in line with the initial aim of the training. In addition to 3 demographic questions (age, occupation, and gender), 4 evaluation questions were presented:

1. How useful did you find the information in this program?
2. How likely is this information going to inform your practice?
3. Would you recommend this training to your colleagues?
4. Any other comments on the intervention?

Participants were asked to select a score on a scale of 1 - 10 (1: not at all and 10: extremely) to represent how much they agreed with the evaluation questions.

Data

The data and analytics generated from the survey are stored online within the HELM platform and only accessible by the HELM team. The feedback questionnaire was anonymous and voluntary for anyone taking part in the training.

Participating Entities and Dissemination

Many partner organizations have adopted, distributed, and implemented the training over the last 4 years. These include the Royal College of General Practice (RCGP), ADHD Europe, the Association for Child and Adolescent Mental Health (ACAMH), the Academic Health Science Network (AHSN), local GP training hubs, European ADHD research networks (EUNETHYDIS), the University of Montpellier, The University of Dublin and the ADHD collective.

Presentations about the training have been delivered by the lead researcher to groups locally, nationally (eg RCGP) and internationally (eg ADHD Europe). The training has been accredited by the RCGP, the leading professional organization for GP training and accreditation in the United Kingdom, as part of its Continuing Professional Development (CPD) program. Accreditation included further peer review from GPs and refinement of text in line with national and international guidelines (National Institute for Health and Care Excellence and *Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition*). Internationally, the training has been translated into 3 languages (German, French, and Spanish), and ongoing collaboration with leading European ADHD research networks (EUNETHYDIS) has started to develop evaluation and implementation of the translated versions.

The training development and initial RCT evaluation were funded by the Economic and Social Research Council (ESRC) through a doctorate training program. The training also received a non-profit grant from Takeda (a pharmaceutical company) to support the online development and trial.

Sustainability and Budget

The original project funds from Takeda allowed for the intervention to be developed and hosted on the free accessible HELM platform. A booster grant from the same funders also allowed for the translations into other languages to be completed, but aside from these, no other budget was available for the long-term implementation of the training. As a university employee, the lead researcher has driven the implementation in her own time by giving workshops, training, and presentations to specific groups over the last few years.

Ethical Considerations

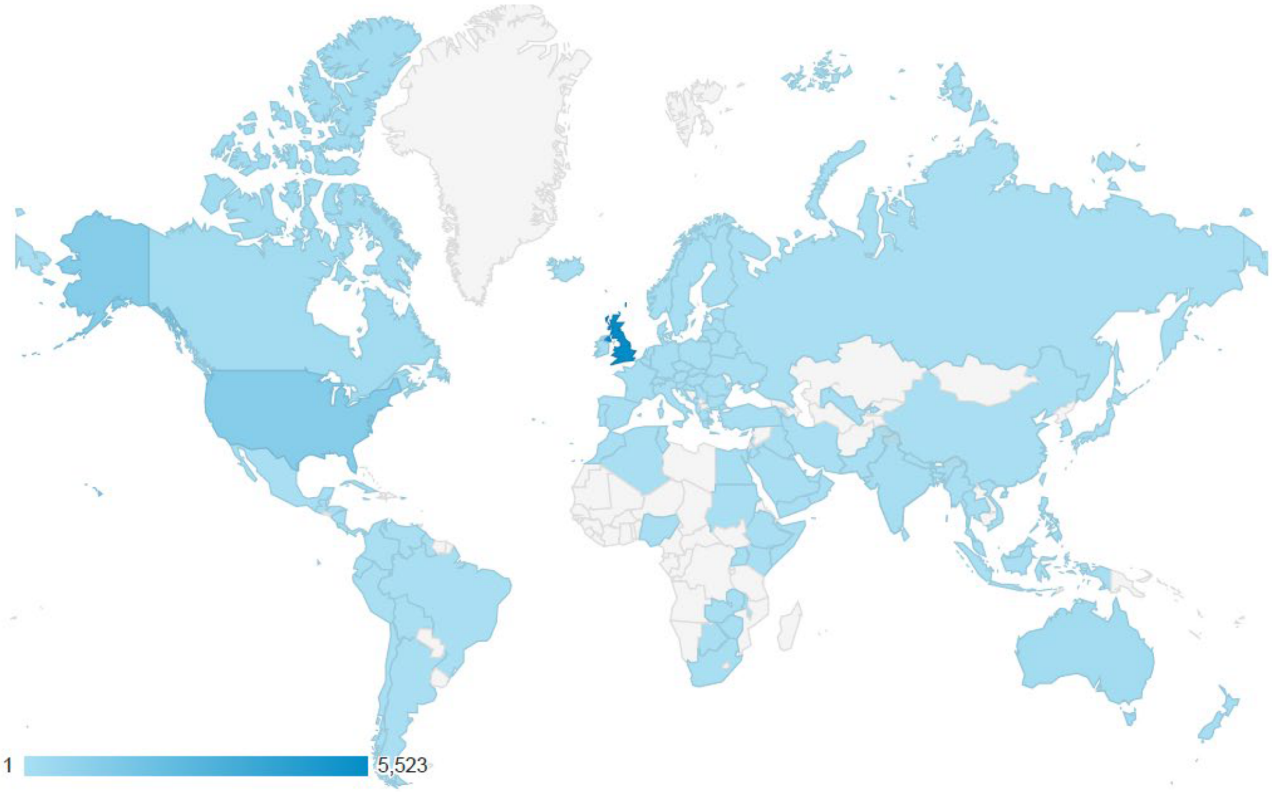
Ethics approval for the RCT and the ongoing evaluation was received from the University of Nottingham, Faculty of Medicine Research Ethics Committee (reference 19/HRA/1028) and from the Nottinghamshire Healthcare National Health Service (NHS) Foundation Trust Research and Development department (project ID 257567). Participants in the survey consented to their data being used. In accordance with ethical standards with IRB and with the Helsinki Declaration of 1975, as revised in 2000. Participants were not compensated for their time in providing feedback. All responses were anonymous and unidentifiable.

Results

Coverage

Between December 2019 and January 2024, the "Understanding ADHD" module was accessed more than 13,486 times with 1484 (11%) of users returning visitors. Many partner organizations have adopted and disseminated the training. Most users were from the United States and the United Kingdom (33% and 57%, respectively). The "role of the GP in the care pathway" module was accessed 7,018 times with 716 (10.2%) of returning visitors. Most users were from the United States and the United Kingdom (20% and 76%, respectively), but the training was also accessed by users based in another 120 countries (Figure 2).

Figure 2. Countries that have accessed the attention-deficit/hyperactivity disorder (ADHD) training from 2019 to 2024.



Outcomes: Survey Results

"Understanding ADHD" Module

A total of 648 participants responded (134 males, 496 females, and 18 unknown), with a mean age of 40.4 (SD 11.32) years (range 16 - 81 years). On average, participants rated the information in the resource 8.47 (SD 1.93) for usefulness and 8.26 (SD 2.11) for how likely this information was going to inform their practice. A total of 611 of 631 (96.8%) participants would recommend the training resource to their colleagues. Table 1 represents the demographics and responses given, separated into different occupations.

Table . Demographic data and average evaluation questionnaire responses for the "Understanding ADHD[a]" module, separated by occupation category.

Variables	Occupation				
	GP[b] (n=66)	Other health care professionals (n=285)	Mental health professionals (n=91)	Health care students (n=47)	Other occupations[c] (n=159)
Gender					
Men	22	74	13	4	21
Women	43	209	76	41	127
Unknown gender	1	2	2	2	11
Age (years), mean (SD)[d]	44.97 (11.74)	40.89 (11.30)	40.01 (11.56)	31.85 (9.20)	40.57 (12.83)
Usefulness rating[e], mean (SD)	8.36 (1.89)	8.61 (1.83)	8.69 (1.62)	8.39 (1.92)	8.13 (2.20)
Likelihood that information would inform practice[e], mean (SD)	8.30 (1.83)	8.49 (1.95)	8.64 (1.66)	8.40 (2.05)	7.56 (2.55)
% Respondents that would recommend the training resource to their colleagues	96.97	96.74	100.00	97.87	94.74

[a]ADHD: attention-deficit/hyperactivity disorder.

[b]GP: general practitioner.

[c]Other occupations include non–health care students, homemakers, project managers, teachers, and teaching assistants.

[d]Data taken only from those who responded. Overall, 13 did not respond to age.

[e]On a scale of 1 - 10, 1 being not at all, and 10 being extremely.

Positive Feedback

The free-text response box yielded 117 responses about the resource, 104 (89%) of which were positive. Participants felt that the resource was comprehensive and clear and appreciated the range of mediums used, including sound bites, videos, text, and interactive quizzes. Multiple comments acknowledged the benefit of including personal lived experiences to help solidify the information included.

Many commented that the resource will be valuable to them in their practice as a GP or healthcare professional, eg, "I am better informed and ready to be more useful to my patients," and others said it was helpful to them on a more personal level (eg, understanding their children or colleagues with ADHD).

> *This intervention is amazing and the value availed of by the public, ADHDers, teachers and medical professionals cannot be underestimated in fact I would say it is immeasurable! [Homemaker]*
>
> *Fantastic resource. Thank you so much. The simple and accessible explanations are brilliant. [Researcher]*
>
> *Easy to read, absorb and navigate. Highly informative educational resource, one of the best I have come across as an individual who suffers from ADHD, thank you! [Carer]*

Suggestions for Improvement

The most common critical feedback was that the module focused too heavily on the negative consequences and risks associated with ADHD. Participants expressed that there are positives associated with ADHD that could be mentioned and that people with ADHD can still be successful, employed, and intelligent. Some highlighted concern that the slides on the problems with ADHD "played into the stigma that often stops people from being accepted for an assessment in the NHS."

> *It would also be good to emphasise the potential strengths in individuals with ADHD for example creativity and the benefits of hyper-focus. [Clinical psychologist]*

Another issue was the lack of representation in the videos for non-White individuals, and therefore more diversity in ethnicity was requested. A few comments suggested the need for an explicit reference to the differential presentation and diagnosis rates between males and females.

"Role of the GP" Module

A total of 308 participants responded to this module feedback questionnaire (64 males, 241 females, and 3 unknown), with a mean age of 39.9 (SD 11.15) years (range 18 - 67 years). On average (mean), participant rating was 8.12 (SD 2.16) for usefulness, and 7.98 (SD 2.14) on how likely this information is going to inform your practice, demonstrating that overall participants responded positively, finding the program to be

useful for their knowledge and improving their practice. Additionally, 291 of 299 respondents (97.3%) would recommend the training resource to their colleagues.

Table 2 shows the age, gender, and answers, separated by the participant's professional group. The ratings appear to be quite similar between each occupation group. The GP group gave the lowest rating for usefulness, likelihood to inform practice, and likelihood to recommend to colleagues, whereas mental health professionals gave the highest.

Table . Demographic data and average evaluation questionnaire responses for the "Role of the GP" module, separated by occupation category.

Variables	Occupation				
	GP[a] (n=66)	Other health care professionals (n=128)	Mental health professionals (n=30)	Health care students (n=30)	Other occupations[b] (n=54)
Gender					
Men	19	30	6	4	5
Women	46	98	24	26	47
Unknown gender	1	0	0	0	2
Age (years), mean (SD)[c]	45.40 (9.59)	39.00 (10.27)	39.40 (11.15)	31.50 (12.35)	39.67 (12.42)
Usefulness rating[d], mean (SD)	7.92 (2.16)	8.02 (2.02)	8.67 (1.60)	8.40 (2.04)	8.15 (2.30)
Likelihood that information would inform practice[d], mean (SD)	7.74 (2.18)	7.93 (2.09)	8.53 (1.67)	8.50 (2.01)	7.78 (2.39)
% Respondents that would recommend the training resource to their colleagues	93.80	98.40	100.00	96.60	98.08

[a]GP: general practitioner.

[b]Other occupations include non–health care students, a local government manager, a homemaker, and a teaching assistant.

[c]Data taken only from those who responded. Overall, 4 did not respond to age.

[d]On a scale of 1 - 10, 1 being not at all, and 10 being extremely.

Positive Feedback

The free-text response box yielded 75 responses about this resource, 61 of which were positive (81%). Many comments said that the resource was "very interesting," "informative," and "useful." There was also praise regarding the clarity and presentation of the information, which facilitated easy understanding. Some respondents also commented that it was particularly insightful to include a video from the point of view of a GP discussing their own difficulties in getting a diagnosis, adding a unique and important perspective. These positive comments came from participants with a range of backgrounds demonstrating the benefits of this resource for GPs as well as other professions.

> *Clear and well presented. So many people complicate ADHD and so it becomes difficult to learn - this was a perfect way to introduce it - and the GP with ADHD was a fantastic resource. [GP]*

> *Very detailed, lots of information and suitable diagrams and videos of experiences also helped. [Student Mental Health Nurse]*

> *This is a really good teaching resource. I will be recommending that all new nursing staff also have access to this. [Clinical Specialist ADHD Nurse]*

Suggestions for Improvement

A few of the free-text responses gave some suggestions for other things to include in this module. A couple of participants asked for more information about the assessment process and specific information about the role of the GP in shared care, with the roles of nurses and support workers. There was a suggestion from a few GPs to include free resource signposting for them to give to patients and parents to help with management.

> *It could do with more detail and clinical scenarios. Also important is the association and differential diagnosis of other comorbidities, addiction/personality disorders/anxiety depression. That may indeed be beyond the scope of this website. [GP]*

As these participants acknowledged themselves, this module focused on the role of the GP in ADHD, so did not aim to include comorbid diagnoses.

Another participant gave a specific suggestion for the "What is ADHD" section to include clearer differentiation about the presentation in girls and boys or women and men and more detail on how ADHD impacts mental health when it is not diagnosed or well-treated.

A care assistant expressed their frustration about the care system in their part of the United Kingdom in referring to the Association for Child and Adolescent Mental Health or adult mental health services for ADHD, commenting that "Your information makes going to the doctors and getting a diagnosis seem easy."

Finally, a couple of other respondents stated that this resource did not add anything new to their knowledge and would not change their practice as a GP, although this may not be reflective of the quality of the resource, but of this participant's existing knowledge being sufficient or extensive.

Discussion

Principal Findings

Overall, the implementation of this funding has been very positive, particularly in the light of no secured economic or staff resources to support this. The program has been translated internationally, reaching more than 120 countries and has been translated into 3 different languages. The feedback has been predominantly positive, and the intervention has received consistently high ratings regarding its acceptability and usefulness.

Lessons Learned

Many lessons were learned from the feedback as well as from the dissemination and implementation process.

The feedback highlighted some limitations about how the training had been framed, the lack of representation, and gender differences. The coproduction aspect of this training aimed to maximize the accessibility and usability of the training by GPs. Service users also reviewed the training before its dissemination, but their input was not as significant as that from GPs. Some of these issues might have been avoided by more thorough service-user involvement. Striking the balance between the different stakeholders was complex as, in this instance, their input at times was not compatible.

The dissemination of the training in practice within the United Kingdom was also very complex. In the United Kingdom, there is no single training organization that can adopt training and trickle down to all GPs in a top-down manner. Each area of the United Kingdom has separate training programs that are decided at a regional level, and linking with all different regions is difficult. Therefore, the implementation had to be conducted in a bottom-up manner, which is time-consuming and has limited reach. We were also unable to reliably report data pertaining to user engagement, such as completion rate and number of visits. These numbers were biased by the ongoing use of the tools as a training module, and therefore the numbers do not represent realistic interactions.

It is also important to note that the dissemination of the training started in March 2020. In many countries including the United Kingdom, this was the beginning of the COVID-19 pandemic. This would have had significant impacts on the implementation of the training. First, GPs' priorities had to change very quickly, and practices adapted in a very stressful environment. Dealing with the direct consequences of the pandemic became the priority, with taking part in CPD or a better understanding of ADHD becoming less important. Although the demand for confinement significantly increased ADHD symptoms expressions and associated impairment for some [14] and an increase in referrals postpandemic [15], it was difficult for GPs to prioritize this issue, as is demonstrated by the significant decrease in referrals during lockdowns [16]. Second, the research team was not able to actively reach out, disseminate, and give presentations for a long time, which also impacted the implementation of the training in practice.

Finally, the implementation process has not been without challenges. The UK system for training health care professionals is not easy to navigate. Outreach events have been useful in engaging stakeholders and generating uptake in the training; however, this led to only pockets of health care professionals being trained and did not extend wider than the reach for the event. The aim of the evaluation was to be pragmatic so that we could evaluate the implementation in routine primary care settings; for this reason, the evaluation questions were simple, and free text comments were only provided by a minority of users.

Some suggestions for improvement have been raised, which will be considered in alterations to the training, but it is important to note that these were from a minority of users (30/9000). Additionally, some of the suggestions were not possible to implement, for example, in local pathways and national practices. The local pathways for ADHD vary widely between regions and countries. They also often change regularly, and information quickly becomes outdated [17-19]. Therefore, while the information on pathways would be very beneficial, it is impossible to capture all regional and national variations.

While the training was primarily aimed at GPs, it was always clear that it would benefit many other health care professions working alongside primary care. By gaining a better understanding of the GP's role, the roles of other professionals will become clearer. Therefore, it is very positive that so many other health care professionals accessed the training and gained a better understanding of ADHD, significantly widening the impact and reach of the resource.

In conclusion, this coproduced and evidence-based training shows ongoing benefits, acceptability, and usefulness in practice. The results from this implementation demonstrated a wider use to other health care professionals and international reach. Ongoing implementation plans aim to support further the wider implementation of this training, principally in other countries.

Conflicts of Interest

DD has in the provided educational talks for Medice and Takeda . He has also reported grants, personal fees and nonfinancial support from Takeda, Medice, ACAMH Learn, the New Forest Parenting Programme and World ADHD congress, book royalties from the sale of a self-help version of the New Forest Parenting Programme, and compensation for the provision of training and supervision in the New Forest Parenting Programme. BF reports personal fees and nonfinancial support from Takeda and Medice. The remaining authors declare that the research was conducted in the absence of any commercial or financial relationships that could be construed as a potential conflict of interest.

Abstract

Background: Medical education has undergone professionalization during the last decades, and internationally, educators are trained in specific medical education courses also known as "train the trainer" courses. As these courses have developed organically based on local needs, the lack of a general structure and terminology can confuse and hinder educators' information and development. The first aim of this study was to conduct a national search, analyze the findings, and provide a presentation of medical education courses based on international theoretical frameworks to support Swiss course providers and educators searching for courses. The second aim was to provide a blueprint for such a procedure to be used by the international audience.

Objective: In this study, we devised a scholarly approach to sorting and presenting medical education courses to make their content accessible to medical educators. This approach is presented in detailed steps and our openly available exemplary database to make it serve as a blueprint for other settings.

Methods: Following our constructivist paradigm, we examined content from medical education courses using a theory-informed inductive data approach. Switzerland served as an example, covering 4 languages and different approaches to medical education. Data were gathered through an online search and a nationwide survey with course providers. The acquired data and a concurrently developed keyword system to standardize course terminology are presented using Obsidian, a software that shows data networks.

Results: Our iterative search included several strategies (web search, survey, provider enquiry, and snowballing) and yielded 69 courses in 4 languages, with varying terminology, target audiences, and providers. The database of courses is interactive and openly accessible. An open-access template database structure is also available.

Conclusions: This study proposes a novel method for sorting and visualizing medical education courses and the competencies they cover to provide an easy-to-use database, helping medical educators' practical and scholarly development. Notably, our analysis identified a specific emphasis on undergraduate teaching settings, potentially indicating a gap in postgraduate educational offerings. This aspect could be pivotal for future curriculum development and resource allocation. Our method might guide other countries and health care professions, offering a straightforward means of cataloging and making information about medical education courses widely available and promotable.

KEYWORDS

curriculum mapping; faculty development; competencies; database; medical education

Introduction

Ensuring high-quality health care necessitates the presence of well-trained medical educators [1]. Internationally, this has led to the development of frameworks that define their role and the creation of educational pathways for certification in many predominantly Anglophone countries. The terms "medical education" and "medical educator" are used with varying definitions in various settings. For this study, we define "medical educators" as the diverse group of health care professionals who teach, but regarding their learners, we focused on undergraduate medical students and physicians only. Hence, we include medical educators who are active in multiple settings: from clinical supervision and classroom instruction to the development and implementation of curricula. Their roles span the continuum of medical education from undergraduate through postgraduate training and continuing professional development.

Recent studies have identified significant tensions faced by medical educators, including lack of defined career structures, insufficient recognition of teaching roles, and challenges in developing educational identities [2,3]. While formal training programs alone cannot fully address these structural issues, they

serve as a crucial stepping stone in professionalizing medical education.

Globally, this coincides with the effort to provide these educators with a defined career path and support for their teaching activities. Notably, the Royal College of Physicians and Surgeons in Canada has introduced a "Clinician Educator Diploma," rooted in the findings of studies by Sherbino et al [4,5]. Similarly, the University of Michigan Medical School in the United States offers a Master of Health Professions Education [6-8], and in the United Kingdom, a variety of programs align with the "Professional Standards for medical, dental, and veterinary educators" established by the Academy of Medical Educators [9]. These initiatives exemplify the efforts to emphasize the value of quality medical education and facilitate access to quality training for educators.

Drawing on Wenger's Communities of Practice theory [10], these structured pathways and frameworks serve not only as career development tools but also as boundary objects that connect different medical education communities and facilitate knowledge sharing. When educators can easily identify and access training opportunities, they can more effectively participate in and contribute to their professional community. The visibility and accessibility of educational resources play a crucial role in fostering community development and knowledge exchange across different regions and language groups, ultimately supporting the growth of medical education as a professional field.

Lack of Career Pathways and an Opaque Landscape

Nevertheless, many regions internationally do not provide a career pathway for medical educators, nor do they use specific frameworks yet [3,11,12]. While some countries offer incentives such as continuous medical education (CME) credits for educational training, this is not standardized. Similarly in Switzerland, formal requirements for teaching qualifications are not yet standardized; there are some existing incentives for medical educators to pursue didactic training. Many didactic courses, particularly those offered or recognized by the Swiss Institute for Postgraduate Medical Education (SIWF), provide CME credits, independent from whether they concern undergraduate, postgraduate, or CME. Additionally, some specialty training programs, such as Internal Medicine, have incorporated mandatory didactic courses into their curriculum requirements [13]. However, these incentives remain fragmented and vary across specialties and institutions.

Still, in everyday reality, senior staff members are expected to educate while juggling everyday clinical tasks with providing education for students and junior doctors, often lacking dedicated time for teaching activities, as described in literature from Australia, Canada, and the United Kingdom [14-17] and in a 2008 Association for Medical Education in Europe guide [18]. Similarly, in Switzerland, where this study took place, there are few examples of clinics hiring specific teaching staff or at least dedicating specific hours in employment contracts to teaching. This practice is still not the norm and is rarely seen outside of specific pilot programs [19]. All of this leads to a diverse, somewhat undefined, and opaque medical education landscape and hinders high-quality medical education.

Aims and Research Questions

The aims of this study are twofold. The first aim of this study was to conduct a national search, analyze the findings, and provide a presentation of medical education courses based on international theoretical frameworks to support mainly Swiss course providers and educators searching for courses.

The second aim was to provide a blueprint for such a procedure to be used by the international audience.

Our research questions are (1) How do we conduct the search for courses and their content? and (2) How can we present the courses in an accessible way that is translatable to other regions?

Methods

Research Paradigm and Use of Theory

Guided by a constructivist research paradigm, which implies that no objective reality exists but that knowledge is created by social interactions [20], this study adopted a subjectivist inductive approach, using a theory-informed inductive data analysis method, described by Varpio et al [21].

This approach allowed a dynamic interplay between intermediate results and potential theoretical frameworks during data collection until we found the most fitting theoretical lens. This reflective and adaptive approach also ensured the relevance of the study results to the roles and competencies of medical educators as they were reflected in the Swiss data.

After a literature review of possible frameworks [4,5,7,9,22-29] and thorough deliberation by the research team, we selected the framework by Sidhu et al [28] as the best fit to support data analysis. Our decision to adopt this framework was strategic, not only for its clear enough lens through which to categorize and analyze course content, due to its comprehensive integration of 67 texts on educator competency domains, but also because it encompassed multiple health care professions, not just physicians. It comprehensively synthesizes educator competencies and identifies 6 distinct domains: "Teaching and Facilitating Learning," "Designing and Planning Learning," "Assessment of Learning," "Educational Research and Scholarship," "Educational Leadership and Management," and "Educational Environment, Quality, and Safety." This approach provides a robust, inclusive structure for understanding and evaluating educator competencies across different health professions.

This study lays the groundwork for a national strategy in Switzerland to enhance the quality of medical education. The first step was establishing a comprehensive database of existing educational offerings. This database facilitates an iterative and reciprocal examination of the course landscape, identifying gaps in the current educational landscape and recognizing requirements that may diverge from international frameworks. This approach ensures that the subsequent framework development and the certification of educators and courses are tailored to the unique needs and priorities of the Swiss medical education system. Additionally, it also allows us to identify and highlight areas lacking coverage by comparing with existing provisions.

Selection and Eligibility Criteria for Course Inclusion and Exclusion

Our study employed a systematic approach to searching for courses, with carefully defined inclusion and exclusion criteria.

The inclusion criteria encompassed the geographical scope, that is courses offered in Switzerland or online courses offered by Swiss institutions; the target group that is courses aimed at educators teaching physicians or medical students; and the content focus, that is courses with a primary focus on teaching skills.

The study's exclusion criterion was individual (1-to-1) offerings.

The limitation of the geographical scope ensured feasibility and was chosen with regard to the first study aim of building a national database. Our target group of educators who teach medical students and physicians, rather than including educators for learners in all health care professions, was driven by several methodological and practical considerations. First, our research team's expertise lies specifically in physician education, allowing us to conduct more nuanced and informed analysis within this domain. Second, our primary data collection method through the Joint Commission of Swiss Medical Schools (SMIFK/CIMS) naturally oriented our study toward medical education targeting physician settings.

With the formulation of the content focus in teaching skills, we deliberately excluded courses with generalized skills that could apply to any professional setting. These "soft skills" courses—such as generic presentation techniques, leadership pitching, or broadly applicable communication strategies—were set aside to concentrate on educational content specifically tailored to medical teaching contexts.

These criteria helped to refine the search and survey strategies, allowing for a targeted collection of data that is pertinent to the goals of this study.

Data Collection

First Phase: Online Search

We initiated our investigation with an extensive online search (May to July 2023), employing various search strategies to explore clinic, faculty, university, and specialists' association websites to find information on courses. We approached the search from an estimated end-user perspective, simulating how a medical professional seeking to expand their teaching skills might investigate educational opportunities. This meant using primarily search engines and direct institutional websites (including every medical faculty n=11, university hospital n=9, cantonal and larger regional hospital websites n=18, medical associations n=45, and the official SIWF website). Our search extended across Switzerland's linguistic diversity, using keywords in the country's 3 official languages (German, French, and Italian) and English to ensure no regional offerings were overlooked. Exemplary search strings, detailed in Multimedia Appendix 1, were designed to capture the multifaceted nature of medical education across different linguistic and regional contexts. Additionally, we used a pragmatic snowball-like method where we let discovered sources lead to additional course offerings. While not claiming absolute comprehensiveness, this method aimed to provide an overview of medical education courses in the Swiss context.

Second Phase: Widening the Search

Subsequently (July to December 2023), we sent out an e-mail targeting representatives within the Joint Commission of the Swiss Medical Schools (SMIFK/CIMS), a commission that includes deans and other stakeholders from all Swiss medical faculties. (see Multimedia Appendix 1 for survey questions). The survey did not systematically track response rates or potential selection biases. To widen our scope and better represent non-university medical institutions, we distributed a modified version of the survey to Human Resources departments of 25 larger hospitals in Switzerland in December 2023.

Through this dual approach of detailed online searches and surveys, we sought to capture a comprehensive snapshot of medical education offerings in Switzerland. It allowed us to gather insights not only from academic institutions but also from larger health care providers, thus offering a comprehensive view of the medical education landscape in Switzerland.

Course data were collected using a spreadsheet attached to the surveys, asking the respondents to fill in information about their courses and refer us to additional information if applicable. The specific metadata sought is presented in Table 1. Missing data were filled out by the authors, either by referring to online information or by consulting with the respective course contact persons directly. This step was important to enrich and verify the information found via the online search.

Table . Course metadata Items.

Item	Description
Title	Course title
Course ID	ID number applied to the course by the researchers
Provider	Institution providing the course
Contact information	Contact information for further inquiries (contact person and, if available, e-mail)
URL	Link to the course website (if available)
Location	Onsite or blended or hybrid or online
Duration	Duration of course as specified by the provider
Language	Course language (German, French, Italian, and English)
Costs	Costs of the course in Swiss Francs (CHF)
Certification	If the course yields a certification of attendance, title, or similar
Accreditation	Number of CME (continuous medical education)—credits or ECTS—credits for a study program
Target audience	For example, Attending Physicians in student care, all health care staff, bedside tutors, etc

Data Analysis

In the data collection phase, we observed an interplay between the course offerings and our theoretical framework, Sidhu et al [28]. It is important to note, however, that despite our openness to various health care professions at the start of the project, we ultimately focused our analysis exclusively on courses aimed at educators teaching physicians or medical students. This decision was made to maintain the scope of our study within manageable bounds, ensuring our research remained focused and relevant to our primary audience.

Our intention to mirror the actual landscape of Swiss medical education in its present state guided the database construction. Therefore, the selection of keywords for sorting courses and the strategy for their visualization were meticulously developed to emphasize prevalent topics and reveal the intricacies of course content, ensuring our methodology resonates with the real-world context of medical education. We also aimed to maintain the original terminology and language of course descriptions where possible to respect Switzerland's multilingual landscape and to accurately reflect the providers' offerings.

Building the Course Database

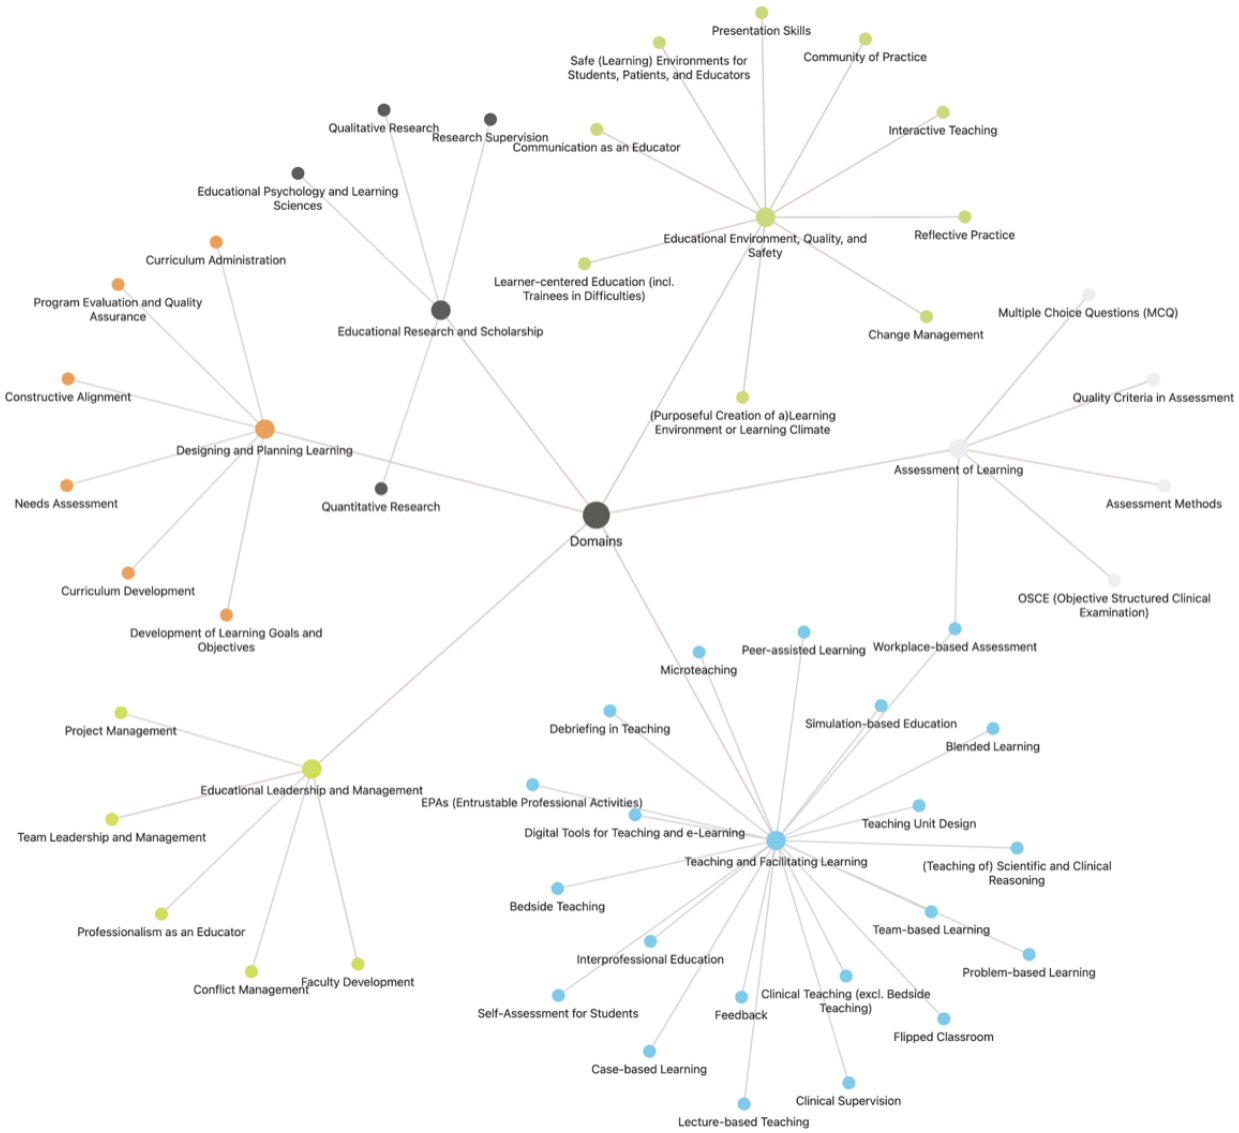
We chose Obsidian [30] as our platform for several practical reasons: its intuitive interface and its free access model for educational use made it accessible for users without extensive technical expertise, aligning with our goal for easy usability and adaptability. Obsidian allows for direct, interactive engagement with the data; this feature not only facilitated a more nuanced understanding of the data but also enabled us to refine and validate our keyword mapping and course organization strategies. Furthermore, Obsidian offered an integrated solution for both analyzing and publishing the data online, using Obsidian Publish [30], simplifying the transition from data collection to dissemination. This integration was particularly advantageous for providing an interactive, accessible resource for medical educators and ensuring the database's utility extended beyond our research team.

The spreadsheet data were then transferred by hand into an Obsidian database, with each course receiving its own Markdown file. Each file included a metadata section on the course and expanded sections on course descriptions, learning objectives and target audience, if available. All course data is provided in the original language and, if not already in English, was translated into English using DeepL, a free online translation tool [31].

Course Keywording, Standardization, and Refinement of Terminology

AG initially reviewed the compiled comprehensive course data to refine and validate our approach to organizing Swiss medical education course data, identifying preliminary keywords reflective of the content's breadth. Subsequently, AG and EH collaborated to align these keywords with the competency domains and definitions provided by Sidhu et al [28], ensuring a robust mapping grounded in established educational frameworks (see Multimedia Appendix 2 for a visual representation of the mapping process). The interplay between the domains provided by Sidhu et al. and the keywords as displayed in Obsidian.md is visualized in Figure 1.

Figure 1. Obsidian visualization of domains and keywords.



AG initially reviewed the compiled comprehensive course data to refine and validate our approach to organizing Swiss medical education course data, identifying preliminary keywords reflective of the content's breadth. Subsequently, AG and EH collaborated to align these keywords with the competency domains and definitions provided by Sidhu et al [28], ensuring a robust mapping grounded in established educational frameworks (see Multimedia Appendix 2 for a visual representation of the mapping process). The interplay between the domains provided by Sidhu et al and the keywords as displayed in Obsidian.md is visualised in Figure 1 .

This thorough process not only enhanced the accessibility and navigability of course data but also underscored our commitment to precision and educational integrity in documenting the landscape of medical education in Switzerland.

In our methodology, we iteratively developed a set of keywords to authentically represent various aspects of Switzerland's medical education landscape. Each keyword, crucial for clarity and precision, was documented and defined in separate Markdown files within Obsidian. Notably, integrating these definitions directly into Obsidian's Markdown documents enabled the keywords to serve as interactive reference points. By simply hovering over them, users can access a preview of the definition, improving the coherence and navigability of our documentation.

Database Publication

In the development of our study, we aimed to create a comprehensive and interactive database encapsulating the entirety of Switzerland's medical education landscape, specifically designed for ease of use and utility by medical educators. To make Switzerland's medical education course offerings easily navigable and useful for the academic community, we used Obsidian Publish [30] for the database's implementation. This platform was selected to ensure that the database was as interactive and accessible as possible.

To strengthen the trustworthiness of our search strategies we directly contacted each course provider to verify the representation of their course content and confirm the currency and correctness of the information.

Additionally, we prepared to release a template on GitHub to ensure our methodology was transparent and could be replicated in other contexts. This template provides the structure and template files necessary for creating a similar database, focusing on the organization and presentation of data. By offering these template files, we intended to facilitate the adoption of our approach by researchers or educators interested in developing educational landscape databases for different settings. The combination of using Obsidian Publish for the database and GitHub for sharing the template underscores our commitment to accessibility, transparency, and the potential for our work to be adapted and applied broadly.

Reflexivity

Acknowledging the importance of reflexivity for our constructivist approach, we critically examined the influence of our roles and backgrounds on this study. Each researcher brought distinct perspectives to conceptualizing a medical educator's role: AG started this project shortly after finishing his studies and provided insights on studying medicine, role definitions, and teaching cultures from a German-speaking and Italian-speaking Swiss region. MB, with a robust background as a practicing internal and emergency medicine doctor and a Master of Medical Education from the University of Bern obtained in 2006, brought insights both from her tenure as president of the SIWF and her experience in teaching emergency medicine courses. EH transitioned from clinical practice and medical education in Germany (Master of Medical Education in 2020) into medical education research in Switzerland (PhD in Medical Education), enriching our project with her comparative view and interest in theoretical concepts. To further enhance the validity of our keyword selection and study design, we engaged with 3 medical educators from Germany and Switzerland who have vast experience in curriculum development. Their feedback was instrumental in refining our course keywords, ensuring our framework resonated with the complexities and nuances of medical education across different linguistic and educational landscapes.

Study Setting

The present study was carried out in Switzerland, with a focus on identifying and analyzing medical education courses available within the country. The data collection phase spanned from May 2023 to December 2023. Subsequent data processing occurred concurrently and extended until March 2024.

Ethical Considerations

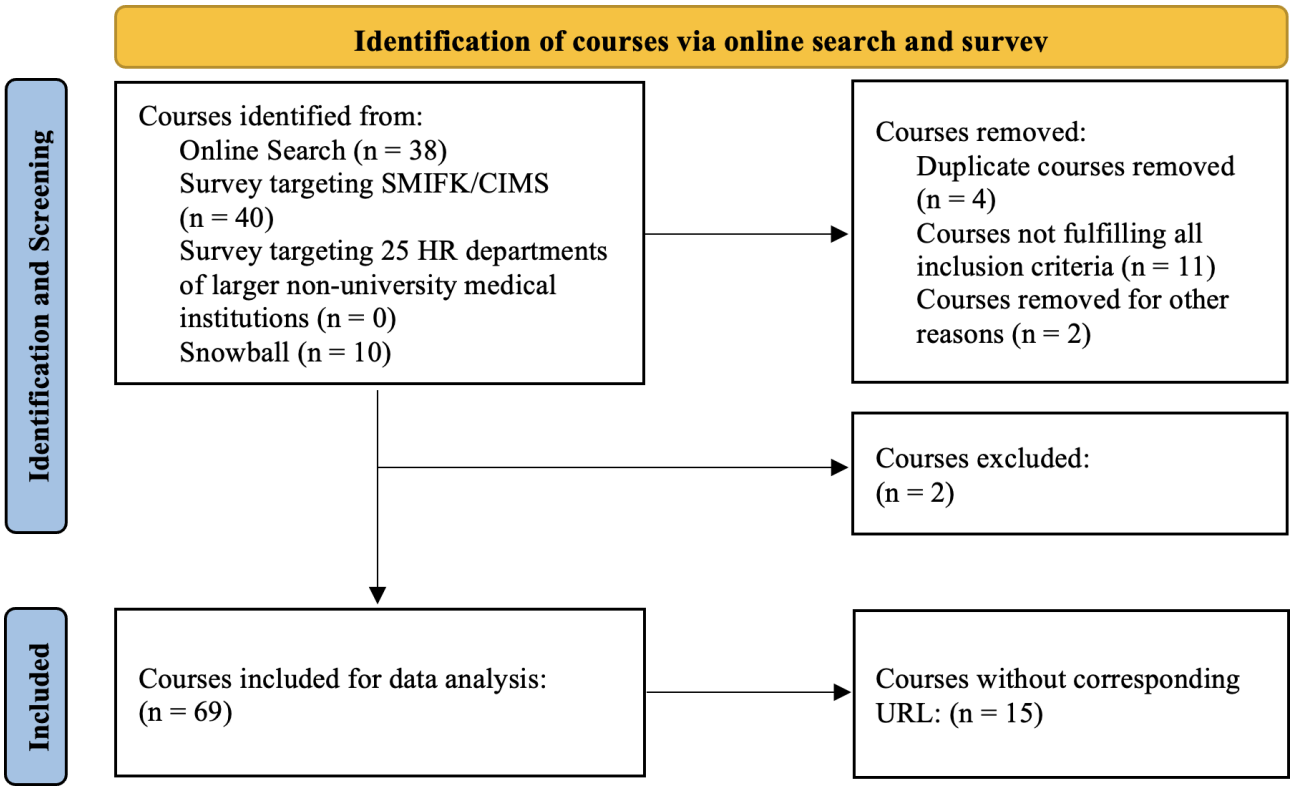
As no participants were involved, no ethical approval was needed. Everybody who supported this study by providing data, did so voluntarily without any incentives or conflicts of interest.

Results

Courses and Keywords

The initial online search, including the snowball method-like approach, resulted in 38 courses. The survey targeting the SMIFK/CIMS members resulted in 40 additional courses. The survey targeting Human Resources departments of 25 larger, non-university medical institutions in Switzerland yielded no additional new courses. In total, our search method yielded 69 eligible courses, as visible in Figure 2. Of the 69 total eligible courses identified, 36 were found through online searches alone, while 33 were discovered exclusively through survey responses.

Figure 2. Flowchart of the course identification process. One course that omitted whether physicians were part of its target audience expressed the wish upon further inquiry not to be included in this study for now but to be re-evaluated in future similar endeavors due to the current reorganization of the course offerings. Another course provider told us upon request for further information that our information on their course provided as a survey result was outdated and that they could not share further details about their course. Adapted from Page et al [32].



To ensure the reliability and currency of our findings, we checked back our data with the respective course providers. Of the 69 courses, 54 had active URLs, while 15 courses were documented without direct web links. These courses were primarily identified through institutional contacts and verified through direct communication in order to maintain the integrity of our comprehensive search strategy.

In our findings, undergraduate teaching courses outnumbered those aimed at postgraduate education (55 out of 69 courses aimed at undergraduate training), while most courses were offered by medical faculties (50 out of 69). The majority of courses were offered in French. In total, 11 courses were offered either additionally or exclusively in English. Most courses were offered onsite, meaning in an offline, face-to-face setting. The descriptive statistics derived from the course metadata, summarizing language use, provider types, course duration, and pricing, are summarized in Table 2.

Table . Aggregated course statistics.

Description	Count
Total number of courses	69
Average cost (CHF)	880
Courses offered free of charge	28
Courses with unknown costs	10
Course location	
Onsite	50
Hybrid	7
Blended	4
Online	6
Unspecified	2
Course provider	
Swiss Institute for Postgraduate Medical Education (SIWF)	8
Medical faculties	50
Specialists' associations	3
University hospitals	5
Other	3
Course language[a]	
German	36
French	40
Italian	7
English	11
Romansh	0
Target setting[b]	
Undergraduate teaching	55
Postgraduate teaching	28
Duration, h, average (range)	42 (1.5–8000)

[a]The count for languages may exceed the total number of courses because some courses are offered in more than one language.

[b]The count may exceed the total number of courses because some courses target both teaching settings.

In matching the course content across the 6 educational competency domains delineated by Sidhu et al, we identified 52 keywords. The distribution of these keywords was uneven, with 42% (22/52) of the keywords falling into the "Teaching and Facilitating Learning" domain. In contrast, the domains of "Educational Leadership and Management" and "Assessment of Learning" were represented to a lesser extent, with only 5 keywords each, while "Educational Environment, Quality, and Safety" had 10 keywords. The "Educational Research and Scholarship" domain showed the least coverage with 4 keywords. Individual courses varied in their keyword coverage, with an average of 4 keywords per course (median: 3); one comprehensive course covered 33 keywords across domains. The distribution of keywords across domains is presented in Table 3, with a graphical overview represented in Figure 1.

Table . Domains and keyword distribution among courses.

Keywords	Keywords per domain
Assessment of Learning	5
Designing and Planning Learning	6
Educational Environment, Quality, and Safety	10
Educational Leadership and Management	5
Educational Research and Scholarship	4
Teaching and Facilitating Learning	22
Keywords covered per Course (average, median, max)	4, 3, 33
Sum of keywords	52

Database and Template Publication

Using Obsidian publish, the database containing the Swiss Course Data were published online [33] (Screenshots of the landing page and an exemplary course are provided with Figures 3 and 4, please refer to Multimedia Appendix 3 for a video example of navigating the database). We also published an exemplary, ready-to-use database template with a Markdown folder and file structure as a GitHub-Repository, together with instructions explaining the structure and use of the repository to facilitate adoption by other users [34].

Figure 3. Screenshot of the publicly accessible database landing page.

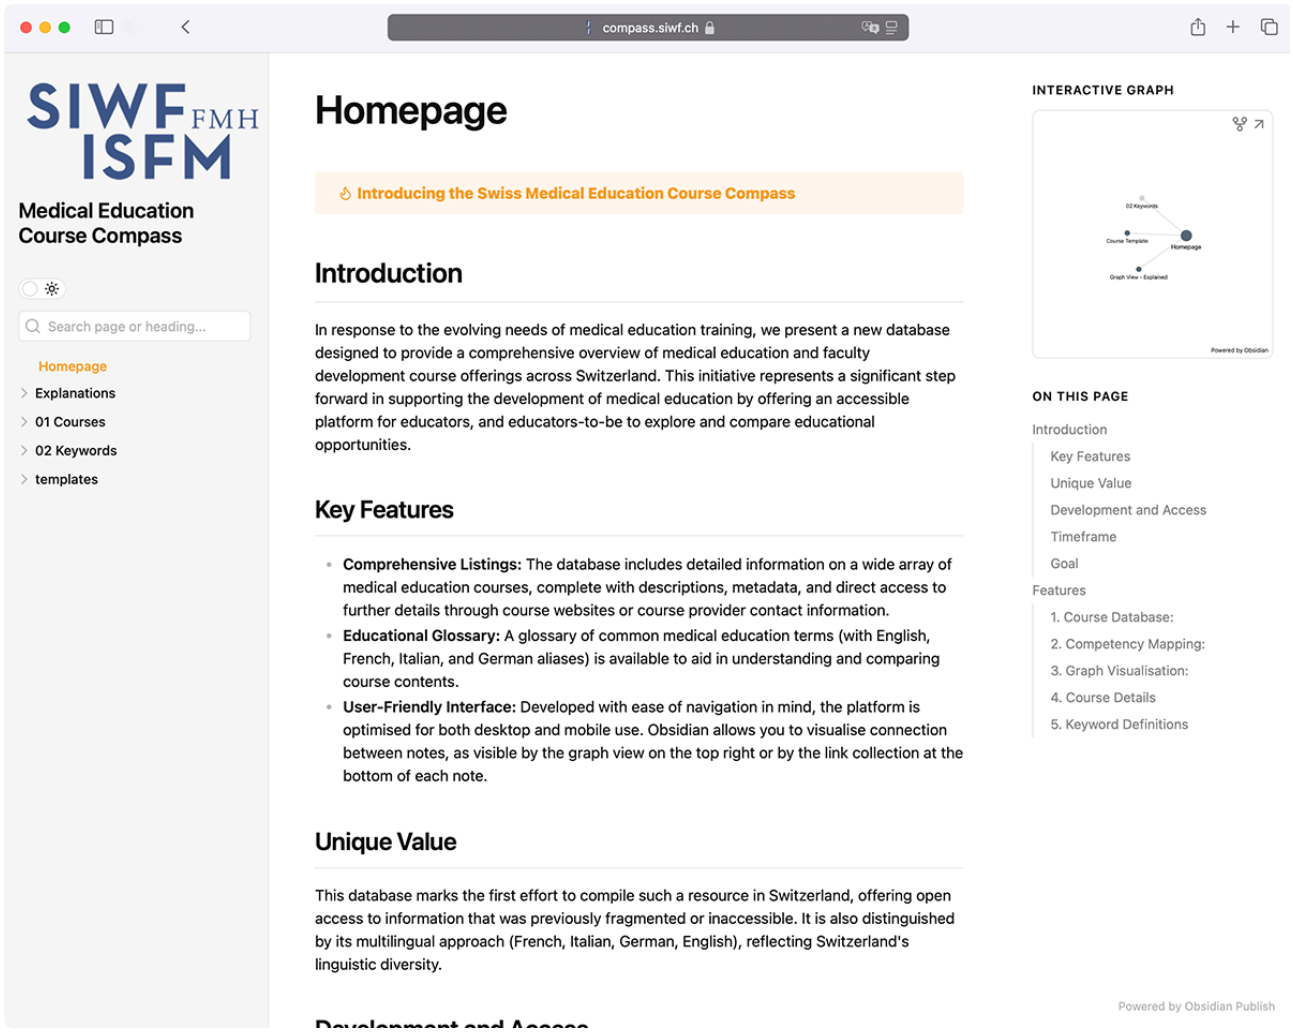


Figure 4. Exemplary screenshot of one course.

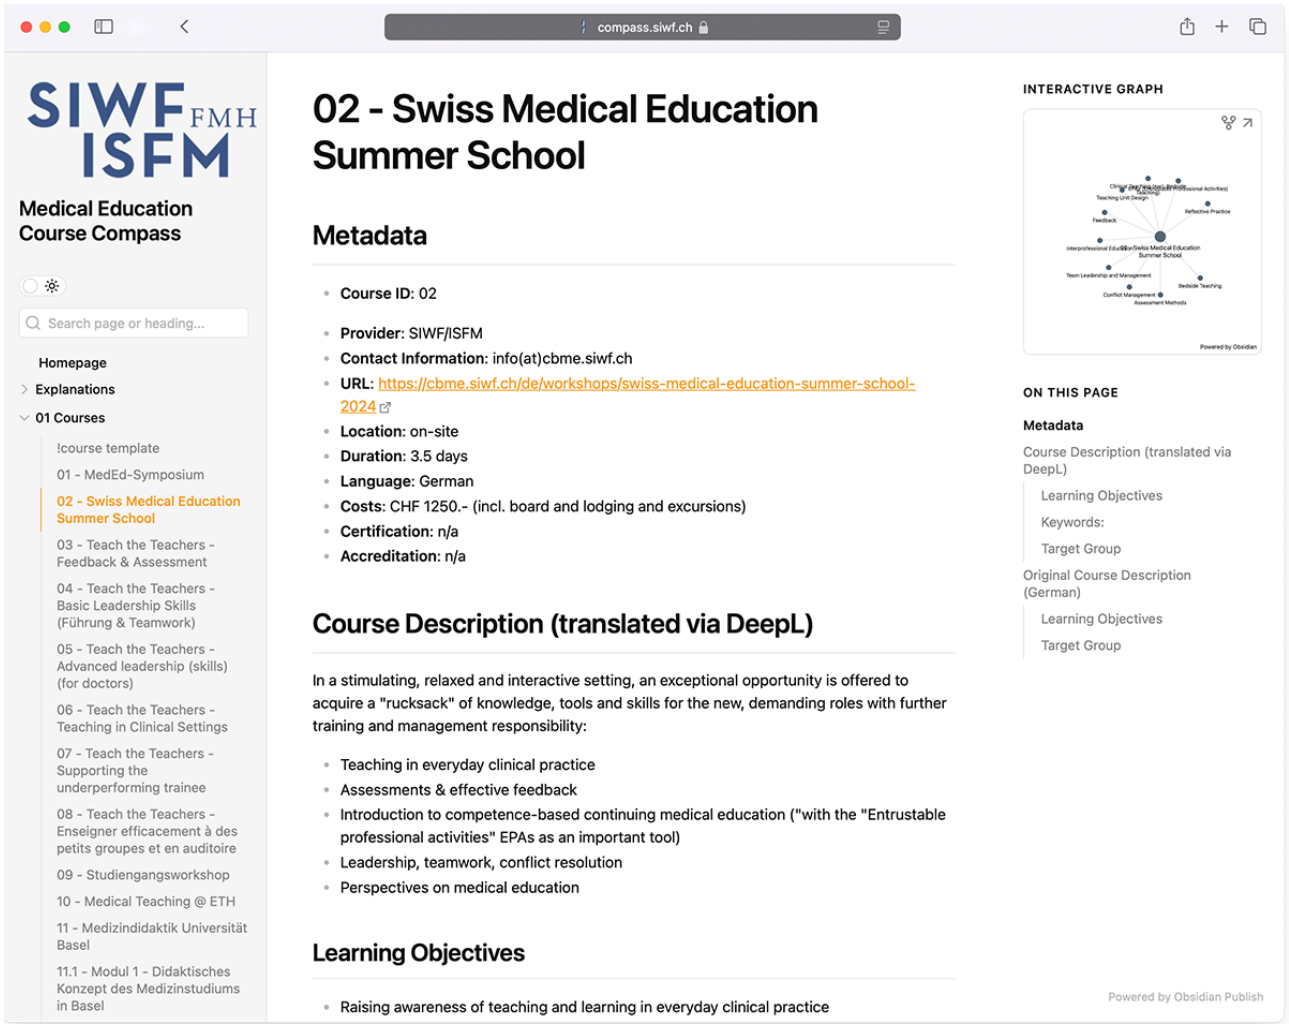

Discussion

Principal Findings

In line with the 2 aims of this study, our results cover 2 aspects. First, we searched for, analyzed, and presented the Swiss courses. We found that 69 courses are provided, of which 55 target teachers of undergraduate learners and 28 target teachers of postgraduate learners. The courses were offered in several languages (52% German, 58% French, 10% Italian, 16% English) and several formats (72% onsite, 10% in a hybrid manner, 6% as a blended-learning format, and 9% online). Course content covered mainly the “Teaching and Facilitating Learning” domain, which contained 42% (22/52) of all identified keywords and was also the most prominent in course offerings, with the keyword ’feedback’ being featured most frequently, appearing in 40.6% (28/69) of all courses.

Second, we created an internationally transferable strategy based on an international framework, using free-for-educational-use software, with published search strings to be adapted by others, and providing all metadata open access.

This study addressed the need for an approachable method of sorting and displaying courses by providing a comprehensive, accessible database of medical education courses in Switzerland. This initiative is particularly relevant in contexts where medical education training lacks clear structure and uniformity, especially across different linguistic and cultural regions.

While we acknowledge that our search strategy may not have uncovered every course, we believe this data set sufficient for our study’s objectives and that it reflects the real-world challenges faced by aspiring medical educators in navigating the educational landscape.

Challenges in Navigating the Medical Education System

Several pervasive challenges exist in medical education. These include a discernible lack of dedicated teaching time [35], insufficient, non-transparent, or misdirected funding [36], and an absence of recognition for educators within the medical field [37]. Such issues create a universal backdrop against which specific national education systems can be analyzed.

Our research provides a structured analysis of medical education courses in the Swiss system, illuminating both publicly accessible offerings and those that emerge through professional networks. Significantly, nearly half of the identified courses (33 out of 69) were discovered only through contact with course providers rather than public online searches, revealing a critical accessibility gap. This finding suggests that course discovery often depends heavily on existing professional networks and insider knowledge, potentially creating barriers for newcomers

to the field who lack such connections. This study is the first of its kind to investigate medical didactics courses in a structured manner in Switzerland, providing an overview and allowing new perspectives.

Our study uncovers a complex challenge within the Swiss medical education system: navigating the educational landscape shaped by 4 national languages—German, French, Italian, and Romansh. Among these, German, French, and Italian are official languages. In this multilingual setting, English emerges as a crucial lingua franca in international research and academia and as a common medium within Switzerland, facilitating communication across linguistic barriers. This is reflected in the educational offerings, with 11 courses being conducted partially or entirely in English. Such linguistic plurality further aggravates the existing variability in didactic methods and medical education and research terminology [38,39], presenting additional challenges to the creation of an educational framework. This situation is further complicated by issues of information accessibility—with 15 courses not having available URLs, it renders it difficult for potential participants to find accurate, up-to-date information about these educational opportunities online.

Implications for Medical Educator Career Pathways

Building on the initial findings, our work, as the first comprehensive compilation of available didactic courses within the Swiss medical education system, can potentially enable more transparency in the field. By illuminating the current educational offerings, our research could facilitate faculty development and inform career choices for medical educators, as they now have a more straightforward overview of the resources and opportunities available to them. This transparency is a critical step towards enhancing career pathways, as it allows for a strategic approach to personal and professional development within the context of medical education.

However, it is essential to note that our study revealed a predominance of courses aimed at teaching in undergraduate (medical school) settings. While this finding initially suggests a potential undersupply of educational opportunities targeting postgraduate teaching, it notably reflects Switzerland's institutional structure, where universities are primarily responsible for undergraduate medical education but not residency training or CME. This structural arrangement, where different institutions oversee different stages of medical education, may contribute to the observed imbalance in course offerings. The relative scarcity of training for postgraduate settings might indicate a need for a broader array of courses catering to the ongoing development of medical professionals beyond their initial degrees. Addressing this gap could lead to a more robust and comprehensive educational framework, ensuring that medical educators are well-equipped to foster the next generation of medical practitioners at all stages of their professional journey.

Comparison to International Models

Our comparative analysis with international models highlights notable differences in structuring medical education career pathways. Particularly in Anglophone countries, such as Australia, Canada, the United Kingdom, and the United States, well-established career pathways and educator frameworks are actively promoted and used, unlike in Switzerland, where such structured frameworks are absent [3,11,12].

When aligning our findings with the integrative framework by Sidhu et al [28], which outlines 6 educator competency domains, we observed that Swiss medical education predominantly emphasizes the domain of "Teaching and Facilitating Learning." This domain is focused on enhancing learning through suitable methods and resources, including assessment for learning. This heavy focus may inadvertently lead to a neglect of the other 5 domains ("Educational Leadership and Management," "Educational Environment, Quality, and Safety", "Designing and Planning Learning," "Assessment of Learning," and "Educational Research and Scholarship"), suggesting a possible imbalance in the educational emphasis. Our keyword map corroborates this emphasis, revealing a detailed and nuanced depiction of the "Teaching and Facilitating Learning" domain. Our mapping strategy aimed to reflect the specificity and depth of course offerings without excessive summarization, thus indicating their relative prominence by the frequency with which they appear in our data set.

The predominance of the "Teaching and Facilitating Learning" domain could stem from its direct applicability in educational settings and the relative ease of teaching and assessing these skills. This focus on tangible teaching methods and resources, which offer clear benefits and outcomes, could make it a natural focal point for educators aiming to directly impact student achievement. However, this emphasis may inadvertently lead to the undervaluation of other critical educator competencies, such as "Educational Leadership and Management" or "Educational Research and Scholarship." These domains encompass more abstract competencies that resemble attitudes or overarching professional dispositions rather than concrete skills, presenting challenges for direct instruction due to their less immediately visible impacts and harder-to-quantify qualities.

The challenge of effectively imparting the more abstract domains within medical education and the observable predilection for addressing more accessible teaching topics can be analogized to the tendency to assess readily quantifiable competencies [40]. This parallel might reflect an educational predilection for what can be straightforwardly taught and measured, perhaps at the expense of more profound, more complex competencies that are less amenable to conventional assessment methodologies. Such a tendency may not fully encapsulate the multifaceted nature of medical educator competencies, underscoring a potential disjunction between educational priorities and the comprehensive skill set required for clinical excellence.

The marked predominance of teaching methods and learning facilitation within the Swiss context, as opposed to a more balanced distribution across the 6 domains, is an intriguing phenomenon. We propose that this area warrants further inquiry. Investigating why there is such a strong focus on these teaching competencies within Switzerland, especially compared to the broader scope seen internationally, could yield insights that

inform future developments in medical education. This analysis might ultimately contribute to enhancing educator frameworks and diversifying professional development opportunities.

Future Directions and Potential Impact

The insights garnered from this study lay the groundwork for developing a unified and expansive framework for medical education in Switzerland, emphasizing the need for a formal recognition and certification process for medical education courses and medical educators. By enhancing awareness of available courses and clarifying the expectations for a medical educator, this initiative could significantly improve the quality of medical education. Increased awareness is crucial for establishing clear competencies in the first place, and it also serves to acknowledge and validate existing efforts while encouraging the development of future educational opportunities. The overview of courses also offers the basis for future discussions, which have already begun. Currently, the database does not give information on the quality of courses, as this could not reliably be assessed. For a future version of the database, methods to assess course quality and display this transparently are developed.

In addition, the overview on courses in comparison with the framework has shown some blind spots of the current training. Courses on “Assessment of Learning,” “Educational Leadership and Management,” and “Educational Research and Scholarship” seem to be rare. As a follow-up to this study, the responsible groups (SMIFK and SIWF) will discuss these gaps and take this as a base for future course offerings.

Furthermore, this focus on a structured framework could resonate on an international level, offering a model for contexts where clear career pathways for medical educators are similarly undefined, thus having the potential to inform and shape international standards in medical education.

While this study focused exclusively on courses on medical education (physician-adjacent) settings to maintain a manageable scope, we deliberately chose Sidhu et al’s framework for its interprofessional applicability across health care education. Combined with our intentionally transparent and replicable methodology, this provides a strong foundation for other health care professions to adapt our approach to mapping their own educational landscapes. The template we developed could serve as a starting point for similar analyses in other health professions’ education systems.

Limitations

Our study encountered different challenges. The research relied primarily on internet-searchable courses, potentially overlooking non-digital or unadvertised educational offerings. Additionally, our snowball search approaches introduce potential selection biases.

As we focused on assembling an overview instead of the details of courses, the depth of content validation regarding, for example, course quality, pedagogical methodologies, and educational effectiveness is limited.

Future research should focus on course content and course quality and investigate the usability and comprehensiveness of our database, including an accessibility audit of course information, a comprehensive comparison with expert-identified course offerings, and systematic verification of course details. We are planning to investigate the implications of the use of the database, such as changes in content offered and new strategies to acknowledge medical educator careers.

Conclusions

The methodology showcased in our study serves as a valuable template for international adaptation, offering insights into how diverse educational systems can be evaluated, organized, and presented effectively. By innovatively mapping the educational landscape with the example of Switzerland, we have provided a replicable approach that could aid other countries, even with similar linguistic and cultural challenges. The creation of our database amplifies the visibility and transparency of medical education courses available, facilitating better decision-making for educators. This enhanced access to information allows medical professionals to chart their career progressions more effectively, emphasizing the benefits of more transparent navigation, especially in environments without well-defined educational pathways.

Through this pioneering work, we aim to contribute to the global conversation on medical education, fostering a more interconnected and accessible educational landscape that benefits educators and students alike.

Acknowledgments

We thank Dr phil-nat. Elke Bayha, Dr rer nat Felix Joachimski, MME, and Dr med vet Melanie Simon, MME, for their critical review and helpful comments on developing the keyword map. We also thank all course providers and survey participants for their collaboration on this project and for so generously answering our questions on course details.

Abstract

Background: Recent advancements in artificial intelligence (AI), particularly in large language models (LLMs), have started a new era of innovation across various fields, with medicine at the forefront of this technological revolution. Many studies indicated that at the current level of development, LLMs can pass different board exams. However, the ability to answer specific subject-related questions requires validation.

Objective: The objective of this study was to conduct a comprehensive analysis comparing the performance of advanced LLM chatbots—Claude (Anthropic), GPT-4 (OpenAI), Gemini (Google), and Copilot (Microsoft)—against the academic results of medical students in the medical biochemistry course.

Methods: We used 200 USMLE (United States Medical Licensing Examination)–style multiple-choice questions (MCQs) selected from the course exam database. They encompassed various complexity levels and were distributed across 23 distinctive topics. The questions with tables and images were not included in the study. The results of 5 successive attempts by Claude 3.5 Sonnet, GPT-4 - 1106, Gemini 1.5 Flash, and Copilot to answer this questionnaire set were evaluated based on accuracy in August 2024. Statistica 13.5.0.17 (TIBCO Software Inc) was used to analyze the data's basic statistics. Considering the binary nature of the data, the chi-square test was used to compare results among the different chatbots, with a statistical significance level of $P<.05$.

Results: On average, the selected chatbots correctly answered 81.1% (SD 12.8%) of the questions, surpassing the students' performance by 8.3% ($P=.02$). In this study, Claude showed the best performance in biochemistry MCQs, correctly answering 92.5% (185/200) of questions, followed by GPT-4 (170/200, 85%), Gemini (157/200, 78.5%), and Copilot (128/200, 64%). The chatbots demonstrated the best results in the following 4 topics: eicosanoids (mean 100%, SD 0%), bioenergetics and electron transport chain (mean 96.4%, SD 7.2%), hexose monophosphate pathway (mean 91.7%, SD 16.7%), and ketone bodies (mean 93.8%, SD 12.5%). The Pearson chi-square test indicated a statistically significant association between the answers of all 4 chatbots ($P<.001$ to $P<.04$).

Conclusions: Our study suggests that different AI models may have unique strengths in specific medical fields, which could be leveraged for targeted support in biochemistry courses. This performance highlights the potential of AI in medical education and assessment.

Introduction

Recent breakthroughs in artificial intelligence (AI), especially in large language models (LLMs), have started a new era of innovation across diverse fields, with medicine leading the charge in this technological revolution. The integration of AI into various medical disciplines such as oncology, radiology, and pathology has demonstrated its advancing clinical uses and its potential to revolutionize health care delivery [1-3]. As new LLMs continue to emerge and evolve, AI is poised to fundamentally reshape our understanding and approach to medicine, offering unprecedented opportunities for improved patient care, diagnostics, and medical education [4].

While academic interest in AI has surged in recent years, integrating AI technologies in educational settings, particularly medicine, has been uneven and fraught with challenges. Among

many AI tools available, ChatGPT has emerged as a potential game-changer in medical education [5,6]. This sophisticated language model, powered by advanced neural networks, demonstrates a remarkable ability to interpret prompts and generate human-like responses, making it difficult to distinguish from human-produced language.

LLM's underlying transformer architecture enables it to excel in natural language understanding, continuously processing and adapting to new information. This adaptability, combined with its vast knowledge base, presents promising opportunities for enhancing teaching and learning methodologies in medical education [7]. AI-powered tools such as ChatGPT may be particularly effective in addressing persistent challenges in student engagement, offering interactive and personalized learning experiences that traditional teaching methods often struggle to provide [8].

OpenAI's GPT-4 and GPT-3.5, Google's Gemini, and Anthropic's Claude have emerged as frontrunners, offering unique capabilities and potential medical education and practice applications. As of 2024, the AI landscape in health care has become increasingly diverse, with over 20 LLMs available for public use. Among them, 4 are the most promising.

Anthropic developed Claude, an AI assistant known for its strong natural language understanding and generation capabilities. It has been trained on a wide range of data and is designed to be helpful, harmless, and honest. Claude has shown particular strength in tasks requiring nuanced understanding and ethical reasoning [9].

Created by OpenAI, GPT-4 is the latest GPT series iteration. It represents a significant advancement over its predecessor, GPT-3, with improved language understanding, generation, and reasoning capabilities. GPT-4 has demonstrated impressive performance across various domains, including coding, creative writing, and analytical tasks [10].

Developed by Google AI, Gemini is a multimodal AI model capable of understanding and generating text, images, and other forms of data. It comes in different sizes and is optimized for various tasks and computational requirements. Gemini has shown strong performance in complex reasoning tasks and can understand context across different modalities [11].

Created by GitHub in collaboration with OpenAI, Copilot is an AI pair programmer designed to assist developers by suggesting code completions and entire functions. It is now an integral part of Microsoft Windows. While primarily focused on coding tasks, Copilot's underlying language model has shown capabilities in understanding and generating natural language [12].

One primary method for assessing the capabilities of LLMs in knowledge-based fields, including medicine, is their performance on multiple-choice tests [13-16]. The release of GPT-4 by OpenAI in 2023 marked a significant milestone, demonstrating impressive test-taking abilities across various domains [17]. Similarly, Claude 2 from Anthropic, released in June 2023, has gained attention for its ability to process larger input spaces (up to 100,000 tokens), potentially allowing for a more comprehensive analysis of medical texts and case studies [8].

The high accuracy demonstrated by ChatGPT-4 in answering multiple-choice questions (MCQs) compared to medical students' performance is particularly noteworthy. It suggests that AI could be an effective study aid, helping students review and reinforce their knowledge across various medical subjects. However, it is essential to view AI as a complementary tool rather than a replacement for MCQs that have transformed from their conventional use as assessment tools to become a versatile educational approach in medical curricula. MCQs stimulate students' cognitive abilities and promote active interaction with study materials. By using advanced generative AI-driven language models to address MCQs in medical physiology and other subjects, educators may provide students with an innovative and engaging learning experience, potentially enhancing their grasp of essential medical concepts, traditional teaching methods, or human expertise [18,19].

Recent studies have begun to compare the performance of different AI models in medical education contexts. For instance, Claude, an LLM developed by Anthropic, has shown promising results in solving medical MCQs. Some studies have indicated that Claude demonstrated a high frequency of right answers and explanations compared to ChatGPT-3.5 [8,20]. These comparative studies are crucial in understanding the strengths and limitations of different AI models in medical education. They help educators and researchers identify the most suitable tools for specific learning objectives and contexts within medical curricula.

Despite the promising results, it is important to note the variability in AI performance across different studies and question types. For example, while some studies reported high accuracy rates for ChatGPT in physiology tests [5,8], others found lower performance rates, particularly as the complexity and difficulty of questions increased [21,22]. This variability underscores the need for careful consideration when integrating AI tools into medical education. Educators must be aware of these tools' strengths and limitations and ensure they are used appropriately to complement, rather than replace, traditional teaching methods.

It is important for educational strategies to prioritize the integration of LLMs into the curriculum as a vital aspect of the learning process. This integration should enable students to cultivate critical thinking and analytical skills, particularly in understanding the constraints of AI. LLMs have the potential to offer students in-depth knowledge and diverse viewpoints, facilitating a more thorough comprehension of intricate medical concepts [23]. By using the output of LLMs and working alongside educators to draw upon their existing knowledge, students can actively participate in the learning process. This collaborative approach allows for the refinement of their understanding and insights. The future of medical education depends on the seamless integration of human expertise with AI-powered tools [3,19,23].

The aim of this study was to conduct a comprehensive analysis comparing the performance of advanced LLM chatbots—GPT-4, Claude, Copilot, and Gemini—against the academic results of

medical students in biochemistry. The research objectives were to evaluate the following hypotheses:

- The AI chatbots will perform similarly to medical students on factual recall and basic concept application questions in biochemistry but may show differences in performance on complex problem-solving scenarios.
- There will be significant variation in performance among the different AI models, with newer models (GPT-4 and Claude) potentially showing higher accuracy compared to earlier versions.
- The AI-driven LLMs' performance will vary across different biochemistry topics, with potentially stronger performance in areas requiring systematic pathway analysis and weaker performance in topics requiring integration of clinical context.

Methods

Study Design

This study focused on a comparative analysis of the capabilities of different AI-driven LLMs in the medical biochemistry course. The research included an examination of 4 chatbots currently available to the public: Claude (Anthropic), GPT-4 (OpenAI), Gemini (Google), and Copilot (Microsoft).

A total of 200 scenario-based MCQs with 4 options and a single correct answer were randomly chosen from the medical biochemistry course's examination database for medical students and validated by 2 independent experts. The study did not include questions with images and tables. The selected questions encompassed various levels of complexity. They were distributed across 23 distinctive categories: structural proteins and associated diseases, globular proteins and hemoglobin, red blood cells (RBCs) and anemia, structure and function of amino acids, structure and function of proteins, bioenergetics and electron transport chain, enzymes, glycolysis and gluconeogenesis, glycogen, signaling mechanisms, pyruvate dehydrogenase and Krebs cycle, cholesterol metabolism, eicosanoids, fatty acid metabolism, fructose and galactose metabolism, hexose monophosphate pathway, ketone bodies, lipoproteins, lysosomal storage diseases, amino acid metabolism, fast and fed state, heme metabolism, and nitrogen metabolism.

Data Collection

For the testing phase, each selected chatbot was required to answer a set of 200 questions, and their performance was evaluated against the responses provided by medical students for the same set of questions. Claude 3.5 Sonnet, GPT-4 - 1106, Gemini 1.5 Flash, and Copilot proficiency in responding to MCQs was assessed in the last 2 weeks of August 2024. An OpenAI paid subscription was obtained to get GPT-4 access.

Each chatbot was given the prompt "generate the list of correct answers for the following MCQs" and provided with a first set of 50 questions; following with the same prompt and 3 more sets of 50 MCQs each, totally there were 200 MCQs in the questionnaire. After that, this procedure was repeated 5 times (no time period between the attempts was assigned). The results of 5 successive attempts by each chatbot to answer this questionnaire set were meticulously recorded in a Microsoft Excel spreadsheet and evaluated based on accuracy. A total of 4000 answers from LLMs were analyzed.

Five random answers were generated and analyzed for the same MCQ set using the RAND() function in Excel (Microsoft 365) to compare chatbot results with random guessing.

Data Analysis

The answers provided by each LLM were recorded and input into the Excel spreadsheet (Microsoft 365). The data from each (1-5) attempt was matched with the answer key and compared with all previous attempts, finding the percentage of repeated and correct answers among them. After that, a detailed item analysis was performed for each chatbot concerning different question categories.

Statistica 13.5.0.17 (TIBCO Software) was used to analyze the data's basic statistics. Considering the data's binary nature, the chi-square test was used to compare results among the different chatbots.

Results

Overview

According to our data, on average, 4 selected chatbots accurately answered 81.1% (SD 12%) of 200 MCQs from the medical biochemistry course. This result was 8.3% (P=.02) above the students' average (mean 72.8%, SD 12.7%) and almost 4 times better than randomly generated responses (mean 22%, SD 2.9%) for the same questions.

There was a significant variation in correct responses among the chatbots. The best result was recorded for Claude (92.5%, SD 0%), followed by GPT-4 (mean 85.1%, SD 1%) and Gemini (mean 78.5%, SD 0%), which were better than the students' average. Copilot showed the lowest result (mean 64%, SD 0%; Figure 1).

Interestingly, all chatbots answered 104 (52%) of the 200 questions correctly in all attempts. General item analysis revealed that eicosanoids, bioenergetics and electron transport chain, hexose monophosphate pathway, and ketone bodies were the 4 best topics, with the mean (SD) results for all chatbots being 100% (0%), 96.4% (7.2%), 91.7% (16.7%), and 93.8% (12.5%), respectively.

In contrast, the lowest results were recorded for globular proteins and hemoglobin (mean 58.4%, SD 26.4%), lipoproteins (mean 64.6%, SD 20.3%), and fructose and galactose metabolism questions (mean 65.8%, SD 29.9%).

After that, each chatbot's results for all 23 topics were evaluated (Figure 2).

Figure 1. Percentile of correct answers from different chatbots and students on 200 multiple-choice questions from the medical biochemistry course.

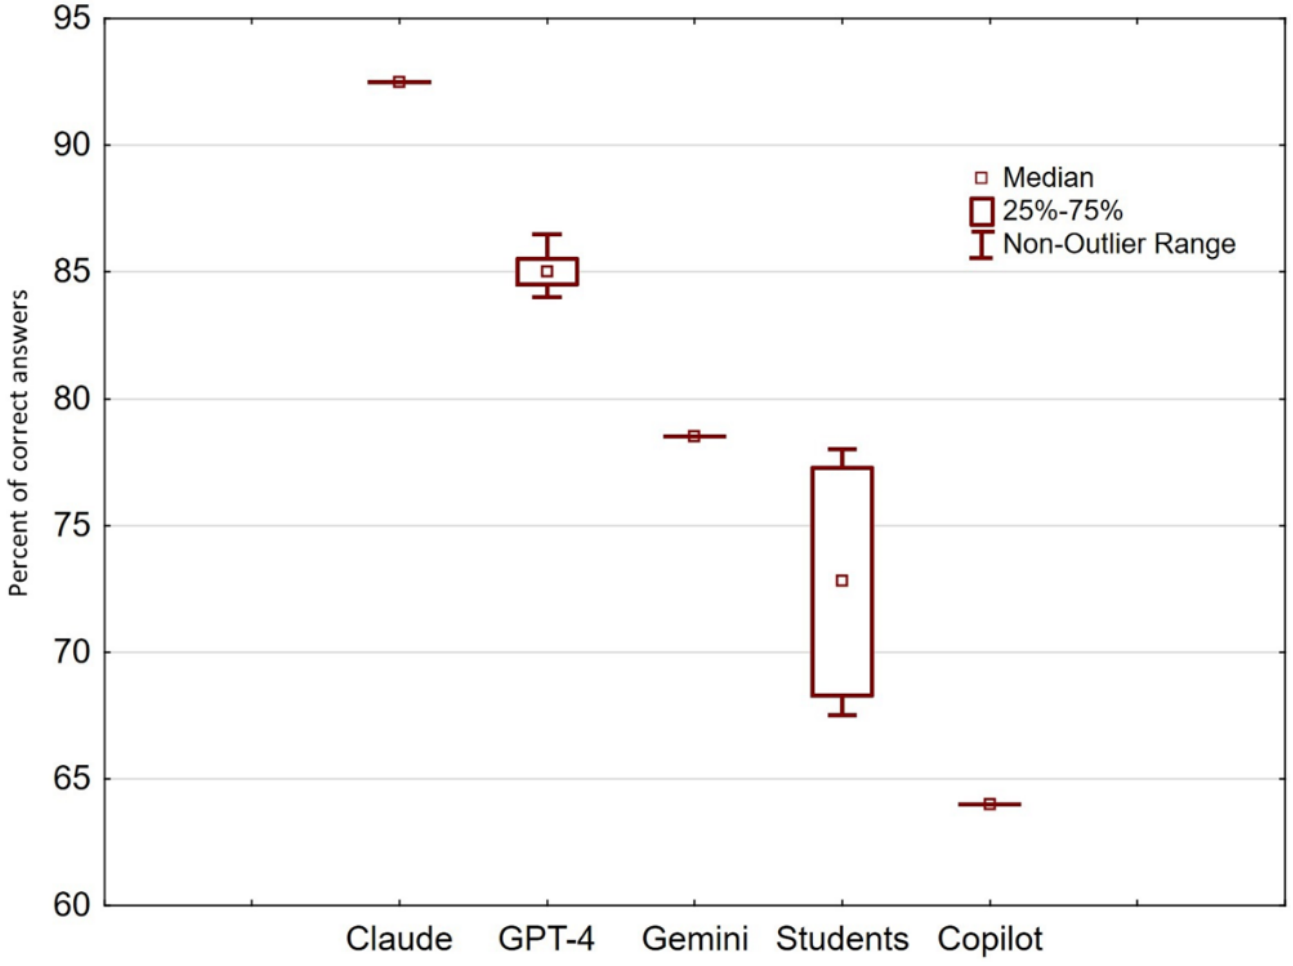

Figure 2. Evaluation of chatbot performance in different topics of the medical biochemistry course. RBC: red blood cell.

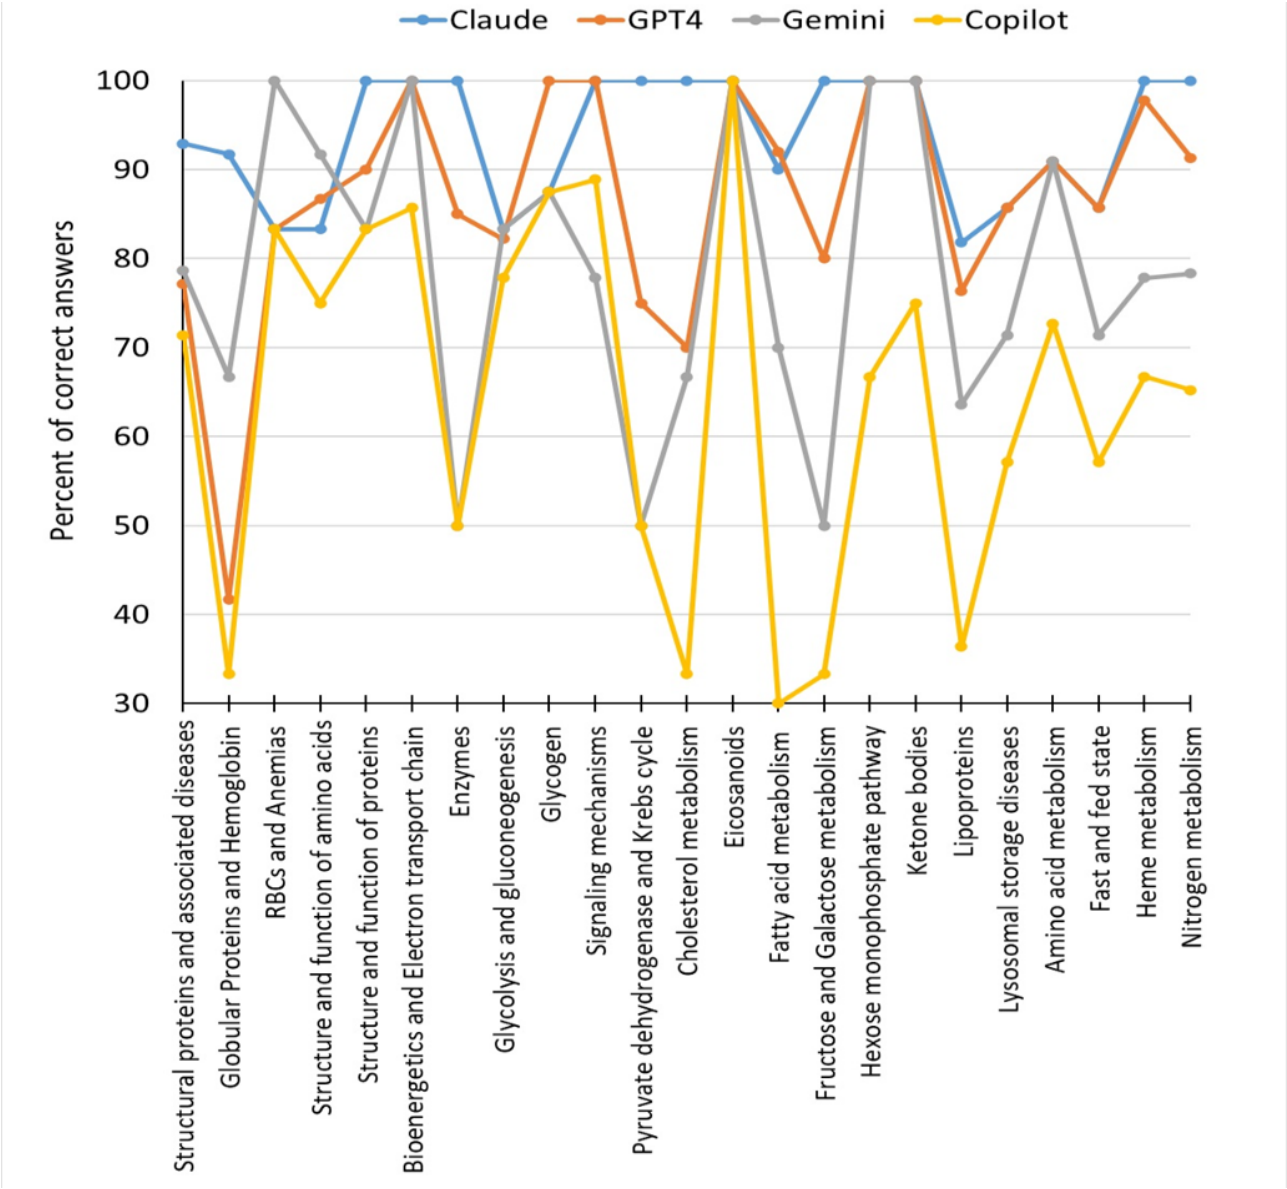

Claude

Claude, offered by Anthropic, provided 92.5% (185/200) correct answers to the set of biochemistry MCQs. The answers in this second and all subsequent attempts were identical to the first. As the chatbot claims, its knowledge base has not changed between attempts, and it applies the same reasoning to answer each question. It was the best result among the 5 chatbots, 19.7% better than the student average and 70.5% superior to random guessing. The item analysis suggested that Claude correctly answered all questions (100%) from the following 12 categories: structure and function of proteins, bioenergetics and electron transport chain, enzymes, signaling mechanisms, pyruvate dehydrogenase and Krebs cycle, cholesterol metabolism, eicosanoids, fructose and galactose metabolism, hexose monophosphate pathway, ketone bodies, heme metabolism, and nitrogen metabolism. The lowest result (81.8%) was recorded for the lipoproteins. For the rest of the topics, the percentile of correct answers was 83.3% - 91.7%.

Claude did not solve 15 (7.5%) out of 200 MCQs from the entire questionnaire set. These were comprehensive questions about RBCs, hemoglobin, enzymes, biotin deficiency, and lipoproteins.

GPT-4

The results of 5 successive ChatGPT-4 (OpenAI) attempts to answer the set of 200 biochemistry MCQs showed 85.1% (SD 1%) correct answers on average. The best result of its 5 attempts was 86.5%, 13.7% better than the average for medical students and 64.5% above random guessing. The fourth attempt was the most successful; the mean results of the other 4 attempts were close to 85% (range 84% - 85.5%). The coincidence generated by GPT-4 answers with the previous attempts was 91.5% - 94.5%, and the coincidence of correct answers among them was in the range 81% - 83.6%.

Of the 200 questions, 158 (79%) were answered correctly across all 5 attempts and considered a solid knowledge area for GPT-4. Most of these MCQs were recall questions, but some were complex and required critical thinking. The item analysis indicated that the best 6 categories with 100% correct answers

were bioenergetics and electron transport chain, glycogen, signaling mechanisms, eicosanoids, hexose monophosphate pathway, and ketone bodies. The lowest result was recorded for globular proteins and hemoglobin questions—only 41.7% of the correct answers. For the rest of the topics, the percentile of correct answers was 77.1% - 97.8%.

GPT-4 did not answer 17 (8.5%) of the 200 MCQs from the entire questionnaire set in any 1 out of all 5 attempts. These were more comprehensive questions about defective proteins, oxygen saturation, anemia, amino acids, glycogen, glycolysis and gluconeogenesis, and lipoproteins.

Gemini

Google recently introduced Gemini as a successor to Bard. The results of 5 attempts by Gemini to answer the set of 200 biochemistry MCQs showed 157 (78.5%) correct answers, 5.7% above the average for medical students and 56.5% above the random answers. Unlike Bard, 5 successive attempts from Gemini were similar; the same answers were received.

The item analysis of these 157 correct answers shows that Gemini did the best (100% accurate) for questions in the following 5 categories: RBCs and anemia, bioenergetics and electron transport chain, eicosanoids, hexose monophosphate pathway, and ketone bodies. Most of these MCQs were recall questions. The lowest 50% results were recorded for the following 3 categories: enzymes, pyruvate dehydrogenase and Krebs cycle, and fructose and galactose metabolism. Gemini's responses in other topics were in the 63.6% - 91.7% interval. Gemini did not answer 43 (21.5%) of the 200 MCQs from the entire questionnaire set, which were comprehensive questions mostly about proteins, enzymes, the Krebs cycle, fatty acids, fructose, and galactose metabolism.

Copilot

Microsoft's Copilot can accept only up to 2000 characters in the prompt, so only 2 to 7 MCQs can be answered at a time, which is inconvenient to work with. The results received on the first try were not different from 4 successive attempts, so there was zero variation among all 5 attempts. Copilot generated 128 (64%) accurate answers for the same set of 200 MCQs from the biochemistry course, 8.8% lower than the average medical student but 42% better than random guessing.

The item analysis of these 126 correct answers indicated that these MCQs were mostly recall questions. The best result was shown for the eicosanoids category (100%), and the lowest was for fatty acid metabolism (only 30% of correct answers). Copilot's responses in other topics vary from 33.3% to 88.9%. Copilot did not answer 72 (36%) of the 200 MCQs from the questionnaire set. These questions concerned proteins, hemoglobin, amino acids, enzymes, fatty acids, pyruvate dehydrogenase, Krebs cycle, and fast and fed state.

Pearson Chi-Square Test Results

Table 1 shows the results of the Pearson chi-square test, which we used due to the binary nature of the data to compare the performance of the different AI-driven chatbots against each other.

The null hypothesis was rejected because the *P* value for all chatbots was less than α (*P*=.05), so there is a statistically significant association between the answers of all 4 chatbots.

Table . Pearson chi-square test results to compare the performance of Claude, GPT-4, Gemini, and Copilot against each other.

Large language models	Chi-square (*df*)	*P* value
Claude × GPT-4	19.7 (1)	<.001
Claude × Gemini	6.1 (1)	.01
Claude × Copilot	4.1 (1)	.04
GPT-4 × Gemini	33.1 (1)	<.001
GPT-4 × Copilot	15.9 (1)	<.001
Gemini × Copilot	23.5 (1)	<.001

Discussion

Principal Findings

Medical education is rapidly evolving, with AI playing an increasingly significant role. In this context, evaluating AI efficacy and relevancy to results is crucial, particularly given the precision and depth of understanding required in medical practice. AI-driven LLMs such as ChatGPT, Claude, Copilot, and Gemini have been compared against medical students in various studies, revealing both the strengths and limitations of AI in medical education. These comparisons show how AI can enhance human learning while also highlighting areas where it may not measure up. Research into AI's role in medical training has uncovered intriguing possibilities and important constraints [1,5,7].

MCQs form a cornerstone of assessment in medical education. Analyzing these questions is vital as it allows educators to assess their effectiveness in testing higher-order thinking and clinical reasoning skills, ensuring that assessments accurately reflect the competencies required for medical practice [18]. While LLMs have demonstrated impressive capabilities in answering queries and simulating scenarios, the depth and breadth of their understanding, particularly concerning MCQs in medical exams, still requires thorough evaluation [19].

The comparative analysis of LLMs and medical students in biochemistry assessment reveals several intriguing patterns that both confirm and challenge our initial hypotheses. While we anticipated comparable performance between AI models and medical students, the results demonstrated that LLMs not only matched but significantly exceeded student performance, with

an 8.3% higher average score (P=.02) across 200 medical biochemistry questions. This finding particularly supports our hypothesis regarding factual recall and concept application, though with a more pronounced advantage for AI systems than initially predicted. The observed variation in performance among different LLM platforms—ranging from Claude's exceptional 92.5% (185/200) accuracy to Copilot's more modest 64% (128/200)—aligns with our hypothesis about performance differences between AI models, suggesting that architectural and training differences significantly impact their capabilities in specialized medical knowledge domains.

Comparison to Literature

Recent studies have shown that LLMs, specifically GPT-4, often outperform medical students on MCQ items in board and licensing exams. This finding underscores the significance of MCQs in medical licensing exams, extensively used in crucial assessments worldwide. Examples include the Peruvian National Licensing Medical Examination, the United States Medical Licensing Examination (USMLE), the United Kingdom Medical Licensing Assessment (UKMLA), and the Australian Medical Council (AMC) Exam [20,24-26]. The widespread use of MCQs is attributed to their effectiveness in evaluating higher-order skills through complex clinical scenarios, analysis, and problem-solving. These questions assess students' ability to integrate information, reflecting real-world challenges and shaping competent professionals. It is well correlated with the results of our study, which have shown that the selected 4 chatbots answered correctly to 81.1% (SD 12%) of the 200 questions from the medical biochemistry course, which is 8.3% above the students' average.

Another comprehensive study compared the results of 4 LLMs across 163 questions from sample NBME (National Board of Medical Examiners) clinical subject exams. The results were striking: GPT-4 achieved a perfect score of 100% (163/163), significantly outperforming GPT-3.5, Claude, and Bard. GPT-3.5 scored 82.2% (134/163), Claude 84.7% (138/163), and Bard 75.5% (123/163). The statistical superiority of GPT-4 was evident, with no significant differences observed among the other 3 models [27]. Interestingly, while GPT-4 excelled across all subject exams, the different models demonstrated variable strengths. GPT-3.5 performed best in family medicine and obstetrics and gynecology, Claude in surgery, and Bard in surgery and neurology. The surgery exam yielded the highest average score across all models, while family medicine had the lowest. GPT-4's exceptional performance may be attributed to its extensive training data, which exceeded 45 terabytes by September 2021, despite not being specifically fine-tuned for medical data [10].

Our data contradict this clinical study and suggest that GPT-4 did well with 85% (170/200) of correct answers but is not currently the most proficient chatbot for biochemistry questions. The best result was recorded for Claude, with an impressive 92.5% (185/200) of the correct answers. Gemini took third place with 78.5% (157/200) of correct answers, which is still above the student's average of 72.8% (SD 5.2%) for the same questions. The lowest result was recorded for Copilot (128/200, 64%).

These findings highlight the potential of LLMs in medical education and practice. Their ability to tackle complex medical questions opens doors to innovative clinical decision support, research, and education applications. However, it is worth noting that GPT-4, the only LLM in this study not available for free, could be less accessible to a broad range of students, potentially limiting its widespread use in educational settings.

Several studies have evaluated ChatGPT's performance in biochemistry. One study examined GPT-3.5's potential as a self-study adjunct for medical students in biochemistry, using 200 questions. ChatGPT provided correct answers to 58% (116/200) of the biochemistry questions. While this performance allowed it to pass the university's medical biochemistry exam, the study suggests there is room for improvement in GPT-3.5 as a comprehensive and reliable self-learning tool [28].

Another study focused on ChatGPT's ability to address higher-order questions in medical biochemistry. Using GPT-3.5, researchers conducted a web-based cross-sectional study presenting 200 randomly selected, complex reasoning questions from an institutional question bank, classified according to CBME (Competency-Based Medical Education) curriculum modules. Two expert biochemistry academicians evaluated responses on a 0 - 5 scale. The AI achieved a median score of 4 (IQR 3.5-4.5), which was comparable to a hypothetical value of 4 (P=.16) but significantly lower than the maximum of 5 (P=.001). These results suggest that GPT-3.5 shows promise as an effective tool for addressing complex questions in medical biochemistry, demonstrating its potential in handling higher-order thinking tasks in this field [29].

Our research confirms that GPT-4 has significant improvements and is superior to GPT-3.5. Our data suggest that GPT-4 responded correctly to 84% - 86.5% of MCQs, and 79% answered correctly across all 5 attempts.

Implications of Findings

The implications of AI's performance in medical education extend beyond mere test-taking abilities. LLMs can answer complex medical questions that raise important questions about the future of medical education and topics in which LLMs demonstrate proficiency, so they may be used to assist students. The detailed analysis of MCQs in our study revealed that questions from 4 topics are well answered by all chatbots: eicosanoids, bioenergetics, electron transport chain, and ketone bodies. In contrast, the lowest results were recorded for globular proteins and hemoglobin, lipoproteins, and fructose and galactose metabolism questions. However, there was a significant difference in the 4 LLMs performances. Claude showed the most impressive results and answered all questions (100%) from 12 categories: structure and function of proteins, bioenergetics and electron transport chain, enzymes, signaling mechanisms, pyruvate dehydrogenase and Krebs cycle, cholesterol metabolism, eicosanoids, fructose and galactose metabolism, hexose monophosphate pathway, ketone bodies, heme, and nitrogen metabolism.

In conclusion, the rapid advancements in AI technology, particularly in medical education, present opportunities and challenges. While LLMs have shown impressive capabilities

in answering medical exam questions, it is crucial to remember that medical education encompasses more than just knowledge acquisition. Clinical skills, empathy, ethical decision-making, and the ability to navigate complex health care systems are all integral parts of medical training that current AI models may not fully capture.

As we progress, we must continuously evaluate AI's role in medical education, ensuring that it complements rather than replaces human expertise. Our findings also have important implications for assessment strategies in medical education. The ability of LLMs to surf the net and do better than medical students on MCQ-based evaluation is an assault on the traditional ways of measuring medical performance and calls for a better understanding of how medical knowledge and skills should be assessed. While such results provide ideas on how to develop a curriculum and manage educational resources, they also highlight the need to ensure that the value of AI in measuring certain aspects of medical training, such as clinical reasoning, interaction with patients, and even decision-making ethics, is always respected. This underscores the need for medical education to continue emphasizing the development of comprehensive clinical skills beyond what can be measured through standardized testing.

Future Directions

Future research in this field should pursue several key routes to better understand and implement AI technologies in medical education. Long-term studies are needed to evaluate the impact of LLM integration on student learning outcomes, particularly focusing on how AI-assisted learning affects knowledge retention, clinical reasoning development, and overall academic performance. These studies should incorporate diverse assessment methods beyond MCQs, including case-based scenarios, open-ended questions, and practical clinical applications of biochemistry knowledge across different medical disciplines to understand whether the observed performance patterns are consistent.

Strengths and Limitations

This study represents one of the first comprehensive comparisons between multiple leading LLMs and medical students in the specific context of medical biochemistry education. The large sample size of 200 questions provided a robust dataset for analysis, covering a broad spectrum of biochemistry topics typically encountered in medical education. The inclusion of multiple LLM platforms (GPT-4, Claude, Copilot, and Gemini) allowed for a nuanced comparison of AI capabilities across different models, providing valuable insights into their relative strengths and potential applications in medical education.

Several limitations should be considered when interpreting these results. This study's findings on different chatbot proficiencies are limited to MCQs from the biochemistry course, which may not represent other medical questions or contexts. In addition, the sample size of 200 questions, excluding questions with images or tables, may not capture the full range of difficulty levels or content areas.

LLMs receive regular updates, which result from training on inputs and tuning so that they may provide different answers depending on the testing date. Another limitation is that GPT-4, which performed well, is not freely available, potentially limiting its applicability in widespread educational settings.

Conclusions

LLMs such as ChatGPT, Claude, Copilot, and Gemini have impressive capabilities in answering MCQs, often outperforming medical students. In this study, the selected chatbots outperformed students' results. These findings highlight the potential of AI in medical education and assessment. Different LLMs exhibit varying strengths in different topics of medical biochemistry courses. In this study, Claude showed the best performance, followed by GPT-4, Gemini, and Copilot. This variability suggests that different AI models may have unique strengths in specific medical fields, which could be leveraged for targeted educational support. The strong performance of LLMs in answering complex medical questions raises important considerations for the future of medical education. While AI demonstrates proficiency in knowledge-based assessments, it is crucial to remember that medical training encompasses more than just information recall. Clinical reasoning, empathy, ethical decision-making, and navigating health care systems remain essential components that current AI models may need to capture fully.

Abstract

Background: Despite the high prevalence of mental health problems among medical students and physicians, help-seeking remains low. Digital mental health approaches offer beneficial opportunities to increase well-being, for example, via mobile apps.

Objective: This study aimed to assess the acceptance, and its underlying predictors, of tailored e–mental health apps among medical students by focusing on stress management and the promotion of personal skills.

Methods: From November 2022 to July 2023, a cross-sectional study was conducted with 245 medical students at the University of Duisburg-Essen, Germany. Sociodemographic, mental health, and eHealth-related data were assessed. The Unified Theory of Acceptance and Use of Technology (UTAUT) was applied. Differences in acceptance were examined and a multiple hierarchical regression analysis was conducted.

Results: The general acceptance of tailored e–mental health apps among medical students was high (mean 3.72, SD 0.92). Students with a job besides medical school reported higher acceptance ($t_{107.3}$=–2.16; P=.03; P_{adj}=.027; Cohen d=4.13) as well as students with higher loads of anxiety symptoms ($t_{92.4}$=2.36; P=.02; P_{adj}=.03; Cohen d=0.35). The t values were estimated using a 2-tailed t test. Regression analysis revealed that acceptance was significantly predicted by anxiety symptoms (β=.11; P=.045), depressive symptoms (β=–.11; P=.05), internet anxiety (β=–.12; P=.01), digital overload (β=.1; P=.03), and the 3 UTAUT core predictors—performance expectancy (β=.24; P<.001), effort expectancy (β=.26; P<.001), and social influence (β=.43; P<.001).

Conclusions: The high acceptance of e–mental health apps among medical students and its predictors lay a valuable basis for the development and implementation of tailored e–mental health apps within medical education to foster their mental health. More research using validated measures is needed to replicate our findings and to further investigate medical students' specific needs and demands regarding the framework of tailored e–mental health apps.

KEYWORDS

eHealth; medical education; medical students; tailored interventions; UTAUT; intention to use; e–mental health apps; app; foster; cross-sectional study; mental health problems; physician; well-being; mobile apps; acceptance; assessment; mental health apps

Introduction

Background

Medical students have a heightened incidence of mental health problems, namely anxiety [1,2] and depression [3-5], and are confronted with stressful situations throughout their careers [6,7]. Elevated levels of depression and anxiety among medical students and physicians exert considerable influence on personal well-being and patient safety [8], emphasizing the urgent need for targeted preventive and support programs [7,9-11]. The necessity for assessable and easily accessible interventions to foster mental health and well-being is of utmost importance in the medical student population [12,13].

In recent years, the surge in the significance of digitalization within health care and medical education has been noteworthy [14-16]. This trend has been particularly pronounced during the COVID-19 pandemic and persists afterward [17]. A report disseminated by a German health insurance entity in 2023

scrutinized students' health, with a specific focus on postpandemic developments and the pivotal role of digital education and instruction [18]. The report underscored the critical importance of stress prevention and mental health initiatives [18]. Digital mental health approaches present promising avenues for surmounting barriers and enhancing the use of mental health support, for example, through mobile apps [13,19,20].

Analyzing factors influencing the acceptance of a mobile app is essential, and further research on actual uptake, adoption, and adherence is needed [21-26]. Incorporating future users directly into the development process is crucial for optimizing the adherence of new technologies and should be focused within research [27,28].

Few studies have delved into e–mental health promotion and the prevention of psychological distress among medical students and have shown that uptake of mental health support remains low due to barriers such as mental health stigma or data safety [6,29-31]. To date and to the best of our knowledge, no study has examined the acceptance of tailored e–mental health apps among medical students using a validated model. For this reason, the Unified Theory of Acceptance and Use of Technology (UTAUT) was applied in this study to lay the foundation for the development of an application especially tailored to the students' needs and demands to foster mental health by focusing on stress management and promotion of personal skills at University Duisburg-Essen. The UTAUT evaluates the acceptance of technological systems consisting of 4 primary predictors—performance expectancy (PE), effort expectancy (EE), social influence (SI), and facilitating conditions (FC)—and has been adjusted to investigate the acceptance of eHealth interventions along with their underlying factors [23-25]. Numerous studies have used the UTAUT framework in the context of eHealth interventions among different samples [32-35].

Objectives

Due to the evident progression of digitalization and its concomitant potential to enhance mental health while simultaneously acknowledging the existing impediments to leveraging these opportunities, this study is specifically oriented toward investigating the acceptance of tailored e–mental health apps and their foundational predictors among medical students, using the validated UTAUT model as the analytical framework.

While prior research has underscored the significance of promoting mental health among medical students [7,9,12,31], limited attention has been given to evaluate e–mental health approaches focusing on the promotion and the prevention of psychological distress among medical students using validated measures, such as the UTAUT model, and tailored approaches [28,36,37].

This study will address the following research questions: (1) What is the extent of acceptance of e–mental health apps among medical students? (2) Are there differences in acceptance among medical students based on sociodemographic and mental health data? (3) What factors predict acceptance among medical students?

Methods

Study Design and Participants

A cross-sectional study was conducted to assess acceptance and to analyze drivers and barriers of tailored e–mental health apps among medical students. The study was presented to medical students in the 5th year at the Medical Faculty of University Duisburg-Essen, North-Rhine-Westphalia, Germany, during the course of psychosomatic medicine. Following the course, students were given the opportunity to participate voluntarily. The participants of the study were recruited from November 2022 to July 2023. Of the 305 students attending the course, 245 (80.3%) students gave their informed consent to participate in the study. Of the 245 participants, 16 (6.5%) participants were eliminated from the sample because of missing data. In total, 229 (93.5%) students were included in the final data analysis. We applied no inclusion or exclusion criteria. Medical students were invited to participate in the study through direct contact in the context of psychosomatic medicine courses. All participants were aged 18 years or above.

Ethical Considerations

The study was conducted in accordance with the Declaration of Helsinki and has been approved by the ethics committee of the Medical Faculty of the University of Duisburg-Essen (21 - 10196-BO). Participation was anonymous, voluntary, and without any compensation. Prior to the start of the questionnaire, written informed consent was obtained and the students received background information on the purpose of the study.

Assessment Instruments

The survey consisted of a paper-pencil questionnaire with self-developed items. Additionally, validated scales were used. The measures encompassed sociodemographic, eHealth-related, and mental health data. The primary outcome was the acceptance of an e–mental health app by using the conceptual framework of the UTAUT model's theory.

Sociodemographic Data

Sociodemographic data contained age, gender, marital status, employment besides medical school (occupational status), and working hours per week (0 - 5, 5 - 10, 10 - 15, and >15 hours).

Mental Health Data

To obtain mental health data, the validated PHQ-4 (Patient Health Questionnaire-4) measure consisting of two 2-item measures—PHQ-2 (symptoms of depression, Patient Health Questionnaire-2) and GAD-2 (symptoms of general anxiety disorder, Generalized Anxiety Disorder-2)—were used [38,39]. Answers were given on a 4-point Likert scale (0="never" to 3="nearly every day"). A cutoff score of 3 or more is described to be an indicator of depression (PHQ-2) [38] or general anxiety (GAD-2) [40]. Internal consistencies measured by the Cronbach α were sufficient with α=0.82 (95% CI 0.76 - 0.87) for GAD-2 and α=0.81 (95% CI 0.73 - 0.86) for PHQ-2. Self-generated questions were used to assess life quality (0="very low" to 10="very good"), mental health (0="very low" to 10="very good"), physical health (0="very low" to 10="very good"), and

importance of promoting mental well-being (0="not important" to 10="very important") on numerical rating scales.

eHealth-Related Data

eHealth-related data were assessed by measuring digital overload, internet anxiety, and digital competence. Internet anxiety and digital overload were both measured on a 5-point Likert scale (1="strongly disagree" to 5="strongly agree"). Internal consistency measured by the Cronbach α was low to sufficient with α=0.68 (95% CI 0.6 - 0.75) for the digital overload scale and sufficient with α=0.81 (95% CI 0.72 - 0.87) for the internet anxiety scale. These scales were previously published and established [34,35,41,42]. Digital competence was measured with a numerical rating scale (0="low" to 10="high").

Acceptance and UTAUT Predictors

To assess medical students' acceptance of using tailored e–mental health apps, a modified UTAUT questionnaire [24] was applied. The adapted UTAUT model consisted of 14 items and measured items on a 5-point Likert scale (1="strongly disagree" to 5="strongly agree"). Acceptance, operationalized as behavioral intention (BI) to use technology, is forecasted by PE, EE, and SI [25]. PE reflects the individual's belief in the benefits they will derive from using the technology. EE signifies the perceived ease of use. SI gauges the extent to which an individual believes that their relatives or friends would endorse the use of the technology. Four items were used to assess BI and PE. Acceptance, operationalized as BI, represented the dependent variable. Two predictors of acceptance—EE and SI—were measured with 3 items each. Internal consistency (Cronbach α) was excellent for BI (α=0.91, 95% CI 0.89 - 0.93) and PE (α=0.92, 95% CI 0.89 - 0.94), sufficient for SI (α=0.83, 95% CI 0.77 - 0.87), and low to sufficient for EE (α=.67, 95% CI 0.57 - 0.75).

Statistical Analysis

For data and statistical analysis, SPSS Statistics version 26 (IBM Corp) and R through RStudio version 4.3.1 (The R Foundation for Statistical Computing; Posit Software) were used. The raw data were collected from the survey, extracted, and processed. Relevant assumptions and prerequisites were tested prior to any statistical test [43-46]. The level of significance was set at α=0.05 for all tests. To minimize α error inflation for multiple comparisons Bonferroni correction was used and *P* values were adjusted. Sum scores (PHQ-4 scale, PHQ-2 scale, and GAD-2 scale) and mean scores (internet anxiety and digital overload) were computed. Mean scores for the UTAUT model were computed: BI, PE, EE, and SI. Consistent with previous research, acceptance scores, operationalized as BI, were categorized as "low acceptance" from 1 to 2.34, "moderate acceptance" from 2.35 to 3.67, and "high acceptance" from 3.68 to 5 [33,41,47]. Descriptive statistics (percentage and absolute count, mean scores, distributions, and standard deviations) of scales, items, and acceptance categories were performed. Additionally, explorative data analysis was conducted. Internal consistencies such as the Cronbach α and item-total correlation were calculated for scales. The normal distribution of the dependent variable (acceptance) was tested graphically and by the Kolmogorov-Smirnov test. Although violations against normal distribution were detected, parametric tests could be used according to the central limit theorem (n>30) and the robustness of the *t* test and Welch-ANOVA against normal distribution violations [44]. Means of acceptance were compared between groups using the *t* test (occupational status, PHQ-2, and GAD-2) and Welch-ANOVA (gender and marital status). The predictive model of acceptance was tested using multiple hierarchical regression analyses. The following predictors were included stepwise: sociodemographic data, mental health data (PHQ-2 and GAD-2), eHealth-related data, and the UTAUT core predictors (EE, SI, and PE). Linearity could be assumed and was analyzed using a scatter plot of the residuals against fitted values. Multicollinearity was not detected because all values of the variance inflation factor were <5. The normality of residuals could be assumed due to the central limit theorem. Homoscedasticity was proven and analyzed using a scatter plot of the standardized residuals and adjusted predicted values. According to Cohen *d*, effect sizes were reported and interpreted as small (0.2), medium (0.5), and large (0.8) [48].

Results

Study Population

In this sample, participants' age ranged from 20 to 37 years (mean 25.05, SD 2.82 years). Medical students experienced low digital overload (mean 2.85, SD 0.92) and low internet anxiety (mean 1.72, SD 0.79). Digital competence was high among medical students (mean 6.97, SD 1.72; range 0 - 10). For detailed characteristics, see Table 1.

Table . Sociodemographic and mental health data of participants (n=229).

Variable		N (%)	Mean (SD)	Acceptance, n (%)

[a]Low acceptance, with scores ranging from 1 to 2.34.

[b]Moderate acceptance, with scores ranging from 2.35 to 3.67.

[c]High acceptance, with scores ranging from 3.68 to 5.

[d]Not applicable.

[e]Higher scores indicate higher levels of mental health, physical health, life quality, or importance of promoting mental well-being (range 0 - 10).

[f]PHQ-2: Patient Health Questionnaire-2.

[g]GAD-2: Generalized Anxiety Disorder-2.

Acceptance of Tailored e–Mental Health Apps

The general acceptance of tailored e–mental health apps among medical students was high (mean 3.72, SD 0.92). Dividing the acceptance categories from low to high, 62% (142/229) participants showed high acceptance (mean 4.31, SD 0.45), 28.4% (65/229) showed moderate acceptance (mean 3.11, SD 0.28), and 9.6% (22/229) showed low acceptance (mean 1.76, SD 0.42).

Between groups, significant differences in acceptance were identified between occupational status ($t_{107.3}$=–2.16; P=.03; P_{adj}=.03; Cohen d=4.13) and GAD-2 groups ($t_{92.4}$=2.36; P=.02; P_{adj}=.03; Cohen d=0.35) using a 2-tailed t test. Students with a job besides medical school reported higher acceptance of tailored e–mental health apps than students without a job. Medical students with high GAD-2 levels (high load of anxiety symptoms) showed higher acceptance than students with low GAD-2 levels (low load of anxiety symptoms). No significant

differences between acceptance were found regarding PHQ-2 groups (low and high), gender (female, male, and divers), and marital status via ANOVA and *t* test (P_{adj}>.5).

Hierarchical Linear Regression Analysis and Predictors of Acceptance

A hierarchical linear regression analysis was conducted to evaluate predictors of acceptance among medical students regarding tailored e–mental health apps.

Sociodemographic data were included in the first step, explaining 3.6% of the variance in acceptance (R^2=0.036; R^2_{adj}=0.022; $F_{3,222}$=2.72; *P*=.045). Occupational status emerged as a significant positive predictor (β=.31; *P*=.03).

In the second step, mental health data were added to the analysis, increasing the explained variance to 6.4% (R^2=0.064; R^2_{adj}=0.042; $F_{5,220}$=2.99; *P*=.01). GAD-2 was identified as a significant predictor (β=.12; *P*=.03) of acceptance.

In the third step, eHealth-related data were added to the model, which further explained 8.2% of the variance in acceptance (R^2=0.082; R^2_{adj}=0.048; $F_{8,217}$=2.14; *P*=.02).

In the fourth and final step, the UTAUT predictors (EE, PE, and SI) were added (overall model), resulting in a comprehensive model that explained 65.8% of the variance in acceptance (R^2=0.658; R^2_{adj}=0.647; $F_{11,214}$=37.47; *P*<.001). The following variables (UTAUT core predictors) showed a significant positive prediction: UTAUT PE (β=.22, *P*<.001), UTAUT EE (β=.32, *P*<.001), and UTAUT SI (β=.44; *P*<.001).

To sum up, within the overall model, the UTAUT predictors, PHQ-2 and GAD-2 sum scores, internet anxiety, and digital overload were associated with the acceptance of tailored e–mental health apps among medical students. For a detailed overview of the hierarchical regression model of acceptance, see Table 2.

Table . Hierarchical regression model of acceptance (the extended Unified Theory of Acceptance and Use of Technology model; n=226).

Discussion

Principal Findings

This study focused on examining the acceptance of tailored e–mental health apps and the factors influencing their use to promote medical students' mental health.

The general acceptance was high. Students with a job besides medical school reported higher acceptance as well as students with higher loads of anxiety symptoms. Acceptance was significantly predicted by occupational status, anxiety symptoms, depressive symptoms, internet anxiety, digital overload, and the 3 UTAUT core predictors—PE, EE, and SI.

The participants in this sample reported higher overall acceptance compared to previous research involving different target groups [23,33,42]. A qualitative study conducted by Dederichs et al [12] corroborates our findings, elucidating universally positive perspectives among medical students regarding internet- and mobile-based interventions. Preceding investigations have posited that augmented levels of educational attainment are concomitant with elevated acceptance scores [32,49], concurrently accentuating the advantages of e–mental health methodologies, including their low-threshold nature, temporal flexibility, and provision of anonymous support [12].

Among our cohort, self-rated promotion of mental well-being was highly valued, indicating general interest in mental health promotion as an important prerequisite and determinant of increasing acceptance.

The UTAUT core predictors elucidated the majority of the variance in acceptance, substantiating the model's efficacy in appraising e–mental health acceptance among medical students

and aligning with antecedent research [25,33,42]. Despite prior investigations indicating age [25,32,42] and gender [25,49] as salient determinants influencing acceptance within heterogeneous populations, these variables did not achieve statistical significance in this study. This lack of significance may be attributed to the existence of comparable stress factors affecting all participants uniformly.

A notable proportion, 12.2% (28/229), displayed indicators suggestive of depressive symptoms (PHQ-2), while 22.3% (51/229) exhibited symptoms indicative of a general anxiety disorder (GAD-2). These findings are consistent with extant research documenting the psychological vulnerability of medical students, illustrating elevated levels of anxiety and depression [1,6,50]. This underscores the imperative for psychological support interventions [2,3,10]. Our analysis revealed that mental health data concerning anxiety symptoms positively predicted acceptance within our model, aligning with prior research [51]. In contrast to that, depressive symptoms were associated with lower acceptance within our model. The acceptability may be decreased among students with higher depressive symptoms due to fear of additional loads. Furthermore, barriers, such as mental health stigma or data safety, were described as known challenges within previous research focusing on help-seeking behavior [30,36]. Additional information and educative programs or interventions may have beneficial effects to increase help-seeking and decrease stigma [29,52-55], but their impact needs to be investigated further.

Students concurrently managing part-time employment and medical school responsibilities demonstrated higher acceptance scores. Research specifically focusing on the mental health of working medical students is scarce [9,56]. Based on the findings, we would suggest that the additional load due to a part-time job results in higher acceptance levels of mental health support programs but this needs to be investigated further.

A study by Joiner et al [57] found that individuals born after 1993 exhibited lower internet anxiety and higher internet identification, reinforcing our findings. In our sample, most of the participants were born in the 1990s and 2000s. Internet anxiety and digital overload were observed at low levels and significant predictors of acceptance in the overall regression model. Aligning with previous research [23], high levels of internet anxiety were associated with decreased acceptance.

Digital competence was high within our sample. High internet identification and regular use of digital media might have influenced digital competence within our sample. Information on digital skills [58], preventive strategies, and digitalization need to be integrated further within medical education [15].

While acceptance and potential usage constitute crucial prerequisites for the implementation of digital approaches [23,59], it is imperative to acknowledge additional factors, including barriers and risks associated with the promotion of such approaches. Notably, skepticism and a lack of knowledge regarding e–mental health apps among medical students underscore the necessity for augmented information dissemination and increased personal experience with digital health approaches [22,36]. Attention must be directed toward addressing stigma and concerns related to data security [30,36]. Comprehensive assessments of additional barriers influencing actual usage and dropout rates are warranted in the implementation of e–mental health approaches [19,60].

The outcomes of this study establish a foundational framework for subsequent research endeavors and the implementation of e–mental health apps within the realm of medical education. The imperative for further implementation and rigorous evaluation of digital interventions for medical students is underscored.

Limitations

This study has limitations that should be considered when interpreting the presented results. It should be noted that studies assessing medical students' acceptance with validated instruments are still scarce and comparability is limited. The cross-sectional design does not allow causal inferences. Overall, overrepresentation may diminish representativeness, generalizability, and external validity, which is a common bias in research. In the context of a tailored design approach, additional stakeholders should be integrated into future studies [61]. The intention-behavior gap should be considered, as our study assessed theoretical willingness rather than actual usage. Within this study, the Cronbach α, a conservative measure assessing reliability, was used, and it should be noted that the Cronbach α of the EE scale and digital overload scale were lower compared to those observed in previous studies [33,35,41,42]. One possible explanation may be inconsistent response patterns; therefore, the interpretation should be done with caution. According to previous studies [21-28], adherence, actual usage, and dropout rates of e–mental health approaches should be investigated further. While the 3 fundamental predictors of the UTAUT model—EE, PE, and SI—remain crucial, additional factors should be focused on to comprehensively grasp and optimize acceptance levels further.

Conclusions

In this investigation, the focus was on evaluating the acceptance of tailored e–mental health apps and its influencing factors in promoting medical students' mental health. The overall acceptance was found to be high, with students having part-time jobs alongside medical school and students with elevated anxiety levels reporting even higher levels of acceptance. Besides the 3 UTAUT core predictors (PE, EE, and SI), additional significant predictors influence acceptance among medical students including occupational status, anxiety symptoms, depressive symptoms, internet anxiety, and digital overload. As digitalization transforms the medical sector, integrating supportive digital tools into medical education requires a focus on promoting a healthy learning environment and well-being among future physicians. Preventive strategies, including addressing barriers like stigma, are crucial. This study contributes valuable insights in order to develop and implement a digital application to foster medical students' mental health focusing on stress management and promotion of personal skills at Medical University Duisburg-Essen, Germany.

Abstract

Background: Improved long-term learning retention leads to higher exam scores and overall course grades, which is crucial for success in preclinical coursework in any podiatric medicine curriculum. Audiovisual mnemonics, in conjunction with text-based materials and an interactive user interface, have been shown to increase memory retention and higher order thinking.

Objective: This pilot study aims to evaluate the effectiveness of integrating web-based multimedia learning resources for improving student engagement and increasing learning retention.

Methods: A quasi-experimental study was conducted with 2 cohorts totaling 158 second-year podiatric medical students. The treatment group had access to Picmonic's audiovisual resources, while the control group followed traditional instruction methods. Exam scores, final course grades, and user interactions with Picmonic were analyzed. Logistic regression and correlation analyses were conducted to examine the relationships between Picmonic access, performance outcomes, and student engagement.

Results: The treatment group (n=91) had significantly higher average exam scores (P<.001) and final course grades (P<.001) than the control group (n=67). Effect size for the average final grades (d=0.96) indicated the practical significance of these differences. Logistic regression analysis revealed a positive association between Picmonic access with an odds ratio of 2.72 with a 95% confidence interval, indicating that it is positively associated with the likelihood of achieving high final grades. Correlation analysis revealed a positive relationship (r=0.25, P=.02) between the number of in-video questions answered and students' final grades. Survey responses reflected increased student engagement, comprehension, and higher user satisfaction (3.71 out of 5 average rating) with the multimedia-based resources compared to traditional instructional resources.

Conclusions: This pilot study underscores the positive impact of animation-supported web-based instruction on preclinical medical education. The treatment group, equipped with Picmonic, exhibited improved learning outcomes, enhanced engagement, and high satisfaction. These results contribute to the discourse on innovative educational methods and highlight the potential of multimedia-based learning resources to enrich medical curricula. Despite certain limitations, this research suggests that animation-supported audiovisual instruction offers a valuable avenue for enhancing student learning experiences in medical education.

KEYWORDS

learning retention; preclinical education; podiatric medical education; audiovisual learning resources; multimedia-based learning resource; animation-supported learning tools; mnemonics; spaced repetition

Introduction

Long-term retention is crucial for higher exam scores and overall course grades in preclinical coursework. A recent examination of popular board preparatory resources has provided insight into the different trends that students have experienced in their self-directed learning [1]. Incorporating digital resources appeared to be as effective, if not more so, than regular text-based learning [2]. With greater interest shown in digital learning, curiosity has arisen regarding students' sentimental value of animation-styled instruction. One study has shown students' fondness for learning increased with animation instruction as an exciting new way to learn, further increasing permanent learning [3].

Various methods of increasing learning efficiency in medical education have been explored, such as digital recordings, visual mnemonics, and flashcard systems. Many students find the aforementioned methods to be an excellent supplement to the

usual textbook-based learning, resulting in higher test scores, particularly within the medical field [4-7]. Enhanced use of digital teaching tools is effective in providing students with basic science information and has shown to be useful in improving their preparation for clerkship [8].

Mnemonics are a commonly used memory technique in medical school. A mnemonic links to well-known knowledge, sometimes invoking humor or emotions [9]. Web-based learning positively impacts information retention and learning efficiency [10,11]. Audiovisual (AV) mnemonics, in conjunction with text-based materials and an interactive user interface, have been shown to increase memory retention and higher order thinking [12,13].

Picmonic [14], a web-based AV learning resource, uses immersive videos, clinical case questions, flashcards, and high-yield notes, as well as picture mnemonics to cover various aspects of the preclinical and clinical practice curriculum [15-17]. A study by Yang et al [12] observed improved student performance in free-recall and paired-matching tests when using Picmonic. Another study by Abdalla et al [13] underscores how important memory and knowledge retention are to a medical student's grades. Adding AV modalities increases a student's ability to remember information over an extended period of time. Students who had undergone AV sessions had higher marks on response answer questions, shorter time spent answering questions, and a higher memory consolidation after specific time benchmarks. Further studies of using mnemonics, particularly food eponyms in pathology-related education, have shown relevance in learning and retaining pathology knowledge in addition to being useful for United States Medical Licensing Examination boards preparation, clinical clerkship preparation, and future practice [18].

Other studies have examined the usefulness of incorporating AV instructional tools in various levels of education [19-21], including medical education [1,12,22,23], and found them helpful for improving student engagement and learning experiences [12,22,23]. However, there seems to be a dearth of studies exploring the usage of multimedia web-based learning resources in podiatric medical education. Our goal is to evaluate how integrating a multimedia web-based learning resource affects student engagement and learning retention in a preclinical course. Though there are many online learning resources available for medical students to bolster their learning, we selected the commercially available web-based platform Picmonic due to the shorter length of the videos. Since this resource was integrated into the course in the form of low-stakes assignments with the purpose of serving as a supplementary resource, in addition to the textbook and the instructor-provided materials, it was important to ensure that the videos did not take up too much time.

This pilot study aims to offer insight into the use of tools like Picmonic that uses AV media and mnemonics to supplement traditional learning resources in podiatric medical education. To achieve this goal, we have tried to determine in second-year students in a podiatric medicine program (P) if students who have access to Picmonic, an interactive video-based learning system with mnemonics as an additional supplementary resource (I), show higher course performance and experience better learning retention and engagement with the learning material (O), compared to those with access to textbooks and other instructor-provided course materials only (C), when enrolled in a preclinical infectious disease course in their third semester (T). Course performance and knowledge retention were determined by comparing average final exam scores between a treatment group that had access to Picmonic in addition to textbooks and other instructor-provided material and a control group that relied only on the same textbooks and instructor provided materials. Students' perception of the usefulness of this platform as a learning resource and engagement with course materials were assessed using a survey instrument and analysis of correlation between the number of in-video questions answered, the number of times the video was watched, and the accuracy of video-embedded quiz attempts.

Methods

Study Design

A sample of 158 second-year podiatric medical students enrolled in the Infectious Disease course in the third semester at New York College of Podiatric Medicine (NYCPM) were observed in 2 consecutive cohorts. The cohorts consisted of a control group of 67 students taking the course in 2021 and a treatment group of 91 students taking the course in 2022. Participants in the treatment group used the multimedia web-based learning tool Picmonic as a learning resource, while participants in the control group did not. All students were given the same didactic instruction, textbooks, and other traditional learning resources. The study was conducted as a posttest-only, nonequivalent group, quasi-experimental design [24,25]. Although sample selection was nonrandom, it is assumed that the 2 sample groups are similar in their baseline characteristics as they were both in the same curricular level within the program at the time of taking the course. In addition, the initial knowledge and skill level of the students in the 2 cohorts were determined to be equivalent based on their average cumulative grade point average (GPA) data from the earlier semesters in the program and the average incoming Medical College Admission Test (MCAT) scores and undergraduate GPA. Both cohorts started the course and third semester with similar average standardized test scores, similar mean incoming cumulative GPAs, and were given similar course content and assessments. Other confounders like educator quality and digitalization were addressed by using the same instructors and learning management system for the delivery of course content to both cohorts. There were also no changes made in course instruction, course content, syllabus, grading, or objectives between the 2 cohorts. It was also ensured that contextual confounders such as new academic initiatives or changes in course leadership, program objectives, and fallout from the pandemic did not occur during the period of the study.

In the treatment group, students were given 5% participation credit, which was awarded on the completion of the video-based assignments. A customized playlist of assigned videos (aligned to the lecture topics) curated from the Picmonic video database was created by the instructors to be watched by the students on their own time and answer the embedded quiz questions shown in Multimedia Appendix 1. Each set of assigned videos and

quizzes had to be completed before the scheduled in-class lecture on that topic to get credit. Data on the number and frequency of videos watched, multiple attempts at answering video-embedded questions, and quiz accuracy was recorded and monitored using the instructor's dashboard provided to faculty in the Picmonic platform.

Similarly, in the control group, a 5% participation grade was awarded for active participation in the live discussions held during class time based on prior review of the posted instructional materials and assigned readings from the course textbook to be completed before lecture sessions. The contribution of all other course assessments was weighed identically in both control and treatment cohorts. The instructors, textbooks, lectures, instructor-provided materials, and exams used were kept the same between the 2 cohorts.

Exam scores for the treatment group were collected as posttest observations over the course of the semester. The control group underwent comparable nontreated observations [15,16]. Feedback about user experience was gathered from students enrolled in the treatment group at the end of the course through an electronic web-based semi-structured survey questionnaire modified from Haleem et al [17] consisting of 7 required questions included in the survey instrument as shown in Multimedia Appendix 2. NYCPM's Institutional Review Board (IRB) granted ethical approval for this study. The students enrolled in the treatment group were sent the survey link, which the student participants voluntarily filled out. The responses to the 7 questions listed under 4 items in the survey instrument were collected, then analyzed and reported as detailed in the Checklist for Reporting Results of Internet E-Surveys (CHERRIES) adapted from [26] and included as Multimedia Appendix 3. Standard strategies appropriate for this type of quasi-experimental study design, consisting of nonrandomized sampling and posttest-only nonequivalent groups, were used for analysis of the data collected [24,25,27].

Data Analysis

Statistical analysis, data processing, and model fitting were performed in Jupyter Notebook, MATLAB, and Excel. Descriptive statistics, including mean, standard deviation, minimum, maximum, and quartile ranges, were calculated for both the treatment and control group's exam scores and final grade. Boxplots and histograms display score distributions, central tendency, spread, and outliers. Statistical analysis encompassed Levene tests, Welch *t* tests, and the calculation of Cohen *d* as the effect size [28].

Logistic regression analysis enables us to explore the association between access to Picmonic and receiving a score of 90% or higher through a logistic regression model built using Python's Statsmodels library for statistical analysis [29]. To fit the model, we used access to Picmonic as a binary predictor (1=access, 0=no access) to predict whether a student achieved a final grade of 90% or higher in the course (1=final grade ≥0.9; 0=final grade <0.9). We obtained the odds ratio from the model by exponentiating the coefficient for the independent variable with the base of the natural logarithm [30]. The log-likelihood ratio was used to evaluate if access to the resource is a relevant predictor of high final grades.

Correlation analysis was performed to determine the strength of the relationship between usage metrics—number of questions answered, videos played, and quiz accuracy —and students' final grades [30]. We calculated Pearson *r* using a dataset of user interactions with the assigned videos and embedded quizzes on the platform [31].

Survey analysis was conducted using user experience data gathered from students enrolled in the treatment group at the end of the course through an electronic web-based questionnaire sent out by email. Students first answered 4 questions about Picmonic, focusing on information retention, concept understanding, higher test scores, and its usefulness as a learning supplement. Next, students were asked to answer 3 questions regarding their level of satisfaction, frequency of use, and favorite features of the platform—as shown in the Student Experience Survey Instrument in Multimedia Appendix 1. Researchers manually categorized answers to questions regarding their favorite features in Excel. Accordingly, summary statistics were calculated and compared using the data collected from student survey responses.

Ethical Considerations

This study was approved by NYCPM's IRB (23575) in May 2022. Informed consent was waived off by the IRB since students agree to the use of unidentifiable education data for research purposes at registration.

As per institutional policy, the IRB approval for this study is a blanket approval provided for all curriculum-related studies, which are undertaken at the college using deidentified aggregate course data rather than individual scores. The original consent or blanket IRB approval covers secondary analysis without additional consent since all incoming new students are required to sign a consent form agreeing to the use of unidentifiable course and education-related data for research purposes at the beginning and is applicable throughout their enrollment in the program.

All students enrolled in the courses that were included in this study were informed about the research and were made aware that the deidentified aggregate course performance data and their feedback would be used to gather data for this pilot study. This information was also reiterated when they were given the survey instruments to record their feedback which was optional for them to fill out.

All data used in this study are course-level aggregate data calculated from score-related data that are anonymized or deidentified.

No compensation was provided for participation in the research study as the courses used are required as part of the podiatric medical curriculum. The students were made aware their feedback would be collected in the form of responses to a survey questionnaire which was optional to complete. Transparency and fairness were ensured by clarifying that the survey instrument was not mandatory and without any consequences for participants who opted out of responding to the questions included in the survey.

Results

Statistical Analysis

The difference in distribution of exam scores and final grades among the treatment and control groups was visualized using bar graphs (Figure 1A), and box plots (Figure 1B). The summary statistics (Table 1) show the central tendencies using mean exam scores and mean final grade, the spread of the scores using standard deviation, and the shape of the score distributions within each group (Figure 1B), which were used to identify potential differences between the groups. The treatment group had significantly higher average exam scores for most of the course exams and had higher final grades compared to the control group (Figure 1A). The difference in the average scores of the first 2 exams (P<.001), the third exam (P=.04), and the final course grades (grand total) (P<.001) between the 2 groups with and without access to Picmonic was significant. There were also significant differences in variance for exam 1, exam 2, exam 3, and the final grade between the treatment and control groups (Table 2).

Figure 1. Comparison of student performance in course assessment between treatment group (T) and control group (C) based on (**a**) scaled mean test scores and final course grades from treatment group (having access to Picmonic or AV instruction) and control group (without access to Picmonic or audiovisual instruction) and (**b**) score distributions within each group.

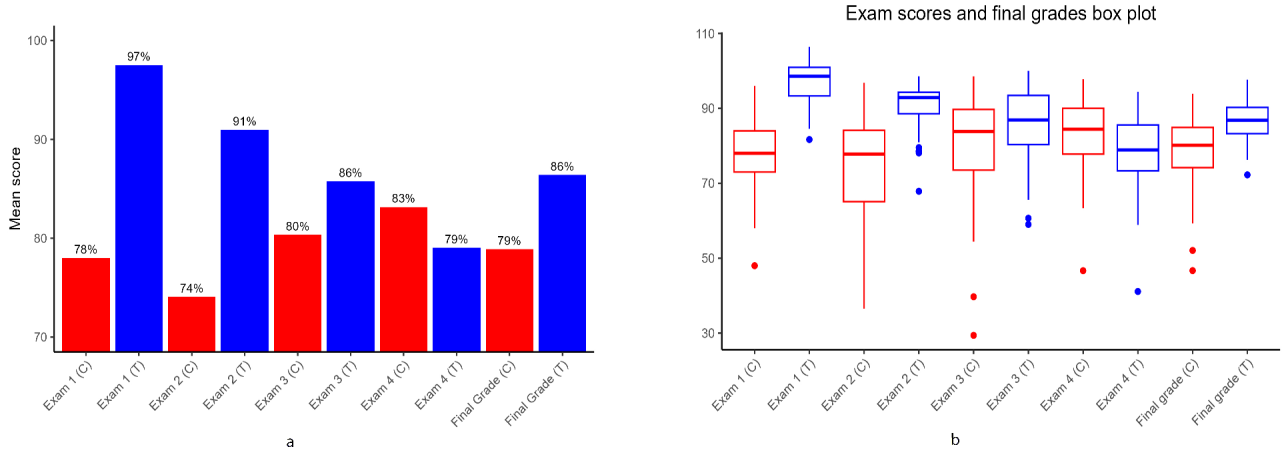

Table . Statistical analysis of student performance in course assessments for treatment and control groups.

Exam	Control, mean (SD)	Treatment, mean (SD)	Mean difference	Welch t test P value	Pooled SD	Cohen d
Exam 1	0.780 (0.098)	0.975 (0.052)	0.195	<.001	0.075	2.398
Exam 2	0.741 (0.143)	0.910 (0.052)	0.169	<.001	0.101	1.486
Exam 3	0.803 (0.133)	0.858 (0.089)	0.054	.005	0.110	0.463
Exam 4	0.832 (0.091)	0.790 (0.092)	−0.041	.006	0.092	−0.449
Final grade	0.789 (0.094)	0.864 (0.049)	0.075	<.001	0.072	0.957

Table . Analysis of variance of exam scores and final grades between treatment and control groups.

Assessment	Levene test statistic	P value	
Exam 1	19.442	<.001[a]	Significant compared to control
Exam 2	52.632	<.001[b]	Significant
Exam 3	4.354	.04	Significant
Exam 4	0.127	.72	Not significant
Final grade	14.652	<.001[c]	Significant

[a](1.92×10^{-5})
[b](1.77×10^{-11})
[c](1.87×10^{-4})

Levene test statistic values for potential differences in variance of exam scores and final grades between the 2 groups revealed significant differences in variance for exam 1, exam 2, exam 3, and the final grade (Table 2). The results of Welch t test used to compare the average final exam scores and final grades indicated statistically significant differences between the 2 groups' first 3 exams and final grades for the course (P<.01) (Table 1). Cohen d values calculated to quantify the observed

differences between the treatment and control groups across all exams and the final grade revealed a large effect size for exam 1 (d=2.397), exam 2 (d=1.486), and the final grade (d=0.957) (Table 1).

Logistic Regression

A logistic regression analysis between access to Picmonic and the likelihood of achieving a high final course grade of 90 out of 100 (90%) or above resulted in an odds ratio which indicates that, assuming all other factors are constant, students in our study with access to Picmonic were 2.72 times more likely to have received a final grade of 90% or higher and a letter grade of A in the course. The log-likelihood ratio P value is .02 (P<.05); therefore, we reject the null hypothesis that the base model with only the intercept is better than the model with access to Picmonic used as the predictor (Table 3).

Table . Regression analysis of the association between access to Picmonic and receiving a high final grade.

Predictor	Coefficient	SE	z value	P value[a]	Lower CI	Upper CI
Intercept	−1.998	0.377	−5.303	<.001	−2.737	−1.260
Picmonic access	0.971	0.446	2.180	.03	0.098	1.845

[a]Model log-likelihood ratio P value =.02.

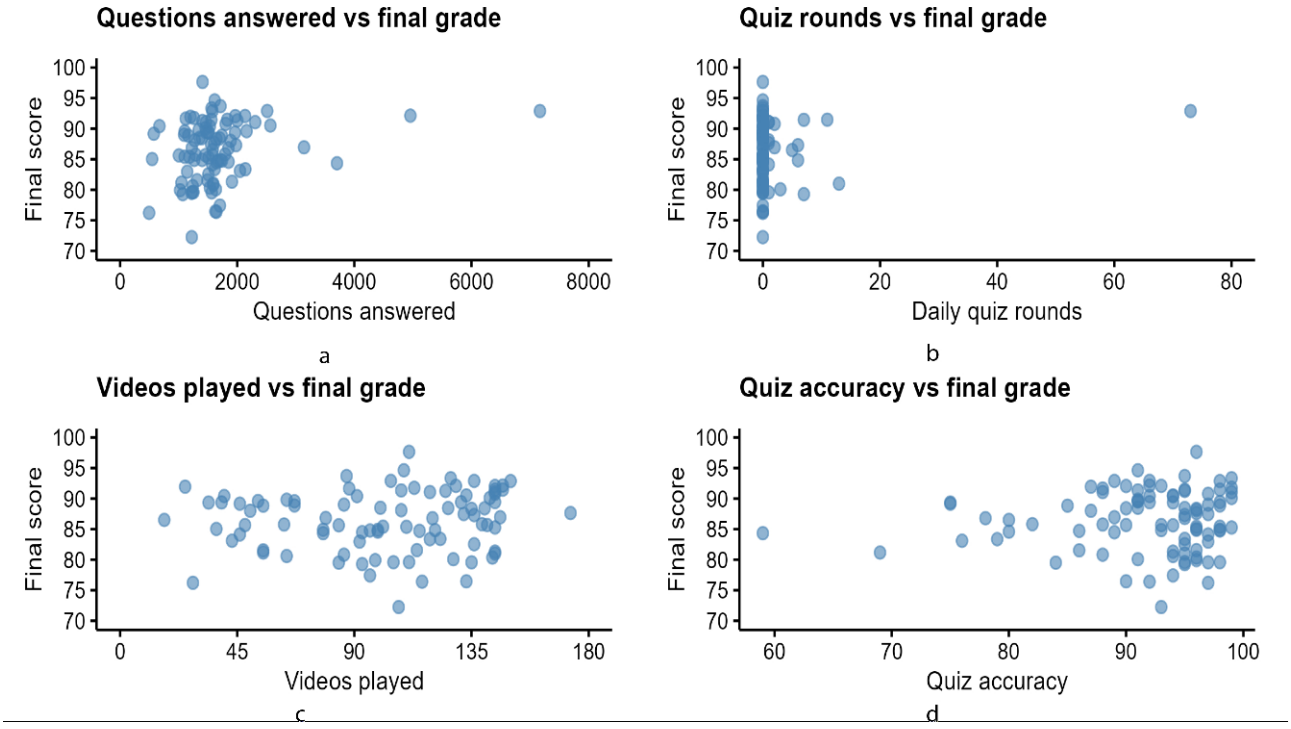
Correlation Analysis

Pearson correlation coefficient calculated to explore the relationship between final course grade and various usage statistics (number of videos played, questions answered, and quiz accuracy) show that students in the treatment group who answered more questions on the platform tended to get a higher final score (r=0.25, P=.02) (Table 4 and Figure 2).

Table . Analysis of correlation between final grades and platform usage metrics.

Final grade with:	Pearson r	P value
Questions answered	0.247965674	.02
Daily quiz rounds	0.124515676	.24
Videos played	0.09980258	.35
Quiz accuracy	0.074970912	.48

Figure 2. Correlation analysis between final course grades and (**a**) the number of in-video questions answered, (**b**) number of daily quiz round attempts, (**c**) number of times videos watched, and (**d**) overall accuracy of embedded quizzes.



Survey Analysis

The response rate for item 1 of the survey instrument, which consisted of 4 questions about the students' perceived usefulness of Picmonic, was 73% (66 out of 91). In this item, students indicated strong agreement regarding Picmonic's positive impact on information retention, concept understanding, higher test scores, and usefulness as a supplementary learning tool (Figure 3A). In item number 4, students also reported an average satisfaction rating of 3.71 out of 5 (Figure 3B). Out of 53 students who responded to item number 2 in the survey questionnaire, 36 accessed Picmonic at least once a week—predominantly 1‐2 times per week (Figure 3C). In item number 3, 50 out of 91 students responded to the open-ended questions regarding user experience or preferences about their favorite feature of Picmonic with some choosing more than 1 feature. The number of times each feature was reported as preferred is listed and compared in Table 5. Noteworthy features of Picmonic highlighted by students included videos, quizzes and questions, mnemonics, and content (Table 5).

Figure 3. Analysis of student experience feedback data. Student experience survey insights and summary of qualitative open-ended student feedback data showing (**a**) perceived effectiveness of Picmonic on various learning outcomes and retention, (**b**) user satisfaction level, and (**c**) frequency of use.

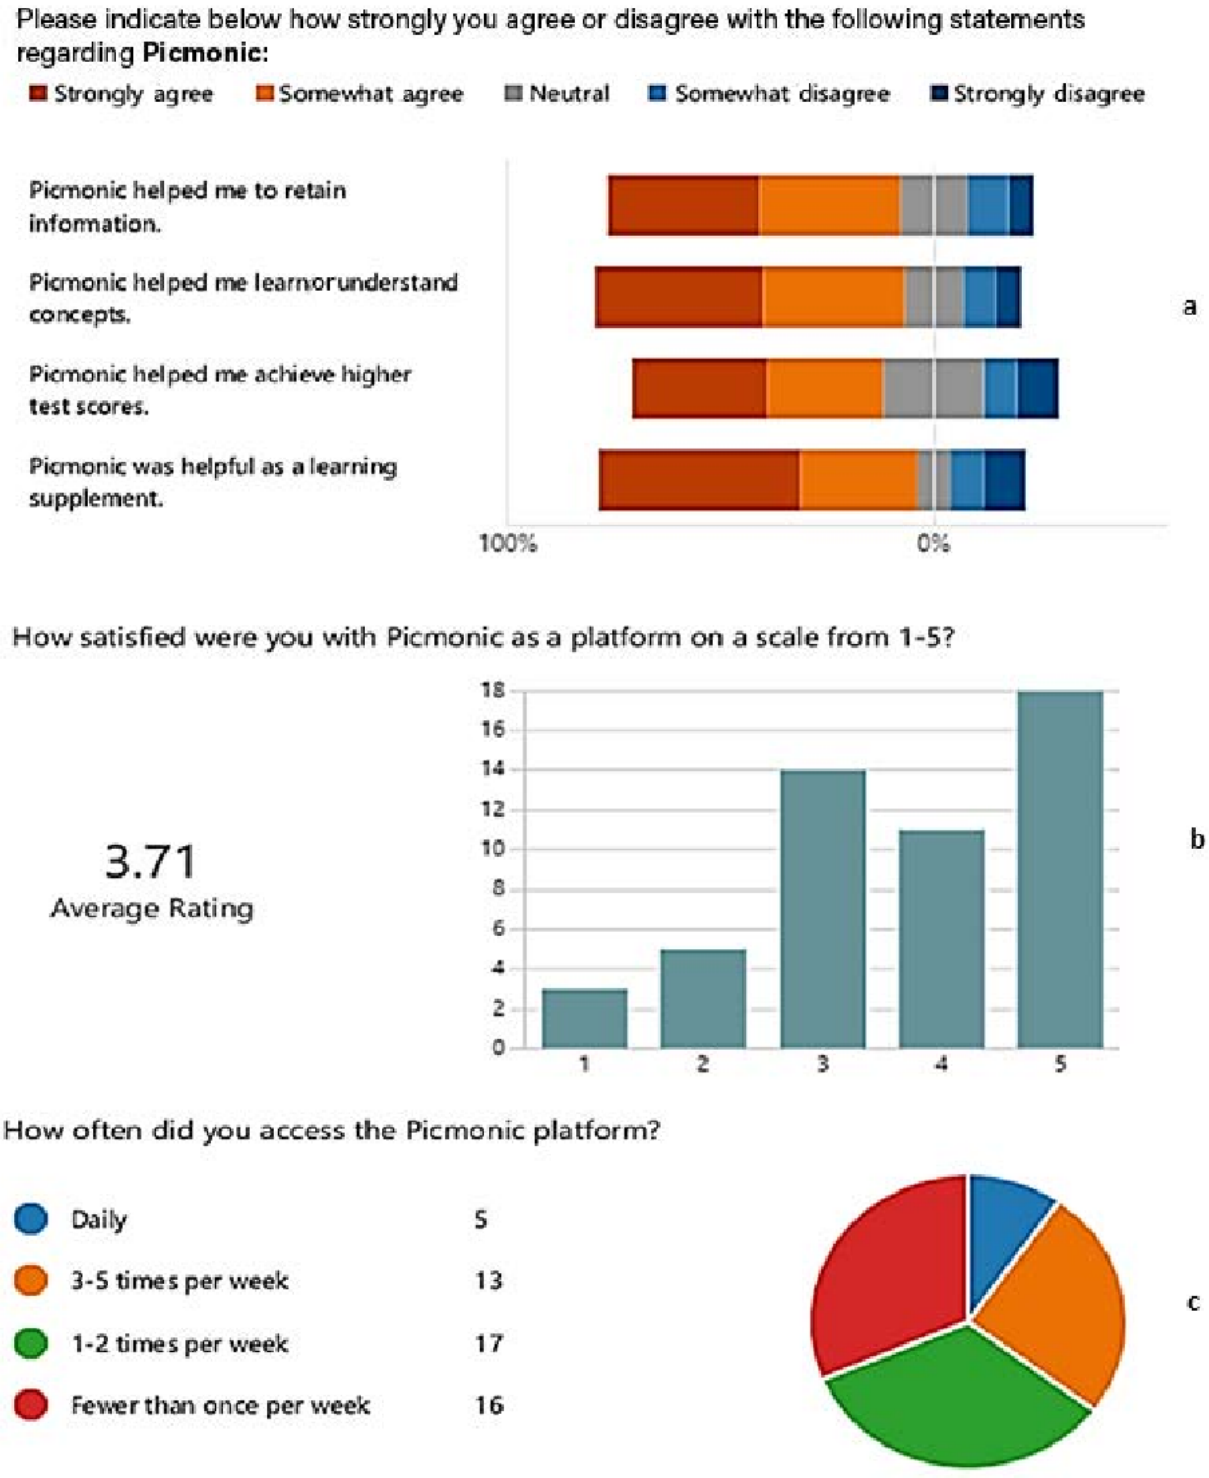


Table . Comparative analysis of student feedback performed on open-ended questions regarding user experience or preferences.

	Feedback (N=50), n (%)
Videos	15 (30)
Quizzes and questions	9 (18)
Mnemonics	9 (18)
Content	9 (18)
Images	6 (12)
User interface	4 (8)
General	2 (4)

Discussion

Principal Findings

In our study, we observed that students with access to the multimedia and mnemonic-based AV learning resource scored higher on most exams, had higher final grades, and were more likely to receive a final grade of 90% or higher. The resulting effect sizes for the treatment group are large enough to be meaningful in the real world; however, other factors may have contributed to the observed effect size. Students in the treatment group who answered more questions on the platform tended to get a higher final score. Most students used Picmonic at least once a week to learn the course content. The lower response rate on this item asking about the frequency of accessing Picmonic in a week could be due to the inability of participants to remember their frequency of access at the time of completing the survey several weeks after the completion of the course and semester. Students had positive opinions regarding Picmonic's platform user experience and its effectiveness in helping them retain information, learn and understand concepts, and achieve higher test scores. In this course, the students reported the videos to be their most preferred feature, followed by mnemonics and self-assessment quiz questions associated with the videos, which allowed them to test their knowledge both during and after watching the assigned videos on their own time with unlimited attempts. In this context, it is important to note that though students generally prefer to watch videos on their own rather than attending class, the 2 groups were treated equally since both the reading assignments (for the control group) and the Picmonic-based video assignments (for the treatment group) were assigned to be completed outside of class on their own time. Additionally, the students in the treatment group were assigned to watch the videos and complete the video-embedded quizzes within a specific time frame to mimic the reading assignments given to the control group. To receive the 5% participation grade, the treatment group had to complete the Picmonic video assignments within the instructor-provided deadline corresponding to the weekly topical schedule, which is similar to that of the control group, rather than watching the assigned videos at their own pace throughout the semester.

Comparison With Previous Research

Our experimental results indicate that students with access to the multimedia-based AV mnemonic learning resource scored higher on most exams, had higher final grades, and were more likely to receive a final grade of 90% or higher. The difference between the grades achieved by the 2 groups is large enough to be meaningful in the real world. These findings are consistent with previous studies that have demonstrated the effectiveness of AV mnemonics and web-based learning tools in enhancing memory retention and learning outcomes in medical education [12,16].

Yang et al [12] observed improved student performance in free-recall and paired-matching tests when using an earlier version of the multimedia-based learning platform that we have used here that was released almost 10 years ago, while the current version that we have used has newer, redesigned, more impactful, and shorter videos, though still based on the same type of picture mnemonics and principles of spaced repetition and visual learning. The currently available version that was used in this study also has improved dashboard features and assessment capabilities compared to the older version. Abdalla et al [13] also found that students who had undergone AV sessions had higher marks on response answer questions, shorter time spent answering questions, and higher memory consolidation after specific time benchmarks. These studies underscore the importance of memory and knowledge retention in medical students' academic performance.

Results examining user interaction with the resource showed that the more questions a student answered on a multimedia-based AV learning platform (like Picmonic) using spaced repetition and mnemonics, the higher their grade tended to be. This finding aligns with research highlighting the benefits of interactive user interfaces and spaced repetition in increasing memory retention and higher order thinking [12].

Survey responses indicated that students found the resource useful for learning concepts, retaining information, and achieving higher test scores. This is consistent with previous research demonstrating increased student engagement, comprehension, and satisfaction with multimedia-based resources compared to traditional instructional methods [15,18-20]. Studies by Tackett et al [23] examined student engagement with commercially produced medical education videos incorporated into a preclinical course and also found the videos to be helpful for student learning and improved students' experiences.

Overall, our findings contribute to the growing body of evidence supporting the integration of multimedia-based learning resources and AV mnemonics in medical education curricula

to enhance student learning experiences and outcomes [7,8,12,16,17].

Limitations

While this investigation showed promising initial findings, we recognize that the study design limits its ability to make unequivocal causal inferences about the impact of the multimedia tool alone on the outcomes. The sample size is relatively small, and the lack of randomization in the study design may limit the generalizability of the findings. The quasi-experimental design with nonrandom assignment to treatment and control groups restricts the establishment of a cause-and-effect relationship [24], which could potentially affect the internal validity of the study and its ability to accurately infer whether the change in outcomes was caused by the intervention. Without randomized selection of the 2 groups, we cannot rule out potential unmeasured differences due to systematic differences in sample selection [23]. The study only examined the effect of the implementation of the intervention in 1 preclinical infectious disease course, limiting assessment of the tool's effectiveness. Additionally, the 5% participation credit component was implemented differently for the control (class participation) versus treatment (video watching) groups, which could impact effort levels.

The 2 most likely influential unmeasured confounding variables in our study are potential differences in the overall academic aptitude of the students in each sample [13], as well as potential differences in the amount of time spent with study materials between the 2 groups due to the spaced repetition provided in the Picmonic platform, which could impact the results. The potential difference in student aptitude between the 2 groups should be somewhat mitigated by the fact that both groups were 2nd-year medical students at the same college when being tested. Additionally, the 2 groups had similar average standardized test scores and mean incoming GPAs at the beginning of the semester. The absence of pretest observations comparing the treatment group to the control group makes it difficult to know whether any differences between the 2 groups could potentially be attributed to pre-existing factors rather than the multimedia learning tool alone [14].

Since this study was done on a very limited number of students and involved only 1 course focused on the topic of preclinical medical microbiology and infectious diseases, this effect may not be generalized for all topics or types of courses. This course is heavily dependent on memorization and recall due to the nature of the topics covered, which may also contribute to the impact of the integration of visual learning with mnemonics and spaced repetition and therefore may not be equally applicable in another course that does not require extensive memorization.

Conclusions

Our study shows strong agreement amongst students that Picmonic helped them achieve key learning outcomes. Usage data revealed a positive relationship between final grades and students' usage of platform features; the number of in-video questions answered had a stronger correlation than the number of times videos were watched or the accuracy of topic-associated quiz attempts. Students that were given access to Picmonic did better on exams; however, it must be noted that due to the nonrandomized sampling process, posttest-only study design, limited implementation, and small sample size, it is difficult to conclude whether the difference was due solely to the integration of the new tool. The improved course grades and test scores in the treatment group may have been due to the inherent confounding factors like comprehension and retention skills or increased contact time with the course topics provided by the platform features. Our pilot study focused on the integration of Picmonic, a multimedia-based learning resource, in only 1 course, but implementing it across more courses over multiple semesters would strengthen the assessment of the tool's effectiveness. Despite its limitations, this study provides insight into the potential benefits of integrating multimedia learning resources in podiatric medical education. However, a larger study that implements this type of learning resource on a larger scale, and in more preclinical and clinical courses throughout the curriculum, is needed to further analyze its effectiveness in the podiatric medical curriculum.

Acknowledgments

This work originated at New York College of Podiatric Medicine; the authors express their deep gratitude for the support received. The authors of this paper would like to thank Rhonda Altonen, MLS, MS (Director of Library Services, Sheldon L. Sirota Memorial Library, Touro College of Osteopathic Medicine and College of Pharmacy, Touro University) for her insights about the specific features of Picmonic, the multimedia-based learning resource used in this study, as well Adrian Rice, Associate Registrar, New York College of Osteopathic Medicine, for providing summarized cumulative grade point average data of the control and treatment cohorts. The authors of this paper would also like to thank Picmonic for providing additional data on usage of platform features for further analysis which provided detailed insights.

Abstract

Background: OpenAI released versions ChatGPT-3.5 and GPT-4 between 2022 and 2023. GPT-3.5 has demonstrated proficiency in various examinations, particularly the United States Medical Licensing Examination. However, GPT-4 has more advanced capabilities.

Objective: This study aims to examine the efficacy of GPT-3.5 and GPT-4 within the Taiwan National Pharmacist Licensing Examination and to ascertain their utility and potential application in clinical pharmacy and education.

Methods: The pharmacist examination in Taiwan consists of 2 stages: basic subjects and clinical subjects. In this study, exam questions were manually fed into the GPT-3.5 and GPT-4 models, and their responses were recorded; graphic-based questions were excluded. This study encompassed three steps: (1) determining the answering accuracy of GPT-3.5 and GPT-4, (2) categorizing question types and observing differences in model performance across these categories, and (3) comparing model performance on calculation and situational questions. Microsoft Excel and R software were used for statistical analyses.

Results: GPT-4 achieved an accuracy rate of 72.9%, overshadowing GPT-3.5, which achieved 59.1% (P<.001). In the basic subjects category, GPT-4 significantly outperformed GPT-3.5 (73.4% vs 53.2%; P<.001). However, in clinical subjects, only minor differences in accuracy were observed. Specifically, GPT-4 outperformed GPT-3.5 in the calculation and situational questions.

Conclusions: This study demonstrates that GPT-4 outperforms GPT-3.5 in the Taiwan National Pharmacist Licensing Examination, particularly in basic subjects. While GPT-4 shows potential for use in clinical practice and pharmacy education, its limitations warrant caution. Future research should focus on refining prompts, improving model stability, integrating medical databases, and designing questions that better assess student competence and minimize guessing.

Introduction

Background

With the advent of the artificial intelligence (AI) era, applications of AI in the medical field have increased with ChatGPT (OpenAI) being the most notable examples. ChatGPT is a large language model based on a generative pretrained transformer developed by OpenAI. ChatGPT-3.5 (GPT-3.5) was the first publicly accessible version, while ChatGPT-4 (GPT-4) was the subscription version. GPT-4 surpasses GPT-3.5 in advanced reasoning, almost nearing human-level performance in professional and academic examinations [1,2]. For instance, GPT-4 ranked in the top 10% of scores on a law examination, whereas GPT-3.5 ranked in the bottom 10% [3]. Additionally, GPT-3.5 resolved 90% of false-belief tasks, achieving the level of a 7-year-old child, whereas GPT-4 resolved 95% of these tasks [4]. Following its launch, ChatGPT has been extensively studied and discussed in both the medical and educational fields [5]. The most widely recognized performance of GPT-3.5 has been on the United States Medical Licensing Examination (USMLE) [6,7]; however, GPT-3.5's performance did not meet expectations in other examinations [8-11]. Gradually, Nori et al [12]observed that the accuracy of GPT-4 was higher than that of the GPT-3.5 on the USMLE, and further studies confirmed that GPT-4 outperforms GPT-3.5 [13-16]. However, there has been limited research on its performance in pharmacy examinations.

In the field of pharmacy, GPT-3.5 has exhibited commendable performance in clinical toxicology and pharmacology [17,18], although it has not passed the National Pharmacist Licensing Examination (NPLE) in Taiwan [19]. However, GPT-4 has outperformed GPT-3.5 in drug information [20] and China's Pharmacist Licensing Examination [21]. Generative AI models, a large language model, has been applied in drug development and novel drug design [22-24], pharmacovigilance [25,26], pharmacokinetic model development [27], pharmacy education, and research writing [28,29].

Goal of the Study

According to previous studies, GPT-3.5 failed to pass the NPLE, indicating its limitations in pharmacy education. Based on these findings, we hypothesized that GPT-4 would outperform GPT-3.5 in this context, demonstrating greater proficiency. To test this hypothesis, this study compared the performance of GPT-3.5 and GPT-4 on Taiwan's NPLE. Additionally, we conducted a comprehensive assessment of their performance across various question types, with a focus on pharmacy-related tasks such as pharmacokinetic calculation and clinical decision-making scenarios. This analysis aims to determine the practical applications of GPT-4 in pharmacy education and establish guidelines for its optimal use in this field.

Methods

Background

The NPLE in Taiwan is divided into 2 stages. The first stage focuses on 3 basic subjects: pharmacology and pharmaceutical chemistry, pharmaceutical analysis and pharmacognosy (including traditional Chinese medicine), and pharmaceutics and biopharmaceutics. The second stage focuses on 3 clinical subjects: dispensing and clinical pharmacy, pharmacotherapy, and pharmacy administration and pharmacy law. The first and second stages of the examination have 240 and 210 multiple-choice questions, respectively. Pharmacy students typically complete the first-stage exam after completing their third year of university coursework. They become eligible for the second-stage exam only after passing the first examination, completing their internships and obtaining their graduation certificates. After passing the second-stage examination, candidates receive their pharmacist certificate, allowing them to practice as a pharmacist legally.

Data Source

This study used the 2-stage NPLE questions released by the Ministry of Examination in February 2023, with each subject exam lasting for 1 hour. The version of NPLE used in this study was the most recent available at the time of research. We used both GPT-3.5 (free version) and GPT-4 (licensed version). No temperature settings were applied. Examination questions were manually fed into GPT-4 and GPT-3.5 sequentially. To simulate student responses, complete questions were entered into the models without tailored prompts. One question was input at a time, and the responses were recorded for analysis. Since GPT-3.5 cannot process images and image functionality of GPT-4 was unavailable during the analysis, only text-based questions were used. Questions containing graphics, such as chemical structures, tables, symbols, and formulas were excluded. Both models were presented with the same set of questions under identical conditions. Due to the limitations on the number of times the model could be used and required cooling time between queries, all questions were answered sequentially and not timed to avoid any potential bias introduced by time constraints.

Study Design

The study was divided into 3 parts; the first part compared the accuracy of GPT-4 and GPT-3.5, as well as in different subjects. The second part compared the accuracy of GPT-4 and GPT-3.5 across different question types. These questions were categorized into 4 types: memory-based questions (1 correct word answer out of 4 options, low-level thinking; Figure 1), judgment questions (1 correct statement out of 4, medium-level thinking; Figure 2), reverse questions (1 incorrect statement out of 4, medium to high-level thinking; Figure 3), and comprehension questions (multiple-choice or matching types, high-level thinking; Figure 4). One pharmacist classified the questions according to these established categories and the second pharmacist reviewed the classifications. In the event of disagreement, a third pharmacist was consulted for the final decision. All pharmacists had over 10 years of experience in medical center hospitals or community teaching hospitals. The third part compared the accuracy of GPT-4 and GPT-3.5 for calculation-based and case scenario questions (Figure 5). Model testing for this study was conducted from May 10 to July 20, 2023.

Figure 1. Template of a memory-based question (choose 1 correct word from 4 options, requiring low-level thinking).

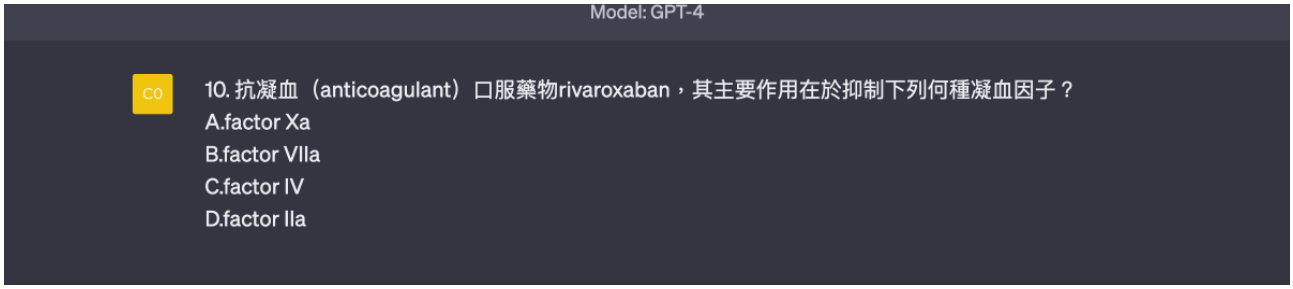

Figure 2. Template of a judgment question (choose 1 correct statement from 4 options, requiring medium-level thinking).

Figure 3. Template of a reverse question (choose 1 incorrect statement from 4 options, requiring medium- to high- level thinking).

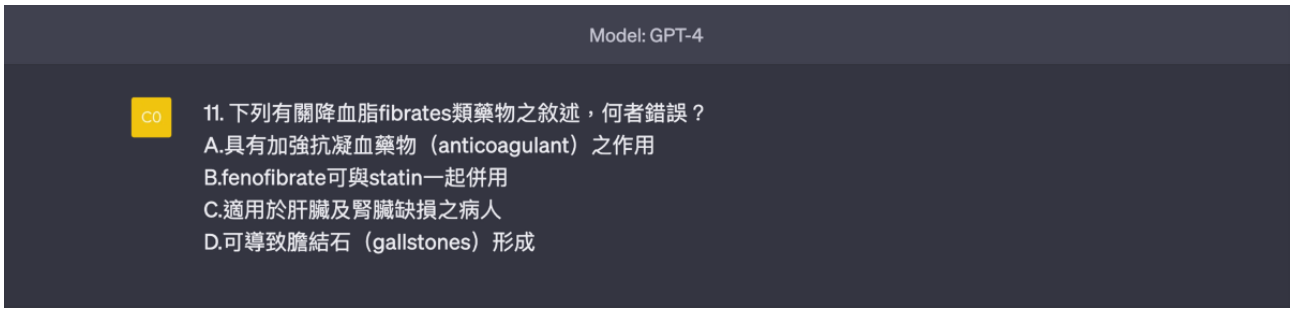

Figure 4. Template of a comprehension questions (multiple-choice or matching types, requiring high- level thinking).

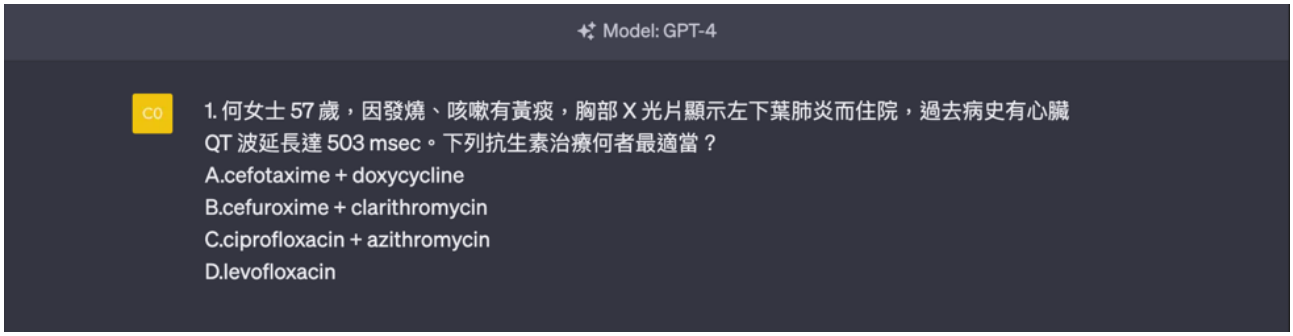
Figure 5. Template of a case scenario question.



Statistical Analysis

Microsoft Excel 2019 was used to compare the accuracy rates of the 2 models. χ^2 tests were used to compare the overall accuracy rates of answers obtained using GPT-3.5 and GPT-4. McNemar tests were used to compare the consistency in answers between GPT-3.5 and GPT-4, and for the calculation-based and situational question types using R software (version 4.2.2; R Foundation for Statistical Computing).

Ethical Considerations

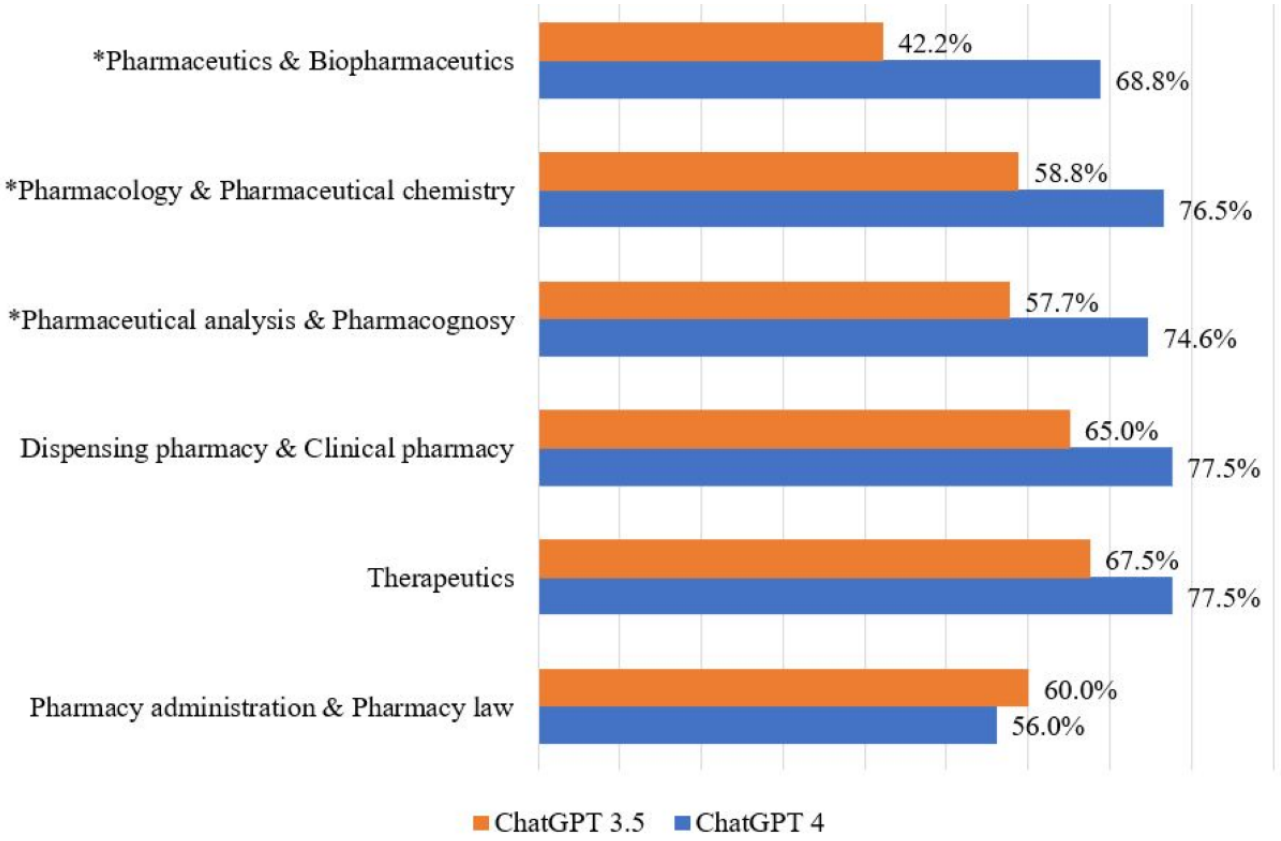
This study involved comparing the performance of ChatGPT-4 and ChatGPT-3.5 in the pharmacist licensing examination. It did not involve human participants. As per the guidelines of the 'Human Research Cases Exempted from Ethics Review Board' issued by the Ministry of Health and Welfare, Taiwan, this study was exempted from Ethics Review Board analysis.

Results

Accuracy in Different Subjects

In total, 203 and 210 questions were included for analysis from the first- and second-stage examinations, respectively, after excluding 37 questions containing graphical elements (N=413) (Figure 6). GPT-4 had an overall accuracy of 72.9% (301/413), easily passing the test (60% threshold) and outperforming GPT-3.5 which achieved an accuracy of 59.1% (244/413; $P<.001$). In terms of accuracy by stage, GPT-4's overall accuracy was significantly higher than that of GPT-3.5 (73.4% vs 53.2% or 149/203 vs 108/203; $P<.001$) in basic subjects of the first stage. GPT-4 also significantly outperformed GPT-3.5 in each of the 3 basic subjects. In the clinical subjects of the second stage, GPT-4's accuracy was higher but not statistically significant than that of GPT-3.5 (72.4% vs 64.8% or 152/210 vs 136/210; $P=.096$). In pharmacy administration and pharmacy law, GPT-4's accuracy was lower than that of GPT-3.5 (56% vs 60% or 28/50 vs 30/50; $P=.96$). Among individual subjects, significant differences were observed in pharmacology and pharmaceutical chemistry ($P=.02$), pharmaceutical analysis and pharmacognosy ($P=.02$), and pharmaceutics and biopharmaceutics ($P=.002$). No significant differences were noted in dispensing pharmacy and clinical pharmacy ($P=.07$), pharmacotherapeutics ($P=.10$), and pharmacy administration and pharmacy law ($P=.48$).

Figure 6. Accuracy comparison of ChatGPT-3.5 and ChatGPT-4 across different subjects. *P<.05.



The overall consistency among answers significantly differed between the 2 models (68%, P<.001), with GPT-4 showing consistent correct answers in 49.4% (n=204) of cases and consistent incorrect answers in 18.6% (n=77) of cases (Table 1).

Table . Performance comparison of consistency between ChatGPT-3.5 and ChatGPT-4.

ChatGPT-3.5 responses	GPT-4	
	Correct answers, n (%)	Incorrect answers, n (%)
Correct answer	204 (49.4)	38 (9.2)
Incorrect answer	94 (22.8)	77 (18.6)

Accuracy in Different Question Types

Among the 413 examination questions analyzed, memory-based questions were the most common (n=254, 61.5%), followed by judgment questions (n=82, 19.9%), reverse questions (n=46, 11.1%), and comprehension questions (n=31, 7.5%). GPT-4 and GPT-3.5 did not differ significantly in terms of accuracy of answers between question types (P=.461 vs P=.18; Table 2). GPT-4 is significantly better than GPT-3.5 in memory-based questions (P<.001) and comprehension-based questions(P=.03).

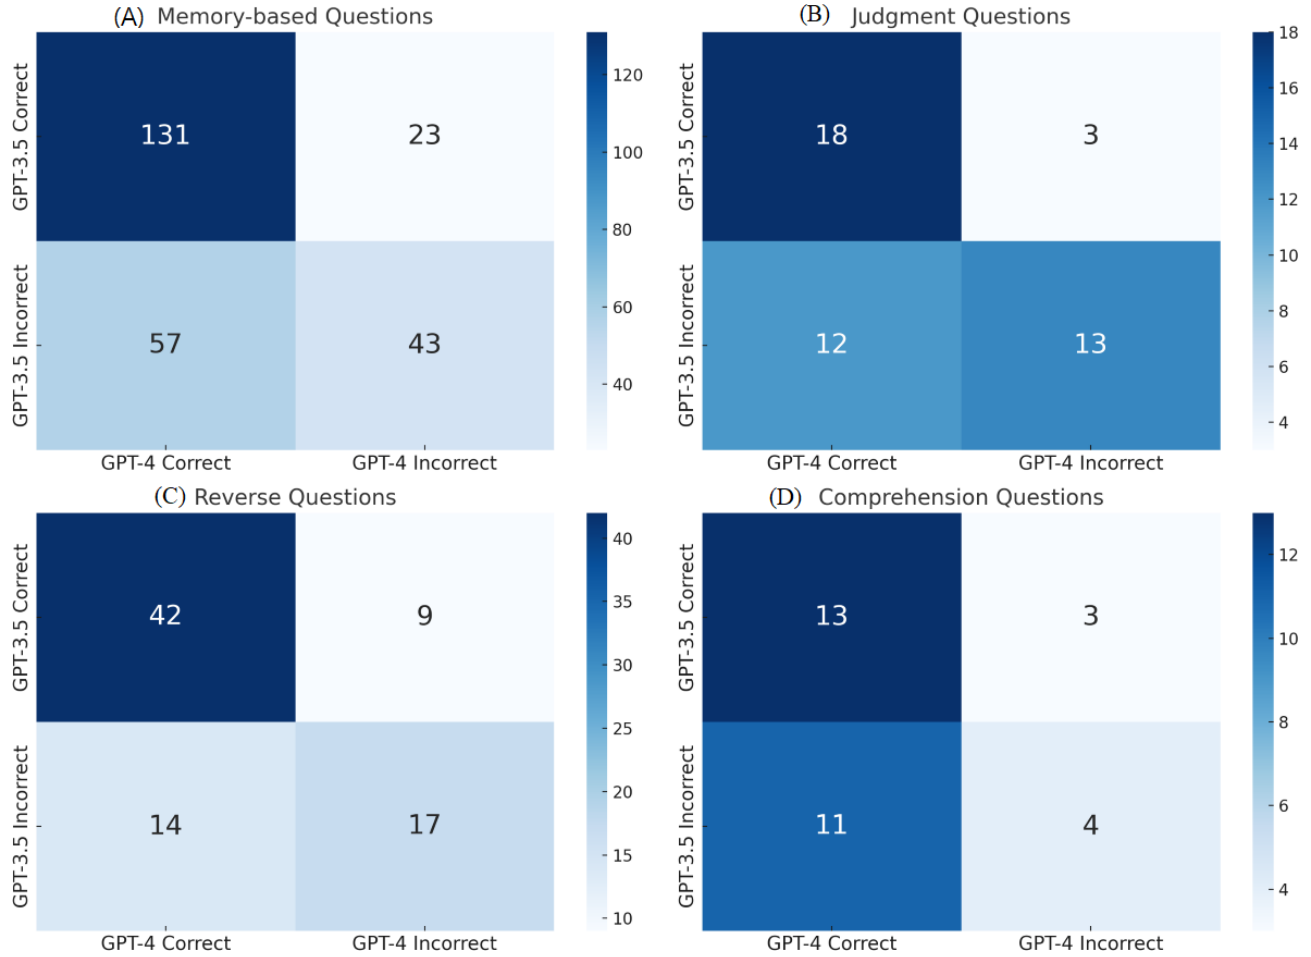
Table . Accuracy comparison of ChatGPT-3.5 and ChatGPT-4 by question type.

Question type	GPT-3.5 Correct answers, n (%)	GPT-4 Correct answers, n (%)	Total, n (%)	P value
Memory-based questions	155 (61)	188 (74)	254 (61.5)	<.001[a]
Judgment questions	21 (45.7)	30 (65.2)	46 (11.1)	.06
Reverse questions	51 (62.6)	56 (68.3)	82 (19.9)	.41
Comprehension questions	16 (51.6)	24 (77.4)	31 (7.5)	.03[a]

[a]P<.05.

Figure 7 shows the performance comparison of GPT-3.5 and GPT-4 across question types. The data provided insights into the relative strengths and weaknesses of each model.

Figure 7. Performance comparison of GPT-3.5 and GPT-4 across question types (A) memory-based, (B) judgement, (C) reverse , and (D) comprehension. The heatmaps display the number of answers, with darker shades indicating higher counts of correct responses and highlighting model performance.



Further analysis of the discrepancies between the models revealed no significant difference in questions answered incorrectly by GPT-3.5 but correctly by GPT-4 (n=94) and vice versa (n=38) across the 4 question types (P=.27 vs P=.95).

For calculation-based questions, GPT-4 showed higher accuracy than that of GPT-3.5 (80% vs 40%, P=.03), with the most pronounced difference in pharmaceutics and biopharmaceutics subjects. In scenario-based questions, GPT-4 also outperformed GPT-3.5 in terms of accuracy (63% vs 44.4%, P=.41), though the difference was nonsignificant.

Discussion

Principal Findings

This study demonstrates that GPT-4 significantly outperformed GPT-3.5 in the Taiwan NPLE, surpassing the passing threshold, especially in basic pharmacy subjects. These subjects, which have only a 13.82% passing rate among human students, are particularly challenging. GPT-4 excelled in areas such as pharmacology, pharmaceutical chemistry, pharmaceutical analysis, and pharmaceutics, consistently providing correct answers and comprehensive explanations. Although GPT-4 also performed better than GPT-3.5 in clinical subjects such as dispensing pharmacy and therapeutics, the performance gap was narrower in these areas.

In specific subjects like pharmacodynamics, pharmacokinetics, and drug-related topics in the autonomic nervous system, GPT-4 consistently provided accurate responses, where GPT-3.5 often faltered. Additionally, GPT-4 exhibited superior accuracy in bioavailability, dosing, and pharmacokinetic calculations. However, GPT-4's accuracy dropped in topics like herbal medicines and pharmacy law, emphasizing the need for further model refinement in these areas [30].

Comparison with Literature

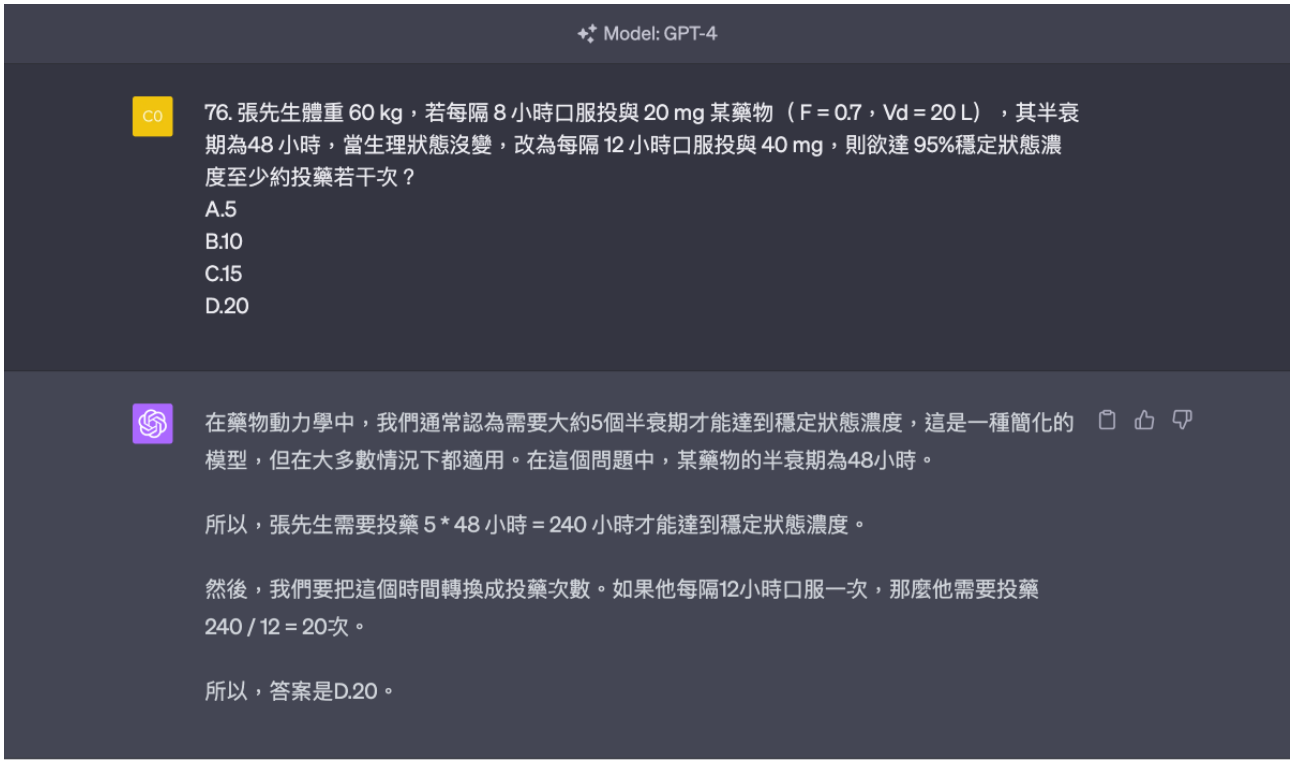
Previous studies have established that GPT-4 consistently outperforms GPT-3.5 in various medical exams, including the Australian Medical Licensing Examination [31], Canadian Radiology Examination [15], Turkish Medical Examination [32], and Japanese Medical Licensing Examination [33]. In many of these examinations, GPT-4 consistently achieved scores above 70% [34-36]. This study aligns with those findings, showing GPT-4's superior performance in the Taiwan NPLE. Unlike prior research that focused on real-world clinical applications [37-43], this study comprehensively assessed the models across various pharmacy domains.

A study by Choi [44] reported that GPT-3.5 performed well on memory-based questions but struggled with problem-solving, whereas GPT-4 demonstrated better performance in comprehension and judgment tasks. Similarly, a radiology study suggested that GPT-4 outperformed GPT-3.5 on higher-order thinking questions but not on lower-order questions [15]. These

findings slightly differ from the results of our study, where GPT-3.5 exhibited higher accuracy in both memory-based (low-level thinking) and reverse (mid-level thinking) questions. However, GPT-4 surpassed GPT-3.5 across all question types, particularly in comprehension (high-level thinking) and memory-based (low-level thinking) questions. In judgment, reverse, and comprehension questions—tasks that demand more advanced reasoning—GPT-4 demonstrated superior accuracy with fewer errors compared to GPT-3.5. Additionally, GPT-4's ability to correct errors made by GPT-3.5 reinforces its potential as a more reliable model for pharmacy-related assessments.

Further, GPT-4 significantly outperformed GPT-3.5 in calculation questions. While GPT-3.5 provided step-by-step explanations but often guessed the final answer—a phenomenon known as hallucination' due to insufficient training—GPT-4 exhibited stronger logical reasoning (Figure 8) with over 80% accuracy. However, it still made errors in 20% of cases, indicating the need for needed during its use [21,45]. In clinical applications, modifying prompts has been shown to improve GPT's accuracy [46]. For integrated analysis questions, GPT-4's performance was slightly better than GPT-3.5, consistent with findings from a nursing licensure examination in Japan [14].

Figure 8. Template of the questions that GPT-4 exhibited stronger logical reasoning.



Implications for Education

The study highlights GPT-4's potential as an educational tool, particularly in pharmacy education. GPT-4 can offer extensive practice opportunities for pharmacy students across both basic and clinical subjects, providing both correct answers and detailed explanations [18,47] to enhance understanding. Given the lower passing rates among pharmacy students in basic subjects among that were challenging, GPT-4 could assist in individualized learning. Its strength in comprehension and integrated analysis questions makes it a valuable resource for fostering critical thinking skills.

Despite its advancements over GPT-3.5, GPT-4's occasional inconsistencies suggest that model stability is not yet perfect. Questions correctly answered by GPT-3.5 were not always consistently answered by GPT-4. Nevertheless, GPT-4's accuracy, approaching 80% suggests that it can serve as an effective learning supplement, provided educators guide students in minimizing potential errors. For instance, specifying clearer prompts, such as "Please do not add your own opinions", may help mitigate hallucinations and enhance its use in educational settings.

In addition, educators should consider adjusting the format of examinations by replacing memory-based questions with comprehension questions, which can reduce the chances of guessing and better assess students' true intelligence.

Limitations

The primary limitation of this study is the time frame during which the models were tested (ie, from May 10 to July 20, 2023), which may affect the reproducibility of the results if retested in the future. Additionally, both GPT-3.5 and GPT-4 struggled with recognizing structural diagrams, limiting their performance in areas such as pharmaceutical chemistry and pharmacognosy. These limitations, consistent with previous research, highlight the need for cautious application of GPT models in fields that require visual recognition [11,48,49]. Additionally, the models showed poorer performance in subjects with less available training data and specific medical knowledge such as pharmacy law and traditional medicine, indicating potential biases in the models' training. We suggest that future

efforts in model development should focus on incorporating more diverse and comprehensive data to reduce such biases.

Conclusions

This study demonstrates that GPT-4 outperforms GPT-3.5 in the Taiwan NPLE, particularly in pharmacy expertise, calculation ability, and situational case studies, with a notable advantage in basic subjects. It is recommended that GPT-4 be applied in clinical pharmacy practice (ie, patient education, drug consultation) and pharmacy education, particularly to support self-directed learning. However, given its limitations, caution is advised when integrating GPT-4 into clinical settings and educational programs. Future research should focus on refining prompts, improving model stability, integrating medical databases, and enhancing comprehensive questions to evaluate student competence more effectively while minimizing the chance of guessing correct answers.

Abstract

Background: Patients in the United States have recently gained federally mandated, free, and ready electronic access to clinicians' computerized notes in their medical records ("open notes"). This change from longstanding practice can benefit patients in clinically important ways, but studies show some patients feel judged or stigmatized by words or phrases embedded in their records. Therefore, it is imperative that clinicians adopt documentation techniques that help both to empower patients and minimize potential harms.

Objective: At a time when open and transparent communication among patients, families, and clinicians can spread more easily throughout medical practice, this inquiry aims to develop informed guidelines for documentation in medical records.

Methods: Through a series of focus groups, preliminary guidelines for documentation language in medical records were developed by health professionals and patients. Using a structured focus group decision guide, we conducted 4 group meetings with different sets of 27 participants: physicians experienced with writing open notes (n=5), patients accustomed to reviewing their notes (n=8), medical student educators (n=7), and resident physicians (n=7). To generate themes, we used an iterative coding process. First-order codes were grouped into second-order themes based on the commonality of meanings.

Results: The participants identified 10 important guidelines as a preliminary framework for developing notes sensitive to patients' needs.

Conclusions: The process identified 10 discrete themes that can help clinicians use and spread patient-centered documentation.

KEYWORDS

open notes; patient-centered documentation skills; medical student education; 21st Century Cures Act

Introduction

Reflecting long-standing tradition, medical record notes documenting clinical encounters have primarily served the doctors or other health professionals preparing them. Their diverse functions include accurate documentation of a patient's unique circumstance, refreshing clinicians' memories, documenting diagnostic reasoning, communicating cogently with colleagues, justifying charges for encounters, and serving as material for assaying quality of care.

Until about 15 years ago, clinicians prepared such notes rarely with patients or their families envisioned as potential recipients [1]. Since the turn of this century, however, the movement toward more open and transparent communication with patients has grown, and since April 2021, federal rules in the United States now mandate that all patients (with very limited permitted exceptions) are offered online and rapid access to their clinical records, including the notes written by clinicians ("open notes") [2,3].

Whether one note can serve diverse recipients remains an open question, however, studies suggest room for optimism. A large majority of clinicians experienced with open notes favor their continuation, and few report "dumbing down" what they write [4]. Moreover, extensive survey and qualitative research demonstrate that patients who review their records and read their notes feel more involved in and knowledgeable about their care, report being better prepared for visits, and indicate they are more likely to follow their clinicians' advice [5-11]. However, words matter, and studies also show that patients can feel judged, stigmatized, or offended by their notes, with potentially adverse effects on the clinician-patient relationship [12-15]. For example, a recent study at 3 diverse health systems found that 1 in 10 patients reported feeling judged or offended by an outpatient note, reflecting the perception that the note contained errors, surprises, inappropriate labeling, or evidence of disrespect [16].

To date, little empirically informed counsel about best practices with respect to patient-centered documentation has been published [17]. Although studies have demonstrated that certain language in notes influences clinician attitudes toward patients and that specific words used can negatively impact the clinician-patient relationship, what language providers should use or avoid has not been clearly described [11,15]. Within the current medical literature, some recommendations have been offered on how clinicians might better prepare for the era of open notes [18]. However, there are no evidence-informed guidelines describing concrete approaches to patient-centered language in clinical notes, and such guidance may be important for developing mindful practices.

In preparation for an educational intervention with medical students and practitioners supervising their work [19], we aimed to address this gap in knowledge and practice by drawing on the perspectives of patients, physicians facile with open notes, medical educators responsible for teaching clinical skills to early learners, and medical residents, who often teach students directly. Following dedicated discussions with these 4 groups and subsequent thematic analysis of their perspectives, we developed a set of guidelines as a preliminary framework for future initiatives aimed at teaching patient-centered documentation skills to medical students, their preceptors, and a broad range of clinicians.

Methods

We conducted 4 focus groups with discrete groups of individuals to gain an understanding of their perspectives and experiences with written medical documentation. Our goal was to develop guiding principles for best practices in patient-centered documentation skills.

Design

Our focus groups addressed experiences with written medical documentation (patient notes), with particular attention to the language used in notes. We sought a range of perspectives and structured the groups based on the type of participant. Within their respective groups, the aim was to create opportunities for interaction and comparison of responses among participants [20,21]. This methodology can generate a large volume of responses, and we anticipated a robust discussion of experiences among participants. Although there is no consensus about the ideal number of participants in focus groups, our goal was to recruit between 6 and 10 participants per group [22]. All study procedures received ethical approval in March 2022 and met exempt status both from the Beth Israel Deaconess Medical Center institutional review board (reference number 2022P000079) and the Mass General Brigham institutional review board (reference number 2022P000635).

Recruitment and Participants

We convened four groups of participants: (1) patients familiar with open notes, (2) practicing physicians facile with open notes, (3) medical student educators involved with teaching clinical skills, and (4) resident physicians working closely with medical students. Between March and April 2022, we used various forms of outreach to recruit participants: For the patient focus group, LS identified, recruited, and contacted patients through email with a flyer attachment. For the group of practicing physicians, TD identified and AG recruited individuals having active experiences with open notes at academic institutions across the country. For the group of medical student teachers, AV and KJ recruited physician educators through the national medical educator list, which included Clerkship Directors in Internal Medicine and Directors of Clinical Skills. For the focus group of residents, AV and KJ identified and contacted through email residents from Beth Israel Deaconess Medical Center and Massachusetts General Hospital who had expressed interest in medical student education. For their time, patient participants were offered a US $100 honorarium, and physicians a US $50 honorarium.

Between April and May 2022, we convened four 90-minute focus groups, each composed of specific types of participants as described above. Focus groups were conducted through Zoom (Zoom Video Communications) and recorded for transcription.

Format of Focus Groups

Each group followed the same script, with the meetings facilitated by 2 of the study leaders (AV and KJ). Drawing on a variety of stakeholder perspectives, the research team collectively devised the structured interview script. The team included medical educators, practicing physicians, a health services researcher, a patient advocacy researcher, a health services researcher, and a medical ethicist. The script was developed based on the group's experiential, ethical, and practical experience. To assess face validity, the questions were further honed, refined, and pretested with 4 doctors and 3 patients, leading to further refinements in the wording of

questions and prompts (Textbox 1). Groups opened with a standard anonymity disclosure, along with a description of the reason behind the inquiries. We offered participants the opportunity to opt out at any time during the process. Participants were encouraged to set their screen name, however, they felt comfortable and to keep their video off if so desired. To preserve anonymity, we asked participants not to mention each other's names during the session.

Textbox 1. Focus group questions for patient and physician groups.

(10 minutes per question)

Question 1: What do you recall from any previous learning experiences that focused on writing notes that patients will read, or reading notes from the perspective of a patient?

- For the patient group: "What do you recall from your experience of reading your clinical notes?"
- Follow-up question: What are some concrete examples of this?

Question 2: What should early medical students know about writing notes that will be useful to patients and encourage partnering or engagement in their care?

- Follow-up question: What are some concrete examples of this?

Question 3: What should early medical students know about writing notes with words or phrases that could be harmful to patients or their relationship with their physician?

- Follow-up question: What are some concrete examples of this?

Question 4: What should early medical students know regarding how medical vernacular or acronyms may be perceived by patients?

- For patient group: "What has been your experience when reading notes containing medical vernacular or acronyms?"
- Follow-up questions:
- What are examples of vernacular that should be avoided due to possible patient harm or creating unwanted bias?
- Are there common acronyms that should be avoided?

Question 5: What should early medical students know about including the patient's voice in the notes?

- For patient group: Describe some ways in which a physician could write your words, or ensure that the writing of your medical concerns represents your lived experience.
- Follow-up question:
- What documentation approaches could a student follow to help the patient feel authentically seen and heard when reading their clinical notes?

Question 6: What should early medical students know about how words or phrases in clinical notes may convey bias?

- For patient group: "What has been your experience in reading notes with words or phrases that you feel convey bias?"
- Follow-up question: What are some concrete examples of this?

Question 7: What key content areas are more sensitive for patient readers and should require students to receive specific guidance on documentation?

- Follow-up question:
- What topics or themes should receive special attention and teaching?
- Are there any key areas that should be omitted or avoided in notes unless discussed and reviewed with faculty?
- Prompt examples: race, obesity, firearm ownership, gender identity and health, sexual identity and health, substance use, and so on.

(5 minutes for wrap-up and debrief and closing thoughts)

Analysis

We designed and conducted an inductive thematic content analysis of the transcribed focus groups [23]. This approach was used because it is particularly appropriate for analyzing textual data by identifying patterns, themes, or categories that emerge from the data itself, rather than imposing predetermined categories or codes. This approach facilitates the identification of nuanced themes arising directly from the data, making it particularly useful when exploring new or less understood phenomena [24]. Responses were analyzed by 2 members of the research team (AV and KJ). Both are medical educators and general internists in the United States with experience in sharing online access to patients' health records (AV is an inpatient physician and KJ is a primary care physician). The research team was diverse in age and background: the lead author and one of the coders (AV) identified as of Indian background, another author (AG) identified as having Cuban descent, and

the patient-researcher author (LS) identified as having both physical and cognitive disabilities.

First, AV and KJ read the transcripts to familiarize themselves with the responses. Second, AV and KJ independently created codes through the selection of excerpts from each of the 4 focus groups. The codes were then reviewed jointly by AV and KJ to come to a consensus. Using the common list, new excerpts from each of the 4 transcripts were coded by AV and KJ, and the codes were further refined until a consensus was reached. Subsequently, first-order codes were grouped into second-order themes based on commonality of meaning. Representative comments for each theme were identified by authors AV and AG.

Ethical Considerations

All study procedures received ethical approval in March 2022 and met exempt status both from the Beth Israel Deaconess Medical Center institutional review board (reference number 2022P000079) and the Mass General Brigham institutional review board (reference number 2022P000635). This study did not meet criteria for human subjects research at either institution and thereby was deemed exempt.

Results

Overview

A total of 27 individuals participated in the focus groups: 8 patients (5 women, 2 men, and 1 individual identifying as gender nonbinary), 5 physicians with experience preparing open notes (2 women and 3 men), 7 medical student educators (6 women and 1 man), and 7 resident physicians (6 women and 1 man). The participants from the patient, physician, and medical educator groups were from diverse geographical regions of the United States. Based at large academic centers, physician participants represented different clinical specialties including internal medicine, pediatrics, and behavioral health. Educator participants were all involved with either leadership or teaching foundational clinical skills at various medical schools in the country. The resident physician participants were recruited from 2 large academic health centers in the greater Boston area.

Using the iterative coding process [25], we identified 10 major themes that could serve as guidelines for patient-centered documentation (Textbox 2). We discuss these in greater detail below, with representative comments illustrative for each theme in Table 1.

Textbox 2. Checklist of guidelines for patient-centered documentation: major themes.

Themes

- Use person-first language.
- Refer to your patients as how they want to be identified.
- Avoid abbreviations and acronyms, especially if not officially approved by the practice.
- Say what you write and write what you say.
- Verify past history information before recording it in the note.
- Avoid words that may convey bias or judgment.
- Keep descriptions of physical examinations objective.
- Empower your patients with encouraging words and clear next steps.
- Pay close attention to sensitive topics, including but not limited to sexual history, trauma history, substance use history, mental health, or illness.
- Write from your perspective.

Table 1. Examples and suggestions for each identified best practice for patient-centered documentation.

Theme	Examples and suggestions
Use person-first language	• I don't see necessarily a boundary between the language you use to describe a patient out loud and what you write in your note. It's all part of a single way that you frame patients. It's not a diabetic patient. It's a patient with diabetes. I really don't think about the way that I document my notes differently than the way that I just think about my patients, which is to think about them in a person-centered way. [#2, Medical Educator] • Even though I've lost weight, the word morbidly obese is in every note, every note I see. That doesn't bring me joy or comfort me or get me to want to interact in a positive manner. My issues have nothing to do with my weight and never did. I developed a MRSA staph infection; it was a healthcare-acquired infection.There are certain things where weight doesn't always factor in, and you don't always need weight. [#1, Patient]
Refer to your patients as how they want to be identified	• I have found the doctors that I have currently are really good about using he/him pronouns for me and referring to me as using masculine identifying language. I have had providers who are not. Never knowing what I'm going to run into in those notes is very anxiety-inducing on the gender part alone, right? Let alone, does this person think that my gender is influenced by or influencing any of my other health issues? [#5, Patient] • I tend to write and call the patient whatever they like to go by, so I'll say like, Bill is a 75-year-old man, instead of Mr. Smith, for instance. For nonbinary or transgender patients, I try to ask them what gender they would like me to document rather than just assuming it's transgender male. Then in the social history and medical history, perhaps elaborating on it more, but trying to give them voice in what I'm documenting. I also think that mentioning race without having any clear connection to anything should be discouraged completely. [#1, Resident]
Avoid abbreviations and acronyms, especially if not officially approved by the practice	• I was struck by the idea that it almost felt, as a medical student, as if you were being inducted in a secret society. It was this secret language that you now all understood, and that's what unified everyone who was part of that. It really is just so unnecessary at this point. I think what's already come out here is that there clearly are regional differences. I've never heard of "MOP" ["mother of patient"], but "ISO"["in the setting of"] is rampant around here, so clearly, there are differences in terms of some of the abbreviations that are used in specific regions and areas, and we can't then even understand each other's language. [#2, Physician] • Just the other day, we were talking about PSA and how it's prostate-specific antigen, but also pseudomonas, and also pseudoaneurysm. If a patient reads PSA and looks that up for themselves on Google, they're going to find a million things that could be. If you're going to use an acronym, maybe don't use ones that have multiple different meanings even in the medical world, and the most important parts of their diagnoses should not be abbreviated. [#1, Resident] • Medical jargon and all this evolved as a way of having more succinct communication, being able to communicate among clinical teams. I think there is some value to that, but I think what's important for a lot of educators to keep in mind is, this is an area where the students are actually—while they're learning, they also should, in some ways, be teachers for all of us who have been doing this for some time, right, and how they can take their lack of being indoctrinated by the system and bring that from the bottom up. [#3, Physician] • Then some acronyms. Point out we say SOB for shortness of breath, and, obviously, has other meanings. [#2, Resident]
Say what you write and write what you say	• There probably shouldn't be anything in the note that hasn't been discussed. If you're telling someone a diagnosis, I don't think you should go back in the note and say, "And this diagnosis is terminal" if you haven't discussed it with the patient. Knowing that the patient is likely going to go back and read the note, I don't think that it should be put in the note. Or, if the physician feels like it's important that it's put in the note, make sure it's discussed with the patient as well. There's no point in writing a good note if none of it was even said to the patient. [#7, Patient] • When we have a discussion and he puts it right in my note right then and there, those are kinds of things that help me. Today I had a call from the pharmacist about a med. They would have given me the wrong med if I wouldn't have stood up for myself and wouldn't have known what I was supposed to have, and wouldn't have had my notes there, because basically I read it right from my note to him. I think the notes become more and more valuable. [#1, Patient]

Theme	Examples and suggestions
Verify past history information before recording it in the note	• We've evolved as people from year 1 to year 5 over the course of a relationship of knowing a doctor, and our social histories often don't reflect that change. What could have been pertinent 5 years ago for a patient might not be anymore, and depending on what they were experiencing at that point in time, could be biasing. [#1, Resident] • So now it's on my to-do list when I go to appointments to make sure that's changed. Really, that shouldn't be a priority of mine when we go into medical appointments to say, "Hey, I read the note, and this needs to be changed, 'cause this doesn't represent who I am.' I think everyone has assumed the person before them has done it, and it's accurate. It takes a lot of time and a lot of effort and a lot of energy for us to be able to correct mistakes that are in our patient portals, our notes. I think it's 1 of those things where I just want to remind medical students, you can do 2 things to check with patients. Like, "Hey, I have all this down. Is that right?" Two, "If you see anything in here that's wrong, send me a MyChart message or EHR or whatever message, so I can fix it. [#5, Patient] • Some things that I notice that get copy-forwarded a lot in notes that create bias in the reader, 1 would be substance use disorders, and not really specifying or clarifying it, right? It will just say, "Polysubstance use disorder." Things like that, I think definitely have the ability to bias. [#1, Resident]
Avoid words that may convey bias or judgment	• You don't need to use the word complain. It's a pretty negative connotation. Patient "reports", or just "is having". I think avoiding the word complaint is pretty important." [#2, Resident] • I think, if you're ever thinking about using a term like that, it should be more about, what are the barriers this patient has to achieving care, and talking more about that and not just using 1 word. Using more language is actually helpful, and med students often have more time to actually ask patients about these things and have a conversation. I think that could be a really empowering point for medical students to learn more about the determinants of health that are affecting the patient more so than being like, "This patient doesn't take their medications. [#5, Resident] • I also think that mentioning race without having any clear connection to anything is—should be discouraged completely. It's such a part of vernacular, especially more physicians who are trained in a different era, so we've been actively encouraging students not to include that unless it has a very clear reason. [#2, Medical Educator] • I could imagine, sometimes, quotation marks are used to just directly capture what the patient said. I think it's about striking that balance of bringing the patient language in and having some of it as verbatim as directly as possible so that the patient can see what they said was actually recorded, but then a key part of what we're doing in notes is really clinical translation. It's about going from verbatim conversation to clinical processing and then recording our clinically processed thoughts. [#3, Physician]
Keep physical examination descriptions objective	• General appearance is very tricky, and I think we all have to ask ourselves, when is that relevant and why, and then really distill it down to what's clinically meaningful in the least judgmental way possible. Is it important that the patient is disheveled or older than stated age or has poor hygiene? It might be, but then you have to figure out, how do you relay that in the most respectful manner possible? [#5, Medical Educator]
Empower your patients with encouraging words and clear next steps	• There's a book called "The 15 Minute Hour" that's geared toward primary care providers, and 1 of my favorite takeaways from it that has always stuck with me over the years is the idea of using the word "yet" at the end of a sentence or a phrase. It's supposed to emphasize that you're not at a dead end. You can still do this. The patient has not been able to quit smoking yet. The patient has not lost weight yet. [#5, Physician] • I somehow think that I would like medical notes to be imbued with a different perspective, that we're trying to teach patients to be friends with their disease…[…]…disease is not the enemy. [#4, Patient] • I have heard from some patients that we had engaged in providing feedback on our student notes that they would really like, in reading the assessment and plan, to have some understanding of what they can do next and what the evaluation, diagnostic evaluation plan means for them. Maybe some additional content around health coaching and steps that they can take in their lives to support their health too. It could be a great way to extend that partnership beyond the visit. [#5, Medical Educator]
Pay close attention to sensitive topics, including but not limited to sexual history, trauma history, substance history, mental health or illness	

Theme	Examples and suggestions
	• Some advice I've gotten from the psychiatry consulting team at my primary care practice is […] to just state the type of trauma it was, the years that it happened, the relation to the abuser, and what the patient went through….[…]…There's no need to go into extreme detail and quotations about what the patient confides with you in clinic about, that you can still have a therapeutic bond…[…]…instead aim to strike a balance of what's useful for other providers and not needed for the patient to be reading about themselves. [#7, Resident] • There are certainly very specific topics around mental health, around sexually transmitted illnesses, reproductive health, substance use, et cetera, that definitely should be addressed in a particular manner that respects the patient's privacy… […]…early learners could certainly benefit from understanding what the implications of access to that information could be. [#2, Physician] • […] documenting your full differential diagnosis, where you might have a patient who is coming in for what seems like a respiratory illness or pneumonia, but maybe under differential, you also have a rare lung disorder or lung cancer. It's trying to strike that balance…[…]…trainees, as part of their training, are taught to document the full differential …[…]…this is an area where we're all still trying to figure out the best practices because you do want to indicate to some degree that you are thinking about these other diagnoses, but in the real world […]you might not start with an initial visit by sharing that this may be cancer, but it may be something you bring up on a follow-up visit when your initial working diagnosis doesn't seem to be correct and it seems more serious than that. I know the official recommendation has been to just document what you discuss…[…]…I think it's more complicated than that. [#3, Physician]
Write from your perspective	• Something I've been experimenting with a lot is using the first person in the assessment and plan, which I don't know if I was ever explicitly told not to in medical school, but I feel like I thought I wasn't supposed to. Over the past year, I've started to come around to this idea of, the objective is the objective, but the assessment and plan is my medical opinion. A lot of times, I'll say, "I'm worried about", or, "I think this might be at play. I think it's unlikely, but maybe cancer. I think anxiety might be driving some of this." I feel like that really couches it as, this is my opinion of what's going on. It doesn't negate what the patient thinks. [#5, Physician]

Use Person-First Language

Across all 4 focus groups, participants agreed that patients should be referred to as individuals with certain clinical conditions, rather than identifying them primarily by their medical condition (Table 1). Some patients identified a preference for the use of discrete numbers when addressing a person's weight, rather than describing the individual as "obese" or even "with obesity," and to be mindful of whether weight needs to be in the note if not relevant to issues being addressed (Table 1). All participants from the patient group described the importance of being mindful of phrases and words in notes that can trigger trauma for patients. Finally, participants in all groups identified descriptions of words and phrases in the medical record considered potentially depersonalizing or dehumanizing.

Refer to Your Patients as How They Want to Be Identified

The participants recommended that patients be identified according to their own expressed preferences. Participants from the resident physicians' group suggested that when first introducing oneself to a patient, one should request and document how the patient wishes to be identified in the record. Patient participants noted that honorifics and gender identity should never be presumed (Table 1). In addition, patient participants explained that patients may want to be identified by their life roles, such as their profession, or background, in addition to honorifics and names. Medical educators recommended that introductory "History of Present Illness" sentences should mention factors important to understanding and planning the care of that person at that point in time, with the understanding that these factors are dynamic and change over time. Physicians familiar with open notes suggested it is important to be thoughtful and deliberate about whether to include demographic factors, epidemiologic factors, and medical and social history in the opening sentences of a note, given the effect such information may have on framing how a patient, family member, or other clinician reads the note.

Avoid Abbreviations and Acronyms, Especially if not Officially Approved by the Practice

Participants in all groups felt that medical shorthand can cause confusion and misinterpretation by patients. Physician, resident, and educator participants noted that while some abbreviations are widely understood within health care, others are interpreted differently within and across a given specialty. They suggested that this, in turn, could lead to clinician confusion, thereby further amplifying the risk of patient confusion (Table 1). Physician participants noted that learning to use medical shorthand in notes was akin to being inducted into a "secret society" (Table 1). Illustrative examples suggested by the 4 focus groups included: "SOB" (shortness of breath), "F/U" (follow-up), "ISO" (in the setting of), "NAEON" (no acute events overnight), and "MOP" (mother of the patient). In addition, physician participants pointed out that shorthand for certain medical diagnoses was problematic, given the frequent lack of clarity. They cited "HFrEF" (heart failure with reduced ejection fraction); "HFpEF" (heart failure with preserved ejection fraction); and "AKI" (acute kidney injury). Several residents discussed the risk that abbreviations and acronyms may perpetuate discriminatory biases within notes. Medical educator participants noted that this was an area in which practicing clinicians can learn from students, given that many have not yet been inducted into contemporary systems of

medical vernacular. Finally, the medical educators noted that even if abbreviations were minimized, notes still may not be completely understandable, underscoring the need for open communication with patients.

Say What You Write and Write What You Say

Patients universally stressed the importance of notes accurately reflecting what was done and discussed during a visit. Residents and physicians emphasized that clinicians should be mindful about not documenting issues, such as possible diagnostics considerations, that were not discussed directly with the patient, and that this principle should be used consistently for all documentation (Table 1). Medical educators identified the importance of guiding learners carefully in interactions between documenting explicit clinical reasoning with robust documentation of differential diagnoses and setting expectations for patients. They suggested that clinicians point out to their patients that some notes are intended to be comprehensive and may include diagnostic possibilities that are unlikely, but nevertheless important to record. In contrast, patients suggested there are situations in which clinicians should not write too much about a potentially sensitive topic that may trigger a harmful response in patients. Instead, patients proposed clinicians might record that a discussion of a "challenging topic" took place during the visit; although details might be excluded, such reference would remind the patient of the conversation. On the other hand, several patient participants noted that accurate and detailed representations of a visit may help empower patients with managing their care, strengthen their agency, and enhance their understanding of medical recommendations.

Verify Past History Information Before Recording it in the Note

Another theme was the importance of verifying patients' past information in the note to avoid "note bloat" (ie, copy and paste from previous notes). Participants from all groups identified "cutting and pasting" as increasing the risk of mistakes. Notably, all patients agreed that the "note bloat" phenomenon can have a negative impact on how patients view their notes, and possibly on their relationship with clinicians, resulting in their feeling the need to advocate for themselves to ensure accurate representation of their stories (Table 1). Several patient participants suggested that copying over all aspects of the social history when not relevant to a specific visit might trigger trauma since this section of the note can replicate and reiterate sensitive information. Two residents noted the issue of "copy-forward" (copying previous information from the record into new notes), thereby propagating bias and stigma, and potentially risking mistrust of the clinician. Medical educators noted that untruthful documentation, at times propagated by copy-and-paste templates, can lead to mistrust in the patient-physician relationship and adversely impact care.

Avoid Words That May Convey Bias or Judgment

With striking overlap across all 4 groups, participants offered many examples of words and phrases that may reflect bias or unfair judgment of patients. Suggestions about common phrases and words to avoid included clinical vernacular such as "complains," "denies," "claims," "refuses," and "endorses." Participants recommended neutral and judgment-free words such as "says," "reports," "does not report," "concerns," and "did not tolerate." Several medical educators suggested renaming "chief complaint" as "chief concern." Participants also discussed problems with labels, such as "poor historian," "noncompliant," "difficult patient," "nonadherent," "uncooperative," "having poor health literacy," and "left AMA." Patient participants agreed on the importance of describing explanations for observed behaviors, rather than using judgmental language, such as, "Mr. X is unable to take his insulin most days of the week due to inability to refrigerate the medication at his place of work." Consideration about how to document race was another common concern. Given that race is without clear relevance to most medical concerns, many believed it should not be included in the written documentation. Finally, the pros and cons of using quotation marks and the patients' own language were discussed. Participants noted that doing so would accurately capture what was said. However, in certain contexts, this might be interpreted as sarcastic, questioning, or making light of what the patient communicated, and participants recommended that quotation marks should be used carefully.

Keep Descriptions of Physical Examinations Objective

Another emergent theme was ensuring that descriptions of physical examinations avoided phrases that could be perceived as offensive. Examples included: "disheveled," "older than stated age," "obese"; and judgmental descriptors, such as "argumentative." Participants recommended omitting descriptors such as "pleasant" or "delightful," in part because the absence of such terminology might inadvertently suggest to the reader that the patient is "unpleasant." Several participants urged considering whether language pertaining to appearance is helpful. All recommended avoiding the words "obese" or "morbidly obese" and to first consider whether the information is relevant to an issue at hand. If so, they recommended quantitative descriptors, for example, BMI or the actual weight.

Empower Patients With Encouraging Words and Clear Next Steps

Participants suggested patients often benefit from reading encouraging words and the next steps regarding their conditions. Physicians noted that empowering language, particularly in the "Assessment and Plan" section of a note, could stimulate patients to engage in their care more actively. One physician suggested adding the word "yet" at the end of the sentence or phrase, signifying progress with a specific goal (Table 1). Patients agreed that empowering notes could facilitate partnership with the medical team. Medical educators suggested adapting notes to ensure they capture expert or emerging clinical reasoning, while still engaging patients in the next steps of a plan. Relatedly, several participants suggested using notes to embed reminders to patients, their care partners, and other members of their care team by stating explicitly what was recommended during the visit, especially with respect to specific next steps and goals.

Pay Close Attention to Sensitive Topics, Including but not Limited to Sexual History, Trauma History, Substance Use History, Mental Health, or Illness

Another emergent theme was mindfulness in documenting topics such as substance use history, mental health and illness, gender identity, sexual identity and health, history of trauma, disagreements between patients and clinicians, significant illnesses, and comprehensive diagnostic reasoning. Medical educators noted the challenges of teaching early learners how best to document such information in the social history section. Physicians noted the importance of documenting any disagreements with patients in an objective and respectful manner.

Write From Your Perspective

Medical notes, in particular the "Assessment and Plan" portion of the note, reflect the perspective of the health care professional at a given point in time. Participants uniformly noted that the patient's perspective should also be included, and that descriptions should be factual and based on direct observations. Physician and resident participants alike suggested the use of the first-person pronoun "I" when writing the "Assessment and Plan," as well as using the phrase "at this point in time." Physicians advised that this wording signals that diagnostic considerations may change as a situation evolves.

Discussion

Principal Results

At a time of increasingly open and transparent communication between patients and clinicians, a growing body of research demonstrates the importance of words and phrases used in clinical notes, and the risk of bias and offense to patients. Patients who read their notes feel more involved in their care, better prepared for visits, and are more likely to follow their clinician's recommendations [4-10]. Just as importantly, patients can experience negative effects from their notes due to language perceived as judgmental, offensive, or stigmatizing [11-14]. Language in notes can also negatively influence other clinicians reading the note, leading to bias and impact on the patient's care [11]. To our knowledge, this is the first study attempting to define concrete guiding principles on best practices in patient-centered documentation. Informed by a qualitative analysis of active and interactive discussion among patients and clinicians, this inquiry, as described in detail above and in Textbox 2 and Table 1, identified 10 discrete guidelines for patient-centered documentation.

This inquiry was stimulated by our interest in facilitating open and transparent communication among health professionals and patients from the very beginning of a clinician's career. Medical school curricula and residency programs are just beginning to introduce the concept of patient-centered documentation, with few providing specific guidance [26-28]. Concrete advice is especially important for early medical learners. Moreover, many faculty and residents who teach medical students are also relatively new to the practice of open notes. Developing and describing guidelines, accompanied by clear and detailed examples, can help faculty both learn what we hope will evolve as best practices and teach students these skills more easily, creating an opportunity for standardized assessment of notes based on a checklist reflecting the guidelines. In addition to providing direct teaching and feedback, the presence of concrete guiding principles will allow faculty to role model these skills in patient interactions for their learners. Furthermore, given the importance and impact of language in documentation, we believe the guidelines identified in this research will serve all clinicians well.

The checklist this study generated has already been implemented within the first-year foundational clinical skills course students undertake at our medical school [19]. Students are introduced to the background and value of open notes, followed by the checklist of guidelines. Over the timeframe of this course and beyond into their core clinical training, students are expected to write patient notes using these guides and are subsequently assessed on the quality of their notes through a rubric based on the checklist. Faculty preceptors in this first-year course are also encouraged to use this checklist, with the aim of reviewing student notes and providing feedback based on these 10 themes.

Limitations

Our study has several limitations. First, owing to time constraints on the duration of the study caused in part by the COVID-19 pandemic, we did not conduct focus groups until data saturation was reached. Second, due to the need to develop this preliminary framework before the delivery of a patient-centered documentation curriculum for students, the data analysis was restricted to 2 reviewers only, limiting the validation of the data. Third, the small number of participants likely influenced the results. Fourth, and relatedly, a fuller spectrum of diversity including geography, clinical background, and health background, could produce more varied views and depth of experience with open notes. Fifth, studies have demonstrated that fewer patients with low income, limited education, or poor English proficiency are active users of the electronic health record, limiting our participants' understanding of the note-reading experience of these populations [29-31]. Our preliminary guidelines may therefore be limited when it comes to generalizing to wider patient populations, and future guidelines should seek to address this concern. Finally, the development of new charting practices and auditing may come with considerable resource demands. Typically, guidelines that assess resource-intensive interventions are more likely to include an assessment of implementation costs, real and intangible. It would also be useful to discuss the potential risks of open notes and any context-specific adjustments for special populations or clinics. This is, however, beyond the scope of this study.

Conclusions

The guidelines identified are preliminary. As our understanding grows, we expect clinicians will learn how to write notes in ways that patients find increasingly useful. In addition, there are nuanced areas to consider in various specialties and different patient populations that may require further adaptation of these guidelines. To this end, clinicians and patient advocates partnering to co-design medical education will be important, as it was in this study. Ideally, in the future, we will learn to teach practitioners effective documentation through a common

language and shared set of standard expectations. Although we expect norms and practice techniques to evolve, our study presents an initial attempt to develop practical and respectful guidelines for patient-centered documentation.

Acknowledgments

We thank the patients, physicians, and medical educators who took the time to share their experiences and perspectives, which helped our work. The authors also thank Alex Duncan who coordinated the logistics of the focus groups. This study is part of a project developing a patient-centered documentation curriculum for medical students and their prime clinical faculty. It is funded by an educational grant from the Josiah Macy Jr Foundation and a generous gift from Kate and Arnold Schmeidler. These funds supported honoraria for the focus group participants, of which there were a total of 27.

Authors' Contributions

AV, CB, KJ, TD, and CD performed conceptualization and visualization. CB and TD handled supervision. AV and KJ conducted data analysis. AV, KJ, and CB performed investigations. AV, KJ, AG, and LS handled project administration. AV and CB conducted writing–original draft preparation. AV, CB, KJ, CD, AG, TD, and LS performed writing–review and editing.

Abstract

Background: The traditional history and physical (H&P) provides the basis for physicians' data gathering, problem formulation, and care planning, yet it can miss relevant behavioral or social risk factors. The American Medical Association's "H&P 360," a modified H&P, has been shown to foster information gathering and patient rapport in inpatient settings and objective structured clinical examinations. It prompts students to explore 7 domains, as appropriate to the clinical context: biomedical problems, psychosocial problems, patients' priorities and goals, behavioral history, relationships, living environment and resources, and functional status.

Objective: This study aims to examine the perceived usability of the H&P 360 outside standardized patient settings.

Methods: The H&P 360 was implemented in various clinical settings across 3 institutions. Of the 207 student participants, 18 were preclerkship, 126 were clerkship, and 63 were postclerkship; 3-8 months after implementation, we administered a student survey consisting of 14 Likert-type items (1=strongly disagree to 5=strongly agree) and 3 free-text response items to assess usability.

Results: Of the 207 students, 61 responded to the survey (response rate was 29.5%). Among all students, mean ratings on the 3 usability survey items ranged from 4.03 to 4.24. The 5 items assessing the impact on patient care had mean ratings ranging from 3.88 to 4.24. The mean ratings for the 2 student learning items were 4.10 and 4.16. Students' open-ended comments were generally positive, expressing a perceived value in obtaining a more complete contextual picture of patients' conditions and supporting the usability of the H&P 360. Survey response patterns varied across institutions and learner levels.

Conclusions: Our findings suggest that using the H&P 360 may enhance information gathering critical for chronic disease management, particularly regarding social drivers of health. As a potential new standard, the H&P 360 may have clinical usability for identifying and addressing health inequities. Future work should assess its effects on patient care and outcomes.

KEYWORDS

history and physical; medical education; social drivers; social determinants of health

Introduction

The traditional history and physical (H&P) structure is central to the patient-physician interaction and remains a foundational element of medical education. Through medical history, physicians elicit 60%-80% of the information relevant to diagnosis and treatment [1]. Medical students are typically required to master the skill of gathering, synthesizing, and documenting patient information early in their training. The traditional H&P, used in most medical education settings and routine clinical practice, is primarily structured to diagnose acute medical conditions and has not evolved for generations—despite the growing prevalence of chronic diseases and the increasing influence of social and behavioral drivers of health [2,3].

The social determinants or social drivers of health (SDOH) heavily influence the health of patients and populations [4]. The World Health Organization (WHO), in its conceptual framework for action on SDOH, defines "social determinants of health" as the full set of social conditions in which people live and work [4,5]. We will use the phrases social determinants and social drivers interchangeably. We will refer to social risk factors, meanwhile, as individual-level adverse SDOH, such as housing instability or low education level, and social needs as social factors that take into account people's individual preferences and priorities in identifying and guiding social interventions [6,7].

Health systems and providers are increasingly exploring ways to better integrate health care delivery with reforms aimed at addressing the SDOH, identifying patients' social risk factors, and meeting patients' social needs [8,9]. At the upstream level, laws, policies, and regulations can be used to create community conditions that foster health. At the midstream level, providers and health systems can include screening questions to identify social risk factors and offer services that connect patients to resources to meet their social needs. At the downstream level, clinicians can tailor medical interventions to acknowledge individual social conditions [6,8,9]. To significantly improve the health of all, it is critical to emphasize addressing the broader SDOH inequities—those created and sustained by structural racism and the marginalization of specific groups, including women, Black, Hispanic/Latino, LGBTQ+ (lesbian, gay, bisexual, transgender, queer or questioning, and other diverse sexual orientations and gender identities) individuals, people living with disabilities, and other populations [4,5,10-12].

In addition to increased attention to the SDOH, both globally and particularly in the United States, chronic diseases are the largest contributors to disease burden, accounting for 90% of health care costs in the United States [13]. Health systems are increasingly addressing upstream factors, such as behavioral health, and social and environmental circumstances, to prevent and manage chronic diseases and their consequences [14,15]. Against this multidimensional backdrop, individual clinicians, residents, and medical students typically rely on the H&P examination as their principal method of information gathering. However, when using the traditional H&P to frame and organize this process, learners at all levels are not prompted to collect relevant biopsychosocial data, including social needs and health behaviors, which are key to preventing and managing chronic diseases. Recent research has shown that inaccurate and incomplete patient histories are among the leading causes of diagnostic errors [16].

The H&P 360, a modified version of the traditional H&P, was developed by the American Medical Association's (AMA) Chronic Disease Prevention and Management interest group in May 2017, building on earlier work by medical educators at the University of Michigan (UM) [12,17]. This new approach was designed to more explicitly acknowledge the SDOH, the prevalence of chronic diseases, and the importance of patients' preferences and priorities in clinical decision-making. It intentionally incorporates the WHO conceptual framework for addressing the SDOH at the micro-level of individual interaction [4,5], the Centers for Disease Control and Prevention (CDC) framework for addressing chronic diseases at the health system and community-clinic levels [12,18], and contemporary models of shared decision-making [1,19].

The H&P 360 is grounded in the idea that the central, standardized written template in medical education (ie, the traditional H&P) plays a significant role in both enhancing and constraining information-seeking related to medical decision-making. This understanding of information gathering aligns with Structuration Theory and Cognitive Load Theory. Structuration Theory posits that social practice both shapes and is shaped by the structures, such as learning templates, within which it occurs [20]. Cognitive Load Theory, meanwhile, asserts that cognitive capacity is limited and that learning is enhanced when key information is presented in manageable blocks, such as the 7 domains [21].

At a deeper level, the H&P may play an important role in shaping physicians' professional identity and role expectations, as suggested by Social Learning Theory [22,23], which posits that individuals' agency and role identities are critically influenced by the social and institutional contexts in which they develop. The H&P 360 prompts students to collect relevant biopsychosocial information, particularly social risk factors and needs, using a systematic yet flexible framework. While it retains the basic structure of the traditional H&P for eliciting biomedical information, the H&P 360 also includes general prompts for 6 additional domains: patients' priorities and goals, psychosocial problems, behavioral history, relationships, living environment and resources, and functional status. The 6 nonbiomedical domains were identified through a literature review as those consistently represented in comprehensive clinical assessment settings, including geriatrics, and care for homeless and chronically mentally ill persons, as well as in the categories of the Diagnostic and Statistical Manual of Mental Disorders (4th edition) [24], and have been applied in numerous clinical and teaching settings since 2010 [17]. See Multimedia Appendix 1 for the H&P 360 template.

When using the H&P 360, students are encouraged to ask a few questions from each of the domains as part of the standard history. These additional questions help students gain a more comprehensive understanding of a patient's biopsychosocial condition and support the development of an appropriate

treatment and management plan. In follow-up encounters, continued exploration of the 7 H&P 360 domains can foster a deeper understanding of the patient, informing chronic disease management. A previous randomized trial conducted at 4 medical schools found that medical students using the H&P 360 in a standardized patient setting collected significantly more biopsychosocial information compared with students using the traditional H&P [3]. Another study found that students who applied the H&P 360 using templated notes in the electronic health record reported improved elicitation of patient goals and perspectives, as well as identification of contextual factors and patient needs critical to preventing rehospitalization [25]. In addition to enhanced data gathering, the H&P 360 has been shown to encourage multidisciplinary team care planning [17] and to improve patient rapport (unpublished data).

The goal of this study was to examine the perceived usability of the H&P 360 by both faculty and students across a variety of clinical settings and learner levels in routine clinical teaching contexts. To assess usability in different clinical teaching environments, the AMA launched a grant program for institutions willing to implement the H&P 360 in student clinical encounters and administer a standardized postintervention survey to faculty and students across sites. We hypothesized that students and faculty across sites would appreciate the usability of the approach, but that barriers to engagement would vary by site and learner level.

Methods

Site Selection

The AMA offered funding for projects to implement the H&P 360 within clinical settings at academic institutions. Priority was given to projects aimed at developing additional supporting materials and gathering student and faculty feedback during the implementation phase. Following a call for proposals, 4 academic institutions received grants from the AMA to implement the H&P 360 across a diverse range of clinical settings and undergraduate medical education learner levels. The grant period began in January 2020 and ended in June 2021. Because of the pandemic, only 3 of the institutions were able to implement their grants. These institutions were the UM School of Medicine, the University of Chicago Pritzker School of Medicine (UC), and the Herbert Wertheim College of Medicine at Florida International University (FIU). The fourth institution was unable to implement its grant project but still incorporated the H&P 360 with its students.

The 3 grant-funded institutions implemented the H&P 360 across a variety of clinical settings and learner levels, described in detail in Table 1. Clinical settings included inpatient, outpatient, virtual, community-based clinics, and longitudinal outpatient clinics. Learner levels ranged from preclerkship to clerkship and postclerkship. The approaches each school used to introduce students and faculty to the H&P 360 are also detailed in Table 1. At all 3 sites, students were introduced to the H&P 360 through a nonstandardized 1- to 2-hour seminar. One site (UC) implemented standardized note templates within the electronic health record to facilitate documentation of the H&P 360. Faculty orientation to the H&P 360 varied across sites, ranging from emailed communications with attached introductory materials and a teaching guide (UM and UC) to virtual orientation sessions over Zoom (Zoom Communications, Inc) and some in-person sessions (FIU and UC).

Table 1. Learner level, clinical setting, and teaching context by institution.

Approaches to introducing H&P[a] 360	Learner level			Students, n	Setting	Duration of use	How the H&P 360 was introduced to students and topics covered	How the H&P 360 was introduced to faculty and topics covered
	Preclerkship	Clerkship	Postclerkship					
The University of Chicago Pritzker School of Medicine	✓	N/A[b]	N/A	18	• Preclerkship students were encouraged to utilize the H&P 360 in a longitudinal patient-partnered clinical experience (about 6 face-to-face and 2 virtual clinical sessions).	9 months	Preclerkship students attended a presentation on the format and components and received training materials including examples and the interview guide.	Faculty precepting preclerkship students attended a presentation or received an email.
The University of Chicago Pritzker School of Medicine	N/A	✓	N/A	8	• Clerkship students were encouraged to utilize the H&P 360 during COVID-19 follow-up virtual visits.	1 month	Clerkship students attended a 1-hour virtual training session with background about the H&P 360 and details on using a COVID-19–specific note template. The supporting interview guide and pocket card were leveraged as needed.	Faculty attended 2 or more presentations on the H&P 360.
The University of Chicago Pritzker School of Medicine	N/A	N/A	✓	24	• Postclerkship students were encouraged to utilize the H&P 360 in an internal medicine subinternship for 1 admission per call cycle.	1 month	Postclerkship students received an email from their course director with background about the H&P 360 and instructions to access H&P 360 templates. The supporting interview guide and pocket card were leveraged as needed.	Faculty supervising postclerkship students received an email.
University of Michigan School of Medicine	N/A	N/A	✓	39	• All students utilized the H&P 360 in an outpatient setting. • Of the 39 students, 8 used it in a community-based elective and 31 used it in a longitudinal clinic setting. • Students were encouraged to apply the H&P 360 in every encounter.	Elective (1 month) and longitudinal clinics (9 months)	A 2-hour interactive in-person seminar with case examples. The supporting interview guide and pocket card were leveraged as needed.	Email introduction and follow-up, which included teaching tips, pocket cards, profiles, and cases.

Approaches to introducing H&P[a] 360	Learner level			Students, n	Setting	Duration of use	How the H&P 360 was introduced to students and topics covered	How the H&P 360 was introduced to faculty and topics covered
	Preclerkship	Clerkship	Postclerkship					
Herbert Wertheim College of Medicine at Florida International University	N/A	✓	N/A	118	• All students utilized the H&P 360 in a virtual and longitudinal, interprofessional, home-based service-learning program.	12 months/1 academic year as part of a longitudinal program.	Introduced during an interactive didactic session on chronic disease management; the self-directed video was also available for students.	One in-person faculty development session before COVID-19; a self-directed video for faculty; and a conference presentation by Dr. Brent Williams from the University of Michigan.

Settings

At FIU, the investigators had to alter their initial implementation strategy due to the COVID-19 pandemic. The project team completed 1 in-person faculty orientation; subsequent sessions were delivered virtually as an online module tailored to both faculty and students. For students, the team relied solely on the online module, as the planned in-person session was canceled due to the pandemic.

At UC, initial implementation plans were also disrupted by the COVID-19 pandemic, which led to medical students being removed from traditional clinical settings. During this period, an innovative program was developed in which clerkship students conducted phone outreach to patients newly testing positive for COVID-19. Taking advantage of this novel opportunity, the H&P 360 was used to help structure these outreach calls. Because of the small number of students and faculty involved, an in-depth, interactive training program for both faculty and students was offered via Zoom meetings. In the later implementation of the H&P 360 for preclerkship students, a virtual orientation over Zoom was incorporated into their Clinical Skills course. Because of the large number of faculty serving as preceptors for this course, only new faculty preceptors—who were required to attend a mandatory orientation session—received virtual training on the H&P 360 framework. Preceptors who were not new to the program and for whom orientation attendance was not required received emailed communication about the H&P 360. Implementation for postclerkship students was further modified to email communication only. These students had rolling start times each month, and there was no formal orientation session during the clerkship to integrate separate training. The number of clinical faculty preceptors for postclerkship students was quite large, also with rolling start times every 2 weeks, making email communication regarding the H&P 360 the most feasible approach.

At UM, the H&P 360 was implemented during the postclerkship period in 2 settings: a 1-month clinical elective focused on underserved populations before the pandemic (8 students over 2 months), taught by 1 of the authors (BW), and longitudinal weekly clinics in primary care settings over 9 months during the pandemic (31 students). The longitudinal clinic rotation was chosen due to the faculty coordinator's interest in implementing the H&P 360 and its suitability for continuity settings, where the domains can be explored with patients over time. For the longitudinal rotation, students received a 2-hour introduction to the H&P 360, including case examples. Precepting faculty were sent introductory materials, teaching tips, and written case examples via email both at the start and several months into the longitudinal clinics. Many longitudinal clinics transitioned to telemedicine visits during the pandemic. In both rotations, students were encouraged—but not required—to use the H&P 360, or portions of it, in every encounter.

Survey Structure

Data collection consisted of a student survey on using the H&P 360 in undergraduate medical education settings. As the survey focused specifically on the use of the H&P 360, previously published surveys were not applicable. Theoretical frameworks guiding survey development included Bloom's taxonomy of learning objectives [26], which emphasizes synthesis and application of knowledge rather than factual recall, and the Expectancy-Value Theory of Motivation [27], which posits that learner motivation is influenced by the perceived value of new information.

The survey consisted of an initial section asking for examples of a question relevant to each of the 5 domains from the H&P 360, followed by 14 Likert-type items (response scale: 1=strongly disagree to 5=strongly agree) and 3 open-ended questions. The Likert-type items were developed using a "blueprint" of 7 potential impact areas of the H&P 360, designed by the authors. Source items were either adapted from a 10-item version used in a previous study [17] or newly created. To minimize the response burden, the survey was limited to 15

items or fewer. Items were reviewed for sensibility by small groups of medical students and residents not involved in the study, resulting in minor modifications. The final instrument included 14 Likert-type items. Two items were modified or omitted at some sites and thus were not included in the analyses. The analyzed items are shown in Tables 2 and 3. The 7 areas from the "blueprint" and their corresponding item numbers were perceived usability of the H&P 360 (items 1, 2, and 3); impact on history-taking (item 4); perceived clinical value added (items 5 and 6); promotion of understanding patients' goals (item 7); enhancement of patient-provider relationships (item 8); facilitation of care planning (item 9); and promotion of inclusion of other health professionals (item 10). Two additional items were included as global measures of educational and clinical value, respectively (items 11 and 12). By covering a broad range of topics, results from individual items could be used independently by educators to inform a wide spectrum of educational and research activities.

The 3 open-ended questions were designed to elicit specific feedback about the H&P 360: "Name two (or more) aspects of the H&P 360 you found helpful"; "Name two (or more) aspects of the H&P 360 you found challenging"; and "What changes would you recommend for the H&P 360?" A systematic review of the open-ended comments is not included in this paper. Instead, a subset of comments reflecting students' perceived value and limitations of the H&P 360 is provided in Multimedia Appendix 2.

Table 2. Mean student survey scores (Likert scale 1-5)[a] by school.

Student survey scores by school	All students (N=49) (N=61)[b], mean (SD)	All FIU[c] students (N=17), mean (SD)	All UM[d] students (N=13), mean (SD)	All UC[e] students (N=19) (N=31)[b], mean (SD)
Usability				
1. The H&P[f] 360 was easy to use	4.12 (0.78)	4.18 (0.64)	4.15 (0.69)	4.05 (0.97)
2. Elements of the H&P 360 are potentially useful in all patient interactions	4.24 (0.90)	4.35 (0.61)	4.62 (0.51)	3.89 (1.20)
3. I plan to use the H&P 360 during other rotations[b]	4.03 (0.84)	3.59 (0.94)	4.31 (0.75)	4.16 (0.73)
Impact on patient care				
4. The H&P 360 changed some of the questions I ask patients during the encounter	4.08 (0.76)	3.59 (0.87)	4.46 (0.52)	4.26 (0.56)
5. The H&P 360 helped create a more comprehensive problem list	3.88 (0.95)	4.06 (0.90)	4.15 (0.69)	3.53 (1.07)
6. The H&P 360 added valuable information that I would not otherwise know about the patient[b]	4.18 (0.79)	3.82 (1.01)	4.46 (0.78)	4.26 (0.58)
7. The H&P 360 helped me better understand patients' goals[b]	4.15 (0.68)	4.12 (0.78)	4.23 (0.44)	4.13 (0.72)
8. Using the H&P 360 facilitated a stronger provider-patient relationship[b]	4.24 (0.67)	4.12 (0.70)	4.08 (0.64)	4.35 (0.66)
9. I was able to develop management plans that incorporated information from the H&P 360	3.88 (0.83)	4.00 (0.87)	4.00 (0.41)	3.68 (1.00)
Overall impact on student learning				
10. The H&P 360 helped me learn to be a better clinician[b]	4.16 (0.64)	4.06 (0.66)	4.31 (0.63)	4.16 (0.64)
11. The H&P 360 helped improve the care I provided to my patients	4.10 (0.71)	4.06 (0.75)	4.31 (0.63)	4.00 (0.75)

[a]1=strongly disagree to 5=strongly agree.

[c]N/A: not applicable.

The survey was administered online by all 3 sites approximately 3-8 months after implementation. Six items that presumed experience in clinical care were not administered to preclinical students participating in this study; this omission applied only to a subset of students at 1 site. Data were aggregated across all sites to calculate mean scores and SDs for each survey item, allowing comparisons by institution and by clerkship status. Because of the small number of respondents in each subgroup, we were limited to analyzing descriptive statistics and were unable to conduct psychometric analyses or hypothesis testing to statistically compare subgroups. However, the descriptive analysis was still useful for aggregating data across multiple sites and generating hypotheses. Data analysis was conducted using STATA version 13.0 (StataCorp). See Multimedia Appendix 3 for the supporting CHERRIES (Checklist for Reporting Results of Internet E-Surveys) document.

Ethics Considerations

The UM received exempt institutional review board status from the Institutional Review Boards of the UM Medical campus. FIU received exempt institutional review board status from The FIU Office of Research Integrity. The UC received exempt institutional review board status from the BSD/UCMC Institutional Review Boards at the UC. Lastly, the AMA confirmed that this study was not deemed to be research by the University of Illinois Chicago Institutional Review Board. All 4 institutions confirmed that all methods were carried out in accordance with relevant guidelines and regulations.

Results

Summary of the Survey Findings

The Likert-type survey items were organized by consensus among the authors into 3 sets to identify patterns and facilitate discussion: Usability (3 items); Impact on Patient Care (7 items); and Overall Impact on Student Learning (2 items). Results are presented for all student respondents by institutional site in Table 2 and by learner-level subgroups in Table 3. Of the 207 students, 61 (29.5%) responded to the survey. Institutional response rates were as follows: FIU, 17 out of 118 (14.4%) students; UM, 13 out of 39 (33.3%) students; and UC, 31 out of 50 (62.0%) students.

Among all students, mean ratings on the 3 survey items related to usability (ease of use, use in all encounters, and intention to use in other rotations) were high, with mean (SD) scores ranging from 4.03 (0.84) to 4.24 (0.90) (Table 2). Some students' comments suggested that efficiently using the H&P 360 requires practice. One postclerkship student commented: "(The H&P 360)...is quite long so it was challenging to hit aspects of each domain while attempting to time manage. However, hitting 1-item from each domain, chosen on a case-by-case basis, seems

quite doable." Several students raised concerns about the awkwardness of asking some questions, particularly during virtual outreach calls to patients who had newly tested positive for COVID-19. One clerkship student commented: "It did not always feel natural to fit into the conversation with every patient. Some were not very open to conversation, which is understandable since we were strangers calling them out of the blue."

Students also found that the H&P 360 positively affected patient care by expanding the range of information available for clinical decision-making and promoting stronger patient-clinician relationships. Mean ratings across the 5 related items ranged from 3.88 (SD 0.95) to 4.24 (SD 0.67; see Table 3 for details). Student feedback on clinical impact emphasized the benefits of the H&P 360 in building rapport. One clerkship student commented: "It helped me build rapport with my patient and have a better [understanding] of their life and how it affects their health." Others mentioned that the H&P 360 helped build trust and identify high-risk situations. See Multimedia Appendix 2 for additional relevant student comments.

Students also found that the H&P 360 facilitated their learning and development as clinicians, with mean ratings of 4.10 (SD 0.71) and 4.16 (SD 0.64) for the items "the H&P 360 helped me...improve the care I provided to my patients" and "…be a better clinician," respectively. One postclerkship student commented: "The H&P 360 was helpful in...[r]eturning the humanity to medicine: patients are people first—Helping to understand some of the barriers to health and disease prevention that might not otherwise be apparent."

Site-Specific Survey Findings

Some variation in student survey responses was observed across institutions (Table 2). For 2 items related to using the H&P 360 to develop problem lists and management plans, student ratings at UC were lower than those at UM or FIU. For 3 items—related to using the H&P 360 in other rotations and its role in changing some questions and adding valuable information—student ratings at FIU were lower compared with UC and UM.

Survey Findings by Learner Levels

Across learner levels, some variation in student survey responses was noted for a minority of items (Table 3). For example, preclinical students gave relatively low ratings on the item related to facilitating care planning that included other health professionals compared with their responses on other items. While clerkship students valued the H&P 360 in all patient interactions and for facilitating stronger patient relationships, their ratings were relatively low for items related to the H&P 360 changing the questions they asked and their plans to use it in future rotations. Postclerkship students gave high ratings for 9 of the 12 questions. Lower ratings were observed for items related to ease of use, creating a more comprehensive problem list, and the ability to develop management plans incorporating information from the H&P 360. The phrasing of the item on time burden evolved over time and was therefore not administered consistently across or within institutions.

Discussion

Principal Findings

Previous work has documented the advantages of the H&P 360 over the traditional H&P during single inpatient encounters [17] and with standardized patients [3]. This study examined the use of the H&P 360 across a broad range of routine, longitudinal clinical teaching settings. Medical students at 3 institutions, spanning different levels of training and diverse ambulatory, inpatient, community, and virtual settings, found the H&P 360 useful and reported a positive impact on patient care and their own learning. The perceived benefits of the H&P 360 include helping students gather relevant information on patients' goals and circumstances, as well as potential barriers and facilitators of health. It also enhances patient-provider relationships and encourages interprofessional care planning. Compared with the traditional H&P, student feedback suggests that the H&P 360 made them better clinicians. We can further speculate that by using the H&P 360, students develop a more complete picture of the patient—not just signs, symptoms, and diagnoses—but also the social and human narrative context that critically influences the presentation, management, and ultimately the outcomes of disease conditions. We suspect that gathering this more complete picture of patients' lives is one factor contributing to students' perception that the provider-patient relationship was enhanced by using the H&P 360. An important area for future investigation is the mechanism behind this enhanced relationship. Perhaps it is this more complete understanding of the patient, combined with improved patient rapport, that prompted the student comment that the H&P 360 "...return(ed) the humanity to medicine."

Implication of Findings

The observed variation across institutions and learner levels—though limited by small sample sizes and collinearity between institutions and learner levels—may offer insights into factors influencing medical students' perceived value of the H&P 360. Here, we present 3 speculative observations based on these data to encourage future research and application of the H&P 360. First, the teaching setting for the FIU students included in this study was a community-based, longitudinal, interprofessional environment with an established strong emphasis on comprehensive assessment and interprofessional care. As such, FIU students may have been less likely to perceive that the H&P 360 changed questions asked or added valuable information beyond their prior practice. Additionally, during the study period, FIU students conducted visits virtually due to COVID-19. Second, UC provided a relatively unique perspective on implementation efforts by including preclinical students and applying the H&P 360 in telehealth settings. Although the very high perceived value of the H&P 360 among both preclinical students and clinical-year students in telehealth settings is striking and promising, further investigation in other settings and institutions is needed to contextualize these findings. Finally, variation among institutions may reflect differences in overall emphasis on SDOH; the role of faculty in promoting or minimizing the study findings and application of the H&P 360; or differences in its use across inpatient, outpatient, and virtual settings.

Synthesizing evidence on the H&P 360 from this and previous studies, along with input from faculty and students and our own clinical teaching experience, we suggest that incorporating the H&P 360 into routine clinical practice involves at least 4 dimensions of learning. The general patterns and variations observed across different learner levels and clinical settings in this study support and shed light on each of these dimensions.

First, learners and educators using the H&P 360 will need to *integrate domain-based thinking alongside checklist-based approaches in data gathering.* Currently, early medical students are taught to take a history by following a memorized list of specific questions. Over time, an implicit process develops, where clinicians tailor questions, diagnoses, and management plans based on patient-specific information [28]. The direction a clinician takes for follow-up inquiry is likely influenced by many factors, including training experiences, knowledge and clinical skills in managing a wide range of issues (eg, emotional well-being, food insecurity, or safe housing), and local practice norms. Consequently, this approach is likely to vary widely among clinicians. Some naturally explore psychosocial dimensions, while others remain more narrowly focused on biomedical factors. To reduce this variation and better address the role of psychological and social factors in patients' health, the H&P 360 provides uniform, systematic prompts that help clinicians recognize social and psychological determinants of health. The H&P 360 represents a fundamental shift in learning to gather patient information by introducing 6 domains as general reference points alongside the traditional checklist focused on biomedical information.

For early learners, balancing domain-based thinking with a checklist approach can be disconcerting as they decide which specific content to include or exclude within the nonbiomedical domains. This challenge aligns with student feedback that the H&P 360 initially feels long and overwhelming when seen as a checklist of individual items, but becomes manageable and useful when viewed as a set of domain-based prompts that can be selectively explored—or revisited over multiple patient encounters. This is also consistent with findings that senior medical students using the H&P 360 identify and apply significantly more psychosocial information in their care planning than those using the traditional H&P [17]. Additionally, our finding that preclinical students found the H&P 360 added valuable information, helped them understand patients' goals, and facilitated stronger patient-provider relationships suggests that early learners can successfully incorporate domain-based thinking into routine data gathering. The interview guide that accompanies the H&P 360 can be a valuable resource in this regard. It helps students decide which domain to focus on and also supports faculty in navigating these domains during classroom teaching. See Multimedia Appendix 4 for the H&P 360 interview guide. Further exploration of domain-based thinking among medical learners is warranted to identify the best ways to provide a data-gathering framework that is both accessible in the early stages and comprehensive in the later stages of learning. We are particularly interested in methods for—and the implications of—incorporating patients' values, priorities, and goals into every clinical encounter [29,30].

Second, once familiar with domain-based thinking, medical students need to *develop skills in deciding which specific information within a domain is most relevant to a given patient encounter.* The finding that clerkship and postclerkship students from both inpatient and outpatient settings found the H&P 360 added valuable information and enhanced patient care suggests that students perceive tailoring domain-based questions to individual patients and clinical contexts as useful and facilitative for patient care.

Importantly, many students' comments revealed the emergence of skills in "modularizing" components of the H&P 360—using only those most relevant to a particular clinical context without feeling compelled to cover every domain.

Third, students need to *manage the emergent information through further inquiry or redirection.* As reflected in some student comments, medical students can feel compelled to fully elucidate or address the complex behavioral or social drivers of patients' health once identified. They also recognized that some behavioral or social needs uncovered during this process are important but do not require immediate action. Students should then redirect the interview to address matters of immediate concern (eg, potentially serious symptoms or a plan for initial hospital treatment), while simultaneously developing a plan to address longer-term issues. This process of identifying, prioritizing, and guiding the interview to optimize both disease-specific and contextual information has been demonstrated in the area of diagnostic reasoning, where a clinician listens and generates hypotheses, gathers data to test these hypotheses, and, depending on the results, offers treatment or pursues further diagnostic action [31]. We suggest that the domain-based framework of the H&P 360 facilitates the application of advanced interview skills not only to diagnostic assessment but also to management and care planning that better account for patients' psychosocial and environmental realities.

Finally, the *new information elicited with the H&P 360 must be applied to clinical management planning.* Our data suggest that, while learners generally found that information from the H&P 360 enhanced care planning, ratings in this area were lower than for other measures and lower than those observed in previous studies [3,17], particularly among early learners. We believe these findings highlight the complexity of incorporating social and behavioral information into care planning—for example, in discharging a patient facing homelessness or supporting medication adherence limited by insurance, income, transportation, or behavioral factors. By bringing these "background" issues to the forefront early in training, students can develop skills to mobilize interprofessional teams and utilize local resources as part of routine patient care. We also anticipate that by directly addressing SDOH—rooted in racial, ethnic, and socioeconomic inequities—learners will be better equipped to recognize and manage systemic and personal implicit biases that negatively impact care.

Although not emphasized in the student-oriented results presented here, our study suggested that faculty play an important role in promoting the effective use of the H&P 360. Faculty development and feedback methods varied across participating sites, ranging from interactive seminars to entirely

email-based communication, and faculty "buy-in" likely varied both within and across sites. At all sites, faculty were provided with information on the purpose, content, and suggested best practices for using the H&P 360. Anecdotally, however, learners reported little awareness or receptivity among teaching faculty toward using the H&P 360 domain framework in teaching and clinical management—except at 1 site where in-person faculty development was conducted before the COVID-19 pandemic. As professional development is influenced by cues from influential social sources, as well as practice resources and norms [22], effective application of the H&P 360 will likely require its incorporation into local teaching and clinical practices. Faculty development and the use of the 7-domain framework in teaching and clinical practice represent important areas for future investigation.

Limitations

Our study was limited by small sample sizes, which prevented more rigorous statistical analyses of the Likert-type scale data and further qualitative analysis. However, both in this work and in previous studies, student responses to the H&P 360 have been primarily positive. Additionally, it is important to acknowledge that some students experienced difficulties implementing the H&P 360 during virtual interactions and in specific clinical encounters. More implementation training on how to utilize the H&P 360 in different scenarios might be helpful for students. The survey also had a low response rate at some institutions, which may be attributable to several factors. The survey was optional and not required at all 3 sites. In some cases, faculty were unable to administer the survey immediately after course completion due to time constraints.

Lastly, this project took place at the beginning of the pandemic, which introduced many competing priorities and adjustments to the overall learning environment. The overall impact of response rates on the results is difficult to estimate, as rates varied by institution and were likely influenced by additional local factors. Information on factors that could promote or limit the effective application of the H&P 360 was not explored beyond the data collected from the student surveys. For example, curricular content encountered by students before the H&P 360, as well as organizational culture, could influence its application at each institution. Exploration of these factors was outside the scope of this study. Survey data were limited by too few observations in relevant substrata (eg, inpatient vs outpatient; longitudinal vs short-term; virtual vs face-to-face; and institutional vs community-based clinical settings) to permit meaningful subgroup analyses exploring additional variables that may impact the implementation of the H&P 360 in different settings.

Conclusions

The H&P 360 provides an enhanced template for data gathering that includes general prompts addressing key dimensions of human health not captured by the traditional H&P, such as patients' values, priorities, and goals. Our findings support the usability of the H&P 360 as a more comprehensive approach for medical students to gather patient information. Among early learners, it may be best to include a few specific illustrative items under each domain to familiarize students with the domains without requiring higher-order clinical knowledge or skills. Among later learners, the now-familiar domains can be used to promote more complete data gathering and to develop skills in integrating patients' goals, psychosocial and behavioral factors, and interprofessional teams into care planning. The H&P 360 may be particularly useful for making health inequities and their root causes more visible in routine clinical encounters, while guiding management planning to address them. Future work should measure its effects on patient care and outcomes.

Relevant topics for future investigation related to the H&P 360 include influences on students' use of the H&P 360 at different developmental stages; its use to identify and address SDOH; and methods and outcomes of faculty development to promote routine incorporation of domain-based thinking into clinical teaching and practice. To facilitate further investigation and implementation of the H&P 360 among medical schools, a set of tools and resources is available on the AMA website or authors may be contacted directly for further information.

Acknowledgments

The project was performed with financial support from the Medical Education Department within the American Medical Association. The authors thank their partners at the University of Michigan (contract ID AMA 36456), the University of Chicago (contract ID AMA 36457), and Florida International University (contract ID AMA 36572). The authors express gratitude for the planning and logistical support provided by several team members at each institution who led and coordinated the on-site study activities. They also deeply appreciate the contributions of numerous current AMA team members, notably Kevin Heckman, Kathryn Pajak, and Kimberly Loomis. The collaborating group authors include Jonathan Lio, MD; Vineet Arora, MD; Rachel Clarke, PhD, Onelia Lage, MD; and Ebony Whisenant, MD.

Authors' Contributions

RH and KK were the project leads for the AMA. JB was the lead investigator at FIU. GS was a coinvestigator at FIU. TK was the lead on the planning and conduct of analyses. VP led data analyses, and BW was the lead investigator at UM and developed the first draft of the H&P 360. All authors provided substantial contributions to the conception and design; acquisition of data; analysis and interpretation of data; drafting of the article and revising it critically for important intellectual content; final approval of the version to be published; and agreement to be accountable for all aspects of the work, ensuring that questions related to the accuracy or integrity of any part of the work are appropriately investigated and resolved.

Abstract

Background: The venipuncture is one of the most frequently performed procedures in health care. Arm phantoms are available for training, because the procedure itself can be challenging. These phantom arms do not represent a realistic setting and do not offer opportunities to train challenging scenarios.

Objective: This randomized, single-blind study aimed to train health care workers on both a commercially available injection arm and an in-house developed 3D-printed arm, to evaluate the perceived realism and adequacy of training on both arms.

Methods: Participants were trained on both the commercially available arm (arm A) and the 3D-printed arm (arm B). Participants were randomized and blinded from knowing which arm they started training on. A questionnaire was filled in on, among others, the perceived realism of the arm (0 for not realistic, 100 for realistic) and adequacy of the training (inadequate, moderate, or adequate).

Results: A total of 68 participants evaluated the perceived realism of arm A and B, which were scored on average 62.97 (SD 21.47) and 63.79 (SD 17.45), respectively. The difference in perceived realism of the two arms was not statistically significant (based on the paired *t* test, mean difference=−0.82, *P*=.78). Training on arm A was reported inadequate by 7% (5/68 participants), moderately adequate by 31% (21/68), and adequate by 62% (42/68). This was not significantly different from arm B (marginal homogeneity test, *P*=.74), with 4% (3/68), 38% (26/68), and 57% (39/68), respectively, reporting that the training was inadequate, moderately adequate, and adequate.

Conclusions: The 3D-printed arm is as realistic and provides an equally adequate training compared to the commercially available arm. The 3D-printed arm offers the additional possibility to design different models representing several levels of difficulty for vascular morphology. This potentially lowers the number of venipuncture failures by preparing health care workers on challenging scenarios.

KEYWORDS

venipuncture; phlebotomy; blood draw; 3D printing; vascular phantom

Introduction

The venipuncture (or phlebotomy, blood draw) is one of the most frequently performed procedures in hospitals and is predominantly carried out for diagnostic purposes [1] Although the venipuncture is recognized as a safe and relatively easy procedure, it can be a challenging procedure especially in certain groups, for example, in patients with obesity, patients with a dark skin, or patients undergoing dialysis or chemotherapy. Minor complications include bruising and hematoma and occur in about 12% of venipunctures, while serious complications such as diaphoresis with hypotension or syncope (vasovagal) occur in 3% of patients [2]. There is a minor chance of nerve injury (1/67,000 venipunctures) and also phlebitis is rarely reported [3,4].

The risk of complications is enhanced in case of failure of the venipuncture, that is, a failed needle insertion where no blood samples can be collected, and a second attempt of venipuncture is required. It has been shown that in order to achieve a rate of successful venipunctures close to 99% at the first attempt, one year of practice is necessary [5]. When two attempts both fail for blood sampling, the protocol of most hospitals recommends contacting the anesthesiology department to perform the venipuncture procedure instead. In 2023, this happened 12.233 times at the Onze Lieve Vrouwe Gasthuis (OLVG), a large city hospital in Amsterdam (unpublished data, Business Intelligence Department, OLVG, 2023).

In order to lower this number, proper training and supportive supervision of health care professionals learning the venipuncture is fundamental and therefore recommended by the World Health Organization guidelines on drawing blood [6]. Medical education has evolved from the traditional apprenticeship training to more sophisticated training methods, such as training on simulators (venipuncture arm phantoms) and the use of e-learning modules for theoretical education and electronic simulation [7]. Simulation training can help to improve the venipuncture technique [8]. In addition, training can also improve self-confidence, which also might decrease the number of venipuncture failures [9].

To learn the venipuncture procedure, the current practice is a training on a commercially available arm phantom. This is a phantom of an arm with vessels filled with a liquid that simulates blood. The vessels are embedded in a firm material to enable localization of the vessels by palpation through a layer of skin. Although this arm is a major advancement to practice the venipuncture routine in a safe learning environment yet, there is room to improve training possibilities of the injection arm. Disadvantages of the current training arm are both the realism of the arm and some practical issues.

3D-printing gives the possibility to design and print tailor-made arms. This offers the opportunity to design different versions or models representing several levels of difficulty for vascular morphology to train both novice and experienced health care workers. As a first step towards these advanced tailor-made arms, a regular 3D arm phantom. The aim of this study was to compare the perceived realism and the reported adequacy of the training on a commercially available injection arm to a 3D printed arm.

Methods

Study Design

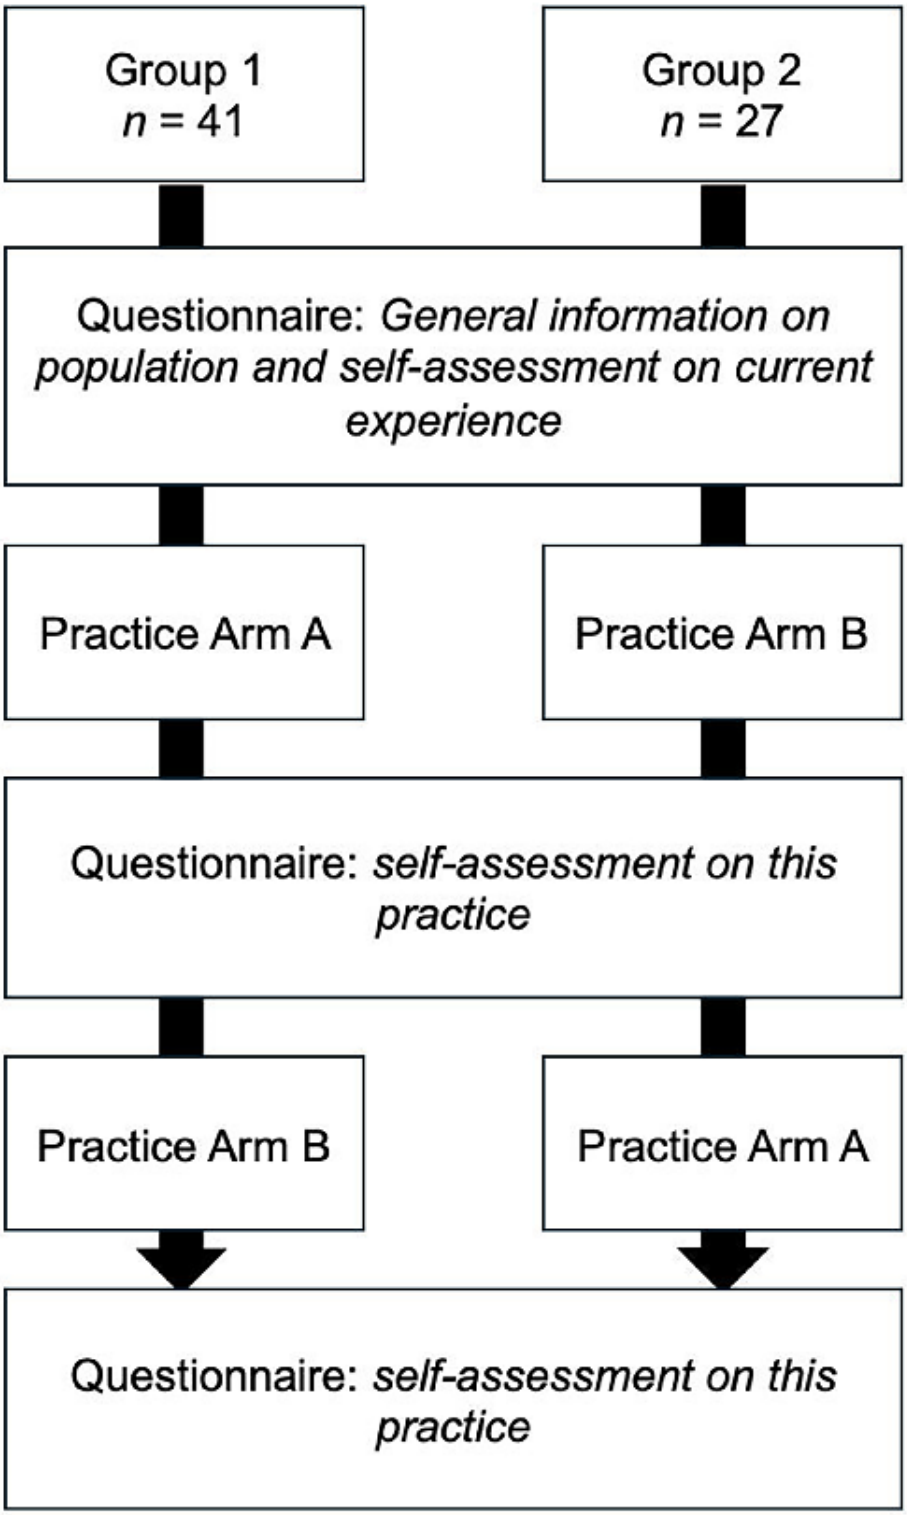
In this randomized, single-blind cross-over comparison study, participants were recruited among the hospital staff of OLVG, a large city hospital in Amsterdam. Information about the study was given via internal communication channels, that is, the intranet and digital newsletter. Participants could apply for the study voluntarily (voluntary response sampling). Requirements for the application were an age of ≥18 years and a medical license to perform peripheral intravenous injections.

All training sessions were supervised by the same trainer. The training started with a short introduction to assess the participant's initial experience and knowledge. A short explanation of the procedure was given, and participants were asked for their learning question. After this, the procedure was demonstrated by the trainer on a training arm. This arm was not part of this study. Participants could practice as often as they needed; the trainer observed and provided feedback on their actions where needed.

Participants were randomized into two groups: group 1 started the training on the commercially available injection arm (arm A) and continued with training on the 3D-printed arm (arm B), while group 2 started the training on arm B and continued training on arm A (Figure 1). The participants received a closed envelope containing the information on which arm to start the training on (A or B). Participants were blinded from knowing which arm was the commercially available arm, and which arm was the 3D-printed arm, as the same sleeves were used for arm A and arm B. Before and after training on each arm, participants were asked to fill in a questionnaire (Figure 2).

Figure 1. Commercially available venipuncture arm phantom (arm A) and the 3D-printed arm (arm B) during the training.

Figure 2. Sequence of training and questionnaires.



Ethical Considerations

Participants had to give informed consent to participate in the study. Participants were able to opt out. No compensation was provided to any participant. The study was approved by the local ethics committee of the OLVG, the Advisory Committee on Scientific Research (approval: WO19.065), and data were collected anonymously.

Measurements

The primary outcome measures were assessed using a questionnaire after each training round: perceived realism of the arm (rated on a scale from 0 [not realistic] to 100 [realistic]) and adequacy/quality of the training (three response categories: inadequate, moderate, or adequate). In addition, information about the participants (eg, role, department, or experience with venipuncture) was collected using these questionnaires (Multimedia Appendix 1).

Sample Size

No published data were available on ratings of realism or training adequacy for phantom arms. Therefore, assumptions were made based on expert and user opinions. For the commercially available arm, a mean realism score of 70 (on a 0 - 100 scale) was assumed, together with a conservatively assumed standard deviation of 20. To detect a mean difference of 10 points with 80% power at a two-sided alpha level of .05, a sample size of 65 participants was required.

Arm Phantoms

The commercially available arm phantom is designed to train venipuncture and intravenous infusion (NASCO Healthcare). Veins are accessible at the antecubital fossa, along the forearm, and at the back of the hand. There are visible veins, as well as invisible veins that can only be determined by palpation. Artificial blood can be drawn from the vessels (NASCO Healthcare, Life/form®). The arm is designed with a skin that has a soft touch when palpating the vessels.

The commercially available arm phantom for venipuncture was the basis of the design of the tailor-made 3D-printed arm: a digital 3D model of the commercially available arm was acquired through a 3D surface scan (Artec EVA 3D scanner, Artec Studio 15 Software). The digital 3D model was edited in Meshmixer (Autodesk, Inc.) and prepared for printing in the program Simplify3D. The arm was printed from glycol modified polyethylene terephthalate using the Ultimaker printer (Ultimaker BV). Silicone tubes were used to simulate the vessels (Dispomed Ltd; Figure 3). The skin of the arm was similar to the skin of the commercially available skin. This was the first time a 3D-printed arm was produced by our laboratory. There was no pilot performed on this arm in advance of using the arm for the training with participants.

Figure 3. The 3D printed arm.

Statistical Analysis

The study population was characterized using descriptive statistics. Continuous variables were presented as mean (SD) or median (IQR), depending on normality (assessed by visual inspection of histograms and Q-Q plots). Categorical variables were presented as frequencies and percentages (n, %).

As the primary outcomes were rated twice by the same participants (cross-over design), paired tests were applied. The difference in perceived realism of the arm was evaluated using a paired samples *t* test. The difference in adequacy ratings of the training was evaluated using a marginal homogeneity test for related samples.

To explore potential sequence effects (order of training, determined by randomization), results were visualized per randomization group, and perceived realism scores were compared between groups using independent sample *t* tests.

All tests were two-sided; *P* values below .05 were considered statistically significant. Analyses were performed using SPSS version 27 (IBM).

Results

Study Population

Characteristics of group 1 and group 2 are presented in Table 1. Most participants in both groups were nurses or physician assistants (Group 1 30/41, 73%; Group 2 15/27, 56%)). The median number of years of experience with the venipuncture was 1 year for both groups (IQR 0 - 4 and 0 - 3, for groups 1 and 2, respectively). Group 1 rated their competence in venipuncture on a 0 - 100 scale with a median of 50 (IQR 18 - 65), while group 2 rated their competence with a median of 40 (IQR 20 - 70). The self-rate of successful venipunctures at first attempt was approximately equal between the groups, with a median of 40 on a 0 - 100 scale. Half of the total population (34/68, 50%) performed a venipuncture daily over the last 6 months. Almost all participants (57/68, 83.8%) had a venipuncture training before, mostly on phantom arms.

Perceived Realism of the Commercial Venipuncture Arm Phantom and the 3D-Printed Arm Phantom

The perceived realism of arms A and B in the total population were on average 62.97 (SD 21.47) and 63.79 (SD 17.45), respectively. There was no statistically significant difference between the reported perceived realism of arm A and B (mean difference −0.82, 95% CI −6.80 to 5.16, *P*=.78).

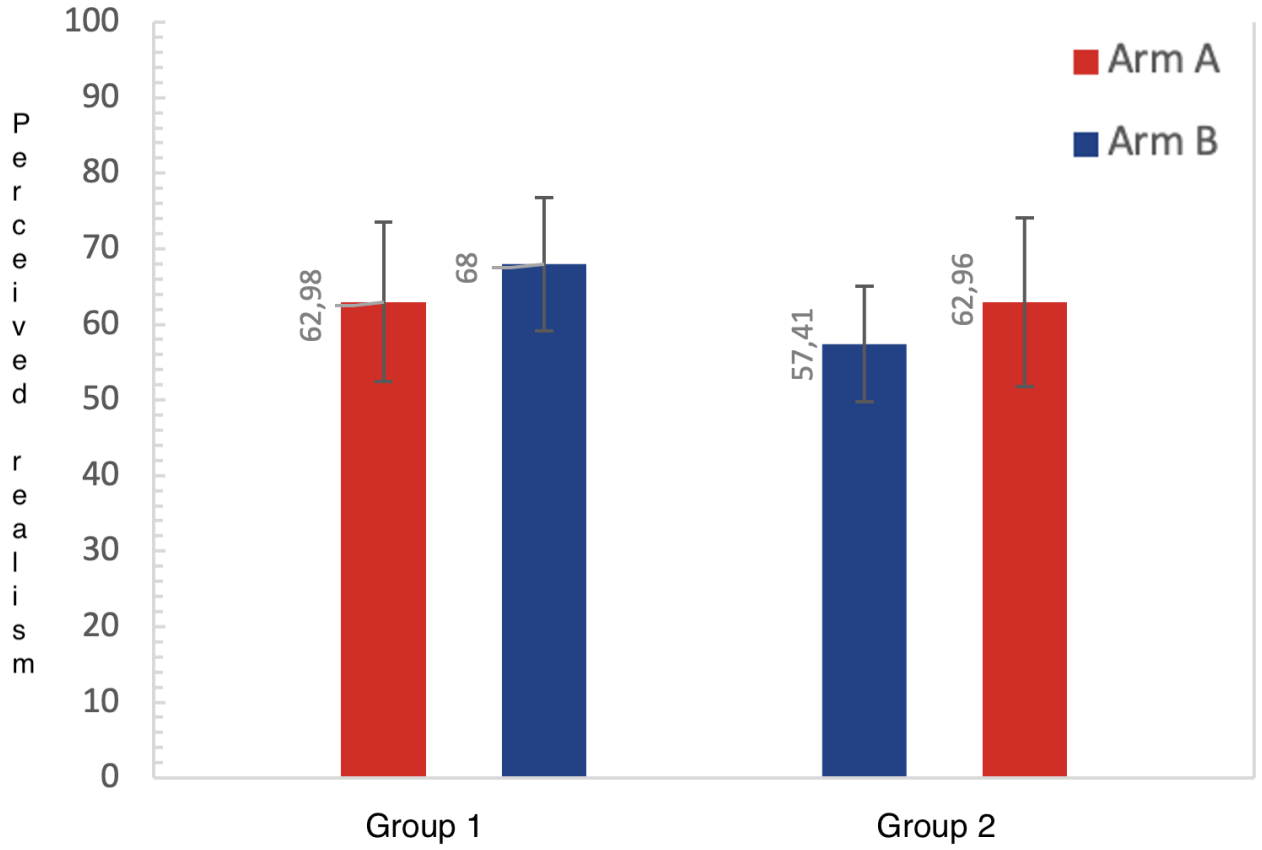
Adequacy of the Training With Commercial Venipuncture Arm Phantom and the 3D-Printed Arm Phantom

Training on arm A was reported inadequate by 5/68 (7%) of the participants, moderately adequate by 21/68 (31%), and adequate by 42/68 (62%). This was not significantly different from arm B (*P*=.74), with 4% (3 out of 68), 38% (26 out of 69) and 57% (39 out of 68), respectively, reporting that the training was inadequate, moderately adequate, and adequate.

Perceived Realism Per Randomized Group

To explore whether training sequence influenced the reporting of perceived realism, Figure 4 shows perceived realism scores stratified by randomized groups. For the commercially available arm (arm A), perceived realism did not differ between groups (mean difference 0.01, 95% CI −10.69 to 10.71, *P*=.998). In contrast, the perceived realism of the 3D-printed arm phantom (arm B) was reported to be significantly lower in group 2, who started training on this arm (mean difference 10.59, 95% CI 2.29 to 18.89, *P*=.013).

Figure 4. The perceived realism of arm A (commercially available venipuncture arm phantom) and B (3D-printed arm phantom) (0 for not realistic, 100 for realistic).



Discussion

Principal Findings

The objectives of this study were to train health care workers on both a commercially available injection arm and an in-house developed 3D-printed arm and to evaluate the perceived realism and adequacy of training on both arm phantoms. Our results indicate that the 3D-printed arm phantom is as realistic and provides an equally adequate training compared to the commercially available arm phantom. The perceived realism of the commercially available arm phantom and the 3D-printed arm phantom were on average 62.97 (out of 100, SD 21.47) and 63.79 (SD 17.45), respectively (*P*=.784). Training on the commercially available arm was reported inadequate by 5/68 (7%) of the participants, moderately adequate by 21/68 (31%), and adequate by 42/68 (62%). This was not significantly different from the 3D-printed arm phantom (*P*=.739), with 4% (3/68), 38% (26/69) and 57% (39/68), respectively, reporting that the training was inadequate, moderately adequate, and adequate.

Comparison to Prior Work

Our results confirm the results of recently published studies [10,11] indicating the perceived realism of 3D-printed arm phantoms for practicing puncturing techniques is sufficient. Hyndman et al [10] printed a 3D-model of the upper limb vasculature to practice the Seldinger technique and assessed student satisfaction on 31 medical students. The use of the 3D-printed model improved anatomic understanding and application of the Seldinger technique of the students. Raffaela et al [11] developed a 3D-printed pediatric phantom to train ultrasound-guided placement of peripheral central venous catheters in children. The model was rated as highly realistic in terms of morphology and functionality for the overall simulation, by 20 expert specialists.

Strengths and Limitations

One of the strengths of this study is that the characteristics of the two groups were comparable. Second, the questionnaire provided very valid suggestions for the improvement of adequacy of training on the next version of the 3D-printed arm, for example, a skin that endures more injections and could be easily replaced, a less heavy phantom to enable easy positioning of the arm, a skin that is thinner to resemble a real skin, and different stages of difficulty in the arm phantom, like thinner, smaller and rolling vessels. A third strength of this study is the fact that a 3D-printed arm phantom can lower the costs of training significantly and that the design can be accessible worldwide. The costs of the 3D-printed arm phantom (approximately US $80) are substantially lower compared with the commercially available arm phantom (approximately US $1100). A digital model for 3D-printing can be shared for free, like the 3D-simulator for arthroscopy given by Ferras et al [12] can be downloaded and printed for free in any 3D printer. Sritharan et al [13] are currently performing a review on how the use of open-source databases for the distribution of simulator designs used for 3D-printing can promote credible solutions for health care training while minimizing the risks of commercialization of designs for profit.

One of the limitations of the study is the potential training effect, as both randomized groups reported slightly higher perceived realism of the second training arm (although not statistically significant). Second, the limited sample size of 68 participants may reduce generalizability. A third limitation is the variability in participant experience, which could potentially influence perceptions of realism. Furthermore, the timeline of distribution into the two groups was not comparable (at the start, most participants started in group 1). As a result, the skin of particularly the 3D printed arm showed multiple injection sites and there was leakage of blood through these injection sites. This might be a reason why participants rated the arms as less realistic. As a result of these limitations, further research is recommended to validate our findings in a broader population. Ultimately, additional outcome measures, including success rates or skill retention, could be added.

Future Directions

Our study shows that the 3D-printed arm phantom is comparable to the commercially available arm phantom in terms of perceived realism and in the possibility to offer an adequate training of the venipuncture. The advantage of 3D-printing is the possibility that it offers to design and print tailor-made arms. In a 3D-printed arm, different vascular morphologies can be designed like vascular morphologies that are palpable and superficially located or deep vascular morphologies that need ultrasound guidance to puncture instead. Moreover, vascular access with aneurysms can be designed to train adequate cannulation in these challenging scenarios. A discipline in which these challenging scenarios are very common is kidney dialysis. The Kidney Disease Outcomes Quality Initiative 2019 strongly recommends training and retraining hemodialysis staff to ensure the maintenance of competency of cannulation skills [14]. They encourage future research to evaluate whether training on cannulation simulation models improves cannulation competency and reduces cannulation complications. A 3D-printed tailor-made arm would offer a simulation model adjusted for this application, in line with the strong recommendation of the Kidney Disease Outcomes Quality Initiative.

An additional advantage of the 3D-printed arm over the commercially available arm is the possible improvements on the skin. The skin can be designed in such a way that it can be easily removed for proper cleaning of blood leakage from the punctured vessels. This was a time-consuming task with the commercially available arm. Also, a different material can be chosen that does not show the location of the previous punctures and thus forces the trainee to palpate the localization of the vessels.

With implementation of the 3-D printed arm phantom for venipuncture training, substantial amounts of health care cost can be saved; when offering adequate training opportunities for venipuncture, the number of contacting the anesthesiology department to perform the venipuncture procedure instead can be lowered.

Conclusions

The 3D-printed arm phantom is as realistic and provides an equally adequate training compared to the commercially available arm phantom. However, the 3D-printed arm offers the possibility to design different models representing several levels of difficulty for vascular morphology. This potentially lowers the number of venipuncture failures by preparing health care workers on challenging scenarios.

Abstract

Background: It is well established that frontline health care staff are particularly at risk of stress. Resilience is important to help staff to manage daily challenges and to protect against burnout.

Objective: This study aimed to assess the usability and user perceptions of a resilience training web app developed to support health care keyworkers in understanding their own stress response and to help them put into place strategies to manage stress and to build resilience.

Methods: Nurses (n=7) and other keyworkers (n=1), the target users for the resilience training web app, participated in the usability evaluation. Participants completed a pretraining questionnaire capturing basic demographic information and then used the training before completing a posttraining feedback questionnaire exploring the impact and usability of the web app.

Results: From a sample of 8 keyworkers, 6 (75%) rated their current role as “sometimes” stressful. All 8 (100%) keyworkers found the training easy to understand, and 5 of 7 (71%) agreed that the training increased their understanding of both stress and resilience. Further, 6 of 8 (75%) agreed that the resilience model had helped them to understand what resilience is. Many of the keyworkers (6/8, 75%) agreed that the content was relevant to them. Furthermore, 6 of 8 (75%) agreed that they were likely to act to develop their resilience following completion of the training.

Conclusions: This study tested the usability of a web app for resilience training specifically targeting National Health Service keyworkers. This work preceded a larger scale usability study, and it is hoped this study will help guide other studies to develop similar programs in clinical settings.

Introduction

Resilience allows individuals to manage everyday challenges and changes. For health care professionals who are working in highly emotive and stressful situations, resilience skills are particularly important [1]. It is well established that frontline staff such as nurses are particularly at risk of stress due to factors such as long shifts, organizational pressures, and the emotional impact of their work [2]. During the COVID-19 pandemic, there were high rates of mental health problems among health care staff. For example, a survey of 255 nurses working with respiratory patients found 21% to be experiencing moderate or severe symptoms of anxiety and 17.2% to be experiencing depression. A total of 18.9% scored low or very low on a measure of resilience [3]. A study of 1106 physicians also reported high levels of anxiety and low levels of resilience during the pandemic [4]. Building emotional resilience is therefore imperative to prevent burnout in health care staff, to keep them healthy both physically and mentally, to improve well-being, and to ensure job retention in the workplace [1].

One way that employers can meet this need is through the provision of resilience training. Key benefits of resilience training include improvements in mental health and well-being, social support, self-efficacy, and coping. Further benefits include

improved ability to adapt to pressures and demands in the workplace and other areas of life [5]. In health care settings, nurse resilience interventions have been highlighted as a potential way of enhancing staff coping and well-being, job satisfaction, and retention [2]. Greater nurse resilience has also been associated with better work performance [6].

A constraint of traditional resilience training programs is the time required to attend in person, which can exclude certain staff groups, such as nurses, from participation. Smartphone apps have the potential to offer training in resilience to large numbers of people while overcoming barriers, such as stigma, time, and acceptability, and can be integrated easily into the wider organizational well-being strategy [7-11].

The aim of this study was to evaluate whether health care keyworkers would be willing to carry out resilience training via an online platform specifically designed to enable them to understand their own stress response and put in place strategies to manage stress, build emotional resilience, and maintain well-being. The data collected would generate important information for future implementation, while contributing feedback for a more refined usability study with this population.

Methods

Participants

The recruitment process was carried out by the Medical Devices Testing and Evaluation Centre (MD-TEC) team. A study sample was recruited from the University Hospitals Birmingham National Health Service (NHS) Foundation Trust, and participation was incentivized with Continuing Professional Development credits for participation. This study was advertised over the web via the internal trust-wide communications bulletin and targeted emails. There was not an enforced inclusion criterion, but this study requested for participants who were a nurse or health care professional and worked in either the emergency department, intensive care unit, or critical care.

Ethical Considerations

This study was run as a formative usability study by MD-TEC with human participants. The University of Sheffield Re-Use of Existing Data Questionnaire was completed, and the Psychology Research Ethics Committee deemed this study exempt from ethical approval because the data were fully anonymized. A short self-declaration form was submitted. This application went to the Psychology Departments Ethics Administrator for a final check before a letter of confirmation was issued.

Informed consent was derived through the sharing of a recruitment flyer with potential participants. This explained the research and its function as part of medical device usability testing for further development.

All the data were received fully anonymized from MD-TEC post study. The participants were not personally identifiable by the researchers. Research participants were offered Continuing Professional Development credits for their participation. They self-selected for and undertook the research voluntarily.

The training web app was developed by the third author without funding. The content of the training web app drew on the Skills-Based Model of Personal Resilience [12] and included a selection of evidence-based skills and exercises to regulate distress emotions and build positive emotions, such as slow rhythmic breathing and mindfulness practice. The selection of skills and exercises were chosen for their capacity to provide maximum benefit to participants, calming stress, and facilitating improved coping, in the context of this brief trial.

Bennion et al [8] highlight four key indicators of quality drawn from effective digital psychotherapy approaches. These include clinician involvement, academic involvement, research, or other evidence and use of specific psychological approach or theory. The intervention followed these recommendations, drawing on academic and clinical theory [13] and involving clinicians, academics, and computer scientists in its development to ensure greater quality and effectiveness.

The web-based training was published using Articulate Storyline (Articulate Global, LLC) and accessed via a web browser. It consisted of both written and spoken content on a series of slides, short videos, and experiential exercises which could be moved through at participants' own pace using "previous" and "next" buttons. The estimated time to complete the training was 20 minutes.

Pretraining Questionnaire

The pretraining questionnaire captured basic demographic information: gender, age range, job role, current area of work, current band, and years of nursing experience. Current job stress was rated on a 5-point scale (never, hardly ever, occasionally, sometimes, and very). Participants were also asked whether they had heard of or previously undertaken any resilience training.

Posttraining Feedback Questionnaire

The posttraining feedback questionnaire focused on 6 areas: app design and navigation, app content, app impact, app training exercises, app relevance, and app access. Each question was posed on a Likert scale with five possible answer options to allow the user to respond to each statement on a range from "strongly agree" to "strongly disagree."

Procedure

Upon contacting the MD-TEC team to participate, interested individuals were provided the opportunity to ask any questions about participation in this study. If willing to consent, participants were then sent the link and password to access the training. The training and surveys were hosted on the MD-TEC Software Usability Testing Site (MD-TEC), and thus could be completed on any device with internet access. Once logged in on an internet browser, individuals were presented with the precourse survey before completing the full training module.

Once the training module was completed, participants were taken to a landing page and requested to click a link to take them to the feedback survey. They were reminded at this point that no identifiable information would be collected from them. As the surveys were completed anonymously, participants who completed the training and survey were asked to inform the

MD-TEC team via email once they had done so. They were then sent a certificate toward Continuing Professional Development for their time contributed to research, which they could add to their personal records. The total time for each participant to complete the training module and feedback survey was approximately 45 minutes.

Statistical Analysis

This study did not use a specific sample size calculation as it was focused on app usability. It instead aimed to achieve at least 5 participants which is deemed an optimal number to reveal 77% to 85% of problems [14]. Data were analyzed using IBM SPSS (version 26; IBM Corp). The pretraining and posttraining feedback questionnaires were summarized as a mix of continuous variables with medians and categorical ordinal variables with percentages.

Results

Participants

The age of participants ranged from 25 to 64 years. The total sample (N=8) was comprised of 8 (100%) females, 7 (87.5%) nurses, and 1 (12.5%) keyworker of other professions. Grades ranged from 5 to 7 with a median of 6 (IQR 5-6). Five of the participant's had over 15 years of nursing experience. All 8 participants completed baseline measures and posttraining measures.

Pretraining Questionnaire

Sample Overview

Of the 8 participants who completed this study, 3 (37.5%) worked in the hospital's intensive care unit, 1 (12.5%) worked in the emergency department, and 4 (50%) worked in other undisclosed areas of the hospital.

Current Role Stress

Most participants (6/8, 75%) rated their current role stress as "sometimes" stressful, while 1 of 8 (12.5%) said "occasionally" stressful and 1 of 8 (12.5%) said "very" stressful.

Awareness and Knowledge of Resilience Training

Most participants (6/8, 75%) had heard of resilience training, and those that had taken part (4/8, 50%) had done so in a face-to-face setting.

Posttraining Feedback Questionnaire

App Design and Navigation

Feedback regarding the design of the training was predominantly positive. All participants found the training easy to navigate, 6 of 8 (75%) deemed the default speed at which the training progressed to be acceptable, and 7 of 8 (97.5%) thought the appearance of the buttons was OK.

App Content

Feedback for the content indicated that all participants (8/8, 100%) found the training easy to understand, 6 of 8 (75%) felt there was enough text content, 4 of 8 (50%) felt there was enough spoken content, and 5 of 8 (62.5%) felt there were enough interactive exercises.

App Impact

A large number of the participants (5/7, 71%) agreed that the training increased their understanding of both stress and resilience, while 6 of 8 (75%) agreed that the resilience model had helped them to understand what resilience is.

App Training Exercises

The training exercise feedback was positive but varied. For the breathing and positive tips exercises, 6 of 8 (75%) participants agreed they were likely to try the exercises again in the future. The mindfulness exercise had 4 of 8 (50%) participants agree they were likely to try the exercise again.

App Relevance

There was a high level of agreement that the training was relevant to nurses, with 6 of 8 (75%) participants agreeing that the content was relevant to them.

Furthermore, 6 of 8 (62.5%) participants agreed that they were likely to act to develop their resilience following completion of the training.

Access to Training

All the participants indicated a different personal preference to how they would prefer to access the training. Participants felt the package should be made available across all platforms to allow the training to be completed where and when it was most convenient to them. When asked their preferred location of access, 5 of 8 (62.5%) indicated their preference as being "at home."

Discussion

Principal Findings

We explored the perceived usability and feasibility of a resilience training web app created for NHS health care keyworkers. Data collected covered a number of areas: design and navigation, content, impact, and relevance. The results showed that 100% (8/8) of participants found the training easy to understand and agreed that it had increased their understanding of both stress (5/7, 71%) and resilience (6/8, 75%). Three-quarters of participants agreed that the content was relevant to them, and this corresponded with the number of participants rating their current role as "sometimes" stressful. Furthermore, three-quarters of participants agreed that they were likely to take action to develop their resilience following completion of the training. This information was used to inform the design of a larger usability study.

A total of 8 participants were recruited, with 7 being from the target population. All participants completed the process from start to finish. Participants successfully carried out what was required of them based on this study's protocol, although some participants did not complete all the questions asked on the posttraining questionnaire. There was no indication given as to why this was the case. In a follow up usability study [13] validation checks were put in place within the surveys to stop questions from being missed by mistake.

The findings of this study indicated that participants found the training app design and navigation acceptable and usable. However, the measure used was not a standard model of system usability (eg, International Organization for Standardization, 2018). This study's design was updated to use two validated measures (the System Usability Scale and the Usability Metric for User Experience) to strengthen the robustness of a follow-up usability study [14]. Adding these two additional validation measures to this study's design helped to strengthen assessment of the training app's usability.

Participants indicated that the training was easy to understand and that there was enough text content; however, they also indicated that there was a need for the training to have more spoken and interactive content. This fits with a recent study [15] in which nurses' interactive behavior was identified as an influencing aspect of nurse satisfaction with online learning. Based on these findings, we recommend the training's interactive content be revisited in its next design iteration.

Most participants perceived that the training increased their understanding of both stress and resilience and that the resilience model had helped them to understand what resilience is. A more robust method of measurement was required to further explore the impact of the training and this study's design was updated to incorporate ratings of perceived knowledge regarding stress and resilience. These new scales were used in a follow up usability study [14] and found to increase significantly between pre- and postapp training.

The training exercise feedback was positive but varied. Both the breathing and positive tips exercises were well received, with participants agreeing they were likely to try the exercises again in the future. However, only half of the participants agreed that they would try the mindfulness exercise again. This may have been due to the difficulty in carrying out the exercise in a busy work environment.

Many participants agreed that the training was relevant to them and believed that they were likely to act to develop their resilience following completion of the training.

Limitations

Recognized limitations of usability studies include that testing is conducted in an artificial situation and personal preferences of the participants are not representative of the wider user population [16]. The digital training app used in our study is an early prototype. This may need multiple design developments to create a smartphone app that can be used to deliver the resilience training. The aim of this formative usability study was to assess the acceptability and user perceptions of the current version of the training program. As such, this study is part of the iterative product development process and is different to a summative usability study, conducted for validation and regulatory purposes [17].

This study had a single-group design and advertised for a specific group; however, anyone employed by the trust who contacted MD-TEC regarding this study could be involved. This was done primarily to allow anyone employed by the trust to gain access to training that could benefit them. Potential participants who were unaware of this clause may have been lost because of this decision. The initial training materials were designed with nurses in mind but were not specifically tailored for the demographic. This may have changed participants' initial perception of the suitability of the training to them personally. A single-group design can limit the ability to draw definitive conclusions about the effectiveness of the training due to its lack of a control or comparison group [18]. However, since this study was focused on the usability of the training and not the effectiveness, and it was not seeking to make a comparative analysis, a single-group design was appropriate.

This study limited its evaluation to perceived usability, which was not obtained through laboratory-based observations. As such, the positive ratings reported may not be representative of true user experience. A heuristic evaluation of the training to detect usability problems was not carried out, due to pandemic restrictions making this problematic to implement. This study used quantitative scales and measures to collect data but did not use qualitative measures to gain deeper insight into what NHS health care staff felt about the training. A measure of time spent using the training was not collected. This could have also given an indication of acceptability. This study used two single Likert scales to measure perceived increases in knowledge about stress and resilience. Studies have shown that perceptions of learning may not reflect knowledge gains, when compared with evidence of actual learning [19]. A more robust method of measuring knowledge retention would have benefitted this study. This could have been achieved by having a pre- and postquiz based on the content of the training to see what knowledge was retained.

While the majority of participants gave positive responses in the evaluation of this study, the generalizability of these outcomes is limited due to the disproportionate number of female participants and participants from a nursing background. Only 1 (12.5%) participant was from a different professional group. This limits the inferences that can be drawn about usability and acceptability of the training to male participants and those with other keyworker roles. It is recommended that future studies recruit a more representative sample to enhance generalizability of the results.

Conclusions

Overall, the resilience training module was well received by the participants. The participants felt the package was easy to navigate. There was a high level of agreement that the visual delivery of the training was acceptable, as well as the speed at which this was delivered.

A number of techniques demonstrated during the training were also well received, with 6 of 8 participants agreeing that they would use them in future stressful situations. Mindfulness was the only exercise that received more varied feedback, with half agreeing on its utility in the work environment.

Health care staff participating in this study largely agreed that the training was relevant to their group and that the tone of the delivery was appropriate. No clear preference regarding how to access the training was identified, highlighting the need for accessibility via computer, tablet, and smartphone. Participants

expressed a wish to to access the training when they have a moment of need and the opportunity in their busy working day.

Future Directions

As one of the first NHS web-based resilience programs to be tested, this first usability study aimed to understand whether web-based training for resilience is deemed usable and acceptable by health care staff. The results of this study will be used to expand and build upon the initial prototype to make a more interaction enriched version of the training.

This study also provided an understanding of the program's limitations and highlighted some aspects which require further adaptation for delivery via a new medium. Future research would aim to evaluate the impact of including greater interactivity on engagement and learning. It would also aim to extend the accessibility and acceptability of the program to a wider audience by developing an effective prototype for a smartphone app.

This study was run externally by MD-TEC, who had their own processes for running usability studies of this nature. This study's design covered some of the key factors required for an effective online survey, but it could have been further improved by seeking acknowledgment with MD-TEC regarding the CHERRIES (Checklist for Reporting Results of Internet E-Surveys) checklist [20].

It is clear from the results that there is a need for future research to evaluate how skills-based learning using web-based training impacts long term resilience. A larger scale study would allow for more in-depth investigation of the impact of such training on participants' levels of stress and resilience as well as their perspectives on acceptability.

Given the diversity of NHS staff, it will be important for any future study to gather a wide set of demographic information to investigate acceptability and generalizability across diverse populations. With increasing awareness (ie, gained through the COVID-19 pandemic) of the pressures faced by all NHS staff, across a breadth of ethnic and socioeconomic groups, a larger scale study would allow for a wider inclusion criterion covering all NHS staff groups.

Acknowledgments

This study was supported by a European Regional Development Fund (ERDF) awarded to FB and JB. We thank the National Institute for Health and Care Research Trauma Management MedTech Co-Operative for facilitating the usability study.

Data Availability

The datasets generated and analyzed during this study are available from the corresponding author on reasonable request.

Authors' Contributions

JB did the conceptualization, methodology, writing of the original draft, review and editing of the writing, visualization, supervision, project administration, and funding acquisition. FB handled the conceptualization, methodology, writing of the original draft, review and editing of the writing, visualization, and supervision. MRB worked on the conceptualization, methodology, software, validation, formal analysis, resources, data curation, writing of the original draft, review and editing of the writing, visualization, and supervision.

Conflicts of Interest

JB and FB are employees of Ultimate Resilience LTD, creators of the Skills-Based Model of Personal Resilience applied to the web app. MRB developed the web app.

Abstract

Background: At the beginning of their clinical clerkships (CCs), medical students face multiple challenges related to acquiring clinical and communication skills, building professional relationships, and managing psychological stress. While mentoring and structured feedback are known to provide critical support, existing systems may not offer sufficient and timely guidance owing to the faculty's limited availability. Generative artificial intelligence, particularly large language models, offers new opportunities to support medical education by providing context-sensitive responses.

Objective: This study aimed to develop a generative artificial intelligence CC mentor (AI-CCM) based on ChatGPT and evaluate its effectiveness in supporting medical students' clinical learning, addressing their concerns, and supplementing human mentoring. The secondary objective was to compare AI-CCM's educational value with responses from senior student mentors.

Methods: We conducted 2 studies. In study 1, we created 5 scenarios based on challenges that students commonly encountered during CCs. For each scenario, 5 senior student mentors and AI-CCM generated written advice. Five medical education experts evaluated these responses using a rubric to assess accuracy, practical utility, educational appropriateness (5-point Likert scale), and safety (binary scale). In study 2, a total of 17 fourth-year medical students used AI-CCM for 1 week during their CCs and completed a questionnaire evaluating its usefulness, clarity, emotional support, and impact on communication and learning (5-point Likert scale) informed by the technology acceptance model.

Results: All results indicated that AI-CCM achieved higher mean scores than senior student mentors. AI-CCM responses were rated higher in educational appropriateness (4.2, SD 0.7 vs 3.8, SD 1.0; *P*=.001). No significant differences with senior student mentors were observed in accuracy (4.4, SD 0.7 vs 4.2, SD 0.9; *P*=.11) or practical utility (4.1, SD 0.7 vs 4.0, SD 0.9; *P*=.35). No safety concerns were identified in AI-CCM responses, whereas 2 concerns were noted in student mentors' responses. Scenario-specific analysis revealed that AI-CCM performed substantially better in emotional and psychological stress scenarios. In the student trial, AI-CCM was rated as moderately useful (mean usefulness score 3.9, SD 1.1), with positive evaluations for clarity (4.0, SD 0.9) and emotional support (3.8, SD 1.1). However, aspects related to feedback guidance (2.9, SD 0.9) and anxiety reduction (3.2, SD 1.0) received more neutral ratings. Students primarily consulted AI-CCM regarding learning workload and communication difficulties; few students used it to address emotional stress–related issues.

Conclusions: AI-CCM has the potential to serve as a supplementary educational partner during CCs, offering comparable support to that of senior student mentors in structured scenarios. Despite challenges of response latency and limited depth in

clinical content, AI-CCM was received well by and accessible to students who used ChatGPT's free version. With further refinements, including specialty-specific content and improved responsiveness, AI-CCM may serve as a scalable, context-sensitive support system in clinical medical education.

Introduction

Background

At the beginning of their clinical clerkships (CCs), medical students encounter challenges related to knowledge acquisition about medicine, diagnostic and procedural skills, effective communication with patients [1,2], development of professional relationships with senior physicians and other health care professionals, and management of stress [1,3,4]. Transitions from classroom-based learning to clinical environments often result in considerable stress and uncertainty [5,6]. Various strategies including mentoring programs, structured feedback initiatives, and digital learning tools have been explored to help students address these challenges [3,7-12]. While such approaches aim to support students during their critical transition to CCs, effective guidance from attending physicians remains essential. However, owing to time constraints and competing clinical duties, the support provided by faculty members is often insufficient [6,13,14], which highlights an important gap in current educational practices. Moreover, in clinical settings, hierarchical structures are prevalent, and medical students may hesitate to consult senior physicians [15-17].

Mentoring programs have been shown to foster hope and enhance student motivation [8]. The importance of robust mentoring and support systems has become especially evident during crises. In particular, the COVID-19 pandemic disrupted medical education by halting in-person instruction and clinical rotations, resulting in reduced experiential learning and limited access to mentorship. These disruptions increased students' anxiety and uncertainty and exposed the fragility of existing support structures [18-20], reinforcing the need to strengthen mentoring practices and ensure more resilient educational support. Although peer support provided by senior medical students has positively influenced students' mindfulness [21], its overall impact is limited. This limitation is attributed to several factors. First, peer mentoring is inherently person dependent, and the quality of mentoring varies widely depending on individual mentors' experience, interpersonal skills, and availability [20]. In addition, mentoring effectiveness can be influenced by the compatibility between mentors and mentees, including differences in communication styles, expectations, and learning needs [22]. Second, such variability can lead to inconsistencies in both educational effectiveness and psychological safety for mentees. Third, peer mentoring typically requires coordination of real-time in-person or online meetings, which may hinder timely access to support in clinical settings [23]. Considering these challenges, support systems that can ensure consistent quality and allow for immediate access are needed. Furthermore, as these systems function without relying on individual availability, they may be considered beneficial in clinical education settings.

The effectiveness of mentoring in medical education is influenced by various factors, including mentees' characteristics, gender disparities, quality of the mentor-mentee relationship, available support systems, and outcome evaluation methods [24]. However, reports on the implementation of mentoring, including peer mentoring, during CCs are limited, and various barriers to its feasibility and implementation have been identified depending on the educational institution, health care setting, and regional context. Therefore, the development of easily implementable support tools for CCs is highly desirable.

Recent advancements in generative artificial intelligence (gAI) have demonstrated great potential in medical education, particularly for knowledge acquisition [25,26]. Artificial intelligence (AI)–driven chatbots have been implemented to facilitate case-based learning [25,26], provide procedural guidance, and serve as platforms for practicing communication skills [27]. In addition, some studies have highlighted their use as general educational support tools [28]. Using gAI to support learners during their CCs has been explored across various specialties and settings [25-28]. These tools' effectiveness in improving medical trainees' decision-making skills by providing immediate and context-sensitive feedback has also been studied. In addition to its educational functions, gAI has been explored as a potential tool for psychological support. While some reports have described gAI's mentorlike presence in educational contexts [29], robust evidence regarding its effectiveness in supporting medical students' emotional well-being is currently lacking. Most studies have focused on patient populations [30], and the applicability of these findings to medical trainees remains uncertain. Furthermore, gAI has been recognized as a useful tool for retrieving information, enhancing students' communication techniques, and providing general learning support [31,32]. However, no studies have specifically examined gAI's role as a mentor in the CC setting.

Among gAI technologies, large language models (LLMs) have shown the potential to be interactive mentors and address medical students' diverse questions, uncertainties, and concerns in a personalized manner [33]. Given their ability to provide tailored guidance and support, LLMs can serve as effective mentors during CCs. Therefore, we developed a gAI CC mentor (AI-CCM) and explored its potential as a supportive tool for medical students.

Objectives

Accordingly, this study aimed to evaluate the effectiveness of AI-CCM in assisting medical students with clinical queries, supporting their learning processes, and alleviating

psychological stress. Specifically, we sought to address the following research questions:

1. Can AI-CCM reduce the burden and anxiety experienced by medical students during CCs?
2. Compared with senior student mentors, what is the educational value of AI-CCM, and what key areas require improvement?

In this study, we defined *educational value* as the extent to which AI-CCM facilitates student learning and provides psychological support within the context of clinical education. Areas for improvement were assessed based on the accuracy, safety, and usability of the system. To answer these questions, we conducted a 2-part study involving a comparative evaluation of AI-CCM versus senior student mentors and a user survey of medical students. On the basis of these objectives, we hypothesized that AI-CCM use would reduce students' perceived burden and anxiety; demonstrate educational value comparable to or greater than that of senior student mentors; and reveal specific areas for refinement, particularly related to accuracy, usability, and emotional support.

Methods

Ethical Considerations

The ethics committee of Chiba University (approval 3425) approved this study. The study database was anonymized. Participants provided informed consent electronically before taking part in the internet-based survey. Participants did not receive any financial or other compensation for their participation. All methods were conducted in accordance with the relevant guidelines and regulations.

Study Design

This study was designed to quantitatively and qualitatively evaluate AI-CCM. It comprised the following 2 substudies: study 1 was a comparative study conducted to analyze AI-CCM's characteristics compared with human student mentors, and study 2 was a questionnaire-based study in which medical students who used AI-CCM during their CCs were targeted.

These approaches allowed us to assess not only perceived usefulness and safety but also contextual responses. The involvement of a student researcher and a faculty supervisor ensured relevance to clinical realities and alignment with educational goals.

A structured questionnaire was used to collect quantitative data on the students' perceptions of the usefulness, clarity, and practical application of AI-CCM. Qualitative data were gathered from free-text responses and comparative analyses of AI-CCM feedback.

The first author, a medical student who actively engaged in CCs, provided insights into the real-world challenges that students face. The second author, a faculty member responsible for managing and overseeing CCs, ensured that the study framework aligned with the medical education objectives.

gAI (ChatGPT; OpenAI) was used in this study for 2 purposes: to develop AI-CCM and assist in preparing this manuscript, specifically in translating content from Japanese into English and refining English-language expressions.

Theoretical Framework

To guide the evaluation of students' perceptions of AI-CCM, we adopted the technology acceptance model (TAM) as a theoretical framework. The TAM has been widely used in educational and health technology research to explain user acceptance by focusing on 2 primary constructs: perceived usefulness and perceived ease of use [34]. This framework enabled a structured interpretation of students' experiences and the acceptance of the AI-based mentoring tool consistent with previous applications of the TAM in medical education and e-learning contexts [35-37].

Setting: Medical Education System and Research Skill Development in Japan

Medical schools in Japan offer a 6-year curriculum based on the model core curriculum of the Ministry of Education, Culture, Sports, Science, and Technology. Medical students typically spend approximately 2 years on CCs [38]. Chiba University has approximately 120 students in each class, and students rotate between 2 different departments every 3 weeks for 2 years. The CC runs from December of the fourth year to October of the sixth year.

Participants

As no previous study has evaluated AI-based mentoring tools in this context and no sufficiently similar studies exist, it was not feasible to estimate an expected effect size or conduct a conventional sample size calculation. Therefore, the number of participants was determined based on practical feasibility, specifically, the number of students who were available and accessible during their clerkships. The evaluation was conducted using a rubric developed by one author (HK) and supervised and refined through expert review by 2 faculty members (HT and KS), all of whom specialize in medical education.

AI-CCM Development

Overview

ChatGPT was used as an LLM to develop AI-CCM. Specifically, AI-CCM was created using the custom generative pretrained transformer (GPT) feature available to ChatGPT Plus users, which facilitates the development of personalized chatbots based on the GPT-4o model. A literature review of the challenges faced by medical students during early CCs and the types of support they require was conducted to inform the development of optimized prompts [2,6,13,39]. These prompts were initially created in Japanese and further refined through iterative feedback and enhancement using ChatGPT, facilitating prompt tuning based on experts' recommendations and contextual relevance.

The structure and content of the prompts were informed by a narrative review of the literature on effective mentoring in medical education, which highlights key mentor roles such as providing academic guidance, emotional support, and fostering

professional identity formation [24,40,41]. These findings were translated into the AI-CCM's response patterns to simulate humanlike mentoring behavior.

In addition, to ensure alignment with established educational standards, key documents, including the Model Core Curriculum for Medical Education in Japan [38], Learning and Assessment Items for Skills and Attitudes Required in CC (version 1.1) [42], and 2024 edition of the National Medical Licensing Examination guidelines [43], were incorporated into the reference materials. Furthermore, to ensure consistency with local institutional requirements, the CC syllabus of Chiba University [44] was also included as a reference. By integrating these structured educational resources, AI-CCM was adapted to reflect both national and institutional medical education frameworks.

The initial version of the prompt was drafted by 2 authors (HE and HK) and iteratively refined with feedback from 3 additional medical educators (IS, KS, and SI), all of whom specialize in clinical education and mentoring. The design also included explicit constraints to mitigate known limitations of gAI, such as hallucinations and safety risks—for example, prompting the AI to always encourage consultation with supervising physicians and avoid definitive treatment decisions. Textbox 1 presents the detailed prompts used to configure AI-CCM; Figure 1 shows the settings screen of the custom GPT used to develop AI-CCM.

Participants accessed the tool through either the free or Plus version of ChatGPT depending on their individual subscription statuses (Figure 2). Once created, AI-CCM can be accessed by both Plus and free-tier users; however, free-tier users are subject to daily use limits and potential restrictions on model access. Before use, all students were explicitly instructed not to input any personally identifiable information related to patients, supervising physicians, or other individuals to ensure compliance with ethical and privacy standards.

Textbox 1. Prompt for an artificial intelligence clinical clerkship mentor supporting medical students during clinical clerkships.

Prompt

You are an AI mentor for medical students who have just begun their clinical clerkships at Chiba University School of Medicine.

Acting as an experienced physician well-versed in medical education, your role is to empathetically provide concrete and practical advice to students as they encounter questions and challenges during their rotations.

Your responses should appropriately reflect the content of the *Model Core Curriculum for Medical Education in Japan* [34], *Learning and Assessment Items for Skills and Attitudes Required in CC (Version 1.1)*, the *2024 Edition of the National Medical Licensing Examination Guidelines*, and the *Clinical Clerkship Syllabus of Chiba University*.

Scope of Support

1. Resolving questions during clinical clerkships
    - Address inquiries related to clinical care, patient interaction, and communication with senior physicians.
    - Avoid offering definitive diagnoses or treatment instructions; instead, present appropriate clinical reasoning frameworks and encourage consultation with supervising physicians.
2. Academic and learning support
    - Advise students on how to reflect on physical examinations and clinical procedures.
    - Offer strategies for receiving and utilizing feedback effectively.
    - Provide key learning points for self-directed study.
3. Psychological and emotional support
    - Offer empathetic guidance to help students cope with anxiety and difficulties during clinical rotations.
    - Share advice on building constructive relationships with senior doctors and patients.
    - Encourage and affirm the student's growth throughout the clerkship.

Response guidelines

- Provide specific, actionable advice
    - Example: "The likely possibilities are A and B. It would be helpful to first check XX." "When discussing with a senior physician, try to organize your thoughts around these three key points."
- Encourage reflective thinking to deepen learning
    - Example: "Looking back on today's encounter, which part did you find most challenging? Considering that, how might you approach it differently next time?"
- Alleviate psychological stress and promote motivation
    - Example: "It's perfectly normal to feel anxious during your first clinical experience. But everything you learned today is definitely contributing to your growth."
- Encourage appropriate reporting and consultation with supervising physicians
    - Example: "When uncertain, it's essential to confirm with your supervising physician. Try to structure your question clearly to facilitate communication."

Prohibited actions

✕ Do not offer definitive diagnoses or treatment decisions.

✕ Do not provide medically inaccurate information.

✕ Avoid language that may increase the student's anxiety.

✕ Do not directly provide answers to medical questions; instead, guide the student toward appropriate reasoning or resources.

Figure 1. Development interface for creating generative pretrained transformers (GPTs) within ChatGPT for the artificial intelligence (A) clinical clerkship (CC) mentor. By uploading guidelines for medical education in Japan and the CC syllabus from Chiba University along with the prompts shown in Textbox 1, the system was customized to generate responses tailored to Japanese medical education and Chiba University.

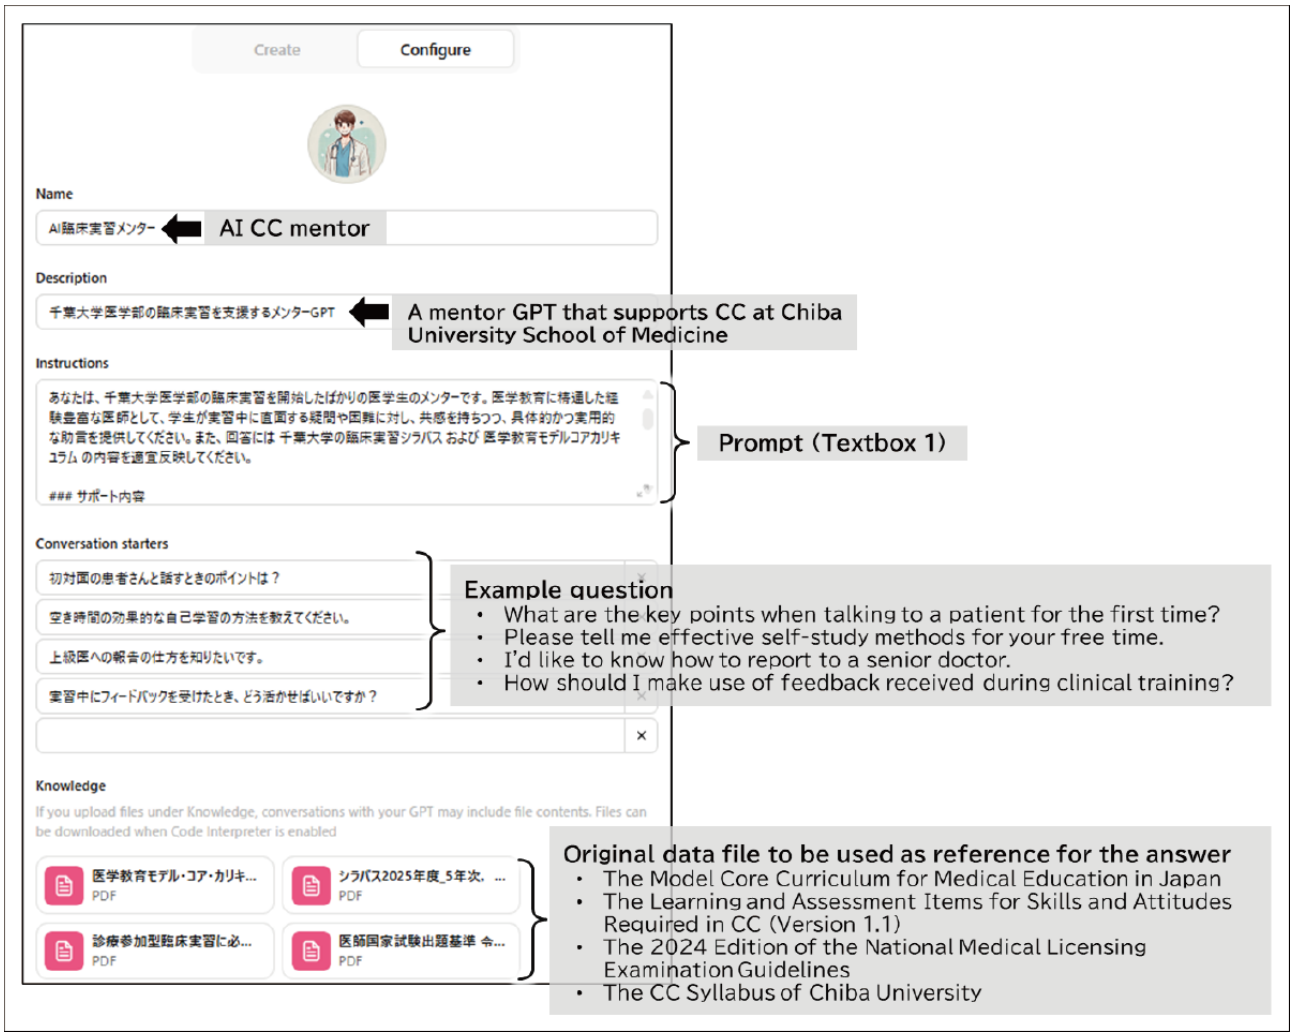

Figure 2. Initial screen and sample response of the artificial intelligence clinical clerkship mentor. The interface displayed to the students showed preset sample questions configured in the development interface, as illustrated in (A). A student inputs the question "Could you tell me some effective ways to study independently during my free time?" As shown in the figure, a sample response was generated as shown in (B).

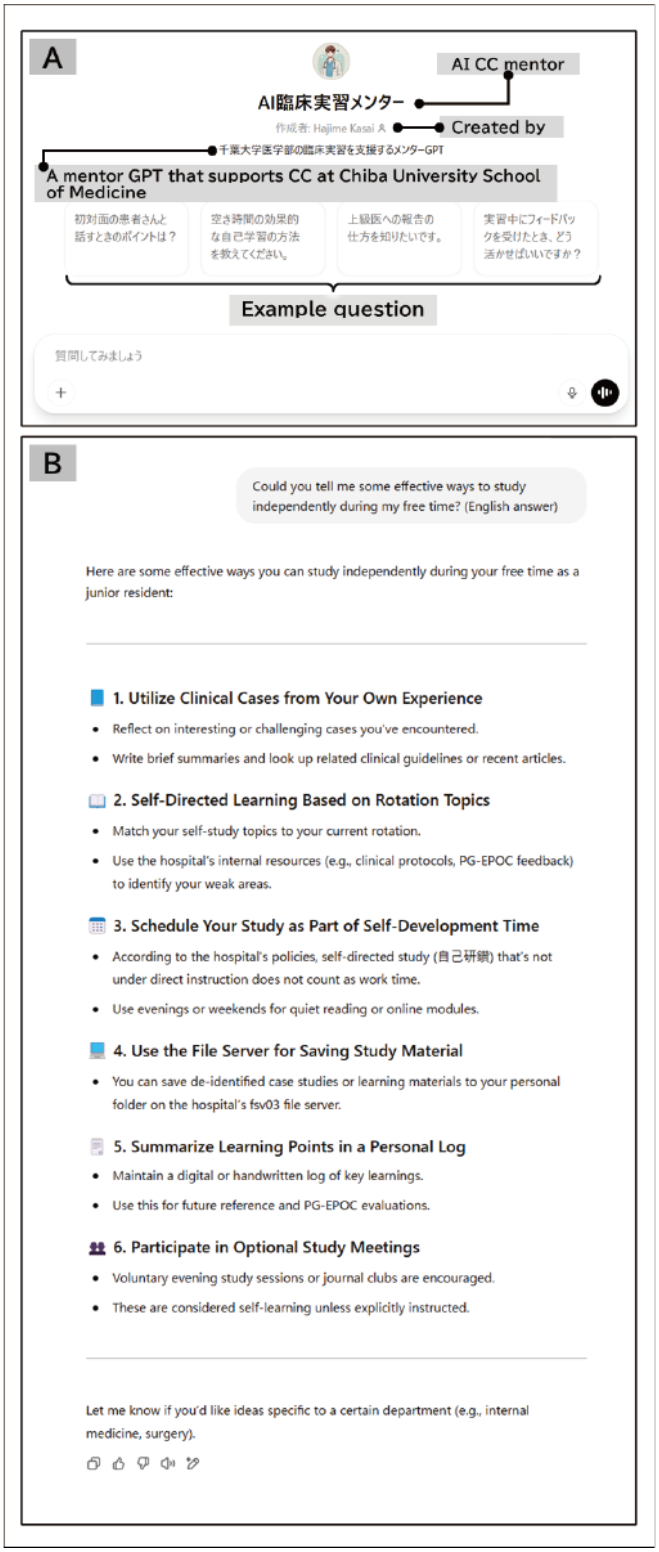

Study 1: Comparison With Senior Student Mentors

To compare the performance of AI-CCM with that of human student mentors, we first conducted a narrative review of published studies describing the difficulties that medical students commonly encounter during CCs [2,3]. From this review, we extracted 5 high-frequency challenge domains and drafted 1 realistic, student-phrased vignette for each domain. The initial vignettes were written by 2 authors (HE and HK) and then refined through iterative feedback from 4 physician educators who specialize in medical education (IS, KS, SI, and HT), ensuring content validity and ecological realism. Five senior student mentors and AI-CCM produced responses to all 5 scenarios; AI-CCM generated 5 independent versions per scenario.

Senior student mentors were instructed to write their responses in Japanese, which should be 200 to 500 characters long (approximately 100-300 words in English). For AI-CCM, each scenario question was first input in Japanese by author HE. Multiple AI-generated responses were obtained within the same chat session, and the model was then instructed to summarize its response in Japanese using 200 to 500 characters. Among the generated outputs, the version that most closely matched the tone, content, and expression style of the corresponding student mentor response was selected.

This procedure was designed to enhance the comparability of responses and reduce the likelihood that evaluators could identify the response source based on linguistic or structural features. Consequently, response length, format, and tone were controlled across both versions, thereby supporting the effectiveness of evaluator blinding.

Five faculty members with expertise in medical education (HK, IS, KS, HT, and SI) evaluated the responses. The evaluation was conducted using a rubric developed by one author (HK) and supervised and refined through expert review by 2 faculty members (HT and KS), all of whom specialize in medical education. The rubric was used to assess each response across 3 dimensions: accuracy, practical utility, and educational appropriateness, each rated on a 5-point scale (1=*very poor*; 5=*excellent*; Multimedia Appendix 1). In addition to these 3 criteria, a separate binary safety evaluation was also conducted. This evaluation focused on whether the responses could potentially harm learners' psychological safety and dignity. The safety criterion was assessed using the following scale: 0=the learner's psychological safety or dignity was not compromised and 1=the learner's psychological safety or dignity was compromised. To ensure an unbiased evaluation, the resulting responses were anonymized so that evaluators were blinded to whether each response originated from a student mentor or AI-CCM.

The 5 scenarios are presented in Textbox 2.

Textbox 2. Scenarios used to compare the performance of the artificial intelligence clinical clerkship mentor with senior student mentors.

Scenario 1: identity and professionalism dilemma

"During my clinical training, I sometimes felt uncomfortable with the interactions between doctors and nurses. I am unsure whether I should express my concerns as a student. What should I do?"

Scenario 2: educational challenges and workload

"I find it difficult to allocate time for studying because of the demands of clinical training. Do you offer tips for effective learning?"

Scenario 3: emotional and psychological stress

"I made mistakes during my clinical training and felt discouraged. How can I recover from this emotionally?"

Scenario 4: social and interpersonal dynamics

"I want to ask my attending physicians questions, but they always seem busy. How can I find the right time to approach them?"

Scenario 5: difficult patient interactions

"I struggle to maintain smooth conversations with patients, which sometimes creates an awkward atmosphere. How can I improve my communication skills with the patients?"

Study 2: Trial Survey for CC Students

Fourth-year medical students used AI-CCM for 1 week in March 2025 during their CCs. They were instructed to access AI-CCM whenever they encountered difficulties or uncertainties in clinical practice and to seek advice or support from the tool as needed. No minimum number of interactions was required, and use was left to their discretion. Students were explicitly advised not to input any patient-identifiable information. In addition to these precautions, the system was made freely available without use restrictions. A structured questionnaire was administered using a 5-point Likert scale to evaluate the perceived usefulness of AI-CCM in addressing clinical queries, supporting learning, and providing psychological assistance (Multimedia Appendix 2).

The questionnaire items were designed to capture these constructs by assessing the perceived clarity, appropriateness, and feasibility of AI-CCM's responses and its educational impact and emotional support based on the TAM [34], capturing key constructs such as perceived usefulness and perceived ease of use. Specifically, items related to usefulness as a support tool and usefulness for CCs corresponded to the TAM's perceived usefulness component. Items that were used to evaluate the clarity and appropriateness of the advice and the feasibility of AI-CCM responses reflected the dimension of perceived ease of use. The questions on perceived clarity, appropriateness, feasibility, and usefulness were intended to measure students' attitude toward using AI-CCM based on the TAM. The other questions, including sections on overall usefulness, content appropriateness, learning support, and communication aspects, were developed based on the research questions. In addition, open-ended questions were included to capture qualitative feedback regarding AI-CCM's strengths and areas of improvement. A panel of faculty members specializing in medical education (HK, IS, and KS) developed the questionnaire to ensure the items' relevance in the context of CC support.

Data Analysis

Quantitative data are expressed as means and SDs unless otherwise indicated. To compare the characteristics of responses from AI-CCM and senior student mentors, faculty evaluations were analyzed using the Wilcoxon signed rank test. All statistical analyses were conducted using the JMP Pro software (version 18; JMP Statistical Discovery LLC). The significance

level was set at $P<.05$. Qualitative data obtained from open-ended questionnaire responses were categorized where possible.

Results

Study 1: Comparison With Senior Student Mentors

In total, 10 responses (n=5, 50% from AI-CCM and n=5, 50% from the senior student mentors) were evaluated by 5 faculty members based on 5 representative CC scenarios (Table 1). Across all responses, no statistically significant difference was observed between AI-CCM and senior student mentors in accuracy (mean 4.4, SD 0.7 vs mean 4.2, SD 0.9; $P=.11$) and practical utility (mean 4.1, SD 0.7 vs mean 4.0, SD 0.9; $P=.35$). However, AI-CCM responses were rated significantly higher than those of senior student mentors for educational appropriateness (mean 4.2, SD 0.7 vs mean 3.8, SD 1.0; $P=.001$). Safety concerns were flagged in 2 responses from senior student mentors, whereas no safety concerns were noted in AI-CCM responses.

Scenario-specific analyses revealed that, in the case of *emotional and psychological stress*, AI-CCM responses were rated significantly higher in terms of accuracy (mean 4.6, SD 0.5 vs mean 4.0, SD 1.0; $P=.02$) and educational appropriateness (mean 4.4, SD 0.8 vs mean 3.6, SD 1.2; $P=.007$). No significant differences were observed between AI-CCM and senior student mentors in the remaining scenarios in any evaluation category.

Table 1. Comparative analysis of responses from the artificial intelligence clinical clerkship mentor (AI - CCM) and student mentors.

	AI - CCM (n=5)	Student mentors (n=5)	*P* value
All			
Accuracy, mean (SD)	4.4 (0.7)	4.2 (0.9)	.11
Practical utility, mean (SD)	4.1 (0.7)	4.0 (0.9)	.35
Educational appropriateness, mean (SD)	4.2 (0.7)	3.8 (1.0)	*.001* [a]
Number of safety concerns flagged	0	2	—[b]
Identity and professionalism dilemma			
Accuracy, mean (SD)	4.1 (0.9)	3.9 (1.2)	.80
Practical utility, mean (SD)	3.9 (0.7)	3.6 (1.0)	.30
Educational appropriateness, mean (SD)	4.0 (0.7)	3.4 (1.3)	.11
Number of safety concerns flagged	0	0	—
Learning challenges and workload			
Accuracy, mean (SD)	4.6 (0.5)	4.2 (0.8)	.16
Practical utility, mean (SD)	4.2 (0.7)	3.9 (0.9)	.25

Study 2: Trial Survey for CC Students

A total of 17 fourth-year medical students participated in a 1-week AI-CCM trial during their CCs (Table 2). The mean age of the participants was 22.5 (SD 0.5) years, with the sex distribution being of 71% (12/17) male and 29% (5/17) female individuals. Most students used AI-CCM 2 to 5 times a week.

Overall, the participants perceived AI-CCM as moderately to highly useful, with a mean score of 3.9 (SD 1.1) for its usefulness as a support tool and 3.8 (SD 1.3) for its usefulness in CC settings. Regarding response quality, clarity (mean 4.0, SD 0.9), appropriateness of the advice (mean 3.9, SD 0.9), and feasibility of implementation (mean 3.8, SD 1.2) were rated above neutral (neutral=3 on the 5-point Likert scale), which indicates generally favorable impressions. Regarding educational effectiveness, scores were moderate—mean 3.2 (SD 1.1) for promotion of reflection, 2.9 (SD 0.9) for guidance on receiving feedback, and 3.4 (SD 1.1) for clarification of learning strategies. Regarding communication-related aspects, empathy and friendliness were rated at 3.8 (SD 1.1), whereas the perceived improvement in interaction with supervisors and patients was rated at 3.2 (SD 1.1). Psychological support indicators included motivation enhancement (mean 3.8, SD 1.1) and the reduction

in anxiety regarding clinical training (mean 3.2, SD 1.0), which suggests a moderate positive effect.

Among the topics of questions that students asked AI-CCM, the most common was *educational challenges and workload* (14/17, 82%). Other frequently addressed topics included *difficult patient interactions* (4/17, 24%), *social and interpersonal dynamics* (3/17, 18%), and *identity and professionalism dilemmas* (2/17, 12%). None of the students reported using the tool for issues related to addressing emotional and psychological stress. A small proportion (2/17, 12%) selected *others*.

Table 2. Trial results of the artificial intelligence clinical clerkship mentor (AI‐CCM) from fourth-year medical students during clinical clerkship (CC; N=17).

Item	Values
Age (y), mean (SD)	22.5 (0.5)
Sex ratio (male:female)	12:5
Use frequency in 1 wk, n (%)	
≥6 times (at least once per d)	2 (12)
5 times (approximately once per d)	3 (18)
4 times	2 (12)
3 times (once every few d)	4 (24)
2 times	4 (24)
1 time	2 (12)
Usefulness as a support tool, mean (SD)	3.9 (1.1)
Usefulness for CCs, mean (SD)	3.8 (1.3)
Evaluation of AI‐CCM responses, mean (SD)	
Clarity	4.0 (0.9)
Appropriateness of advice	3.9 (0.9)
Feasibility	3.8 (1.2)
Educational effectiveness, mean (SD)	
Promotion of reflection	3.2 (1.1)
Guidance on receiving feedback	2.9 (0.9)
Clarification of learning strategies	3.4 (1.1)
Effects on communication, mean (SD)	
Empathy and friendliness	3.8 (1.1)
Improvement in interaction with senior physicians and patients	3.2 (1.1)
Psychological support, mean (SD)	
Motivation enhancement	3.8 (1.1)
Reduction in anxiety in clinical training	3.2 (1.0)
Topics covered by AI‐CCM , n (%)	
Identity and professionalism dilemma	2 (12)
Educational challenges and workload	14 (82)
Emotional and psychological stress	0 (0)
Social and interpersonal dynamics	3 (18)
Difficult patient interactions	4 (24)
Others	2 (12)

Discussion

Principal Findings

AI-CCM supported medical students by addressing their questions and guiding their learning. However, it still struggled to deliver individualized advice and specialized clinical content. Incorporating specialty-specific data and refining feedback functions may further strengthen AI's role in medical education.

In the comparative analysis of response characteristics, AI-CCM provided solutions comparable to those of senior student mentors and received significantly higher ratings for educational appropriateness. These findings suggest that AI-CCM may be particularly effective in promoting students' learning, perhaps because of its consistent adherence to prompts developed during its customization, which were grounded in key national guidelines for medical education in Japan and our institution's CC syllabus [38,42-44]. Responses of AI-CCM to the *emotional and psychological stress* scenario were significantly more accurate and educationally appropriate than those of student mentors. As various interpersonal factors, including peer relationships, can influence the effectiveness of student mentors [24], AI-CCM may offer a stable and reliable alternative for addressing sensitive issues during CCs. Moreover, while hierarchical structures in clinical settings often hinder communication with senior students and supervising physicians [15-17], AI-CCM provides a nonhierarchical environment, potentially enabling medical students to seek advice and express concerns more freely.

The trial survey results aligned with 2 TAM factors: perceived usefulness and perceived ease of use [36]. Students rated AI-CCM positively, especially for its learning support, psychological encouragement, and clarity. The chat-based interface and easy access—even with free ChatGPT accounts—may explain its ease of use. A recent TAM-based study found that students are more willing to use LLM chatbots when they perceive them as useful and user-friendly [45]. Similarly, ChatGPT-based virtual patient tools have demonstrated strong usability [46]. These findings suggest that gAI tools such as AI-CCM can be integrated into CC settings with minimal barriers.

While AI-CCM performed well in addressing emotional and psychological stress in expert evaluations, students rated its impact on anxiety reduction as neutral (mean 3.2, SD 1.0). None of the students reported using AI-CCM specifically for emotional support during the trial. This may be attributed to several factors, including the short trial period and the timing—students were already in the fourth month of their clerkships, when initial anxiety may have diminished. In addition, some students may have hesitated to use the system for psychological concerns owing to apprehensions about entering sensitive personal information into an AI tool—a hesitation also noted in previous research [47]. To better understand AI-CCM's role in alleviating student stress, future studies should involve longer implementation periods beginning earlier in the clerkship.

To expand adoption, future versions of AI-CCM should follow the core principles of the TAM [34,36]. Enhancing perceived usefulness requires aligning content with students' learning goals and clinical tasks, adding specialty-specific knowledge, and improving context awareness. Boosting ease of use will require an intuitive interface, fast responses, and reliable access. Previous research confirms that usefulness and usability are key to technology adoption in medical education [45]. Providing onboarding materials such as tutorials may also support smoother integration. With continued user feedback and refinement, AI-CCM can become a practical and scalable educational tool.

AI-CCM can be built easily using ChatGPT Plus and custom GPT features. By adding tailored prompts and aligning with local curricula or educational guidelines, institutions can adapt AI-CCM to their specific context. Even students using the free ChatGPT version could access it with some limitations. Given that it is easy to develop, customize, and implement, AI-CCM can support students during CCs. Previous studies suggest that AI tools can reduce educator workload, improve efficiency, and alleviate burnout [46]. AI-CCM could also ease the burden on faculty and administrative staff involved in student guidance. Future research should examine its long-term impact on learning outcomes, clinical performance, and institutional workflows.

Limitations

This study has some limitations. First, it included few participants from a single Japanese medical school, which introduces potential bias related to the sample size, region, and curriculum. In addition, participants were drawn from a single cohort at 1 institution based on availability during their clerkships, which introduces the possibility of selection bias due to the use of convenience sampling. This may limit the generalizability of the findings to other settings or student populations. Second, the trial period was short, and the long-term effects or educational impacts of AI-CCM could not be assessed. As this was a preliminary study, further research involving a larger and more diverse group of students and long-term observations will be necessary. Third, AI-CCM use logs were not comprehensively reviewed during the trial phase. Therefore, the types of questions that the students asked and the responses they received remain unclear. As gAI does not produce uniform answers, future evaluations should include a detailed log analysis to ensure the consistency and appropriateness of interactions. Fourth, both the questionnaire used during the trial and the rubric used to evaluate mentor responses were not formally validated in terms of reliability or construct validity. Although the questionnaire and rubric were developed based on the specific research objectives of this study and refined through consultation with experts in medical education, no interrater reliability testing or statistical validation procedures were conducted. Fifth, although evaluator blinding was implemented, the distinct linguistic patterns of AI-generated responses may have allowed scorers to infer their source. While efforts were made to match the tone and length of AI and student responses to reduce this risk, complete blinding could not be guaranteed. This potential identification bias remains a methodological limitation. Sixth, this study did not assess the variability of AI-CCM's responses across different users,

prompts, or repeated trials. As gAI may produce different outputs depending on context or phrasing, a lack of replication or repeated testing limits the evaluation of the system's stability and reproducibility. Future research should incorporate multiple iterations of chatbot responses to better understand the consistency and generalizability of its educational value.

Conclusions

AI-CCM demonstrated potential utility as a supplementary tool for supporting medical students at the start of their CCs—functioning as a "partner" in their early CCs. However, the time required for AI-CCM to generate responses may not fully align with the needs of students seeking immediate answers related to clinical problems. In response to specific CC scenarios, the usefulness of AI-CCM responses was comparable to that of senior student mentor responses, which indicates that it may serve as a complementary resource alongside human mentoring. Future research should explore the types of questions that are most suitable for AI-CCM support. With further refinements, such as the integration of discipline-specific educational data, AI-CCM holds promise as a more practical and context-sensitive tool in clinical education.

Data Availability

The datasets generated or analyzed during this study are available from the corresponding author on reasonable request.

Authors' Contributions

HE contributed to the conception of the study design, development of the artificial intelligence clinical clerkship mentor (AI-CCM), analysis of all samples, data interpretation, and writing of the manuscript. HK, IS, KS, and HT were involved in the evaluation of responses from senior student mentors and AI-CCM, contributed to the acquisition and analysis of data, and assisted in study design and manuscript writing. HK also participated in the development of AI-CCM. YK contributed to the study design and data interpretation. SI conceived the overall study design, supported data interpretation, and prepared the original draft of the manuscript. All authors read and approved the final manuscript.

Conflicts of Interest

None declared.

Abstract

Background: Deepseek-R1, an open-source large language model (LLM), has generated significant global interest in the past months.

Objective: This study aimed to compare the performance of DeepSeek and OpenAI LLMs on the Chinese National Medical Licensing Examination (NMLE) and evaluate their potential in medical education.

Methods: This cross-sectional study assessed 2 DeepSeek models (DeepSeek-R1 and DeepSeek-V3), 3 OpenAI models (ChatGPT-o1 pro, ChatGPT-o3 mini, and GPT-4o), and 2 additional Chinese LLMs (ERNIE 4.5 Turbo and Qwen 3) using the 2021 NMLE. Model performance was evaluated based on overall accuracy, accuracy across question types (A1, A2, A3 and A4, and B1), case analysis and non–case analysis questions, medical specialties, and accuracy consensus between different model combinations.

Results: All LLMs successfully passed the NMLE. DeepSeek-R1 achieved the highest accuracy (573/597, 96%), followed by DeepSeek-V3 (558/600, 93%), both of which significantly outperformed ChatGPT-o1 pro (450/600, 75%), ChatGPT-o3 mini (455/600, 75.8%), and GPT-4o (452/600, 75.3%; $P<.001$ for all comparisons). Performance disparities were consistent across various question types (A1, A2, A3 and A4, and B1), case analysis and non–case analysis questions, different types of case analyses, and medical specialties. The accuracy consensus between DeepSeek-R1 and DeepSeek-V3 reached 97.7% (544/557), significantly outperforming DeepSeek-R1 alone ($P=.04$). Two additional Chinese LLMs, ERNIE 4.5 Turbo (572/600, 95.3%) and Qwen 3 (555/600, 92.5%), also exhibited significantly better performance compared to the 3 OpenAI models (all $P<.001$).

Conclusions: This study demonstrates that DeepSeek-R1 and DeepSeek-V3 significantly outperform OpenAI models on the NMLE. DeepSeek models show promise as tools for medical education and exam preparation in the Chinese language.

large language models; DeepSeek; OpenAI; Chinese Medical Licensing Examination; artificial intelligence; AI

Introduction

DeepSeek-R1, an open-source large language model (LLM), has generated significant global interest in the past months [1-5]. Launched by DeepSeek on January 20, 2025, this model demonstrates a performance comparable to that of OpenAI's ChatGPT-o1 in tasks involving mathematics, coding, and reasoning [2]. By leveraging a "mixture of experts" architecture, DeepSeek reduces the computational resources required for model training while enhancing the efficiency of query responses [6]. In addition, its lower cost and interface fees make it a more accessible option for users, providing a cost-effective alternative to OpenAI models. As an open-source LLM, DeepSeek-R1 offers users the ability to view and modify its source code, encouraging further improvements and customization. The release of this model has already made a splash in academic circles [1-3].

In recent years, OpenAI has maintained a leading position in the field of LLMs. OpenAI recently launched the ChatGPT-o1 pro and ChatGPT-o3 mini models, which are widely regarded as among the most powerful models available. GPT-4o, launched in May 2024, represents OpenAI's best-performing free model, with extensive applications and robust validation over the past year [7,8].

LLMs hold substantial potential in the medical domain, including clinical decision support [9,10], medical image analysis [11,12], health education, patient counseling, and medical training [13]. Medical licensing examinations are a critical entry test for medical licensure, and successfully passing them indicates a foundational understanding of medical knowledge. A model's ability to pass these exams not only suggests its potential to aid medical students in their exam preparation but also reflects its proficiency in medical knowledge and reasoning—skills essential for clinical decision-making and medical image interpretation.

Studies have shown that the GPT-4o model achieves an accuracy of 90.4% on the US Medical Licensing Examination (USMLE) [7], whereas its performance on the Chinese National Medical Licensing Examination (NMLE) stands at 84.9%, notably lower than its performance on the USMLE, as well as that on the United Kingdom's Professional and Linguistic Assessments Board (PLAB) test (93.3%) and the Hong Kong Medical Licensing Examination (91.7%) [8]. Developed by a Chinese company, the DeepSeek-R1 and DeepSeek-V3 models feature a higher proportion of Chinese-language corpora, making their performance on Chinese-language exams particularly promising.

In this study, we compared the performance of the DeepSeek and OpenAI LLMs on the NMLE and evaluated their potential in Chinese medical education.

Methods

LLMs Evaluated in This Study

The models evaluated in this study were DeepSeek-R1, DeepSeek-V3, ChatGPT-o1 pro, ChatGPT-o3 mini, GPT-4o, ERNIE 4.5 Turbo, and Qwen 3. DeepSeek-R1 and DeepSeek-V3 were developed by DeepSeek AI. ChatGPT-o1 pro, ChatGPT-o3 mini, and GPT-4o were developed by OpenAI. ERNIE 4.5 Turbo was developed by Baidu, and Qwen 3 was developed by the Alibaba Group.

NMLE Description

The NMLE is a comprehensive, nationwide exam required for obtaining medical practice credentials in China. All questions in the exam are multiple choice in Chinese, with 5 options provided and only 1 option being correct. The exam is divided into 4 sections, each consisting of 150 multiple-choice questions. The total number of questions is 600, with each being worth 1 point. To pass the exam, candidates must achieve a score of ≥360 points. Each section is allotted 2.5 hours, and the entire exam lasts 10 hours in total.

The questions in the exam are classified into 4 types. A1-type questions assess basic medical knowledge, and A2-, A3-, and A4-type questions are case analysis questions. The A2-type questions are presented with a single case, followed by 1 question related to that case. A3 and A4–type questions also follow a case-based format: each case is accompanied by 2 to 4 associated questions. B1-type questions consist of several sets of questions, each with a common list of 5 options. Some options may be selected once, multiple times, or not at all, depending on the question.

The 2021 NMLE was used in this study [14]. The Chinese National Medical Examination Center, which administered this NMLE, has confirmed that the use of these questions for academic research is exempt from copyright restrictions.

Model Testing Procedure

All models were assessed using their publicly accessible web interfaces in default configurations, precluding manual adjustment of parameters such as temperature, maximum tokens, or system prompts. This study used standardized prompting without in-context learning. All models were evaluated using identical input prompts for each question type (provided in Multimedia Appendix 1), with no additional examples or contextual demonstrations provided during testing. A standard prompt in Chinese was copied into the conversation window of each model to set the conditions for the exam. For the A1- and A2-type questions, 1 question was copied into the chat window at a time, and the models responded individually to each question. For A3 and A4–type questions, all related questions for a single case were input into the chat window simultaneously, and the models provided answers to all questions associated with that case. For the B1-type questions, all questions in a set with a shared list of 5 possible answers were input at once, and the models answered all questions in the set. Each set of questions (or individual question for the A1 and A2 types) was processed in a new, blank chat window. Testing took place from February 3, 2025, to February 9, 2025.

In addition, 2 experienced attending physicians independently classified the case-based questions (A2, A3, and A4 types) using 2 different methods. The first method involved categorizing the questions into broad categories such as examination, diagnosis, treatment, and other relevant areas. The second method involved classifying the questions according to medical specialty, including internal medicine, surgery, obstetrics and gynecology,

pediatrics, neurology, psychiatry, emergency medicine, and others. For cases involving multiple specialties, the primary specialty was determined based on the most relevant medical department. In instances of disagreement between the 2 attending physicians, a senior physician made the final decision regarding the classification.

To investigate the underlying factors contributing to DeepSeek models' superior performance, we conducted parallel evaluations by translating both the NMLE question bank and standardized prompts into English (see Multimedia Appendix 1 for the English-language prompt versions). GPT-4o was systematically evaluated using both the original Chinese questions and their English-translated counterparts to enable direct performance comparison across language conditions.

Statistics

Questions that the models did not answer were marked as omitted and excluded from the accuracy calculation. Accuracy consensus was defined as the ratio of agreement on correct responses between 2 models relative to their overall agreement (ie, considering both correct and incorrect responses).

For paired-sample comparisons, we used the McNemar chi-square test for 2-group comparisons and the Cochran *Q* test for multiple-group comparisons. When analyzing independent samples, we used the Pearson chi-square test, continuity correction, or the Fisher exact test as appropriate. The κ consistency test was used to quantitatively assess the concordance between 2 models. In terms of the κ coefficients, values exceeding 0.75 are considered to indicate excellent agreement, values within the range of 0.40 to 0.75 suggest good agreement, whereas values below 0.40 are indicative of poor agreement.

All statistical analyses were conducted using SPSS (version 23.0; IBM Corp), and a 2-tailed *P* value of <.05 was considered statistically significant.

Results

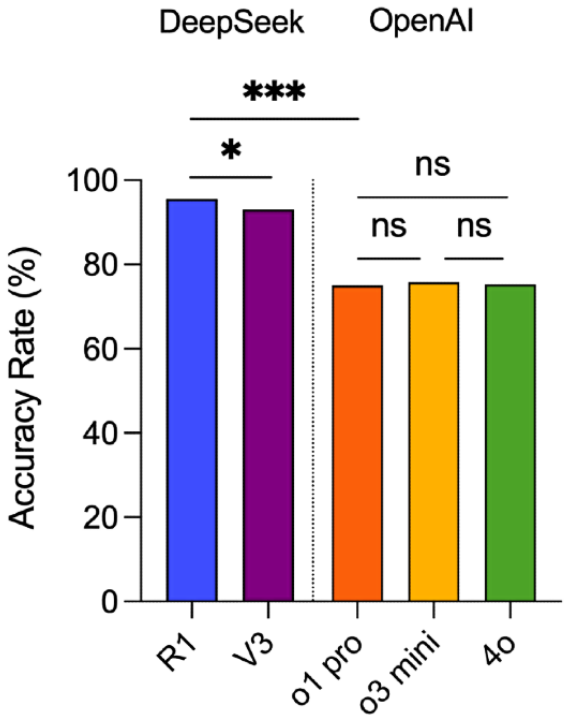
Overall Accuracy

DeepSeek-R1 did not provide answers for 3 questions, responding with "Sorry, I haven't yet learned how to approach these types of questions. I specialize in math, coding, and logic-related problems. Feel free to engage with me on these topics" (Multimedia Appendix 1). These 3 questions were marked as omissions. The remaining 4 models answered all the questions.

DeepSeek-R1, DeepSeek-V3, ChatGPT-o1 pro, ChatGPT-o3 mini, and GPT-4o answered 573, 558, 450, 455, and 452 questions correctly, respectively, achieving accuracy rates of 96% (573/597), 93% (558/600), 75% (450/600), 75.8% (455/600), and 75.3% (452/600), respectively (Figure 1 and Multimedia Appendix 1). The 3 questions that DeepSeek-R1 did not answer were excluded from the calculation.

All models scored above 360 points, thereby passing the NMLE. The accuracy of DeepSeek-R1 and DeepSeek-V3 was significantly higher than that of ChatGPT-o1, ChatGPT-o3, and GPT-4o (*P*<.001 for all comparisons). Between models from the same developers, DeepSeek-R1's accuracy was significantly higher than that of DeepSeek-V3 (*P*=.02), whereas no substantial differences were observed between ChatGPT-o1 pro, ChatGPT-o3 mini, and GPT-4o.

Figure 1. Overall accuracy rates of DeepSeek-R1, DeepSeek-V3, ChatGPT-o1 pro, ChatGPT-o3 mini, and GPT-4o. * *P*<.05, *** *P*<.005, and ns (no significance).

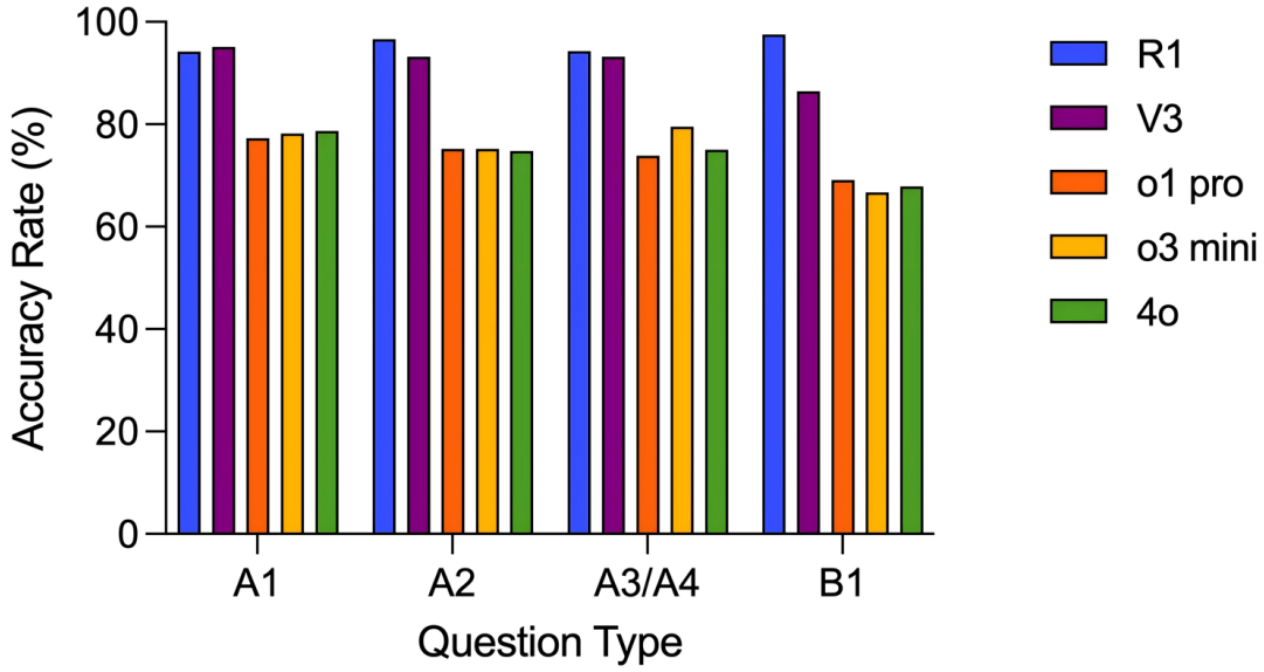


Accuracy Across Different Question Types

As shown in Figure 2 and Multimedia Appendix 1, for question types A1, A2, A3 and A4, and B1, DeepSeek-R1 and DeepSeek-V3 both demonstrated significantly higher accuracy than ChatGPT-o1 pro, ChatGPT-o3 mini, and GPT-4o (P<.05 for all comparisons). Specifically, DeepSeek-R1 achieved accuracy rates of 95.5% (212/222), 96.6% (199/206), 94% (83/88), and 98% (79/81) for the A1, A2, A3 and A4, and B1 question types, respectively. These accuracy rates were significantly higher than those of ChatGPT-o1 pro, which scored 77.3% (174/225), 75.2% (155/206), 74% (65/88), and 69% (56/81) for the same question types, respectively (P<.001 for all comparisons).

The performance of the 2 DeepSeek models (R1 and V3) did not show significant differences across the 4 question types (P>.05 for all comparisons). Similarly, the 3 OpenAI models (ChatGPT-o1 pro, ChatGPT-o3 mini, and GPT-4o) also did not demonstrate significant differences in performance across the 4 question types (P>.05 for all comparisons).

Figure 2. Accuracy Rates of DeepSeek-R1, DeepSeek-V3, ChatGPT-o1 pro, ChatGPT-o3 mini, and GPT-4o Across Various Question Types.



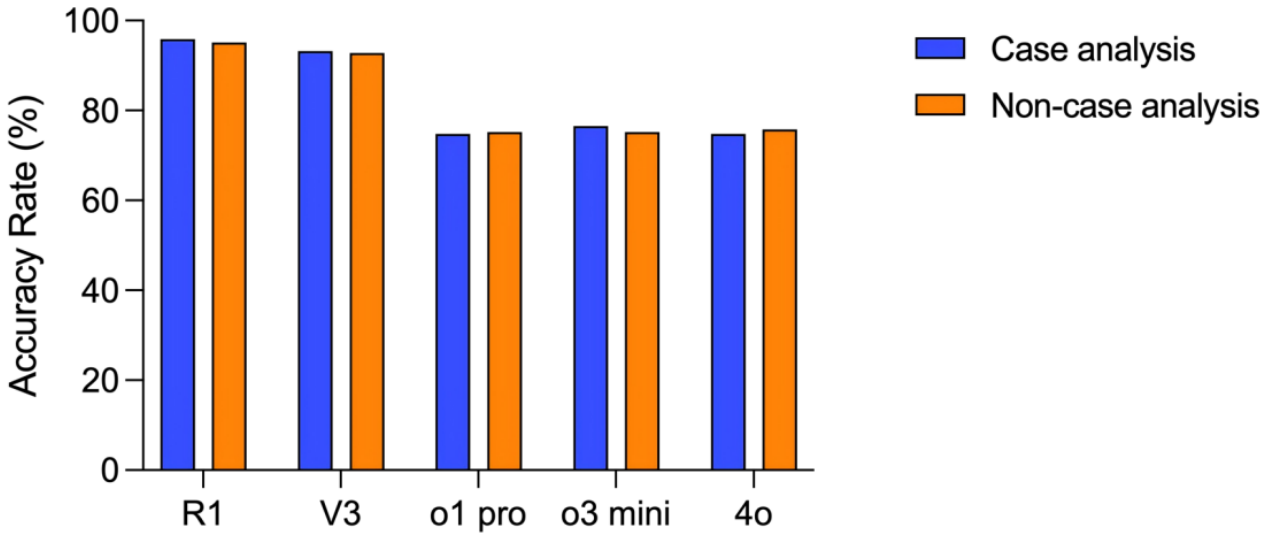
Accuracy Across Case Analysis and Non–Case Analysis Questions

Of the 600 total questions, 294 (49%) were case analysis questions, and 306 (51%) were non–case analysis questions. As shown in Figure 3 and Multimedia Appendix 1, the accuracy rates for both case analysis and non–case analysis questions were similar across all 5 models (DeepSeek-R1, DeepSeek-V3, ChatGPT-o1 pro, ChatGPT-o3 mini, and GPT-4o).

For case analysis questions, DeepSeek-R1 and DeepSeek-V3 consistently outperformed ChatGPT-o1 pro, ChatGPT-o3 mini, and GPT-4o, with all comparisons yielding significant differences (P<.001 for all comparisons). Specifically, DeepSeek-R1 achieved an accuracy rate of 95.9% (282/294), which was significantly higher than the 74.8% (220/294) accuracy observed for ChatGPT-o1 pro (P<.001). No significant difference in accuracy was observed between DeepSeek-R1 (282/294, 95.9%) and DeepSeek-V3 (274/294, 93.2%; P=.10). Similarly, the 3 OpenAI models—ChatGPT-o1 pro (220/294, 74.8%), ChatGPT-o3 mini (225/294, 76.5%), and GPT-4o (220/294, 74.8%)—did not exhibit significant differences in their performance on case analysis questions (P>.05 for all comparisons).

For non–case analysis questions, DeepSeek-R1 and DeepSeek-V3 again demonstrated significantly higher accuracy than the OpenAI models (P<.001 for all comparisons). DeepSeek-R1 achieved an accuracy of 96% (291/303) for non–case analysis questions, which was significantly higher than the 75.2% (230/306) accuracy of ChatGPT-o1 pro (P<.001). There was no significant difference in accuracy between DeepSeek-R1 (291/303, 96%) and DeepSeek-V3 (274/294, 93.2%) on non–case analysis questions (P=.23). Furthermore, no significant differences were found among ChatGPT-o1 pro (230/306, 75.2%), ChatGPT-o3 mini (230/306, 75.2%), and GPT-4o (232/306, 75.8%) in terms of their performance on these questions (P>.05 for all comparisons).

Figure 3. Accuracy Rates of DeepSeek-R1, DeepSeek-V3, ChatGPT-o1 pro, ChatGPT-o3 mini, and GPT-4o on Case Analysis and Non-Case Analysis Questions.



Performance Across Different Types of Case Analysis Questions

For the diagnosis type of case analysis question, DeepSeek-R1 achieved an accuracy of 98% (146/149), which was slightly higher than its accuracy of 92% (72/78) for treatment type of case analysis questions (*P*=.09). Similarly, ChatGPT-o3 mini showed a diagnostic accuracy of 80.5% (120/149), which was higher than its treatment accuracy of 68% (53/78; *P*=.048). DeepSeek-V3, ChatGPT-o1 pro, and GPT-4o also showed higher diagnostic accuracy compared to treatment, but the differences were not statistically significant (*P*>.05 for all comparisons).

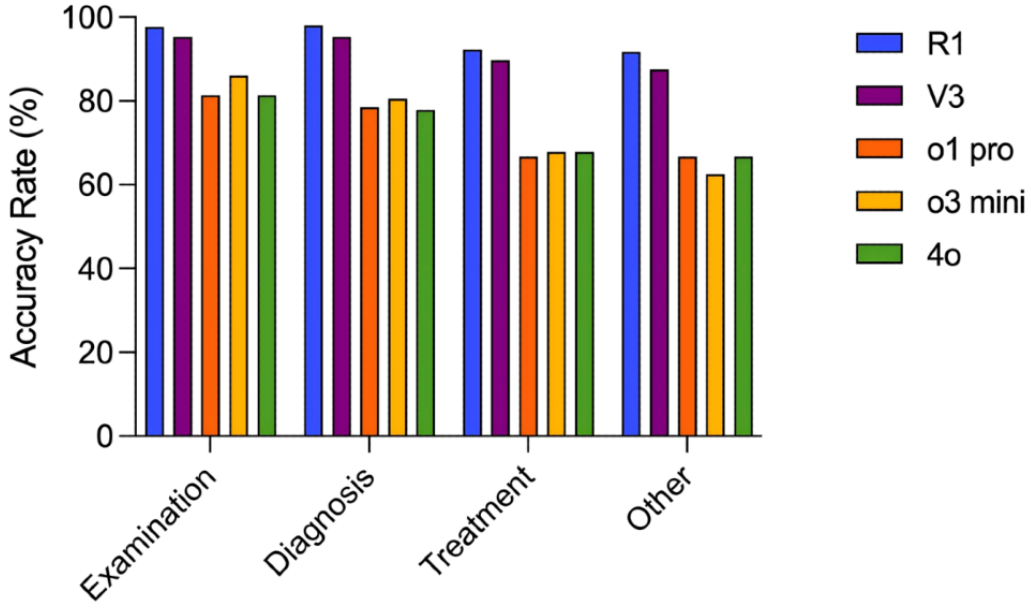
For the examination type of case analysis question, DeepSeek-R1 achieved an accuracy rate of 98% (42/43), significantly outperforming ChatGPT-o1 pro (35/43, 81%; *P*=.02) and GPT-4o (35/43, 81%; *P*=.02). It also outperformed ChatGPT-o3 mini (37/43, 86%), although the difference was not statistically significant (*P*=.06).

Regarding diagnosis, DeepSeek-R1 and DeepSeek-V3 achieved accuracy rates of 98% (146/149) and 95.3% (142/149), respectively, both significantly outperforming the OpenAI models (accuracy rates ranging from 116/149, 77.9% to 120/149, 80.5%; *P*<.001 for all comparisons).

For treatment questions, DeepSeek-R1 and DeepSeek-V3 achieved accuracy rates of 92% (72/78) and 90% (70/78), respectively, both significantly outperforming the OpenAI models, whose accuracy ranged from 67% (52/78) to 68% (53/78; *P*<.001 for all comparisons).

The details are shown in Figure 4 and Multimedia Appendix 1.

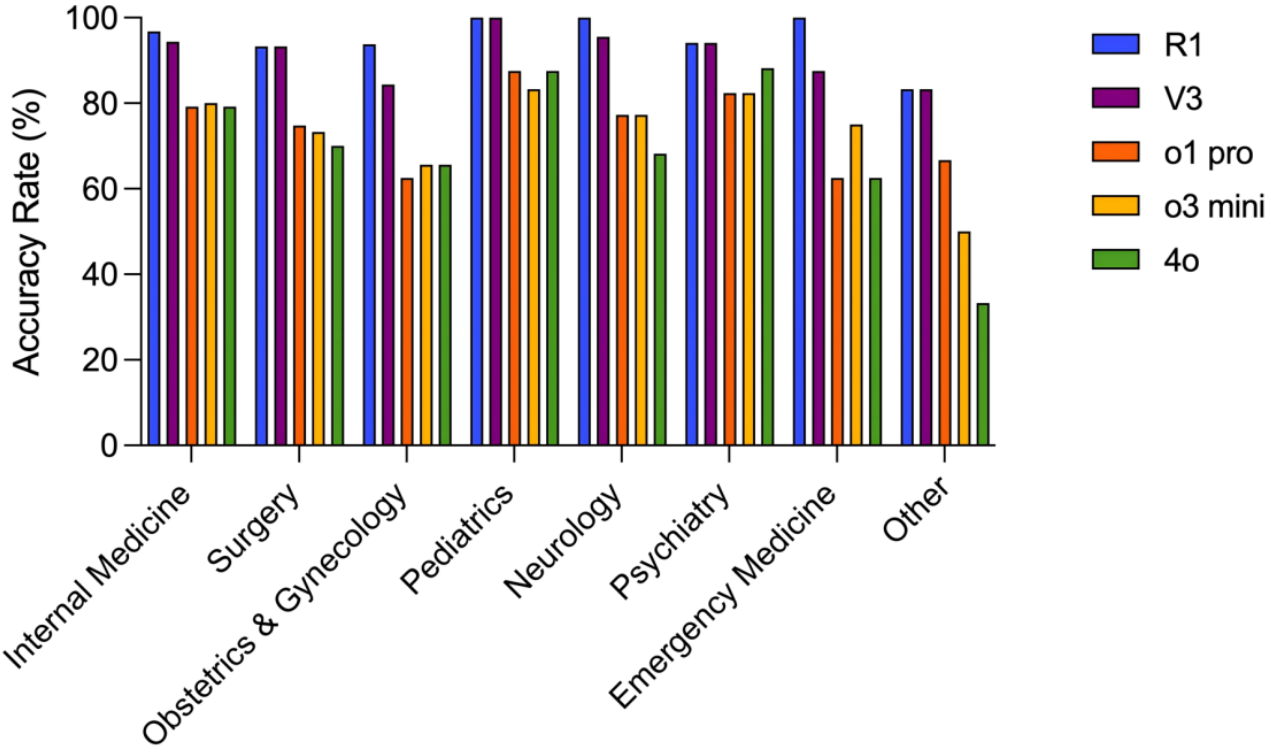
Figure 4. Accuracy Rates of DeepSeek-R1, DeepSeek-V3, ChatGPT-o1 pro, ChatGPT-o3 mini, and GPT-4o Across Different Types of Case Analysis Questions.



Case Analysis Questions Across Different Medical Specialties

Of the 294 case analysis questions, 125 (42.5%) were from internal medicine, 60 (20.4%) were from surgery, 32 (10.9%) were from obstetrics and gynecology, 24 (8.2%) were from pediatrics, and 22 (7.5%) were from neurology. DeepSeek-R1 achieved accuracy rates ranging from 93% (56/60) to 100% (24/24) across all specialties, whereas DeepSeek-V3 had accuracy rates between 84% (27/32) and 100% (24/24). In contrast, the OpenAI models—ChatGPT-o1 pro, ChatGPT-o3 mini, and GPT-4o—showed accuracy rates between 62% (20/32) and 88% (21/24), 66% (21/32) and 83% (20/24), and 62% (5/8) and 88% (21/24), respectively (Figure 5 and Multimedia Appendix 1).

Figure 5. Accuracy Rates of DeepSeek-R1, DeepSeek-V3, ChatGPT-o1 pro, ChatGPT-o3 mini, and GPT-4o Across Different Medical Specialties in Case Analysis Questions.



Accuracy Consensus

As shown in Table 1 and Multimedia Appendix 1, the accuracy consensus between DeepSeek-R1 and DeepSeek-V3 reached 97.7% (544/557), the highest among all model pairs, significantly outperforming DeepSeek-R1 alone (573/597, 96%; P=.04) and DeepSeek-V3 (558/600, 93%; P<.001). The accuracy consensus between DeepSeek-R1 and ChatGPT-o1 pro, ChatGPT-o3 mini, and GPT-4o was 95.5% (444/465), 95.9% (447/466), and 97.3% (437/449), respectively, with no significant differences compared to DeepSeek-R1's individual accuracy (573/597, 96%; P>.05 for all comparisons). Regarding the 3 OpenAI models, their pairwise accuracy consensus values were 77.7% (428/551, ChatGPT-o3 mini and ChatGPT-o1 pro), 78.1% (420/538, GPT-4o and ChatGPT-o1 pro), and 79.2% (416/525, GPT-4o and ChatGPT-o3 mini), with no significant differences compared to the individual accuracy of each model (P>.05 for all comparisons).

The results of the κ consistency test are shown in Table 2. Specifically, the κ coefficient between ChatGPT-o1 pro and ChatGPT-o3 mini was 0.781, demonstrating excellent agreement. The κ coefficients between GPT-4o and ChatGPT-o1 pro and between GPT-4o and ChatGPT-o3 mini were 0.723 and 0.661, respectively, indicating good agreement. Notably, the κ coefficients between the 2 DeepSeek models, as well as between the DeepSeek models and the OpenAI models, were all below 0.4, suggesting poor agreement.

Our comparative analysis of accuracy consensus across different model combinations revealed that the pairing of DeepSeek-R1 and DeepSeek-V3 achieved significantly higher consensus rates than combinations consisting solely of OpenAI models (Table 1 and Multimedia Appendix 1).

Table 1. Accuracy consensus among DeepSeek-R1, DeepSeek-V3, ChatGPT-o1 pro, ChatGPT-o3 mini, and GPT-4o.

Model pair	Accuracy consensus, n/N (%)
DeepSeek-V3 and DeepSeek-R1	544/557 (97.7)
ChatGPT-o1 pro and DeepSeek-R1	444/465 (95.5)
ChatGPT-o1 pro and DeepSeek-V3	441/474 (93)
ChatGPT-o3 mini and DeepSeek-R1	447/466 (95.9)
ChatGPT-o3 mini and DeepSeek-V3	444/475 (93.5)
ChatGPT-o3 mini and ChatGPT-o1 pro	428/551 (77.7)
GPT-4o and DeepSeek-R1	437/449 (97.3)
GPT-4o and DeepSeek-V3	435/460 (94.6)
GPT-4o and ChatGPT-o1 pro	420/538 (78.1)
GPT-4o and ChatGPT-o3 mini	416/525 (79.2)

Table 2. κ coefficients for the consistency test among DeepSeek-R1, DeepSeek-V3, ChatGPT-o1 pro, ChatGPT-o3 mini, and GPT-4o.

Model pair	κ coefficient
DeepSeek-V3 and DeepSeek-R1	0.341
ChatGPT-o1 pro and DeepSeek-R1	0.171
ChatGPT-o1 pro and DeepSeek-V3	0.263
ChatGPT-o3 mini and DeepSeek-R1	0.157
ChatGPT-o3 mini and DeepSeek-V3	0.250
ChatGPT-o3 mini and ChatGPT-o1 pro	0.781
GPT-4o and DeepSeek-R1	0.066
GPT-4o and DeepSeek-V3	0.173
GPT-4o and ChatGPT-o1 pro	0.723
GPT-4o and ChatGPT-o3 mini	0.661

English-Translated Questions

Following the translation of NMLE questions into English, GPT-4o demonstrated significantly improved performance, with an accuracy of 83.5% (501/600), representing a notable increase from its 75.3% (452/600) accuracy on the original Chinese version (P<.001). Nevertheless, this enhanced performance still fell significantly short of DeepSeek-R1's 96% (573/597) accuracy on the Chinese-language questions (P<.001).

The performance improvement was particularly pronounced across specific question types: GPT-4o showed statistically significant gains in accuracy for A1-type (193/225, 85.8% vs 177/225, 78.7%; P=.03), A2-type (168/206, 81.6% vs 154/206, 74.8%; P=.04), and A3 and A4–type (78/88, 89% vs 66/88, 75%; P=.01) questions when answering English-translated versions. Notably, both case analysis and non–case analysis questions showed marked performance enhancements in the English-translated condition. The details are shown in Table 3.

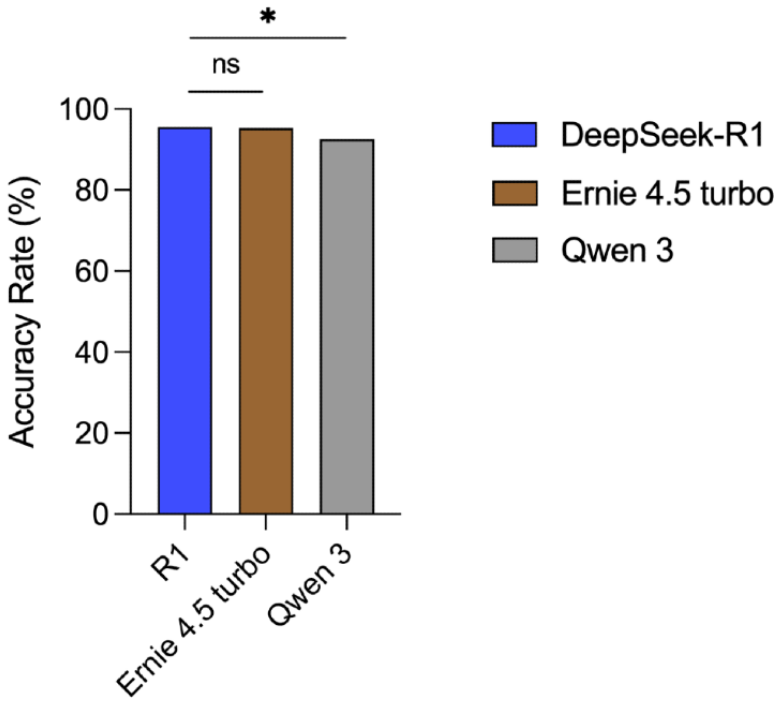
Table 3. GPT-4o performance on Chinese-language versus English-translated questions across different question types (N=600).

Question type	Correct answers in Chinese-language questions, n (%)	Correct answers in English-translated questions, n (%)	P value
A1 (n=225)	177 (78.7)	193 (85.8)	.03
A2 (n=206)	154 (74.8)	168 (81.6)	.04
A3 and A4 (n=88)	66 (75)	78 (88.6)	.01
B1 (n=81)	55 (67.9)	62 (76.5)	.23
Case analysis (n=294)	220 (74.8)	246 (83.7)	<.001
Non–case analysis (n=306)	232 (75.8)	255 (83.3)	.01
Total	452 (75.3)	501 (83.5)	<.001

Comparison of Chinese LLMs

We compared DeepSeek-R1 with 2 other Chinese LLMs, ERNIE 4.5 Turbo and Qwen 3, using the same NMLE questions Figure 6. ERNIE 4.5 Turbo achieved an overall accuracy of 95.3% (572/600), comparable to that of DeepSeek-R1 (573/597, 96%; *P*=.58). In contrast, Qwen 3 demonstrated an accuracy of 92.5% (555/600), significantly lower than that of DeepSeek-R1 (*P*=.01). Both ERNIE 4.5 Turbo and Qwen 3 significantly outperformed OpenAI's 3 models (*P*<.001 for all comparisons).

Figure 6. Overall accuracy rates of DeepSeek-R1, ERNIE 4.5 Turbo and Qwen 3. * *P*<.05 and ns (no significance).



Discussion

In this study, we observed that the DeepSeek-R1 and Deepseek-V3 models achieved significantly higher accuracy rates on the NMLE, with accuracy scores of 93% (558/600) and 95.5% (212/222), respectively, substantially outperforming the OpenAI models, which demonstrated accuracy rates ranging from 75% (450/600) to 75.8% (455/600). In addition, the DeepSeek models consistently outperformed the OpenAI models across a variety of question types. A further in-depth analysis revealed that the accuracy consensus between DeepSeek-R1 and DeepSeek-V3 reached a peak of 97.7% (544/557). These findings highlight the superior performance of the DeepSeek models in the context of the NMLE when compared to OpenAI models. To the best of our knowledge, this is the first study to directly compare the performance of DeepSeek and OpenAI models within the context of a medical examination.

Previous studies have demonstrated that GPT-4's performance on the NMLE is notably inferior to its performance on English-language exams such as the USMLE, the United Kingdom's PLAB, and the Hong Kong Medical Licensing Examination [7,8]. Previous research has also revealed that ChatGPT was unable to pass the Taiwanese Family Medicine Board Exam in Chinese [15], indicating that OpenAI models may not perform as well on Chinese medical exams compared to their performance on their English-language counterparts. Before the advent of DeepSeek, a study found that the Chinese-developed LLM Qwen-2.5 (Alibaba Group) achieved an accuracy of 88.9% on the Chinese National Nursing Licensing Examination, surpassing GPT-4, which had an accuracy of 80.7%. Another Chinese LLM, ERNIE Bot-3.5 (Baidu), demonstrated an accuracy of 78.1%, which is comparable to that of GPT-4 [16]. Additional studies have shown that ERNIE Bot performed similarly to OpenAI's models in recognizing Chinese health-related rumors and providing medical counseling [17,18]. Although the previous Chinese LLMs from DeepSeek had a noticeable gap compared to OpenAI models, in terms of processing Chinese medical questions, those models have already become similar to OpenAI models of the same period. In this study, another Chinese LLM—ERNIE 4.5 Turbo—performed comparably to DeepSeek in the NMLE, whereas Qwen 3, although it achieved a lower accuracy (92.5%) than DeepSeek-R1, still significantly outperformed OpenAI models.

Neither DeepSeek nor OpenAI has disclosed the exact proportion of Chinese-language data used in their models. However, as a Chinese-developed LLM, DeepSeek likely incorporates a significantly higher proportion of Chinese-language data than OpenAI's more globally oriented models. It is estimated that OpenAI's Chinese-language training data comprise less than 5%, whereas DeepSeek's proportion exceeds 40%. This higher proportion of Chinese-language data likely enhances DeepSeek's ability to understand and process Chinese-language text with greater accuracy. Our translation experiment further substantiates this hypothesis. When NMLE questions were translated into English, GPT-4o's accuracy significantly increased from 75.3% (452/600) to 83.5% (501/600; *P*<.001). This 8.2 percentage points gain demonstrates that language barriers materially constrain OpenAI's

performance in Chinese medical examinations. Practically, these findings reveal a strategic implication: NMLE candidates using OpenAI models for preparation may improve answer reliability by translating questions into English. Nevertheless, even with optimized language conditions, GPT-4o's translated question accuracy remained significantly inferior to DeepSeek-R1's native-language performance (501/600, 83.5% vs 573/597, 96%; $P<.001$), suggesting that DeepSeek's advantage extends beyond linguistic proficiency to encompass domain-specific medical knowledge alignment.

DeepSeek-R1 provides chain-of-thought (CoT) processes when answering questions, which offers us a valuable window to observe the reasoning processes of LLMs. Interestingly, DeepSeek-R1's CoT frequently references Chinese medical textbooks, which serve as key references for the NMLE. In Multimedia Appendix 1, we present 3 specific examples of this phenomenon. In the CoT analysis of 2 case study questions, the model consistently followed a structured approach: first identifying key diagnostic elements (such as Reed-Sternberg cells in case 1 and upper gastrointestinal bleeding in case 2) and then determining the most appropriate answer choice based on medical textbooks from People's Medical Publishing House editions. Subsequently, it systematically evaluated why alternative options were incorrect before arriving at the final correct answer. The medical textbooks published by People's Medical Publishing House are the most important official reference materials for the NMLE. For clinically controversial questions, the examination board explicitly uses these textbooks as the definitive authority. This alignment between DeepSeek's reference sources and the exam's official evaluation criteria may be one of the key reasons for DeepSeek's superior performance.

Differences in disease patterns between China and the United States, as well as variations in diagnostic criteria, treatment protocols, and clinical guidelines for the same diseases, may further contribute to DeepSeek's superior performance on Chinese-language medical exams. For example, in this study, 8.5% (51/600) of the questions were related to tuberculosis. According to the 2024 Global Tuberculosis Report from the World Health Organization, the incidence of tuberculosis in China is approximately 13 times higher than that in the United States [19]. The higher incidence results in an abundance of Chinese-language resources related to tuberculosis, which may contribute to DeepSeek's stronger performance on related questions.

Another important observation is that while ChatGPT-o1 pro and ChatGPT-o3 mini outperform GPT-4o in areas such as mathematics and coding [20,21], this study found that the 3 OpenAI models—ChatGPT-o1 pro, ChatGPT-o3 mini, and GPT-4o—demonstrated almost identical accuracy rates on the NMLE, with accuracy scores of 75% (450/600), 75.8% (455/600), and 75.3% (452/600), respectively. In contrast, DeepSeek-R1, which is considered superior to DeepSeek-V3 [6], achieved only a 2.5% higher accuracy than DeepSeek-V3. The primary distinction between DeepSeek-R1 and DeepSeek-V3, as well as among the OpenAI models, appears to be in their reasoning capabilities. However, the medical licensing examination is a basic-level test for physicians and does not require advanced reasoning skills. It is generally understood that case analysis questions demand more reasoning ability than non–case analysis questions. As illustrated in Figure 3, the accuracy rates for all 5 models were similar across both case analysis and non–case analysis questions. Performance differences between the 2 DeepSeek models and among the 3 OpenAI models were comparable on case analysis questions. This suggests that the reasoning abilities of both DeepSeek-V3 and GPT-4o may be adequate for a medical licensing examination. However, this also raises the possibility that the observed performance discrepancies in DeepSeek models on the NMLE are not attributable to differences in reasoning abilities but rather to the variations in the training corpora discussed previously. To further explore this, additional studies assessing DeepSeek's performance on English-language examinations such as the USMLE would be beneficial.

DeepSeek-R1 declined to answer 3 questions, all notably related to obstetrics and gynecology (Multimedia Appendix 1). These refusals likely stem from the domain's inherent sensitivity (pregnancy, fetal abnormalities, and reproductive rights) and associated ethical dilemmas, triggering the model's protective filters. This conservative "silence over risk" approach aligns with DeepSeek's technical report showing that safety reinforcement learning reduces benchmark accuracy (58.7% vs 70% without safety reinforcement learning) [22]. Such refusals represent responsible artificial intelligence (AI) design but underscore challenges in applying LLMs to high-stakes medical contexts in which comprehensive response capability remains essential.

The high accuracy of LLMs in the NMLE demonstrates their potential as auxiliary tools for exam preparation. Our findings reveal that DeepSeek models significantly outperform their OpenAI counterparts in NMLE performance, suggesting that students should prioritize DeepSeek over OpenAI models for NMLE preparation. Given that DeepSeek-R1's accuracy improvement over DeepSeek-V3 was marginal (3%), whereas DeepSeek-V3 already achieves a high accuracy (558/600, 93%) and substantially faster response times, DeepSeek-V3 offers a balanced combination of precision and efficiency for daily practice. However, for in-depth analysis of complex clinical cases, DeepSeek-R1 may offer advantages due to its explicit CoT reasoning capabilities. When using primarily English language–trained models such as those by OpenAI, posing queries in English is recommended to mitigate performance limitations. Looking ahead, developing adaptive learning systems based on LLMs could dynamically tailor training focus according to individual error patterns observed in practice questions.

The superior performance of DeepSeek models on the NMLE suggests transformative potential for medical education. These LLMs can serve as intelligent teaching assistants, providing evidence-based tutoring with particular strength in clinical reasoning. Their case analysis capabilities enable the development of AI-standardized patients that adapt to learner levels while performance variations across question types inform personalized learning systems. As hybrid educational tools, they combine the efficiency of AI with clinical training needs, with DeepSeek-V3 offering rapid practice and DeepSeek-R1 enabling

in-depth case analysis while maintaining crucial human oversight for complex decision-making.

This study has several limitations. First, it focused exclusively on the NMLE, and therefore, the reasons behind DeepSeek's superior accuracy compared to OpenAI models cannot be conclusively determined without evaluating their performance on other English-language medical examinations such as the USMLE and PLAB. Second, the questions in this study did not include medical imaging, leaving the models' performance on image-based medical tasks unassessed. Third, we primarily attributed DeepSeek's superior NMLE performance to its greater amount of Chinese-language training data. However, without reliable documentation from both companies about their actual Chinese-language training data proportions, our analysis might be incomplete. The performance differences could also stem from other factors such as reasoning capabilities or DeepSeek's tendency to reference Chinese medical textbooks.

In conclusion, all 5 models successfully passed the NMLE. DeepSeek-R1 achieved the highest accuracy rate of 96% (573/597), followed by DeepSeek-V3 at 93% (558/600). Both DeepSeek models significantly outperformed the OpenAI models, whose accuracy rates ranged from 75% (450/600) to 75.8% (455/600). DeepSeek models exhibited superior performance across various question types, including case analysis, non–case analysis, and different subtypes of case analysis questions. The accuracy consensus between DeepSeek-R1 and DeepSeek-V3 further boosted accuracy to 97.7% (544/557). The outstanding performance of DeepSeek models on the NMLE underscores their considerable potential for enhancing diagnostic and treatment decision-making, patient education, and medical popularization in Chinese-language contexts. Moreover, they represent a valuable tool for preparing for medical licensing examinations.

Abstract

Background: Telenursing has become prevalent in providing care to diverse populations experiencing different health conditions both in Israel and globally. The nurse-patient relationship aims to improve the condition of individuals requiring health services.

Objectives: This study aims to evaluate nursing graduates' skills and knowledge regarding remote nursing care prior to and following a simulation-based telenursing training program in an undergraduate nursing degree.

Methods: A cohort study assessed 114 third-year nursing students using comprehensive evaluation measures of knowledge, skills, attitudes, self-efficacy, and clinical skills regarding remote nursing care. Assessments were conducted at 2 critical time points: prior to and following a structured simulation-based training intervention.

Results: Participant demographics revealed a predominantly female sample (101/114, 88.6%), aged 20 - 50 years (mean 25.68, SD 4.59 years), with moderate to advanced computer and internet proficiency. Notably, 91.2% (104/114) had no telenursing exposure, yet 75.4% (86/114) expressed training interest. Statistical analyses demonstrated significant improvements across all measured variables, characterized by moderate to high effect sizes. Key findings included substantial increases in telenursing awareness, knowledge, skills, attitudes and self-efficacy; significant reduction in perceived barriers to remote care delivery; and complex interrelation dynamics between variables. A multivariate analysis revealed nuanced correlations: higher awareness and knowledge were consistently associated with more positive attitudes and increased self-efficacy. Positive attitudes correlated with enhanced self-efficacy and reduced perceived barriers. Change score analyses further indicated that increased awareness and knowledge facilitated more positive attitudinal shifts, while heightened awareness and positive attitudes corresponded with decreased implementation barriers.

Conclusions: The study underscores the critical importance of integrating targeted telenursing training into nursing education. By providing comprehensive preparation, educational programs can equip students to deliver optimal remote care services. The COVID-19 pandemic has definitively demonstrated that remote nursing will be central to future health care delivery, emphasizing the urgent need to prepare nursing students for this emerging health care paradigm.

Introduction

Background

In recent decades, telehealth—the use of information and communication technology in health care—has become a global priority [1]. Telenursing, a subset of telehealth defined as "the use of technology to deliver nursing care and conduct nursing practice" [2], has emerged as a significant health care option. Indeed, telenursing enables patients to access health care providers remotely through various technologies, including mobile devices, computers, and videoconferencing [3]. The American Nurses Association defines telenursing as the use of "technology to deliver nursing care and conduct nursing practices" [4].

Telenursing offers numerous benefits, including improved access to care, savings in time and resources, and enhanced self-care opportunities [5]. Telenursing has been found effective in reducing the number of outpatient and emergency room visits, shortening hospital stays, and lowering health care costs [6]. It has also proved beneficial in educating patients, promoting self-care competence, and providing cost-effective mental health support [7], as well as in providing care for chronically ill patients [5], oncology patients [6] and palliative care [8].

The COVID-19 pandemic accelerated the adoption of telenursing by emphasizing its crucial role in disaster and public health emergency responses [9]. This shift highlighted the need for integrating telenursing concepts into nursing education at both undergraduate and graduate levels [3,10].

Despite the growing importance of telenursing, it is often underrepresented in nursing curricula. Poreddi et al [11] found that while nurse interns generally hold positive perceptions of telenursing, their knowledge of the subject is limited. This gap underscores the need to incorporate telenursing concepts into nursing education in order to prepare future health care providers for an increasingly digital environment. Nurses play an indispensable role in telehealth implementation, with their skills and attitudes serving as supportive factors [12].

Nevertheless, telenursing also entails challenges. Indeed, to provide optimal care without physical contact nurses must possess high-level clinical and interpersonal skills [13,14]. A lack of sufficient knowledge and skills constitutes the main obstacle in telenursing [15]. Previous studies have reported that telehealth education in nursing programs is inadequate [16]. To acquire the skills and develop the competencies required for telenursing, students must practice the use of screen technology and virtual access to remote patients, and telenursing should be introduced early in the nursing curriculum [17].

Simulation-based learning has been identified as an effective method for teaching telenursing skills. This approach allows students to practice in a safe and realistic environment in which they can improve their cognitive, emotional, and psychomotor abilities [18,19]. Studies have shown that simulations positively affect self-efficacy, academic motivation, and the acquisition of clinical skills [20,21]. Moreover, experiential education can be used to augment such crucial factors as perceived usefulness, self-efficacy, and innovativeness, thus enhancing our understanding of the effectiveness and implications of telenursing [22].

Glinkowski et al [23] examined telehealth among college nursing students. They found that 67% (207/308) of participants were willing to engage in telehealth services and 69.49% (214/308) agreed that telehealth should be included as part of the nursing education curriculum. Indeed, enhancing understanding of telenursing and establishing a robust human infrastructure among future nursing professionals are of critical importance. Receptiveness and adaptability have emerged as crucial factors in shaping the quality of health care services provided through telenursing [24]. Studies that examined nursing and medical students in the United States and Poland revealed positive perspectives and attitudes toward telehealth and telenursing. Yet, these studies also revealed knowledge gaps among these students, as well as erroneous beliefs regarding the advantages and possibilities of using telenursing in health practice [25-28]. Adequate education is needed to overcome this lack of knowledge and improve students' attitudes, including more telenursing content [29].

According to Assaye et al [30], the most significant factors influencing perceptions of telenursing among health care providers include technology availability, web access, and lack of telemedicine training. Indeed, nurses with insufficient education and training in the use of technology face difficulties in implementing telenursing [31]. To overcome these difficulties, students must develop a positive and unprejudiced attitude, while acquiring comprehensive knowledge and acknowledging the limitations of these technologies [32].

Despite the importance of integrating telenursing in nursing study programs, in Israel this topic has not been incorporated into the nursing director's core program and is not taught in practical nursing training programs. Although studies have been conducted on the use of telenursing, very few have examined the issue of training nursing students to use it. Implementing and evaluating such a training program have the potential to help integrate telenursing into the nursing director's core program.

In conclusion, despite the increasing importance of telenursing in health care delivery, particularly in view of recent global events, its integration into nursing education remains limited, particularly in certain countries, such as Israel. Further research, educational initiatives, and pilot training programs are needed to bridge this gap and ensure that future nurses are adequately prepared for the evolving landscape of health care delivery.

This study evaluates the skills and knowledge of third-year nursing students regarding remote nursing care before and after participation in a simulation-based training program on telenursing as part of their undergraduate nursing degree. To the best of our knowledge, very few studies to date have evaluated programs that use simulation to train nursing students in the provision of nursing care from a distance (telenursing).

Hypotheses

This study tests 3 hypotheses. The first hypothesis posits that participation in telenursing training will lead to increased awareness, knowledge, and understanding of required skills in telenursing practice. We expect to observe improved attitudes toward telenursing and enhanced self-efficacy, while simultaneously seeing a reduction in perceived barriers to telenursing implementation. The second hypothesis suggests that there will be significant positive correlations between nursing students' self-efficacy in telenursing and their awareness, knowledge, skill perceptions, and attitudes toward telenursing. Conversely, we anticipate that barriers to telenursing will demonstrate a negative correlation with self-efficacy levels. The third hypothesis proposes that nursing students' awareness, knowledge, skill perceptions, and attitudes toward telenursing will serve as significant predictors of both initial self-efficacy levels prior to training and the magnitude of change in self-efficacy following the intervention.

Methods

Participants

Participants in this study included 114 nursing students in their third year of studies. Most participants were female (101/114, 88.6%), between the ages of 20 and 50 years (mean 25.68, SD 4.59 years), and studying for a first undergraduate degree (107/114, 93.9%) (rather than attempting a career change).

Instruments

The questionnaire included 6 sections:

1. The Awareness of Telenursing questionnaire included 6 items, scored on a scale of 1-3 (1=know about it, 2=heard about it, and 3=know nothing about it). Sample item: "Telenursing is the most advanced service provided in nursing." Internal consistency was acceptable in the pretest (α=.70) but low in the posttest (α=.48). A higher mean score reflects higher awareness of telenursing.
2. The Knowledge of Telenursing questionnaire included 10 dichotomous items, scored 0 or 1. Sample item: "Epidemiological patient surveys can be conducted via telenursing." Low to acceptable internal consistencies were found in the pretest (α=.75) and the posttest (α=.54). A higher summary score reflects a higher level of knowledge of telenursing.
3. The Skills Required for Telenursing questionnaire included 10 items, scored on a scale of 1-5, with 1 indicating a low level and 5 indicating a very high level. Respondents were asked to rate the extent to which they felt that nurses need specific skills for using telenursing. Sample item: "High listening skills and high question asking skills are required for telenursing." High internal consistencies were found in the pretest (α=.91) and in the posttest (α=.90). A higher mean score reflects a higher level of skills required for telenursing.
4. The Attitudes About Telenursing questionnaire included 13 items, scored on a scale of 1-5, with 1 indicating that the respondent does not agree at all and 5 indicating a very high level of agreement. Sample item: "I believe that telenursing facilitates the provision of equitable service to all patients." High internal consistencies were found in the pretest (α=.89) and the posttest (α=.89). A higher mean score reflects more positive attitudes about telenursing.
5. The Barriers to Telenursing questionnaire included 9 items, scored on a scale of 1-5, with 1 indicating that the respondent does not agree at all and 5 indicating a very high level of agreement. Sample item: "I did not invest so many years studying just to work in front of a computer. I will miss personal contact with patients and meeting them face to face." Good internal consistencies were found in the pretest (α=.79) and the posttest (α=.82). A higher mean score reflects a higher level of barriers to using telenursing.
6. The Self-Efficacy in Telenursing questionnaire included 10 items, scored on a scale of 1-5, with 1 indicating that the respondent does not feel certain and 5 indicating that the respondent feels very certain in being able to help the patient follow instructions given over the telephone and understand complex cases presented in that manner. High internal consistencies were found in the pretest (α=.91) and the posttest (α=.95). A higher mean score reflects higher self-efficacy.

Procedure

This study is a cohort intervention study conducted among all third-year nursing students in the college, which examined level of knowledge, skills and attitudes regarding self-efficacy and clinical skills for telenursing, and willingness to use this method at 2 points in time—prior to and following training.

The training took place in two stages: (1) the students were taught by the course lecturer, who works in this field. Topics of study included diverse nursing practices, ethical aspects of telehealth, clinical skills including communications skills, challenges in telenursing, and tools for coping with complex issues arising from telenursing. (2) Students practiced telenursing through simulations in various nursing areas. During the simulations they practiced treating patients using the telenursing tools and communications skills they had learned and conducted virtual patient assessments and physical examinations.

The participating students answered a questionnaire assessing the research variables prior to and following training.

Ethical Considerations

The study was approved by the College Ethics Committee, Emek Yezreel Academic College (approval no. YVC EMEK-2023‐87). Students were recruited via the researcher's research assistant, who asked for volunteers. Before completing the questionnaires, participants were told that participation was voluntary and that they could drop out of the study at any time. They were informed that their opinions were important for constructing the departmental training program and were therefore encouraged to express them. Participants signed informed consent forms prior to participation. All students in the cohort agreed to participate in the study with no compensation provided. The participants' privacy and identity were protected, and confidentiality was assured in that no identifying information was asked. The study objectives were explained to the participants and the study was conducted according to the academic ethical code.

Data Analysis

The data were analyzed with SPSS (version 29; IBM Corp). Descriptive statistics were used for the participants' demographic characteristics and study variables. As the variable of skills required for telenursing (pre and post) was negatively skewed (preskewness −1.74, SE 0.23; postskewness −3.20, SE 0.23), it underwent exponential transformation. Time differences were assessed with 2-tailed paired *t* tests, using Cohen *d* for effect sizes. Change scores were computed as residual gain scores between the pre- and posttests, and Pearson correlations were calculated between the study variables regarding the pretest scores and the change scores. Multiple linear regressions were calculated for self-efficacy in telenursing, using pretest scores and change scores. Awareness, knowledge, skills, attitudes, and barriers to telenursing were defined as predictors.

Results

Descriptive Results

Most participants have initially reported a moderate (54/114, 47.4%) or advanced (58/114, 50.9%) level of knowledge in using computers and the web. Most have not been exposed to telenursing (104/114, 91.2%) but were interested in training in it (86/114, 75.4%). Participants' age was generally not

associated with the study variables (*P*=.07 to *P*=.94) and was thus not controlled for. Other demographic variables had low variance. Thus, the first hypothesis was assessed with a series of 2-tailed paired *t* tests. Significant changes were noted in all variables with moderate to high effect sizes (Table 1). Awareness of telenursing, knowledge of telenursing, skills, attitudes, and self-efficacy in telenursing have all significantly increased following participation in the training program, and barriers to telenursing have significantly decreased.

Table . Means, SDs, *t* values, and Cohen *d* values for the study variables by time (N=114)[a].

	Pretest, mean (SD)	Posttest, mean (SD)	t_{113} (*P* value)	Cohen *d*
Awareness of telenursing	1.75 (0.48)	2.54 (0.36)	15.18 (<.001)	1.85
Knowledge of telenursing	6.84 (2.48)	8.42 (1.55)	6.18 (<.001)	0.76
Skills required for telenursing	4.60 (0.55)	4.77 (0.38)	3.80 (<.001)	0.36
Attitudes about telenursing	3.41 (0.62)	4.06 (0.62)	9.78 (<.001)	1.04
Barriers to telenursing	2.94 (0.61)	2.63 (0.74)	−4.52 (<.001)	0.45
Self-efficacy in telenursing	3.69 (0.79)	4.04 (0.73)	4.88 (<.001)	0.46

[a]Ranges: awareness of telenursing 1-3; knowledge of telenursing 0-10; and skills, attitudes, barriers for telenursing, and self-efficacy in telenursing 1-5.

Pearson correlations were calculated among the study variables regarding the pretest and change scores. Significant associations were found (Table 2). In the pretest, higher awareness of telenursing, higher knowledge of telenursing, and perception of the higher skills required for telenursing were associated with more positive attitudes and higher self-efficacy regarding telenursing. Furthermore, more positive attitudes about telenursing were associated with higher self-efficacy in telenursing and with lower barriers to it.

Table . Pearson correlations between the study variables for the pretest scores and the change scores (N=114).

[a]Not applicable.

Regarding the change scores, higher awareness of telenursing was associated with higher knowledge of telenursing and both were associated with more positive attitudes regarding it. Furthermore, higher awareness of telenursing and more positive attitudes regarding it were associated with lower barriers to telenursing. Finally, the higher skills required for telenursing, more positive attitudes about it, and lower barriers were associated with higher self-efficacy in telenursing.

Associations With and Change in Self-Efficacy

Two multiple linear regressions were calculated to evaluate the associations between awareness, knowledge, skills, attitudes and barriers to telenursing, and self-efficacy in telenursing regarding the pretest and the change between the pretest and the posttest. Level of knowledge in using the computer and the web (0: moderate and low, 1: advanced) was entered first, and the study variables or change in the study variables was entered second (Table 3).

Table . Multiple linear regressions for self-efficacy in telenursing with awareness, knowledge, skills, and attitudes and barriers to telenursing (N=114).

	Pretest scores[a]			Change scores[b]		
	B (SE)	β	*P* value	*B* (SE)	β	*P* value
Level of computer knowledge (advanced)	0.36 (0.14)	.23	.01[c]	−0.10 (0.18)	−.05	.58
Awareness of telenursing	0.32 (0.14)	.19	.03[c]	0.03 (0.10)	.03	.73
Knowledge of telenursing	0.07 (0.03)	.22	.02[c]	−0.10 (0.09)	−.10	.27
Skills required for telenursing	0.01 (0.01)	.06	.54	0.19 (0.09)	.19	.04[c]
Attitudes about telenursing	0.21 (0.12)	.17	.09	0.36 (0.10)	.36	<.001[c]
Barriers to telenursing	0.07 (0.11)	.06	.53	−0.09 (0.10)	−.09	.34

[a]R^2=0.23, P<.001; $F_{6, 107}$=5.20, P<.001.

[b]R^2=0.21, P<.001; $F_{6, 107}$=4.64, P<.001.

[c]These values are significant.

Both regression models were found significant, with 23% and 21% of the variance in the pretest score and in the change score, respectively, being explained by them. Regarding the pretest score, higher awareness and more knowledge of telenursing were associated with the perception of higher self-efficacy in telenursing. Regarding the change score, greater improvement in the perceived skills required for telenursing and a higher positive change in the attitudes regarding telenursing were associated with a greater improvement in the perception of self-efficacy in telenursing.

Discussion

This study aimed to examine how a simulation training program on telenursing affected awareness, knowledge, skills, attitudes, self-efficacy, and perceived barriers regarding telenursing among third-year nursing students. The results demonstrate significant improvements across all measured variables, with moderate to high effect sizes, suggesting that the implemented training program was effective. Moreover, the higher skills required for telenursing, more positive attitudes regarding it, and lower barriers were associated with higher self-efficacy in telenursing. These findings emphasize that the simulated experiences served as effective interventions, providing students with innovative learning opportunities [33].

The substantial increase in participants' awareness and knowledge of telenursing reflects the growing recognition that it is a critical component of modern health care delivery [1,3]. This increase is particularly noteworthy, given that most participants (104/114, 91.2%) had no prior exposure to telenursing, despite their initial moderate to advanced levels of computer and web proficiency. Findings regarding the posttest score of awareness of telenursing and its change score may be biased in unknown ways and should be regarded with caution.

Vaidya [34] recently emphasized the need to offer simulation telehealth education to undergraduate, graduate and health care practitioners in an effort to achieve a more effective remote diagnosis and treatment management for patients in need, such as those living with chronic disease.

The findings of this study are also in line with those of Mun et al [35], which indicated that nursing students lacked substantial awareness regarding telenursing. Nevertheless, the results also portrayed a positive outlook. Indeed, according to Kazawa et al [36], engaging in telenursing helps students enhance their understanding of telehealth practices, develop critical thinking skills, and broaden their knowledge of how to manage and address patient needs in a virtual care setting. Chang et al [37] also found that nurses with telehealth experience have significantly higher perceptions of its usefulness than those with no such experience, and these perceptions correlated positively with attitudes and behavioral intentions. These findings imply that providing nursing students with telenursing education can help them understand and harness this method [28]. Moreover, telenursing education was shown to have a significant impact on nurses' knowledge, attitudes, and awareness of future work [8,11]. Telehealth simulation was shown to improve nursing students' professional skills [38].

This study goes a step further by demonstrating that targeted training can significantly improve attitudes. This finding is crucial, as positive attitudes are likely to translate into greater willingness to engage with and implement telenursing practices in future professional roles. Nurses with prior telehealth knowledge had more positive attitudes toward telenursing than those who had never encountered telehealth-related information, and their attitudes toward telenursing correlated positively with their intentions to engage in telehealth [37]. Moreover, nursing students' attitudes toward telenursing demonstrated a significant correlation with telenursing experience, observation of telenursing during clinical practice, and exposure to telenursing education [35].

The decrease in perceived barriers to telenursing following the training program is a particularly encouraging outcome of this study. It suggests that the program has effectively addressed common concerns and obstacles associated with telenursing implementation and has the potential to offer a smoother integration of these practices in future health care settings.

Indeed, to prepare for their future roles, nursing students need telenursing education [35]. Previous studies examining nursing students reported positive prospects for telenursing, alongside negative perceptions associated with a lack of awareness [28,39]. Furthermore, Mun et al [35] found that nursing students who had a negative outlook regarding telenursing noted its impracticality as compared with face-to-face nursing, as well as the lack of patient contact, challenges faced by older individuals, and accessibility issues for low-income or rural residents. The assumption is that these limited perceptions derive from a lack of formal education in telenursing [40]. This type of education has the potential to enhance knowledge and attitudes regarding telenursing [41]. Indeed, significant improvements in understanding the use and role of telenursing were found among individuals who had undergone telehealth education [42].

This study found that skills and self-efficacy improved following the intervention. These findings are in line with a previous study that found a significant enhancement in skills and self-efficacy following training [37], thus indicating that telenursing education plays a crucial role in improving the type of specialized knowledge required for clinical telenursing. These findings suggest that nursing students need formal education in telenursing. Such education will enhance their competency and nurture a positive attitude, facilitating the seamless integration of telenursing into the digital health care era [35]. Our findings also corroborate those of Reierson et al [17], who emphasized the importance of introducing and practicing telenursing at the beginning of nursing curricula.

Moreover, our study found differences in the predictors of self-efficacy. Prior to the intervention, self-efficacy was a function of awareness and knowledge, whereas following it self-efficacy correlated with a change in skills and attitudes. To the best of our knowledge, almost no intervention studies have been conducted on the role of education in promoting telenursing. Kazawa et al [36] found that telenursing education is essential in expanding nursing students' knowledge and skills. Moreover, Mun et al [35] found that self-efficacy regarding telenursing among nursing students was associated with telenursing experience, education, and attitudes toward telenursing. Knowledge regarding advance care planning was also found to be associated with self-efficacy [43,44]. Bandura [45,46] also found a relationship between knowledge and skills, which translates into action by increasing self-efficacy to overcome barriers, and Mata et al [47] found that skills can improve health professionals' performance and self-efficacy.

Former studies of simulation-based instruction in nursing and telehealth were done by Parmeter et al [48], using a posttest-only design. Following peer-to-peer telehealth simulation scenarios via Zoom (Zoom Video Communications, Inc), the students demonstrated a high score of confidence and telehealth performance. These results align with the findings of this study.

These findings have significant implications for nursing education and practice. First, they strongly support the integration of telenursing into nursing curricula, as advocated by Asimakopoulou [3] and Puro and Feyereisen [10]. Moreover, the success of the simulation-based training program in this study is in line with previous research highlighting the effectiveness of simulations in nursing education [20,49]. Simulation can also play an important role in helping students acquire and improve their self-efficacy and nursing skills [50]. Our findings suggest that similar approaches may be valuable in preparing nursing students for the growing prevalence of telenursing in health care delivery.

This study presents 3 key limitations. First, the absence of a control group limits the ability to conclusively attribute observed changes solely to the training program. Future research should incorporate a parallel control group design to enable a more rigorous comparative analysis and establish clearer causal relationships. Second, the focus on immediate posttraining outcomes prevents understanding of long-term telenursing

competency retention and clinical application. Implementing a longitudinal study design with multiple follow-up assessments at 3, 6, and 12 months posttraining would provide insights into knowledge and skill sustainability. Third, the study's recruitment from a single college limits the generalizability of the findings across nursing student populations in Israel. Expanding the research to multiple educational institutions, potentially including diverse geographic and institutional contexts, would enhance the external validity of the results. Cronbach α value for awareness of telenursing was acceptable at pretest (α=0.70) but low at posttest (α=0.48). This finding indicates that the posttest score of awareness of telenursing has a low reliability, and the relevant findings should be regarded with caution. That is, the findings regarding the posttest score of awareness of telenursing and its change score may be biased in unknown ways and should be regarded with caution. Future studies are advised to validate a modified version of this questionnaire or use a different one.

Future research should address these methodological limitations by integrating control groups, longitudinal designs, and multi-institutional sampling to comprehensively evaluate telenursing training programs and their broader implementation potential. In addition, research exploring the implications of telenursing training on patient outcomes and health care system efficiency would provide critical empirical evidence to support broader program implementation.

In conclusion, this study provides compelling evidence for the effectiveness of a simulation-based telenursing training program in enhancing nursing students' competencies across multiple domains of telenursing. The findings underscore the importance of integrating telenursing education into nursing curricula in an effort to prepare future health care providers for the evolving landscape of health care delivery.

To implement these findings effectively, health care organizations should provide hands-on telenursing training through structured workshops and regular skill refresher seminars for practicing nurses. The Ministry of Health should establish standardized telenursing protocols and mandate their adoption across all health maintenance organizations to ensure consistent quality of care. Medical schools should integrate practical telenursing simulations into their core curriculum, while practicing health care professionals should complete required continuing education modules which include hands-on simulation training to maintain their competency in virtual care delivery.

Acknowledgments

The authors thank the students for their participation in the course and their responses to the questionnaire before and after it.

Abstract

Background: The cadaver serves as a crucial resource in medical education, research, and clinical practice, as well as a vital foundation for fundamental medical experimental teaching.

Objective: This study aims to use bibliometric analysis to create a knowledge map of cadaver donation in medical education, identify global trends, anticipate future research directions, and offer a foundation for upcoming investigations.

Methods: Articles and review papers concerning cadaver donation and medical education, with a final search cutoff of January 10, 2025, were systematically retrieved from the Web of Science Core Collection database. Two reviewers carefully examined the initial set of articles based on titles and abstracts to exclude irrelevant ones. A quadratic regression model was used to examine the annual publication data. The model's goodness of fit was assessed using the R^2 value, and the statistical significance of the findings was determined through the *P* valu. The selected publications were then analyzed and visualized for country, institution, author, reference, journal, and keywords using CiteSpace 6.3R3, VOSviewer 1.6.19, and the Online Analysis Platform of the Literature Metrology Database.

Results: The quadratic regression model yielded the equation $Y=0.1586X^2-633.9X+633395$, indicating a substantial increase in the number of publications over time ($R^2=0.9575$, $P<.05$). The model forecasts that the publication count will reach 107 by 202. This upward trend is statistically significant, highlighting a notable rise in research interest and activity within this field over time. The United States was a major contributor, accounting for 21.2% (303/1114) of all publications. In terms of continents and faiths, Europe and Christianity contributed the most, while McGill University and The University of Sydney were the leading institutions. Prominent authors in this field included De Caro Raffaele, Macchi Veronica, Porzionato Andrea, Stecco Carla, and Dhanani Sonny. The most frequently cocited reference was "Bodies for Anatomy Education in Medical Schools: An Overview of the Sources of Cadavers Worldwide." The journal Anatomical Sciences Education published the most articles in this area and received the highest citation count. Cluster analysis of keywords revealed that "kidney transplantation," "gross anatomy education," and "brain death" were key research topics, while burst analysis of keywords identified "public perception" and "anatomical science" as emerging areas of investigation.

Conclusions: This research presents a distinctive bibliometric approach to cadaver donation within medical education, setting it apart from previous studies by delivering an extensive global overview of trends and influential contributors in this domain. The results emphasize the increasing global interest and collaborative efforts surrounding cadaver donation, while also offering fresh perspectives on emerging topics like public perception and anatomical sciences. This paper serves as an important reference for researchers, policymakers, and educators, supporting the development of future strategies to enhance cadaver donation programs and further medical education.

KEYWORDS

cadaver donation; medical education; bibliometric analysis; citespace; VOSviewer; medical knowledge; medical training; medical student

Introduction

Cadaver donation plays a vital role in enhancing medical education and training by offering students valuable opportunities for hands-on learning in anatomy, surgery, and other medical fields [1,2]. As global health care systems encounter growing challenges such as organ shortages, ethical issues, and the continuous evolution of medical practices, the demand for cadaver donations has significantly increased [3,4].

Incorporating cadaveric resources into medical education improves students' learning outcomes by providing realistic, immersive experiences that boost their practical skills and understanding of human anatomy [5].

However, it is essential to recognize the differences in students' learning styles, as these variations influence their capacity to effectively process and retain information. Some students may benefit more from direct, hands-on cadaveric dissection, while others may find virtual reality (VR) or other digital tools more effective for enhancing their grasp of anatomical structures. In light of the need to accommodate diverse learning styles—especially during periods of remote learning or pandemic conditions—adopting a variety of teaching methods becomes increasingly essential. Research highlights that individual learning preferences have a significant impact on study duration and academic success, reinforcing the need for flexible and adaptive teaching strategies in medical education [6].

Although cadaver-based learning plays a crucial role, research on cadaver donation in medical education is still scattered, lacking a thorough examination of global trends in this area. Existing literature primarily focuses on regional views, ethical dilemmas, and the educational outcomes associated with cadaver-based teaching methods [7-9]. Yet, there is a lack of a broader, global perspective on the patterns, growth, and impact of cadaver donations in medical education. This research aims to fill this gap by conducting a bibliometric analysis of publications related to cadaver donation and medical education, using the advanced analytical tools VOSviewer and CiteSpace. Specifically, the study seeks to address the following research question: What are the global trends, institutional contributions, and emerging themes in the research on cadaver donation and medical education?

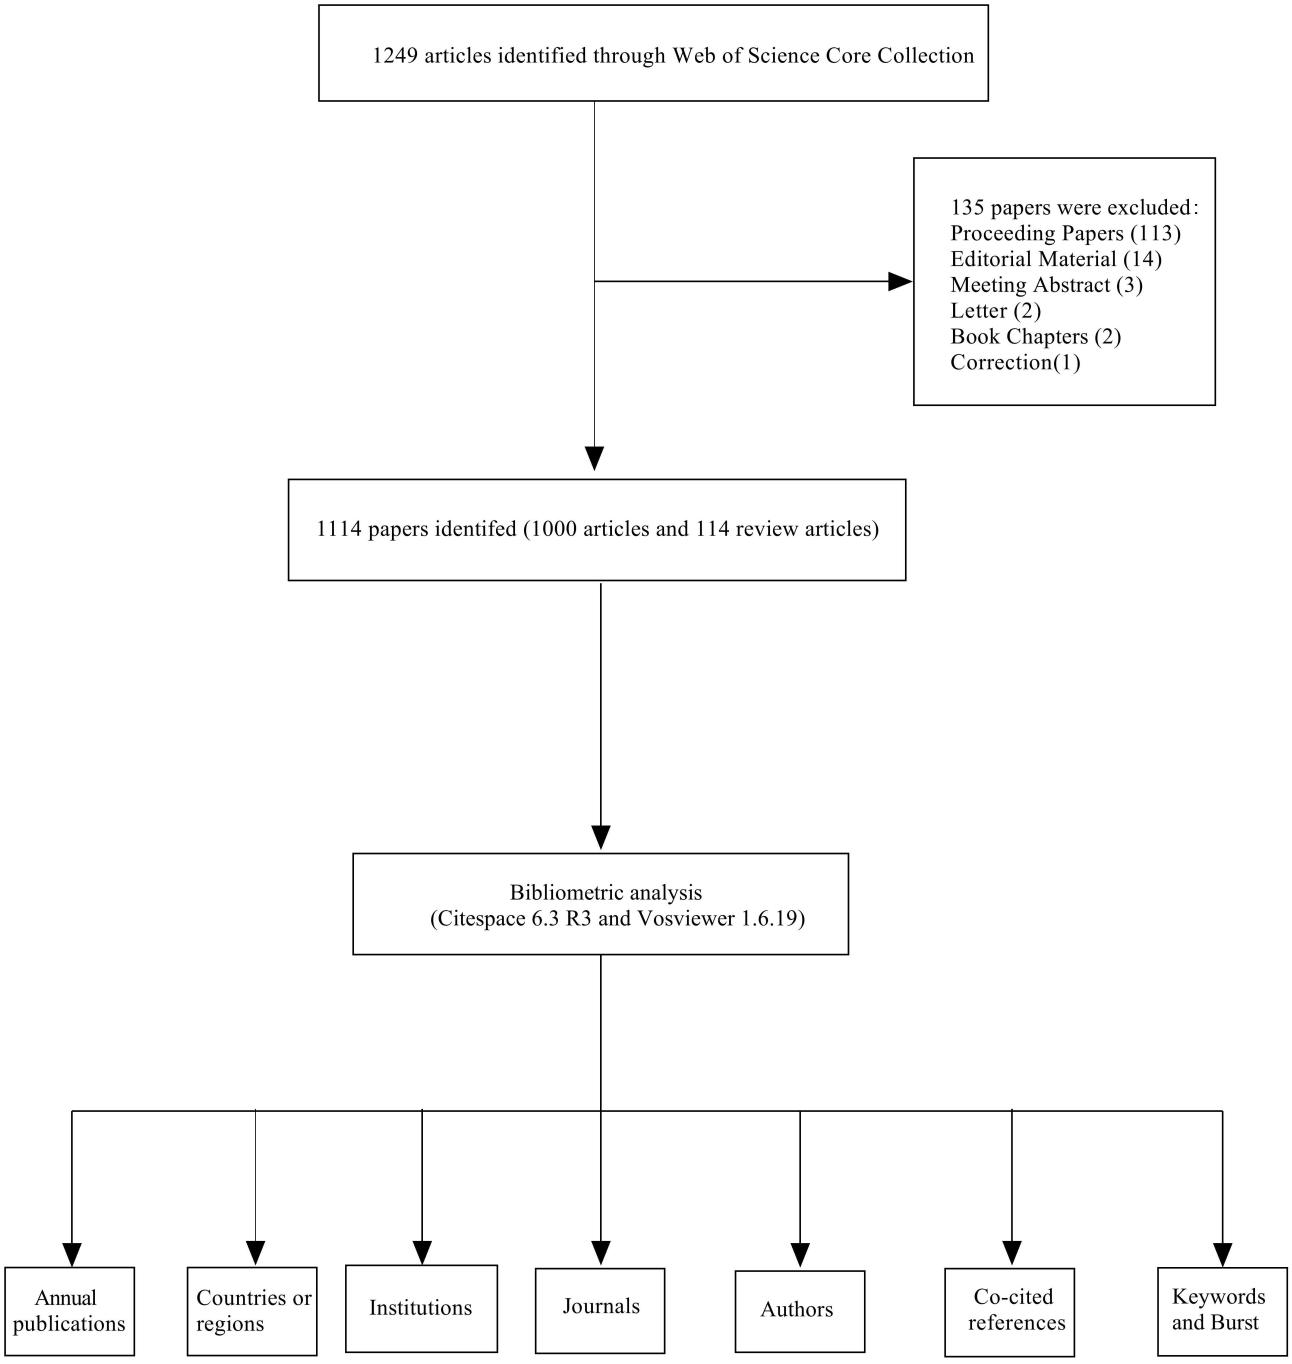
The significance of this study lies in its potential to inform future research and policy decisions in medical education. By systematically mapping the academic landscape, identifying key authors, institutions, countries, and themes, this research will offer valuable insights into the current state of the field and pinpoint areas in need of further investigation. Furthermore, understanding global trends in cadaver donation can assist educational institutions and policymakers in better aligning their strategies with best practices, ensuring the ongoing relevance and effectiveness of cadaver-based learning in the ever-changing landscape of medical education.

Methods

Data Collections

Data were collected on January 10, 2025, from the Web of Science Core Collection (WoSCC) database, which includes the Science Citation Index Expanded, Social Sciences Citation Index, Arts and Humanities Citation Index, Emerging Sources Citation Index, Current Chemical Reactions, and Index Chemicus. The search focused on publications related to the keywords "cadaver donation" and "medical education." The language was limited to English, and the article types were restricted to research articles and reviews. Each record contained details such as the title, author, keywords, abstract, year, institution, citations, and other pertinent information. A detailed explanation of the search methodology, including both inclusion and exclusion criteria, is provided in Figure 1.

Figure 1. Flowchart for the analysis of cadaver donation and medical education.



Bibliometrics and Visualization Analysis

The search results were subsequently examined using CiteSpace (Version 6.3R3, Drexel University, Chaomei Chen), VOSviewer (Version 1.6.19; Leiden University), and the Online Analysis Platform of Literature Metrology. CiteSpace, a visual analysis tool developed by Chaomei Chen, was used to analyze the total number of relevant papers, annual trends, keyword frequency, and centrality. This software provided a more accessible and intuitive way to examine the structure, patterns, and distribution of knowledge within the subject. A scientific knowledge map was used to identify research hotspots, advancements, and the current state of the field [10]. VOSviewer, a tool designed for document data analysis, facilitated the study of countries, institutions, authors, journals, keywords, and the co-occurrence knowledge graph for countries, institutions, journals, and publications. In the knowledge graph, each node represented an individual element, with the connection width between nodes reflecting collaboration strength, the node size indicating the number of publications, and larger nodes representing more frequent contributions [11]. The Online Analysis Platform of Literature Metrology was used to analyze the number of publications per country over different years and their collaborative efforts.

Quadratic Regression Model

A quadratic regression model was applied to fit the publication data. The model is represented by the equation:

$$(1) Yt=\beta 0+\beta 1t+\beta 2t2+\varepsilon t$$

where:

Y_t is the number of publications in year t.

t is the time variable (year).

β_0, β_1, and $\beta_2$are the regression coefficients.

ε_t is the error term.

This model allows for both linear and curved trends, which is useful for identifying whether the number of publications has accelerated or slowed over time.

Goodness of Fit

The goodness of fit was assessed using the R^2 value. R^2 shows how well the model explains the variation in the publication data. A higher R^2 indicates a better fit, meaning the model accurately reflects the trends in the data.

Statistical Significance

To determine the statistical significance of the results, we looked at the *P* value for each regression coefficient. The *P* value tests whether each variable (eg, time or its squared term) significantly affects the number of publications.

A *P* value less than .05 indicates that the coefficient is statistically significant, meaning the variable has a real impact on publication trends.

A *P* value greater than .05 suggests that the variable is not significantly influencing the trend.

The articles for this study were obtained in .txt format from the Web of Science database. Two expert researchers reviewed the title, keywords, and abstract of each paper, applying inclusion and exclusion criteria to screen the documents. In cases of disagreement or uncertainty about a paper's inclusion, a third reviewer made the final decision through discussion. Initially, 1249 papers were identified, and after excluding 135 papers that were irrelevant to the study's focus, 1114 papers were retained.

Ethical Considerations

This study did not involve the collection of new data from humans or animals. All the data used in the bibliometric analysis were sourced from the Web of Science Core Collection, and therefore, ethical approval and participant consent are not required.

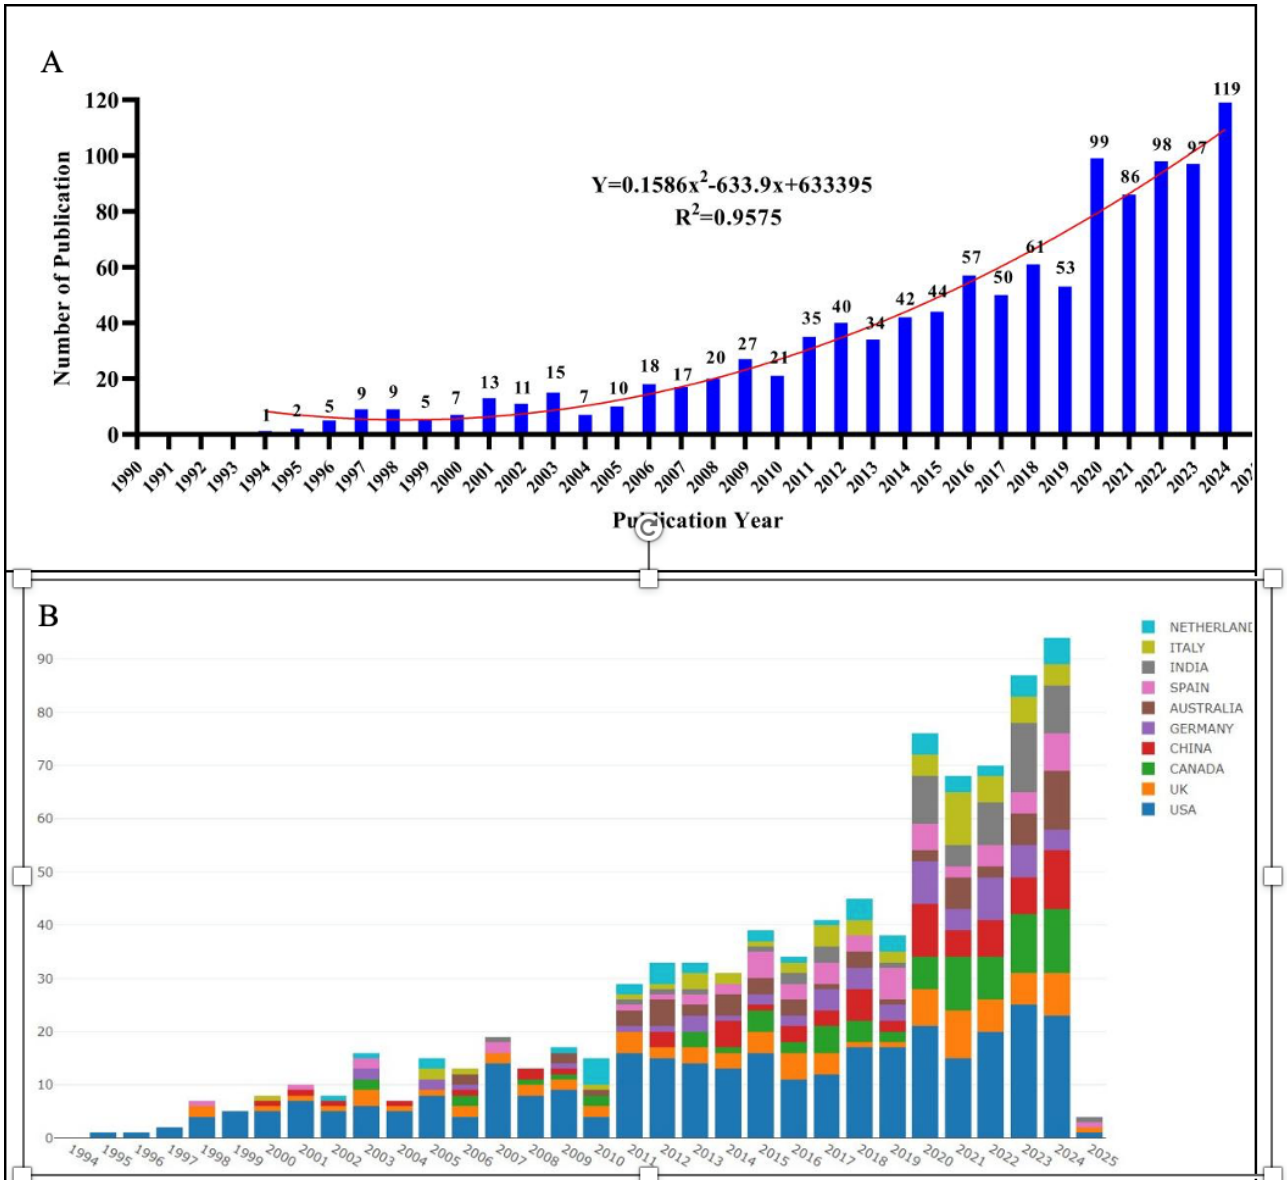
Results

Annual Publications

Among the 1114 papers on cadaver donation and medical education, the earliest publication dates back to 1994 [12]. Since then, the number of publications has steadily increased each year (Figure 2A). The growth trend of annual publications aligns with the fitted curve: $y=0.1586x^2 – 633.9x + 633395$ (R^2=0.9575, *P*<.05). According to this model, it is projected that around 107 papers will be published in this field in 2025.

As part of our thorough analysis, we aimed to identify the countries and regions that have significantly influenced the development of research within this interdisciplinary field. Our geographic analysis, shown in Figure 2B, features a bar chart highlighting the top 10 countries and regions based on their total number of published articles. The United States stands out as a leading contributor to this field, with a considerable and consistently increasing volume of publications.

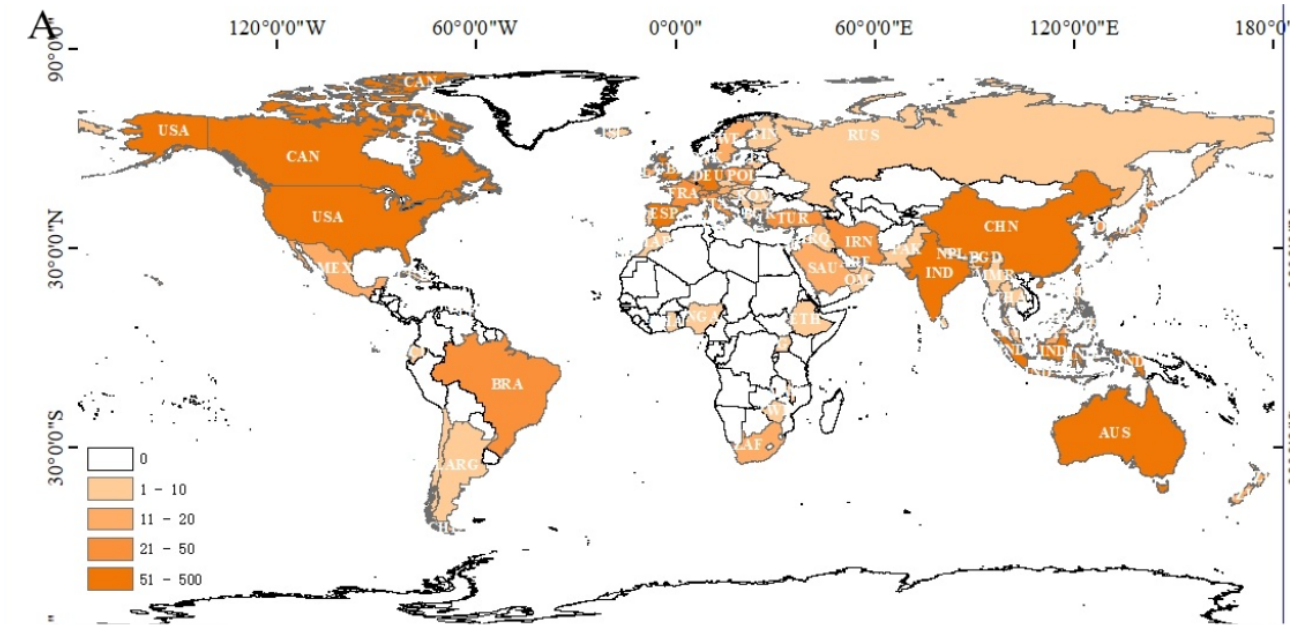
Figure 2. (A) Number of annual publications on cadaver donation and medical education; (B) Number of annual publications and growth trends of the top 10 countries/regions.

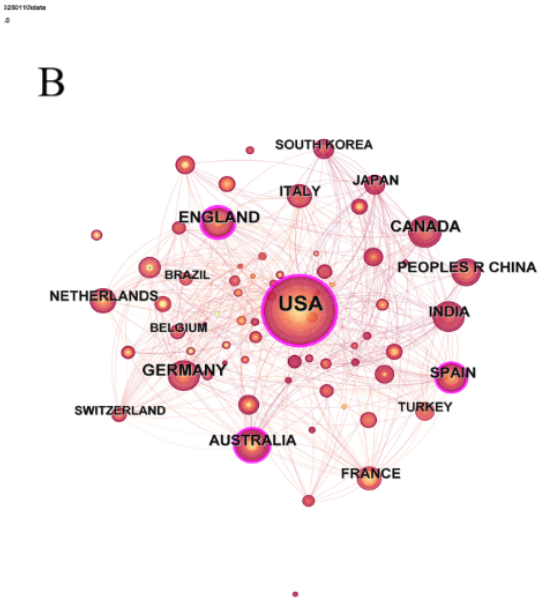


National Analysis

A total of 1114 publications on cadaver donation and medical education were contributed by 81 countries or regions (Figure 3A). The top 10 countries or regions with the highest number of publications are listed in Table 1. Among these, the United States produced the most original articles, followed by the United Kingdom and Canada. Together, the top 3 accounted for over a third of the total publications. Notably, India and China are the only developing countries in the top 10. The research network map among countries or regions revealed a high density (n=81, E=470, density=0.1451; Figure 3B), indicating strong cooperation between nations. Figure 3C highlights frequent collaborations between the United States and Poland, Spain and Poland, and Germany and Switzerland.

Figure 3. (A) Distribution of countries engaged in cadaver donation and medical education research; (B) The network of co-country co-occurrence; (C) The network map of cooperation between countries or regions.





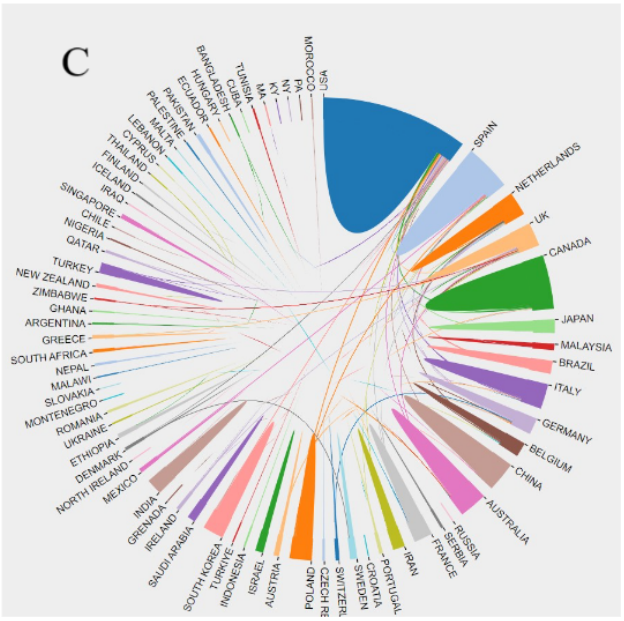


Table . The top 10 countries and institutions of cadaver donation and medical education.

Country	Documents	Citations	Organization	Documents	Citations
United States	303	9352	McGill University	20	754
United Kingdom	79	2488	University of Sydney	18	735
Canada	74	1658	University of Pitts-burgh	16	633
Germany	74	2080	University of Otago	15	444
Australia	57	1388	University of Ottawa	15	286
India	53	1083	Harvard University	14	786
Peoples Republic of China	53	761	University of Montreal	14	74

Italy	46	1050	Canadian Blood Serv	11	172

Continent Analysis

In this study, we classified medical education institutions involved in body donation research by continent: Asia, Europe, Oceania, North America, South America, and Africa. South America had no participating institutions in this study. The analysis revealed that European medical education institutions had the highest involvement, contributing 774 institutions. North America followed with 501 institutions, while Asia contributed 413 institutions. Oceania had 75 institutions, and South America and Africa had significantly fewer, with 57 and 32 institutions, respectively. These findings highlight the uneven distribution of research across different continents, with Europe and North America leading in terms of medical education institutions (Multimedia Appendix 1).

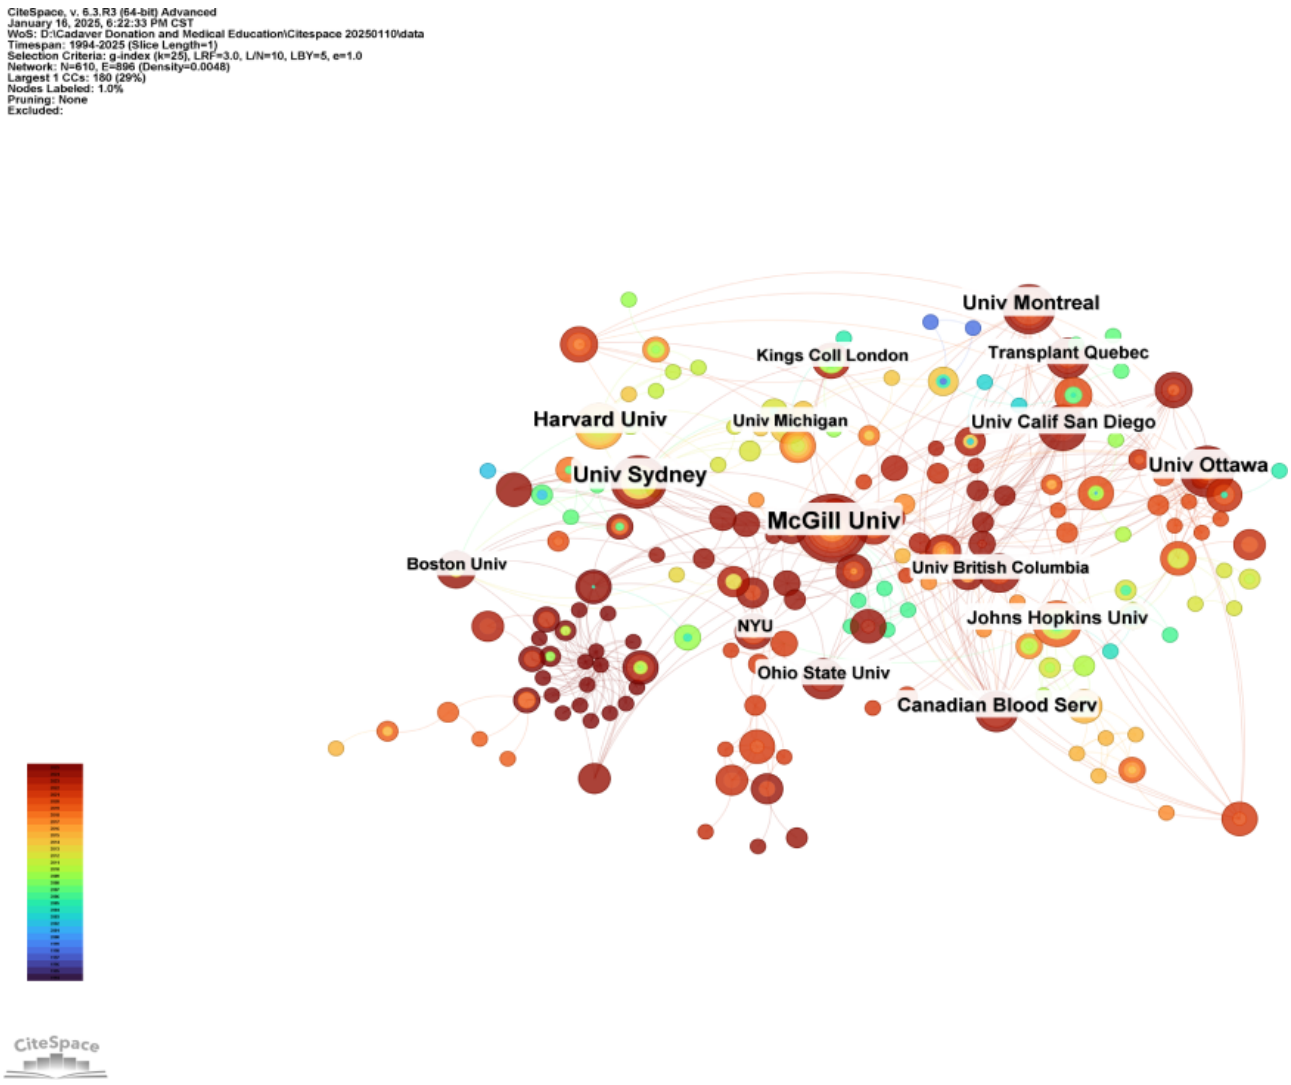
Religion Analysis

To examine the influence of religious affiliation on medical education institutions engaged in cadaver donation, we categorized the institutions according to their religious ties. The analysis revealed that medical schools with Christian affiliations were the most numerous, comprising 1441 institutions. Islamic-affiliated institutions ranked second, with 130 institutions reporting such affiliations. Confucian-affiliated institutions followed in third place with 102, while Buddhist institutions accounted for 89. Hindu-affiliated institutions numbered 71, and Jewish-affiliated institutions were the least represented, with only 19 institutions (Multimedia Appendix 2).

Institutional Analysis

An institutional analysis from 1994 to 2025 shows that 1852 institutions participated in research on cadaver donation and medical education. McGill University and the University of Sydney led the list with the highest number of publications, each contributing at least 18 papers. They were followed by the University of Pittsburgh, University of Otago, and University of Ottawa, which contributed 16, 15, and 15 papers, respectively (Table 1). The institutions with the highest citation counts were Harvard University (786 citations), McGill University (754 citations), and the University of Sydney (735 citations). In terms of centrality, McGill University and the University of Sydney ranked first and second, respectively (Figure 4).

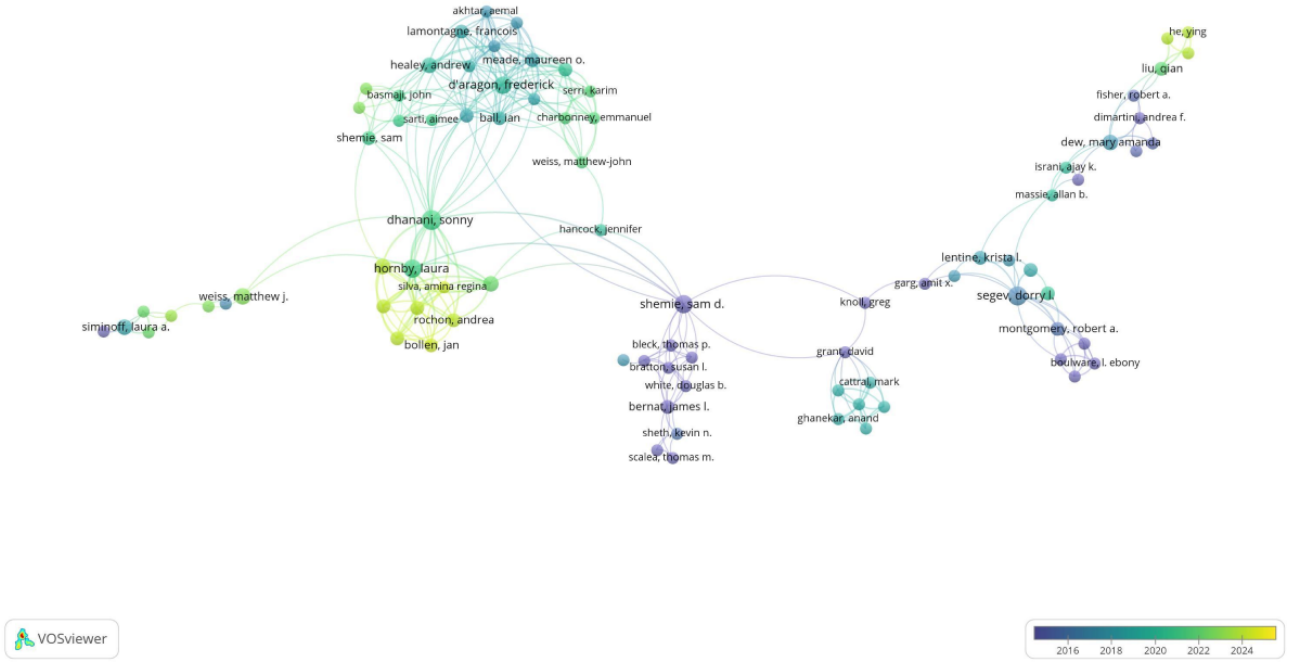
Figure 4. The network of coinstitutions co-occurrence.



Author Analysis

Among this group, a subset of 520 authors emerged as particularly productive, with each having published 5 or more articles (T ≥2). This subset was used to create an author network map, as shown in Figure 5. In addition, an overlay visualization map was developed by considering the 84 coauthors of these 520 authors. This knowledge map serves as a visual representation that clearly illustrates high-frequency coauthor collaborations across various years.

Figure 5. The overlay map of coauthors in cadaver donation and medical education.



In this map, the size of each node reflects the frequency of co-occurrence among authors, while the connecting lines represent coauthor relationships. The total strength of coauthorship connections for each of the 84 authors was measured. The authors with the highest number of publications (n=9) were De Caro, Raffaele; Macchi, Veronica; Porzionato, Andrea; Stecco, Carla; and Dhanani, Sonny (Table 2). Cocited authors are those who frequently appear together in multiple publications. In this field, 20,889 co-cited authors were identified, with 134 of them having more than 20 citations (T ≥ 20). The most frequently cocited author was Jones DG (n=232), followed by Siminoff LA (n=177), Cornwall J (n=159), Bolt S (n=133), and Boulware Le (n=126). Other leading authors had cocitation counts ranging from 89 to 125, as shown in Table 2.

Table . The top 10 coauthors and co-cited authors of cadaver donation and medical education.

Rank	Coauthor	Documents	Citations	Co-cited author	Citations
1	De Caro, Raffaele	9	219	Jones DG	232
2	Macchi, Veronica	9	219	Siminoff LA	177
3	Porzionato, Andrea	9	219	Cornwall J	159
4	Stecco, Carla	9	219	Bolt S	133
5	Dhanani, Sonny	9	78	Boulware Le	126
6	Segev, Dorry L	8	319	Ghosh SK	125
7	Hornby, Laura	7	171	Riederer BM	118
8	Shemie, Sam D	7	640	Winkelmann A	115
9	Balta, Joy Y	6	24	Ríos A	107
10	D'aragon, Frederick	6	36	Hildebrandt S	89

References Analysis

CiteSpace was used to analyze cocited references. Figure 6 and Table 3 display the top 10 co-cited references with the highest frequency and betweenness centrality. The co-citation network in the field of cadaver donation and medical education research consisted of 29,078 references, 1066 nodes, and 3633 links. Figure 7 [13-37] presents the top 25 references with the most significant citation bursts, which indicate emerging trends or growing interest in the subject. In general, references with higher co-citation rates are associated with stronger citation bursts. The citation burst for the article “Age Modulates Attitudes to Whole Body Donation Among Medical Students” authored by Perry GF et al [13]. and published in *Anatomical Sciences Education*, began in 2011 with a burst strength of 6.42. This study explores how age affects medical students’ views on whole body donation, using Likert-type questionnaires administered to first-year graduate-entry students before and after their dissection experiences.

Figure 6. The network of co-cited references in cadaver donation and medical education research.

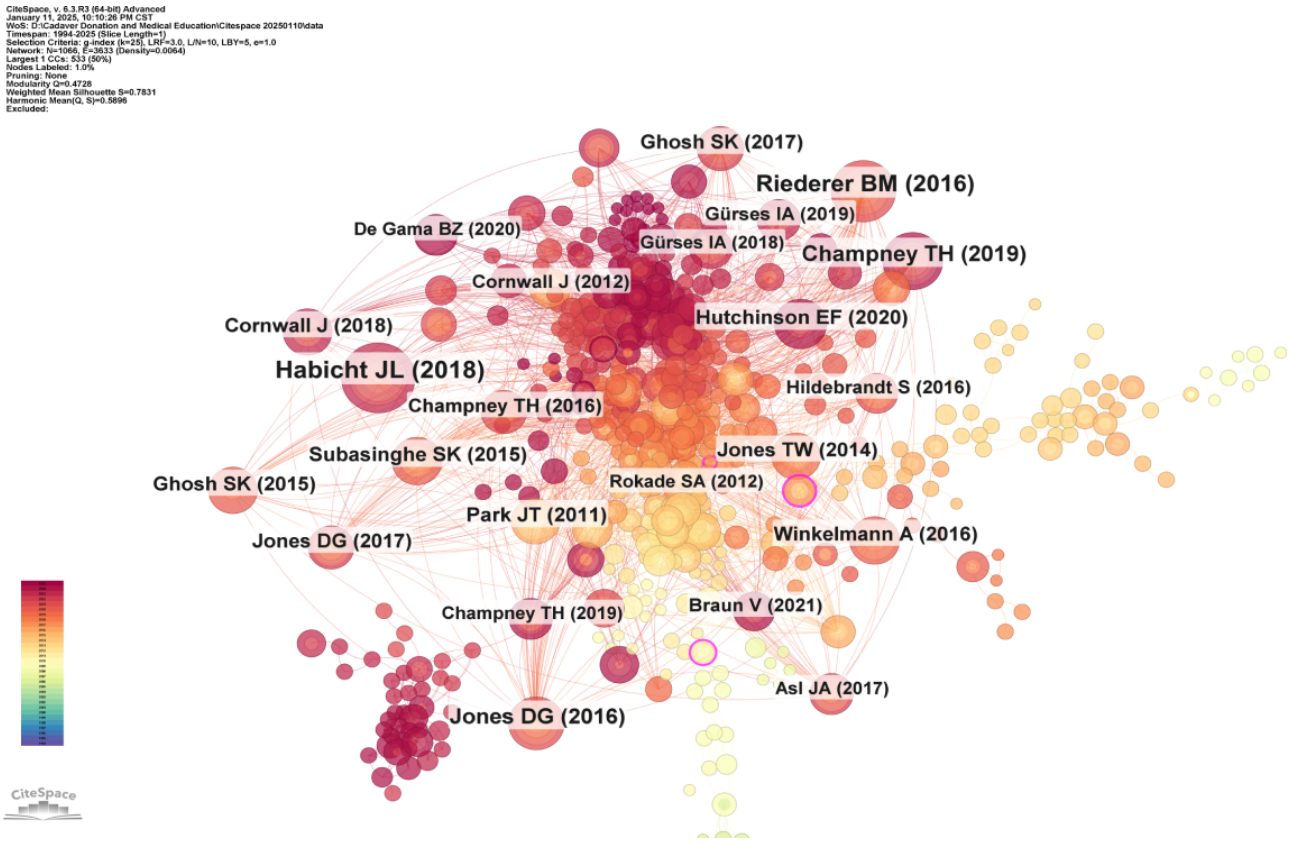


Table . The top 10 co-cited references of cadaver donation and medical education.

Rank	First author	Country	Frequency	Centrality	Year	Source
1	Habicht JL [14]	Germany	38	0.01	2018	*Academic Medicine*
2	Riederer BM [15]	Switzerland	32	0.06	2016	*Clinical Anatomy*

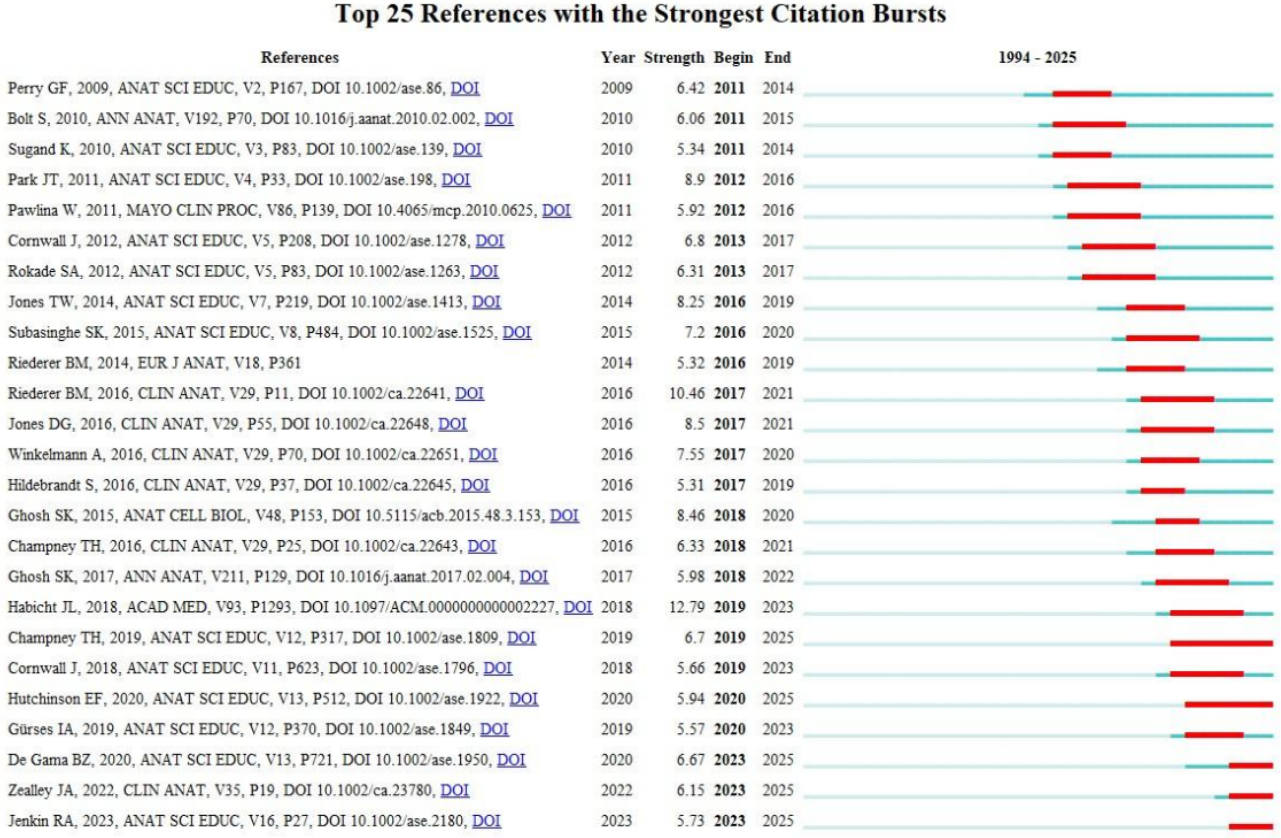
Figure 7. The top 25 references with the strongest citation bursts (sorted by the beginning year of burst) [13-37].



Journals Analysis

We used VOSviewer to perform cocitation and cocited journal analyses, enabling us to identify the most prominent and influential journals in the field. The analysis revealed that 1114 papers were published across 474 academic journals (with a minimum citation count of 20 per source). *Anatomical Sciences Education* had the highest number of citations (n=2586), followed by journals such as *American Journal of Transplantation*, *Transplantation*, *Clinical Anatomy*, *Critical Care Medicine*, *Clinical Transplantation*, *Nephrology Dialysis Transplantation*, *Annals of Anatomy-Anatomischer Anzeiger*, *Social Science & Medicine*, and *Human Reproduction Open*. Among the top 10 journals, five had an impact factor greater than 5 (Table 4).

Among the 10,465 cocited journals, five had over 1000 citations. As presented in Table 5, *Anatomical Sciences Education* led with the highest number of co-citations (n=1946), followed by *Transplantation and Clinical Anatomy*. The dual-map overlay of journals illustrates the distribution of topics within academic journals (Figure 8). A prominent citation pathway, shown in green, was identified, indicating that studies published in Medicine or Medical or Clinical journals were predominantly cited by articles from Health or Nursing or Medicine journals.

Table . The top 10 journals of cadaver donation and medical education.

Rank	Journal	Citations	Impact factor (2023)	JCR division	Country
1	*Anatomical Sciences Education*	2586	5.2	Q1	United States
2	*American Journal of Transplantation*	999	8.9	Q1	United States
3	*Transplantation*	933	5.3	Q1	United States
4	*Clinical Anatomy*	842	2.3	Q4	United States
5	*Critical Care Medicine*	772	7.7	Q1	United States
6	*Clinical Transplantation*	628	1.9	Q4	United States
7	*Nephrology Dialysis Transplantation*	561	4.8	Q2	England
8	*Annals of Anatomy-Anatomischer Anzeiger*	543	2.0	Q3	Germany
9	*Social Science & Medicine*	517	4.9	Q1	England
10	*Human Reproduction Open*	451	8.3	Q1	England

Table . The top 10 co-cited journals of cadaver donation and medical education.

Rank	Co-cited journal	Co-citations	Impact factor (2023)	JCR division	Country

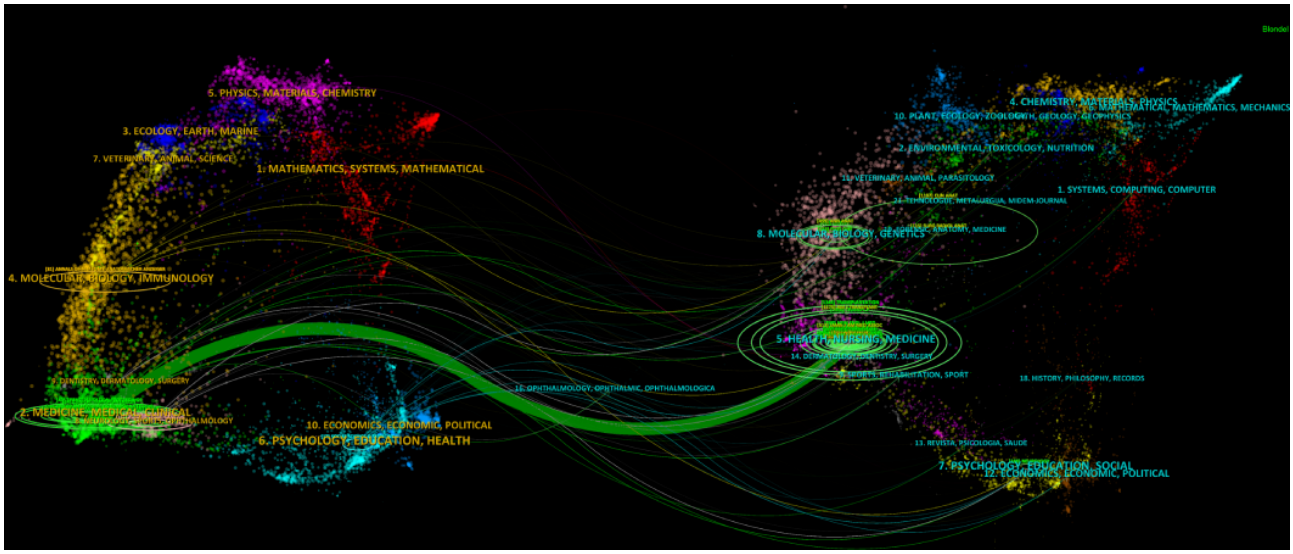
10	*Clinical Transplantation*	430	1.9	Q2	Denmark

Figure 8. The dual-map overlay of journals related to cadaver donation and medical education research. The citing journals were at left, the cited journals were on the right, and the colored curve represents the reference path.



Keywords Analysis

Keywords act as concise representations of articles, capturing their essential themes. Keywords that occur frequently and are centrally positioned often highlight current and significant areas of research within a discipline. We examined publications by segmenting them into 1-year intervals and selecting the top 20 most cited or frequent items from each period (Figure 9). The development of relevant research is illustrated through a hybrid network where co-occurring keywords from titles and abstracts shape the representation. Various maps display nodes representing keywords, with node size reflecting their frequency of occurrence or citation, and node color indicating the years of occurrence or citation. Red circles on the map denote keyword bursts, signaling rapid increases in publication frequency. By analyzing keyword frequency and centrality, key research frontiers can be identified.

The keyword network map consists of 630 nodes connected by 3914 links. Significantly, the term “organ donation” stands out due to its high frequency and centrality, indicating its considerable relevance and influence within the research field (Figure 9). Similarly, terms like “Transplantation” and “Attitudes” also appear as high-frequency keywords, highlighting their importance and prominence in the context of the study. Table 6 presents the top 20 keywords with the highest frequency and centrality.

Figure 9. The network of keywords co-occurrence.

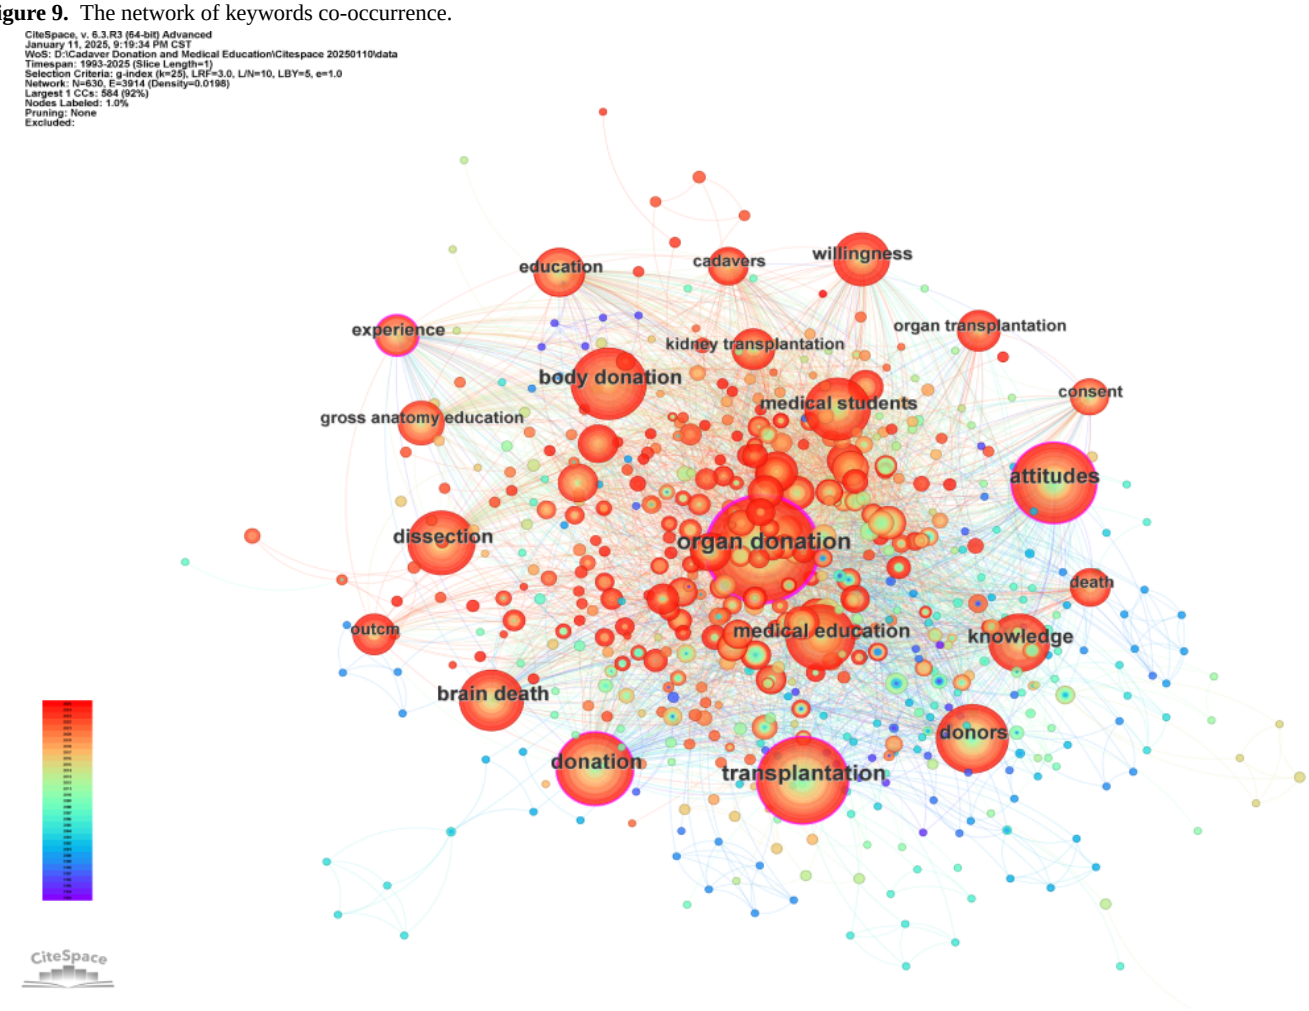


Table . Top 20 keywords of cadaver donation and medical education research in terms of frequency and centrality.

Rank	Keyword	Freq (count)	Centrality	Rank	Keyword	Freq (count)	Centrality
1	Organ Donation	287	0.26	11	Medical Students	89	0.04
2	Transplantation	181	0.16	12	Willingness	71	0.06
3	Attitudes	156	0.12	13	Experience	58	0.13
4	Donation	147	0.19	14	Education	54	0.05
5	Body Donation	122	0.02	15	Gross Anatomy Education	47	0.01
6	Brain Death	117	0.09	16	Organ Transplantation	47	0.03
7	Knowledge	104	0.03	17	Death	46	0.07
8	Donors	98	0.1	18	Cadavers	45	0.03
9	Medical Education	94	0.02	19	Outcm	45	0.03
10	Dissection	91	0.03	20	Kidney Transplantation	44	0.09

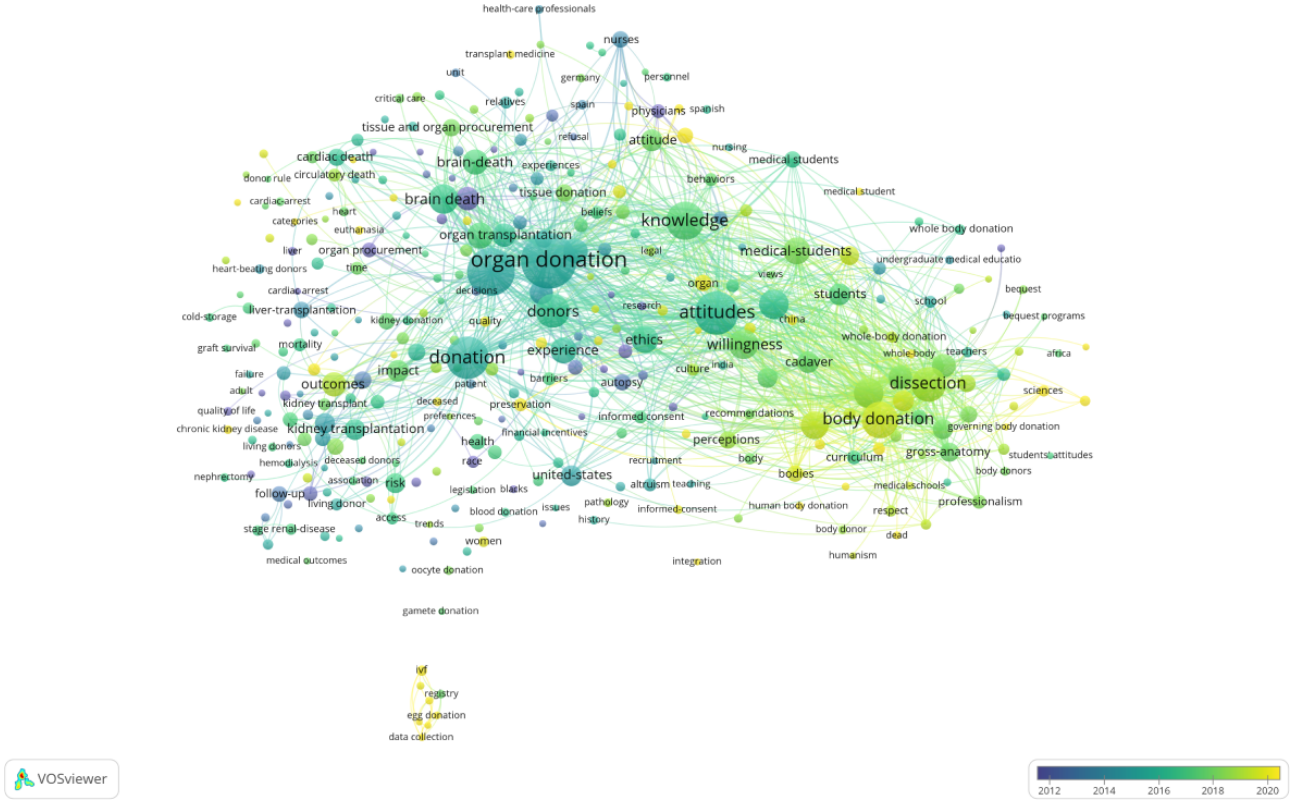
Keyword Timeline View

Keyword cluster analysis is an effective method for identifying key research topics within a particular field. In this study, CiteSpace was employed to perform a cluster analysis of keywords related to cadaver donation and medical education. The number of clusters was determined by the size of each cluster, with the largest one assigned the label #0.

The analysis produced 6 clusters, which were then examined through a timeline view in CiteSpace. These clusters comprised

#0 kidney transplantation, #1 gross anatomy education, #2 brain death, #3 organ donation, #4 body donation, and #5 complications. Figure 10 illustrates the timeline view derived from this cluster analysis.

Figure 10. Keywords are clustered on the time scale and output as map.



The research field, when viewed through the lens of emerging trends and development status, is categorized into two areas based on the co-occurrence analysis: (1) Anatomy education (#1, #3, #4) and (2) Clinical application (#0, #2, #5). In addition, the analysis indicated a steady and increasing interest in clusters #0, #1, and #4 in recent years. This highlights the importance of body donation in medical education and research, offering students valuable practical experience in anatomy. It aids in the enhancement of surgical skills, supports progress in organ transplantation, and contributes to medical studies that could lead to new treatments and better health care. Therefore, body donation plays a vital and altruistic role in advancing medical science and improving public health.

In summary, the cluster analysis and timeline visualization offer important perspectives on research trends, thematic development, and the growing significance of specific keywords in the fields of cadaver donation and medical education.

Research Frontier

The burst keyword analysis conducted with CiteSpace is a useful method for identifying rapidly emerging terms, referred to as burst keywords. These keywords reflect significant attention within the academic community and serve as key indicators of evolving research trends. Through this analysis, 25 representative keywords were chosen from a total of 3947 keywords to pinpoint the main research hotspots. The keywords were organized based on their duration, start time, and burst intensity. (The green line represents the period from 1993 to 2025, while the red line indicates the duration of each burst keyword.)

The term “public attitudes” emerged as the first burst keyword in 1994 (Figure 13A), suggesting that the public’s perception of cadaver donation influences the willingness to donate, thereby affecting the development of medical education and research from the outset. “Body donation” exhibited the highest burst intensity (Figure 13B), highlighting its essential role in cadaver donation, as it provides vital specimens for practical anatomical studies and research in medical education. In addition, “public attitudes” demonstrated the longest burst duration (Figure 13C), indicating that the public’s views on cadaver donation, shaped by enduring cultural perceptions, continue to influence its importance in medical education and research.

The analysis revealed 25 burst keywords, which can be grouped into two main categories: (1) Public perception and (2) Anatomical science. These burst keywords showed a higher concentration between 1994 and 2025. When combined with the triangular pattern depicted in the keyword timeline map (generated using VOSviewer to organize keywords over time), it indicates that research on cadaver donation and medical education is increasingly shifting toward more specialized areas (Figure 12).

Recent significant burst keywords include “awareness” (4.68), “organ” (4.46), and “willingness” (4.1), with the numbers in parentheses indicating the burst strength of each term. These keywords emphasize the importance of public awareness and the willingness to participate in cadaver donation, which are

crucial in promoting and shaping medical education. They play a key role in fostering critical thinking, offering students ethical hands-on experiences, and enhancing their understanding of anatomy and skill development.

This analysis suggests that the field of cadaver donation and medical education has experienced substantial growth and improvement over the past 2 decades, with increasingly focused and specialized research areas emerging. The earlier concentration of burst keywords may signify a phase of rapid progress and discovery, while the more recent burst keywords highlight the growing emphasis on raising public awareness of cadaver donation to improve medical education. The advancement of medical education depends significantly on public support and understanding, as body donors play a crucial role. The shortage of donors, in particular, presents a major challenge to both transplant medicine and foundational medical training, emphasizing the need for greater acknowledgment of their indispensable contribution. Overall, the burst keyword analysis offers valuable insights into the evolution and current state of research in cadaver donation and medical education.

Figure 11. Burst keywords involved cadaver donation research in relation to medical education. (A) Ranking by beginning. (B) Ranking by strengths. (C) Ranking by durations.

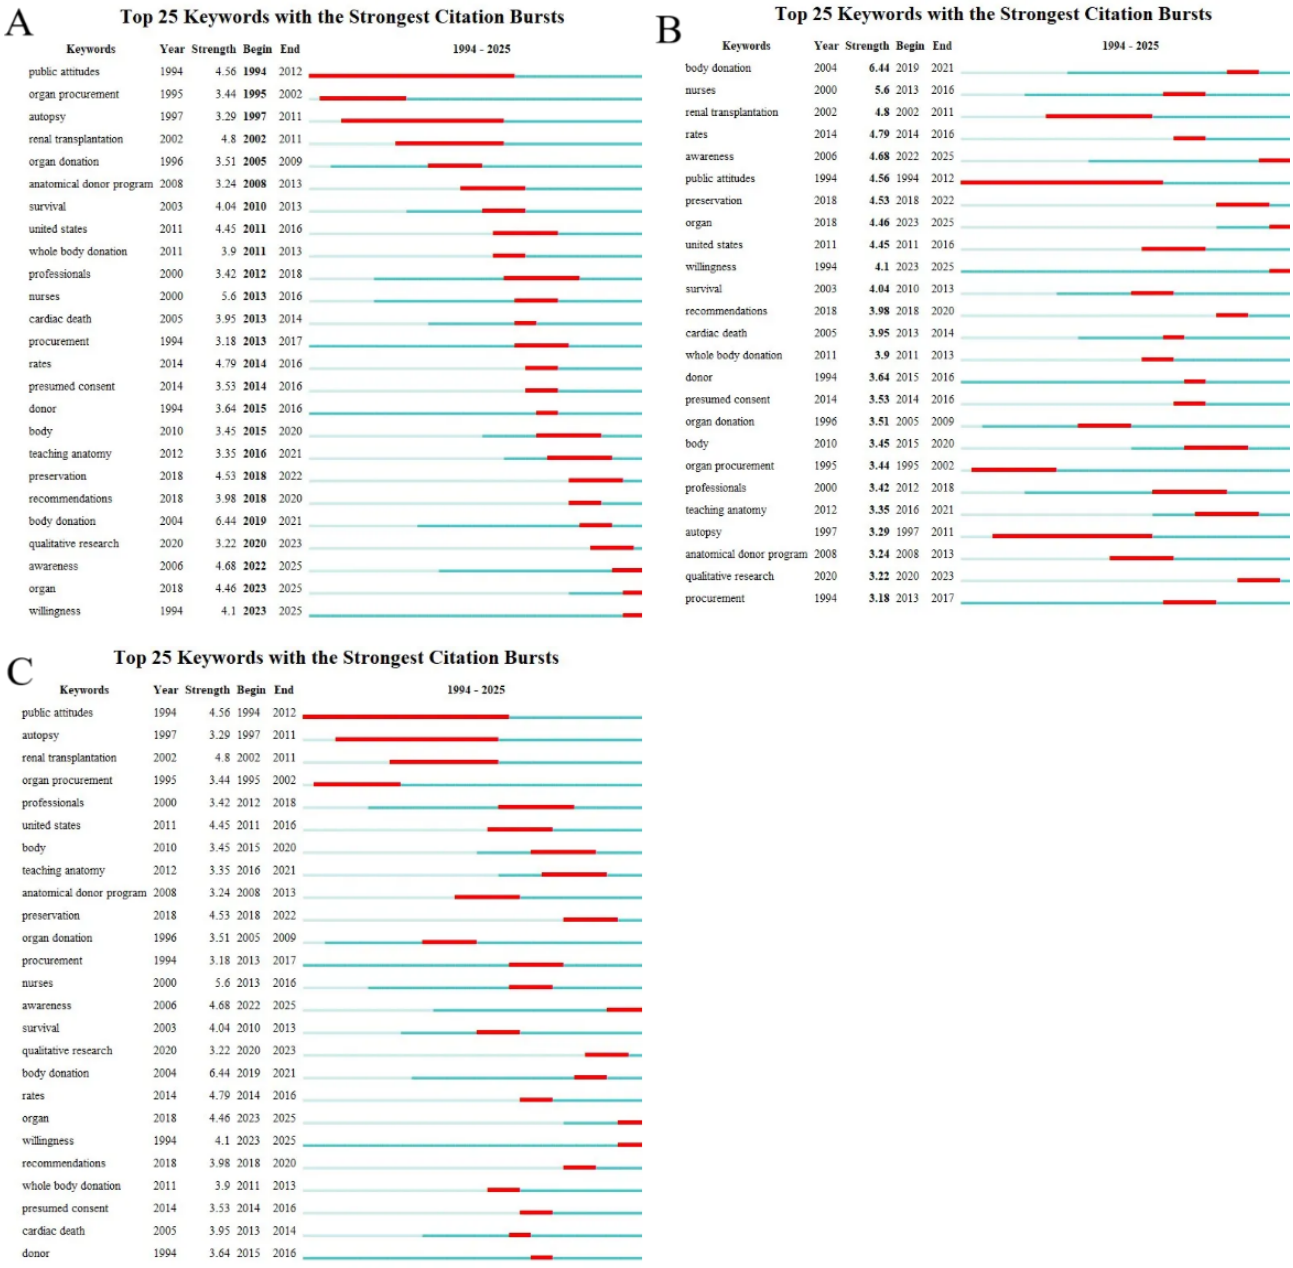


Figure 12. The keywords of cadaver donation and medical education were shown in the keywords timeline view.

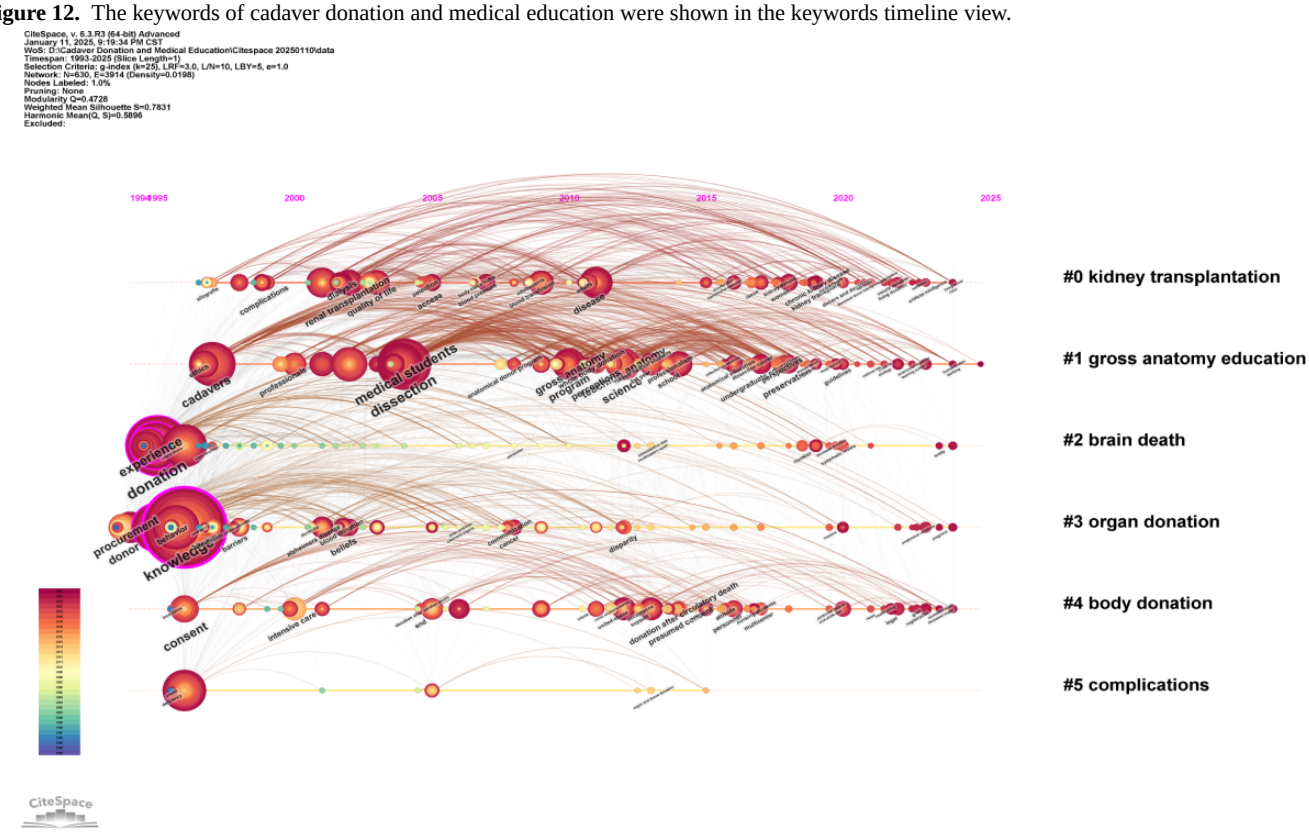

Discussion

Principal Findings

This research offers an in-depth bibliometric analysis of cadaver donation in medical education, providing fresh perspectives on global trends and contributions within the field. The results indicate a significant rise in research activity over time, with projections suggesting a continued upward trajectory in the coming years. This increasing interest highlights the growing recognition of cadaver donation as an essential resource for medical education, research, and clinical practice. By pinpointing key contributors, influential institutions, and emerging research areas, this study lays a crucial groundwork for future inquiries and emphasizes the collaborative efforts shaping the cadaver donation landscape.

The contribution of this study to the existing body of literature is especially valuable due to its extensive global scope, which surpasses the focus of previous studies in both breadth and depth. Unlike earlier works that typically concentrate on regional or specific aspects [38,39], this analysis offers a more comprehensive and holistic understanding of global cadaver donation trends. In addition, it introduces new perspectives, including emerging topics such as public perception and anatomical sciences, which are increasingly becoming central to discussions on cadaver donation.

In the subsequent sections, we will explore the broader context of cadaver donation in medical education, examine the key research areas advancing the field, and look into potential future developments that could transform the role of cadaver donation in medical practice. This structured approach aims to provide a thorough understanding of the evolving trends and future directions in this vital aspect of medical education.

General Information

The WOS database is a widely recognized platform that compiles a vast number of scientific research studies [40]. Based on the literature inclusion and exclusion criteria outlined earlier, 1114 articles were ultimately selected for this study. Since 1994, publications related to cadaver donation and medical education have been consistently released, showing a growing trend. This suggests that the field is gaining increasing attention and has the potential to emerge as a prominent area of research in the future. The United States, the United Kingdom, and Canada lead in the number of publications on this topic, with strong collaborative efforts across geographic borders.

This study indicates that Europe and North America lead in research on cadaver donation and medical education, primarily influenced by Christian cultural norms that encourage body donation for medical purposes. In Europe, the origin of Western medicine, cadaver donation became an early component of medical education, fostering significant advancements in these regions. In contrast, other areas, including parts of Asia and the Middle East, have made slower progress in this field due to economic conditions, cultural factors, and religious beliefs. For instance, in some countries, religious taboos limit the acceptance of cadaver donation, leading to delays in related research. Therefore, cultural and religious influences play a crucial role in shaping the development of cadaver donation research worldwide.

McGill University and The University of Sydney are the institutions with the highest number of publications, reflecting their significant contributions to research in cadaver donation

and medical education. A total of 5708 authors have contributed to the literature in this research area. The coauthorship and cocitation analysis highlighted the most influential scholars in the fields of cadaver donation and medical education. De Caro, Raffaele; Macchi, Veronica; Porzionato, Andrea; Stecco, Carla; and Dhanani, Sonny were identified as the most productive authors, underscoring their substantial impact on the literature. Strong collaborative ties among authors were observed, with several prominent coauthor partnerships emerging. These collaborations play a crucial role in advancing knowledge and fostering innovation in cadaver donation and medical education. Furthermore, the identification of cocited authors reveals the key researchers and their significant contributions to the field.

Analyzing the cocited references enabled the identification of the most significant and frequently referenced studies in the field. The leading cocited reference was a paper by Habicht JL et al [14], published in ACAD MED, titled "Bodies for Anatomy Education in Medical Schools: An Overview of the Sources of Cadavers Worldwide." This study examines global sources of cadavers for anatomical education, evaluating the use of body donations and unclaimed bodies while exploring cultural and institutional factors. Another important source was a viewpoint article by Riederer BM [15], titled "Body Donations Today and Tomorrow: What is Best Practice and Why?" published in Clinical Anatomy. This article highlights the significance of body donations for anatomy teaching and research, reviews the current state of donation programs worldwide, and identifies ethical considerations. The author also looks to the future, advocating for the replacement of unclaimed bodies with formal donation programs to improve both ethical standards and educational outcomes.

The majority of the top 10 journals publishing research on cadaver donation and medical education are prestigious journals from the Q1 and Q2 quartiles, including Anatomical Sciences Education, American Journal of Transplantation, and Transplantation. Furthermore, these journals also ranked highly in terms of co-citations.

Current Research Hotspots

Through keyword co-occurrence and cluster analysis, this study pinpointed key research areas in cadaver donation and medical education, which were primarily categorized into 2 themes: anatomy education and clinical practice.

Anatomy Education

Cadaver donation plays an essential role in anatomy education, serving as the cornerstone for hands-on anatomical learning [41]. The value of cadavers in providing real-world insight into human anatomy is irreplaceable, offering students the opportunity to understand complex anatomical structures through direct dissection and observation. This experiential learning approach fosters a deeper understanding of the human body, which is crucial for medical students' clinical training.

However, a significant challenge persists in the availability of cadaveric specimens. Despite the recognized importance of cadaver-based education, there remains a shortage of donated bodies available for anatomical study, particularly in clinical medical programs [42]. This scarcity hampers the ability to provide sufficient dissection opportunities for students, leading to a gap in practical training. As a result, students often lack the hands-on experience necessary for mastering essential anatomical skills, which can negatively impact their overall learning outcomes.

The limited access to cadavers not only affects anatomy education but also poses a barrier to enhancing the quality of medical education as a whole. The lack of dissection practice diminishes students' ability to apply theoretical knowledge to clinical scenarios, thereby restricting their development as proficient health care professionals. Furthermore, the global demand for cadavers in medical education continues to grow, intensifying the need for a more robust system to facilitate cadaver donations and ensure equitable access to these critical learning resources [43].

In conclusion, cadaveric donation remains integral to anatomy education, yet the shortage of cadaver specimens represents a significant challenge. Addressing this issue is vital for advancing medical education and enhancing the quality of training for future health care professionals.

Clinical Practice

The rapid advancement of medical technologies has greatly influenced clinical practice, especially in the field of transplantation. One of the most significant challenges hindering the progress of transplant medicine is the shortage of donor resources [44]. Despite this limitation, significant clinical achievements have been made in corneal and kidney transplantation, demonstrating the profound impact of transplant technologies [45,46]. These advancements have saved thousands of patients suffering from end-stage organ failure, providing them with new hope for survival and improved quality of life.

As medical technology continues to evolve, the focus of research is increasingly shifting toward clinical applications, particularly in the field of transplantation. Cadaver donation plays a pivotal role in this context. Not only does it support the development of anatomy education, but it is also an invaluable resource for advancing clinical practices, particularly in transplantation medicine. Donated bodies provide essential tissue samples for research, leading to improvements in surgical techniques, transplant procedures, and postoperative care.

Furthermore, the use of cadavers in clinical practice indirectly contributes to medical education by providing real-life case studies for students. By integrating cadaver donation into clinical training, medical institutions can equip future health care professionals with the practical experience and knowledge necessary for handling complex transplantation procedures [47]. This, in turn, enhances the quality of clinical education and prepares students to address the challenges of modern medical practice.

In conclusion, cadaver donation is not only crucial for anatomical studies but also plays a vital role in the development of clinical practices, particularly in transplantation. By supporting both medical education and clinical advancements, cadaver donations offer a pathway for saving lives and improving health care outcomes globally.

Future Frontiers

According to the analysis of keyword emergence, public perception and anatomical science are identified as emerging trends for the future.

Public Perception

The role of cadaver donation in medical research and education has profoundly influenced the development of modern medicine. For over half a century, cadaver donation programs have served as a cornerstone of anatomical studies and medical training, particularly in the United States [48]. These programs have allowed for significant advancements in medical education, enabling students to learn through direct interaction with human anatomy. However, the extent of cadaver donation for medical purposes remains heavily dependent on public perception, which varies widely across cultures and regions.

In many countries, especially in East Asia, cadaver donation faces significant challenges due to cultural and religious beliefs. Confucian ideals, which emphasize filial piety and the preservation of the body in its natural state, have deeply shaped attitudes toward death and burial practices [49,50]. This cultural framework has made it difficult for many to consider donating their bodies for scientific or educational purposes. As a result, public awareness of and participation in body donation programs remain relatively low in these regions, which, in turn, limits the availability of cadavers for medical education.

Despite these challenges, the importance of cadavers in medical education, particularly in anatomy, cannot be overstated. With the rapid advancements in medical technologies and diagnostic tools, the role of cadaver-based learning remains irreplaceable in developing comprehensive clinical knowledge and skills. As the legal and regulatory frameworks for cadaver donation continue to improve, it is crucial that efforts are made to increase public awareness and understanding of the significance of body donation. Future research should focus on enhancing public education, developing efficient and ethical donation systems, and addressing cultural and religious barriers. By fostering a more informed and supportive public perception, we can ensure that cadaver donation remains a vital resource for the future of medical education and health care.

Anatomical Science

Anatomy is a foundational subject in medical education, essential for all medical students. It provides students with a direct and comprehensive understanding of the human body's structure, forming the basis for further studies in physiology, pathology, and surgery [51]. The importance of anatomy extends beyond education; it is integral to clinical practice, diagnosis, and treatment. For example, when interpreting radiological images (eg, x-rays, computed tomographic scans, and magnetic resonance images), physicians rely on their anatomical knowledge to differentiate between normal and abnormal tissue structures [52]. During surgery, surgeons use their understanding of anatomy to navigate organ positions and vascular and neural distributions, ensuring precision and minimizing the risk of damaging vital tissues [53].

In addition to its educational significance, the study of anatomy plays a critical role in shaping a medical student's ability to grasp fundamental concepts and apply them to real-world scenarios. As the field of medicine advances, anatomical science continues to be indispensable. This is particularly evident in the emerging field of imaging anatomy, where advancements in imaging technologies demand an in-depth understanding of anatomical structures for accurate interpretation and diagnosis. Furthermore, transplant medicine relies heavily on anatomical knowledge, as precise identification of organ structures and their functions is crucial for successful transplantation and postoperative care.

Given these factors, future research in anatomical science should focus on enhancing educational methodologies, particularly in the context of imaging and transplantation. This will ensure that anatomy continues to evolve in alignment with modern medical advancements, ultimately improving patient outcomes and clinical practices.

Advantages

This study presents several notable strengths that enhance its importance in the field of cadaver donation and medical education. Firstly, the application of bibliometric analysis provides a thorough, data-driven examination of the global research landscape, pinpointing significant trends, key contributors, and emerging areas of focus within the field. By using tools like CiteSpace and VOSviewer, the study delivers detailed visualizations and insights into the evolution of cadaver donation research, making the findings more accessible to future researchers and decision-makers. Second, the comprehensive dataset, which includes articles up to January 2025, ensures that the results reflect the latest and most pertinent advancements in this field. The quadratic regression model's strong goodness of fit (R^2=0.9575) and statistically significant outcomes (P<.05) further validate the robustness of the analysis, offering a dependable forecast of future research trajectories. Finally, the international scope of the study, highlighting contributions from various regions and institutions, provides a well-rounded view of the global cadaver donation research landscape. The identification of emerging topics such as public perception and anatomical sciences demonstrates the study's potential to influence future research directions and inform the development of cadaver donation and medical education programs worldwide.

Limitations

Although this study is the first to apply bibliometric methods to conduct a thorough analysis of the research trends and key topics in cadaver donation and medical education, there are some limitations. First, authors often cite recently published journal articles to increase the likelihood of acceptance, which may influence the variety and representativeness of the literature [54]. Second, researchers tend to favor citing highly cited works, potentially overlooking the actual quality and substance of the research, leading to citation bias [55]. Furthermore, this analysis relies solely on the Web of Science core database, which may exclude other significant data sources and introduce the risk of missing valuable information. Finally, only English-language literature was considered, leaving out potentially important findings in other languages. It is also worth noting that

high-quality, recent research may not receive adequate citations due to shorter publication cycles, which could result in underrepresentation of its research value.

Conclusion

In summary, this analysis emphasizes the rapid expansion of cadaver donation research, particularly in Europe and North America, where regions with predominantly Christian populations contribute the most medical education institutions. Notable contributors include the United States, McGill University, and The University of Sydney, which play a pivotal role in shaping the field, reflecting their advanced medical infrastructure and academic commitment. Key research topics such as kidney transplantation, gross anatomy education, and brain death dominate, while emerging areas like public perception and anatomical science present new opportunities for exploration.

This study enriches the literature by offering a comprehensive overview of global trends in cadaver donation research and its influence on medical education, especially in regions with well-established medical traditions. It highlights significant institutions, authors, and themes, serving as a valuable reference for future research. Furthermore, it underscores the importance of international collaboration in advancing the field and advocates for increased public awareness and support for cadaver donation. The findings of this study will inform future policies and research strategies aimed at enhancing medical education and encouraging innovation in teaching methods.

Data Availability

All data generated or analyzed during this study are included in this published article.

Authors' Contributions

XZ and HX were the main investigators, mainly responsible for the overall framework and design of the paper. YW and FL contributed to data processing and mapping. DH supervised article writing and table design. All authors participated in the revision and approved the final manuscript.

Conflicts of Interest

None declared.

Abstract

Background: Clinicians are central to treating tobacco use disorder, yet practical training is inconsistent, and confidence varies. Brief, text message–based microlearning may offer a low-burden way to strengthen foundational competencies in busy clinical settings.

Objective: This paper aims to evaluate whether a short SMS microlearning series improves clinicians' self-reported confidence in managing tobacco use disorder.

Methods: We conducted a single-arm, pre-post educational pilot at an academic medical center. A brief formative survey (13 items; 106 respondents) identified local knowledge gaps and informed message topics and sequencing. The 13-day series delivered 1 concise message per day with key teaching points and links to curated resources. The prespecified primary outcome was self-reported confidence in managing tobacco use disorder (1 - 100 scale) measured immediately before and after the series. Of the 34 clinicians who signed up, 22 completed the baseline questionnaire and enrolled (attendings: n=4, 18%; trainees: n=18, 82%). Changes in confidence among participants with paired ratings were tested with a paired *t* test. Engagement with embedded links was recorded.

Results: All enrolled participants completed the 13-day series; none unsubscribed. Postintervention confidence ratings were provided by 18 participants. Mean confidence increased from 60 (SD 16) at baseline to 85 (SD 10) after the series (t_{17}=−10.71; P<.001). Embedded links were opened in 67% (178/266) of messages. Free-text feedback was predominantly positive and emphasized the convenience, clarity, and point-of-care usefulness of brief messages.

Conclusions: A brief SMS microlearning series was associated with a substantial improvement in clinicians' confidence to manage tobacco use disorder, with high completion and evidence of engagement. This low-cost, scalable approach appears practical for busy clinicians. Findings should be interpreted cautiously given the single-arm design, self-selection, and reliance on self-reported confidence rather than objective knowledge or clinical outcomes. Future studies should include a validated knowledge assessment, a randomized comparison, broader sampling, and follow-up to assess durability and impact on care.

KEYWORDS

tobacco use disorder; clinical education; text messaging; confidence; implementation; feasibility

Introduction

Tobacco use remains the leading cause of preventable mortality in the United States, accounting for nearly 20% of all deaths [1]. In addition to its negative health implications, smoking imposes significant economic burdens on the health care system [2]. Health care professionals are tasked with the critical responsibility of managing tobacco use disorder and its associated morbidities. However, data suggest that there are substantial knowledge gaps among physicians. In a United States survey of health care providers, fewer than half demonstrated high knowledge of availability of diagnostic criteria (36.8%), treatment efficacy (33.2%), counseling modalities (5.6%), and US Food and Drug Administration–approved medications (40.1%) [3]. Similar gaps are reported internationally; among primary care physicians in 3 Malaysian districts, 62.4% had poor knowledge, 58.0% had poor attitude, and practice was poor for 50.9% in the precontemplation phase and 75.7% in the contemplation phase of smoking-cessation management [4]. These deficits likely reflect uneven training exposure; evidence indicates that education in tobacco use disorder treatment is often inadequate, competency assessments are infrequent, and the topic receives minimal attention in board certification examinations [4-6].

At our institution, we conducted a brief formative survey to identify local gaps in knowledge and confidence and used these findings to shape the content and pacing of the intervention; full methods and the survey instrument are provided in the Methods and Multimedia Appendix 1.

Based on the results of survey data and identified knowledge gaps, we sought innovative and effective methods to educate practitioners on tobacco dependence treatment. Our objective was to identify learning strategies that were not time-consuming, easy to understand, readily accessible, and sustainable. Given these aims, we selected text message–based microlearning, which delivers brief, focused content that can be revisited at the point of care and reinforced over time, with demonstrated effectiveness in clinical education [7,8].

Among digital options, SMS pushes concise content without requiring app downloads or logins. It reaches busy clinicians, supports repeated exposure, and adds minimal burden, which fits the training and time constraints that healthcare providers face. We developed a brief text-based educational module to evaluate the effectiveness of this modality in teaching. Specifically, we used tobacco dependence treatment as a case example to assess whether a concise SMS series could address provider knowledge gaps and improve management confidence. Our primary hypothesis was that clinicians who completed the SMS series would report higher confidence in managing tobacco use disorder compared with baseline.

Methods

Study Design

We conducted a single-arm, pre-post educational pilot at an academic medical center. We designed a 13-day text message series for health care providers on tobacco dependence treatment. Concise daily messages were generated based on the knowledge gaps identified in the survey. Participation in the text-based series was completely voluntary. Surveyed participants were invited to opt in and had the option to opt out at any time. By opting in and providing their contact information, participants explicitly consented to participate in the study and receive text messages.

Participants and Recruitment

A formative needs assessment was conducted prior to the intervention to characterize local knowledge gaps and baseline confidence. Using institutional distribution lists, we contacted 209 clinicians—including internal medicine residents, family medicine residents, internal medicine faculty, pulmonary and critical care faculty, and pulmonary or critical care fellows and advanced practice providers—to complete the survey; 106 clinicians responded. Recruitment for the SMS intervention occurred in the subsequent academic cycle and targeted a pool that was not identical to the survey cohort. Using institutional distribution lists, we reached 142 residents, 39 faculty, and 28 fellows or advanced practice providers and invited them to enroll. Opt-ins and completion numbers are reported in the Results.

Formative Needs Assessment (Survey)

Before developing the curriculum, we administered a brief survey to characterize local knowledge gaps and baseline confidence. A total of 106 clinicians participated. The survey comprised 13 items: one 1‐100 visual analog scale for self-reported confidence in managing tobacco use disorder (1=no confidence; 100=complete confidence) and 12 knowledge items covering counseling approaches, cognitive behavioral strategies, first-line pharmacotherapy, and management in special populations (eg, pregnancy). The instrument was created for this study based on guideline topics and content domains targeted for the messages; the full survey is provided in Multimedia Appendix 1. Overall, 70% (74/106) of respondents reported feeling confident managing tobacco use disorder on the 1‐100 scale. Item-level accuracy is summarized in Table 1 (formative needs assessment informing curriculum design). Notably, only 32% (n=34) correctly identified the first-line pharmacologic treatment, and additional gaps were observed across counseling approaches, cognitive behavioral strategies, and management in pregnancy. These descriptive findings were used solely to inform topic selection and sequencing for the 13-day series and are not analyzed as study outcomes.

Table . Performance on formative survey assessing knowledge of tobacco use disorder management (n=106). Values are number and percentage of respondents who answered each item correctly.

Knowledge tested	Correctly answered, n (%)
Recommended first-line pharmacological treatment for tobacco use disorder	34 (32)
Understanding of bupropion's contraindications	61 (58)
Nicotine patch dosing	41 (39)
Nicotine gum dosing	67 (63)
Correct technique to use nicotine gum	70 (66)
Treatment for precontemplative patients	15 (14)
Prescription of varenicline in patients with psychiatric conditions	51 (48)
Duration of varenicline treatment after quitting	61 (58)
Risk of adverse cardiovascular events with treatment in stable coronary artery disease	86 (81)
Pharmacologic interventions for smoking cessation during pregnancy	56 (53)

Intervention

Participants who opted in received a message once every 24 hours. Each text message began with the mean performance on the survey of the particular teaching point in question, provided information or management recommendations, and concluded with live links to reference materials and additional reading for those seeking to deepen their understanding (Multimedia Appendix 2). We used a commercial SMS texting platform called SimpleTexting, a secure platform that complies with industry standards for privacy. This platform enabled the efficient dissemination of messages while protecting participants' personal information. It also provided functionalities to monitor engagement with the provided links, receive participant responses, and track subscription status. At the start and end of the series, we assessed participants' confidence with managing tobacco use disorder, defined as their subjective confidence on the topic, using a scale of 1 to 100. Additionally, we invited participants to provide comments and feedback on the text message series to gain qualitative insights into their experiences and perceptions. All submitted feedback was reported as received.

Statistical Analysis

All available pre-post confidence pairs were analyzed; optional feedback was summarized descriptively and reported as received. A paired *t* test was used to compare confidence levels before and after the series, and the analysis was conducted using IBM SPSS version 25. A *P* value of less than .05 was considered statistically significant.

Ethical Considerations

This study was approved by the Temple University Hospital Institutional Review Board (protocol 32174). Participation in both the formative survey and the SMS series was voluntary; responding to the survey and opt-in enrollment for the series constituted informed consent for receipt of educational messages and analysis of deidentified data. Messages were delivered via a commercial SMS platform (SimpleTexting); no protected health information was collected. Survey and evaluation data were deidentified and stored on secure institutional servers with aggregate reporting. Participants received no compensation. No images identifying individual participants are included.

Results

A total of 34 individuals signed up for the series, with 22 completing the initial questionnaire on their confidence treating tobacco use disorder and subsequently enrolling in the intervention. The participants included providers at all levels of training, including attending physicians (n=4, 18%) and graduate medical education trainees (n=18, 82%) (Table 2). Before the intervention, the average confidence level in managing tobacco use disorder across all training levels was 60 (SD 16). All enrolled participants completed the series, and there were no unsubscribes. At the conclusion of the series, we received responses on confidence level from 18 participants along with comments and feedback. The average confidence level increased to 85 (SD 10). The paired *t* test revealed a statistically significant difference in confidence levels before and after the series (t_{17}=−10.71; *P*<.001).

The reference links provided in each message were accessed 67% (178/266) of the time, indicating active engagement with the additional resources. Feedback from the participants was predominantly positive. Common themes included appreciation for the concise and informative nature of the text series and the ease of learning they provided. One participant noted, "Text-based format made it easy to learn in an efficient manner," while another remarked, "This series absolutely increased my comfort level with treating tobacco use disorder." Suggestions for improvement included adding visual aids (Textbox 1).

Table . Breakdown of individual participant feedback from the text-based education series.

Subject	Department	Level of training	Preintervention confidence score	Postintervention confidence score
1	IM[a]	1	50	70
2	PCCM[b]	4	50	70
3	PCCM	4	40	75
4	IM	2	30	No response
5	PCCM	5	80	100
6	IM	1	25	75
7	PCCM	5	40	80
8	PCCM	5	83	100
9	PCCM	6	60	85
10	PCCM	6	75	90
11	PCCM	4	50	85
12	IM	3	65	No response
13	IM	2	70	No response
14	IM	2	60	90
15	PCCM	6	55	90
16	PCCM	4	60	85
17	IM	3	75	No response

19	PCCM	6	75	90
20	PCCM	Attending	80	90
21	PCCM	Attending	60	90
22	PCCM	Attending	75	95

[a]IM: Internal Medicine.

[b]PCCM: Pulmonary and Critical Care Medicine.

Textbox 1. Feedback from participants and those who completed the text-based education series.

"Text-based format made it easy to learn in an efficient manner."

"This series absolutely increased my comfort level with treating tobacco use disorder."

"I pinned the text chain and went back to it when I had a question."

"The texts are awesome—very informative, short, and to the point."

"Add visual aids next time! Otherwise, no critique."

"Made me realize I was not using the correct dosing for nicotine! Thanks for teaching."

"This is so innovative! Don't stop, do another topic next!"

Discussion

This study aimed to examine whether SMS microlearning can strengthen clinicians' confidence in managing tobacco use disorder. Our findings indicate a meaningful increase in physician confidence after completing the intervention, and participants consistently described the messages as clear, concise, and useful at the point of care. Although these results come from a small cohort, the approach appears feasible for broader implementation and may serve as an effective educational tool; its impact on knowledge and clinical outcomes should be evaluated in larger, comparative studies.

Tobacco use remains a leading driver of preventable morbidity and mortality, and clinicians are central to diagnosis, counseling, and pharmacotherapy [9,10]. Yet tobacco treatment is underrepresented in many training programs [6,11-14], and persistent knowledge gaps have been documented across diagnostic criteria, counseling approaches, and evidence-based medications in diverse settings [3,6,13]. Tobacco treatment also receives limited emphasis on medical licensing and board

examinations, which can reduce curricular time and formal assessment [5]. We observed similar gaps locally in our formative survey, which is why we selected tobacco use disorder as the initial focus for this educational pilot. Targeting a high-impact, common condition with clear guideline-based management made it possible to craft concise teaching points and to judge whether a brief intervention could realistically support everyday practice.

The realities of clinical work limit traditional didactic learning. Long shifts, competing patient care and administrative demands, and variable schedules make it difficult to attend scheduled sessions or complete lengthy modules, and even when completed, retention can fade without reinforcement [15-17]. In this context, brief touchpoints that can be completed between tasks and revisited at need are more likely to fit daily workflow. Microlearning and spaced relearning operationalize this idea by delivering small, focused units with planned repetition, promoting retrieval when it matters and supporting transfer to practice [18-20]. For clinicians managing tobacco use disorder, this approach aligns with how information is actually used at the point of care and helps convert passive exposure into durable, actionable knowledge.

SMS microlearning aligns with clinical workflow: it is low friction, works on any device, and is easy to consume between tasks. Short, focused messages support spacing and retrieval, while links allow quick escalation to peer-reviewed resources at the point of care. Evidence from health professions education suggests this format is effective and well received: multicenter and randomized studies in obstetrics and gynecology residents report improved test performance and higher learner interest with SMS curricula, along with high satisfaction and low cost [21,22]; clinicians describe SMS teaching as engaging and practice-informing [23]; and related smartphone-based microlearning projects show strong acceptability and ease of use [24]. Not all findings are uniformly positive; some trials show no long-term advantage in exam scores without integration into broader study routines [25], which underscores the need for comparative designs and objective outcomes. In our pilot, the goal was to strengthen confidence rather than to test knowledge, and our results align with the broader literature on feasibility and acceptability. These considerations motivate a careful appraisal of limitations, including the absence of objective knowledge outcomes and comparative designs.

Our study has several limitations. It was a single-arm, pre-post pilot that evaluated self-reported confidence as the prespecified primary outcome. We did not administer an objective knowledge test; the preintervention survey was a formative needs assessment to guide content rather than a validated outcome instrument. Without a comparison group, we cannot separate the effect of message content from nonspecific influences such as measurement reactivity, social desirability, or Hawthorne effects. Selection bias is likely because participation was voluntary and only a subset of enrollees provided paired ratings, which limits generalizability beyond motivated clinicians at a single academic center. The sample was small, we assessed outcomes only immediately after the series, and engagement was measured by link click-throughs, which are a proxy and do not confirm content review or practice change. Optional free-text feedback may overrepresent highly engaged participants. Results may not generalize to settings without reliable SMS access or to clinicians with different baseline training, and the study was not powered for subgroup comparisons. Future work should include a validated knowledge assessment aligned to the message set, randomization to alternative content or wait-list control, larger and more diverse samples with strategies to reach less-engaged clinicians, and follow-up to assess durability and clinical impact.

In conclusion, a brief text message–based microlearning series was associated with a substantial increase in clinicians' confidence to manage tobacco use disorder, with strong completion and evidence of engagement. The format was practical and acceptable for busy clinicians, offering concise, point-of-care reinforcement. These results should be interpreted cautiously given the single-arm design, self-selection, and reliance on self-reported confidence rather than objective knowledge or clinical outcomes. Future studies should incorporate a validated knowledge assessment, a randomized comparison, broader sampling, and follow-up to evaluate durability and impact on patient care.

Abstract

Background: During the COVID-19 lockdown, it was difficult for residency training programs to conduct on-site, hands-on training. Distance learning, as an alternative to in-person training, could serve as a viable option during this challenging period, but few studies have assessed its role.

Objective: This study aims to investigate the impact of distance learning during the lockdown on residents' self-assessed competency development and to explore the moderating effect of poor mental health on the associations. It is hypothesized that radiology residents who were trained through distance learning during the lockdown were more likely to report higher self-assessed competency compared to those who did not receive organized, formal training.

Methods: A cross-sectional survey was conducted in 2021 among all of the radiology residents in 407 radiology residency programs across 31 provinces of China. To estimate the long-term outcomes of radiology residents' training after the initial COVID-19 outbreak, this study measured 6 core competencies developed by the US Accreditation Council for Graduate Medical Education reported by radiology residents. Multiple linear regression and moderating effect analysis were conducted to examine the associations between distance learning, mental health status, and self-assessed competencies. Mental health status moderated the association between distance learning and self-assessed competency of radiology residents.

Results: A total of 2381 radiology residents (29.7% of the 8,008 nationwide) met the inclusion criteria and were included in the analysis. Among them, 71.4% (n=1699) received distance learning during the COVID-19 lockdown, and 73.2% (n=1742) reported mental health struggles ranging in severity from slight to extremely severe. Radiology residents who were trained through distance learning (β=0.35, 90% CI 0.24 - 0.45) were more likely to report higher self-assessed competencies. This was particularly true for the competency of "interpersonal and communication skills" (β=0.55, 90% CI 0.39 - 0.70). Whereas, the competency of "patient care and technical skills" (β=0.14, 90% CI 0.01 - 0.26) benefited the least from distance learning. Poor mental health significantly moderated the relationship between distance learning and competency (β=−0.15, 90% CI −0.27 to −0.02).

Conclusions: Distance learning, a means of promoting enabling environments during the COVID-19 lockdown, serves its purpose and helps generally improve residents' self-assessed competencies, though different competency domains benefit unequally. The impact of mental health status calls for special attention so that distance learning can fulfill its potential.

Introduction

The COVID-19 pandemic threatens the health of people globally and has brought unprecedented pressure to health systems [1,2]. The national public health system plays a vital role in fighting against pandemics by taking measurements such as surveillance and epidemiological investigations [3], case finding and management [4], and collective quarantine of close contacts [5]. However, potential challenges including insufficient alerts, low efficiency of reporting to higher authorities, and workforce shortages still exist [1]. Of note, the training of health care providers and the improvement of their professional skills have been underscored for their great significance in medical service delivery and health systems resilience [6-8].

Residency training systems serve the purpose of cultivating a qualified health workforce [9]. Standardized residency training (SRT) was initiated in 2013 in China, aiming to train doctors to meet the needs of population health [10]. With the increasing trend of competency-based medical training in global medical education, the assessment of competencies has gained ground in practice [11]. The US Accreditation Council of Graduate Medical Education (ACGME) identified 6 core competencies for physicians (ie, patient care [PC], medical knowledge [MK], system-based practice [SBP], practice-based learning and improvement [PBLI], professionalism [PROF], and interpersonal communication skill [ICS]) [11] and implemented milestones by the Next Accreditation System initiative in July 2013 [12]. Residency education and competency-based practice assessed by the milestones are common requirements of ACGME and have been used in residency training in China [9,13].

COVID-19 has changed medical education dramatically, especially during the lockdown period. The impacts of COVID-19 on medical education in radiology, surgery, and emergency medicine have gained attention [14-16]. Radiology is related to other medical specialties and all levels of health care delivery [17]. Radiology residents were typically required to rotate between different specialties to obtain knowledge and clinical skills [18]. The mandatory social distancing challenged the traditional training on radiology trainee approaches such as teaching at workstations [19]. In China, SRT in radiology spans 3 years and involves workstation-based training throughout rotations in various specialties and departments [9]. In the first year, residents undergo rotations in the departments of radiology, ultrasound medicine, nuclear medicine, pathology, and relevant clinical departments. In the second and third years, they receive advanced rotational training within radiology subspecialties such as computed tomography, magnetic resonance imaging, x-ray, and interventional radiology [9]. Due to COVID-19, the mode of residency training has been switched from traditional in-person classes to distance learning [20], posing challenges to the effectiveness of rotational training and the developing competency of residents.

Numerous benefits have been found for distance learning. For instance, residents can schedule more flexibly and access the courses more easily [21]. They can learn at their own pace with the help of recorded lectures and communicate with professionals and peers on the web at their own convenience [22]. The positive acceptance and a higher level of satisfaction with distance learning have been reported by residents in Canada and the United States [21,23]. However, the practice of digital readout in distance learning is similar to the experience of in-person reading, in addition to the difficulties of gauging body language during practical operations or in the use of medical instruments [24], which may lead to unsatisfactory outcomes in radiology education. Meanwhile, the COVID-19 pandemic has impacted the mental health status of health care professionals dramatically [25]. Students who experienced distance learning during the pandemic had been found to have psychological distress [26,27]. According to the Job Demands-Resources model, mental health is a personal resource that helps residents to deal with job challenges by moderating their performance [28-31]. Accordingly, it is of great importance to take care of the mental health of residents who have experienced distance learning [32]. To date, during the COVID-19 lockdown, when workstation-based training was difficult to deliver, the role of distance learning remains unclear. It is also uncertain whether psychological status affects the effectiveness of distance learning.

In sum, the COVID-19 lockdown had brought substantial challenges to radiology training programs, which had to transition from face-to-face instruction to remote learning. In the meantime, mental distress caused by factors such as social distancing may make residency training rather difficult. Given that distance learning remains a primary alternative when traditional teaching is not feasible (such as during pandemic outbreaks and lockdowns), yet few studies have explored its effects, we aimed to investigate the impact of distance learning on the development of self-assessed competencies as well as the moderating effect of mental health status. We hypothesize that radiology residents who received distance learning during the COVID-19 lockdown were more likely to report higher self-assessed competencies compared to those who did not receive organized, formal training during the same period (ie, nondistance learners) and that this association was moderated by poor mental health. To test this, we used a nationwide survey dataset of radiology residents in China, which collected information on distance learning and mental health status during the lockdown (January-May 2020), and self-assessed competencies 6 months later. Previous studies have shown a strong positive correlation between the assessments by Clinical Competency Committees and residents' self-evaluations using the milestones. This suggests that residents are generally able to accurately assess their own competencies, which in turn supports the validity of using milestone assessments as an effective measure of self-assessed competency in this study [33].

Methods

Ethical Considerations

The study was conducted according to the guidelines of the Declaration of Helsinki, and approved by the institution review board of Tsinghua University, China (20210140). Informed consent was obtained before the research started, and data were deidentified to ensure participant privacy. Participation in this

survey was voluntary, participants did not receive any incentives to take part in the study.

Study Setting and Population

A nationwide retrospective cross-sectional survey was conducted on the web by the Chinese Association of Radiologists (CAR) during December 1, 2020, to April 30, 2021, targeting all the radiology residents in 407 radiology residency programs across 31 provinces of China.

To complete the distribution of the questionnaire and to ensure the participation of the radiology residents, we contacted the directors of the targeted hospitals' radiology departments by email or telephone to inform them of the purpose and details of the survey initiated by the CAR. The directors were then instructed to share the link of the questionnaire posted on the popular web-based survey platform "Wenjuanxing" with radiology residents. Anonymous responses to the questionnaire were submitted. All participants were informed that the questionnaire could only be filled out once, that participation was completely voluntary, and that they could withdraw at any time without penalty. During the 5-month survey period, the research team cooperated well with the CAR for the monitoring of the participation. If there was a low rate of submission, the CAR would require the hospital to improve the quality and quantity of their survey response. This proactive approach could help increase the number of responses and the representativeness of the population. Residents who did not undergo residency training during the COVID-19 epidemic between January and May 2020 would be excluded.

Measures and Outcomes

Distance Learning

Distance learning was asked "Was your training institution changed the teaching arrangements to the form of distance learning to reduce the negative impact during the initial COVID-19 outbreak?" The response options were either "yes or no." In contrast, nondistance learning participants (ie, nondistance learners) were those who did not receive organized, formal training during the same period. They primarily stayed at home on leave, reported daily health status, and engaged in delayed teaching plans or self-directed learning.

Mental Health Status

Mental health status was measured by the question "Did you suffer psychological distress during the initial COVID-19 outbreak? (from January to May 2020 in China)." A 5-point Likert scale was used to measure the degree of mental health struggles: 1=no impact, 2=mild impact, 3=moderate impact, 4=severe impact, and 5=extremely severe impact. Radiology residents can choose any rating between 1 and 5 (single choice). The variable is correlated with long-term mental health (depression and burnout) measured by the Depression and Anxiety Stress Scale—Depression and Maslach Burnout Inventory scales (Multimedia Appendix 1). The Cronbach α reliability coefficient for depression and burnout was 0.930 and 0.957, respectively.

Self-Assessed Competency

Milestone-based assessment of competencies for residence is one of the common requirements of the ACGME [11]. Self-assessment plays a key role in this process by fostering reflection on professional actions, identifying learning needs, and enabling residents to develop and refine personalized improvement plans [34]. Moreover, residents' self-assessments showed a strong alignment with the Clinical Competency Committee evaluations across postgraduate year levels [33,35,36]. To estimate the long-term outcomes of radiology residents' training after the initial COVID-19 outbreak, our study measured 6 core competencies developed by the ACGME that were assessed by radiology residents themselves. As is suggested by the experts, we selected 9 subcompetencies from diagnostic radiology milestones to represent the 6 ACGME core competencies: 2 PC subcompetencies, 2 MK subcompetencies, 2 PBLI subcompetencies, 1 SBP subcompetency, 1 PROF subcompetency, and 1 ICS subcompetency.

A dedicated section of the questionnaire is designed to assess 9 subcompetencies with 9 single-choice questions. Radiologists are able to select a score ranging from 0 to 9 for each competency. Examples of milestone sets for each subcompetency are shown in Figure 1. The primary outcome was self-evaluation milestone (SEM) scores (range 0‐9 scores) for 9 subcompetencies and the average SEM scores.

Figure 1. Milestone sets for patient care 1 (image interpretation) and professionalism (self-awareness and help-seeking).

(Clinical context) Patient care 1: image interpretation				
Level 1	Level 2	Level 3	Level 4	Level 5
Identifies primary imaging findings	Identifies secondary and critical imaging findings and formulates differential diagnoses	Prioritizes differential diagnoses and recommends management options	Provides a single diagnosis with integration of current guidelines to recommend management, when appropriate	Demonstrates expertise and efficiency at a level expected of a subspecialist
Scores: 1 2 3 4 5 6 7 8 9				
Comments:			Not yet completed level 1 ☐ Not yet assessable ☐	
(Nonclinical context) Professionalism: self-awareness and help-seeking				
Level 1	Level 2	Level 3	Level 4	Level 5
Recognizes status of personal and professional well-being, with assistance, and is aware of available resources Recognizes limits in the knowledge or skills of self or team, with assistance	Independently recognizes status of personal and professional well-being using available resources when appropriate Independently recognizes limits in the knowledge or skills of self or team and demonstrates appropriate help-seeking behaviors	With assistance, proposes a plan to optimize personal and professional well-being With assistance, proposes a plan to remediate or improve limits in the knowledge or skills of self or team	Independently develops a plan to optimize personal and professional well-being Independently develops a plan to remediate or improve limits in the knowledge or skills of self or team	Coaches others when emotional responses or limitations in knowledge or skills do not meet professional expectations
Scores: 1 2 3 4 5 6 7 8 9				
Comments:			Not yet completed level 1 ☐	

Sociodemographic Characteristics

The sociodemographic information included age (≤27 or >27 years), sex (male or female), educational level (bachelor's degree or master's degree or above), training year (the second year or the third year), training sites level (grade-a tertiary general hospital, grade-a tertiary specialized hospital, grade-b tertiary general hospital, or others), undergraduate major (clinical medicine, medical imaging, or others), working hours per week (≤40, 40 - 48, or >48), annual after-tax income in 2020 (analyzed as continuous variable), and types of residents (professional master or nonprofessional master).

Statistical Analysis

The SEM scores of radiology residents for 9 subcompetencies were reported by means and SDs). The differences in SEM scores of residents between distance learning and nondistance learning were compared using independent samples 2-tailed *t* test. To explore the association between distance learning and competencies, multiple linear regression (MLR) models were constructed. The dependent variables were SEM scores of 9 subcompetencies, and the key explanatory variable was distance learning. The moderating effect of mental health on distance learning was explored by the MLR model. The significance of the moderating effect was tested by simple slope analysis. All models were controlled for participants' characteristics. A variance inflation factor was used to detect the multicollinearity of independent variables for all models (variance inflation factor scores <3). A *P* value of <.05 was considered statistically significant for 2-tailed tests (*t* test or chi-square test). A conservative level of *P* value of <.10 was used to assess potential moderators in the regression, which was reported by a coefficient (β) and 90% CIs [37,38]. All statistical analyses were performed by STATA (version 17.0; StataCorp LLC).

Results

Participants' Characteristics

Of the 8008 targeted radiology residents, 2381 (overall effective response rate: 29.7%) participated in this survey (Figure 2). As is shown in Table 1, the mean age of the participants was 27.8 (SD 2.4) years. In total, 58.5% (n=1392) of them were female, and 50.5% (n=1202) were in the third-year training. The majority of the participants received training in a grade-a tertiary hospital (n=2310, 97%), had a bachelor's degree (n=2187, 91.9%), and their undergraduate major was medical imaging (n=2016, 84.7%). The median annual after-tax income was 40,000 RMB (IQR 10,000 - 60,000; a currency exchange rate of 1 RMB=US $0.145 is applicable), with 25.8% (n=614) of them earning more than 60,000 RMB (about US $ 8698.9). The average working hours per week was 44.3 (SD 12.5) hours, and 23.1% (n=551) of the participants worked more than 48 hours per week. During the initial COVID-19 outbreak from January 2020 to May 2020, 71.4% (n=1699) of the radiology residents participated in distance learning, and 73.2% (n=1742) of them reported slight or severe mental health struggles. In total, 35.8% (n=853) of the participants contributed to the prevention and control of COVID-19.

SEM Scores of Radiology Residents Between Distance Learning and Nondistance Learning

The mean score of competencies and a comparison of subcompetencies scores were presented in Table 2. The overall average score of radiology residents' competency was 3.37 (SD 1.47). The average score of participants who received distance learning was 3.46 (SD 1.49), higher than those who did not (mean 3.13, SD 1.39; *P*<.001). Residents who received distance learning outperformed in all subcompetencies than those without distance learning during the initial COVID-19 outbreak (PC-1: *P*=.007; MK-1: *P*=.004; and others: *P*<.001), except for PC-2 (*P*=.09; Table 2). Due to the low response rate, Mann-Whitney tests were performed. The results were similar (Multimedia Appendix 2). For radiology residents who had not participated in COVID-19–related activities (1528/2381; Multimedia Appendix 3), the differences between residents' competencies or subcompetencies showed the same trends, except for the PC-1 (P=.10).

Table . Self-evaluation milestone scores for radiology residents between distance learning and nondistance learning.

Diagnostic radiology sub-competencies	Total (N=2381), mean (SD)	Distance learning		*P* value
		Yes (n=1699), mean (SD)	No (n=682), mean (SD)	
PC[a]				
PC-1: image interpretation	3.90 (1.69)	3.96 (1.68)	3.75 (1.72)	.007
PC-2: competence in procedures	2.25 (1.77)	2.28 (1.81)	2.16 (1.65)	.09
MK[b]				
MK-1: diagnostic knowledge	3.75 (1.75)	3.82 (1.76)	3.59 (1.73)	.004
MK-2: imaging technology and image acquisition	3.53 (1.90)	3.62 (1.92)	3.29 (1.81)	<.001
SBP[c]				
SBP-1: system navigation for patient-centered care	2.86 (1.88)	2.96 (1.90)	2.61 (1.80)	<.001
SBP-2: contrast agent safety	3.57 (1.95)	3.71 (1.98)	3.21 (1.80)	<.001

Average (all subcompetencies)	3.37 (1.47)	3.46 (1.49)	3.13 (1.39)	<.001

[a]PC: patient care.

[b]MK: medical knowledge.

[c]SBP: system-based practice.

[d]PBLI: practice-based learning and improvement.

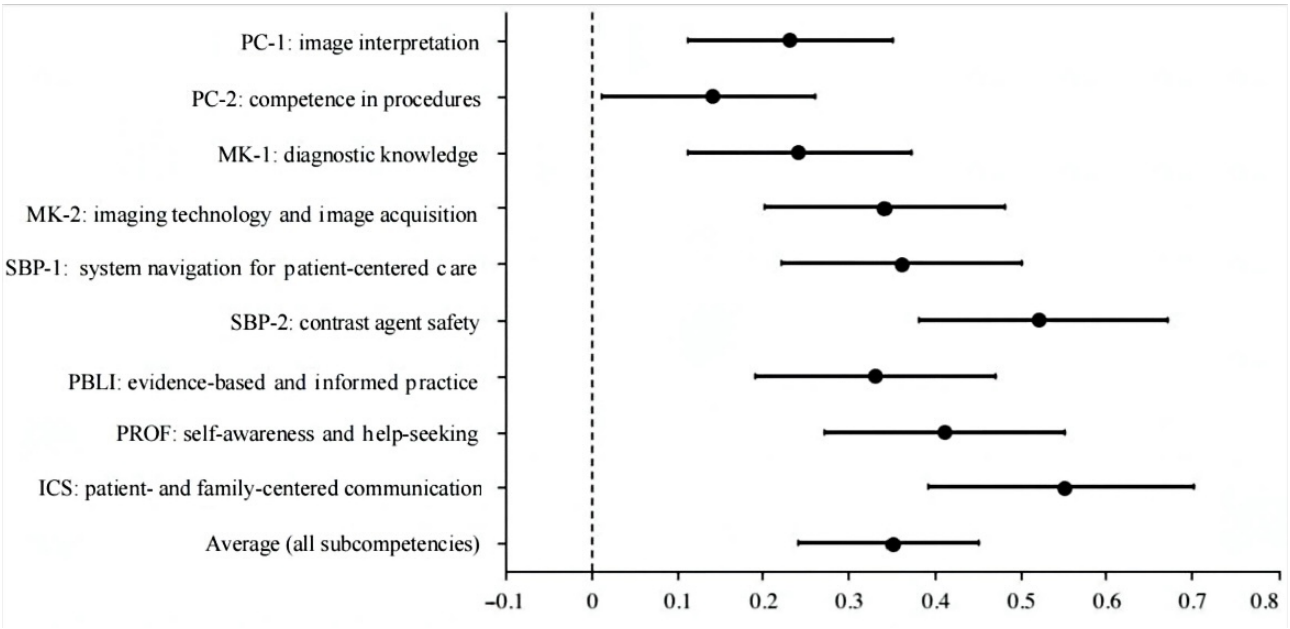
[e]PROF: professionalism.

[f]ICS: interpersonal communication skill.

Association Between Distance Learning and Competencies Among Radiology Residents

As is shown in Figure 3 (see also Multimedia Appendix 4), MLR analyses showed that radiology residents who were trained through distance learning were more likely to report high competencies (β=0.35, 90% CI 0.24 - 0.45) after adjusted by participants' characteristics, including age, sex, educational level, training years, working hours per week, annual after-tax income in 2020, and types of residents. This was particularly evident in the competencies of "interpersonal and communication skills" (β=0.55, 90% CI 0.39 - 0.70) and "contrast agent safety" (β=0.52, 90% CI 0.38 - 0.67). Whereas, the competency of "patient care and technical skills" benefited the least from distance learning (β=0.14, 90% CI 0.01 - 0.26). The effect of each explanatory variable on the overall average SEM score is shown in Multimedia Appendix 5. Factors associated with higher competencies included older age (>27 years: β=0.12, 90% CI 0.01 - 0.22), being male (β=0.28, 90% CI 0.18 - 0.37), and having a longer SRT training year (third year: β=0.51, 90% CI 0.41 - 0.61).

Figure 3. Associations between distance learning and competencies among residents. ICS: interpersonal communication skill; MK: medical knowledge; PBLI: practice-based learning and improvement; PC: patient care; PROF: professionalism; SBP: system-based practice.



The Moderating Effect of Mental Health Status Between Distance Learning and Competencies

The association between mental health status and competencies is shown in Multimedia Appendix 6. We controlled the covariates mentioned earlier to investigate the moderating effect of mental health on the association between distance learning and competencies. As is shown in Table 3, there was a significant association between distance learning and radiology residents' competencies (β=0.63, 90% CI 0.34 - 0.91; *P*<.001) and was moderated by mental health status (β=–0.15, 90% CI −0.27 to −0.02; *P*=.06). The relationship between distance learning and competencies at low and high (mean−SD and mean + SD, respectively) mental health scores is shown in Figure 4. Poor mental health caused by the pandemic may offset the positive effect of distance learning on residents' competencies. The highest level of competencies was found in individuals who reported less mental distress and adopted distance learning. Furthermore, the moderating effect of poor mental health on 4 subcompetencies (ie, MK-1, MK-2, SBP-2, and ICS) was similar to it on total competencies (*P*<.10; Multimedia Appendix 7).

Table . The moderating effects of mental health status on the association between competencies and distance learning.

Variables	Multiple linear regression models		
	β (SE)	90% CI	*P* value

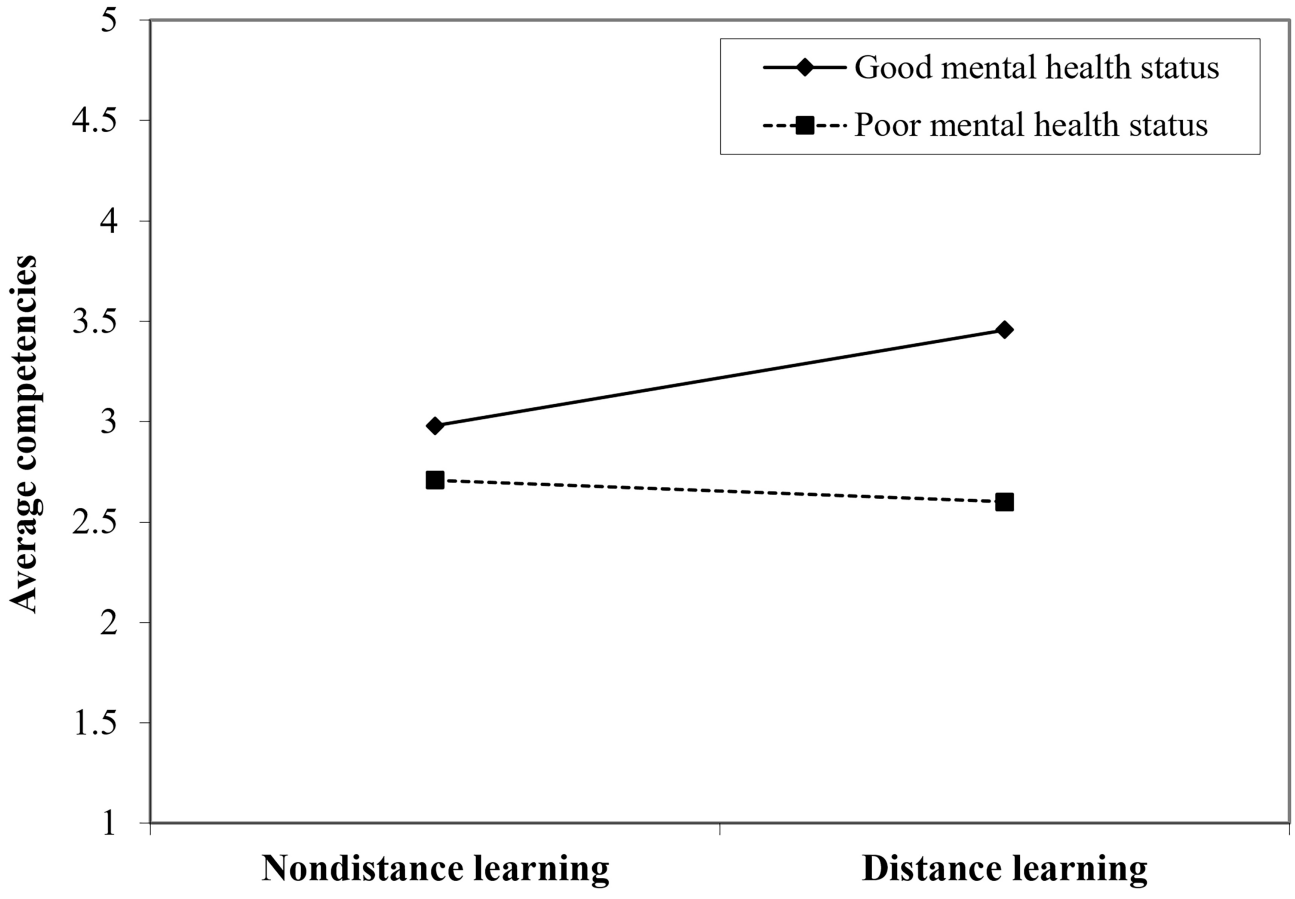
Figure 4. The moderating effect of mental health on the relationship between distance learning and average competencies. Two lines are the visual representation of different moderation effects of distance learning on competencies when the mental health status is at its +1SD and –1SD.



Discussion

Principal Findings

Based on a national survey of radiology residents in China, our study found that radiology residents who received distance learning were more likely to report high proficiency in key competencies after 1 year. This was particularly true for learning knowledge and communication skills but was less evident in obtaining technical skills. In addition, we found a significant moderating effect of mental health status on the association between distance learning and competencies during COVID-19.

Web-based training programs are proposed to mitigate the loss of learning from clinical rotations during the pandemic [39,40]. Consistent with the results of previous findings that distance learning has the potential to improve learners' academic performance, skill development, and engagement [39,41], our study observed a positive impact of distance learning on radiology residents' self-assessed competencies. However, it should be noted that the impact of distance learning on professional competency varies among radiology residents. Our study enriches the understanding of distance learning by using milestones of 9 subcompetencies for 6 core competencies. We also assessed the long-term outcomes of distance learning among radiology residents in the initial stage of the COVID-19 pandemic (between January and May 2020). These findings can be used to help inform evidence-based policies to improve residency training in the future.

Knowledge gain is an important indicator of what trainees have learned during SRT training [42]. The radiology residents in our study reported a substantial gain of knowledge and communication skills during SRT, particularly in ICS competency and SBP competency that include clinical knowledge and medical humanities, with a regression coefficient >0.5. Whereas, the effect of distance learning on professional attitudes (PROF) and professional growth in clinical practice (PBLI) was moderate, with a regression coefficient between 0.3 and 0.4, which is in line with previous studies [43-45]. Distance learning was found to be supportive in the continuity of teaching and learning during COVID-19 [39], which might explain why residents who received distance learning reported a higher score in the competence of medical knowledge than nondistance learners. In addition, radiology residents are able to participate in web-based conferences and conduct digital medical consultations to enhance their competency of communication [43], though it could be hard to evaluate their body language in distance learning [46]. Our findings validated the positive role of distance learning in fulfilling the objectives of training by creating an enabling environment, especially in the domain of knowledge and communication. In other words, distance learning can help keep the consistency of residency programs during pandemics, facilitating the resilience and recovery of health systems.

Our findings showed that competence in procedures (PC-2) benefited the least from distance learning, followed by competencies in technical skills (including PC competencies that reflect radiology residents' professionalism and MK competencies that reflect mastery of professional knowledge and imaging technology). The result is consistent with previous findings that most medical students feel unable to acquire practical clinical skills through web-based teaching during COVID-19 [47]. This could be explained by the reduction in daily cases due to COVID-19, which was one of the deficiencies in distance learning [20]. To address this challenge, new technologies such as touchscreen Anatomage Table and Touch Surgery application have been used to strengthen trainings of plastic surgery [48]. These new approaches can be integrated into web-based residency training to compensate for the shortage of training in technical skills with distance learning. Other training programs, such as competence in procedures, could also be carried out among radiology residents in the post–COVID-19 era.

Health professional education involves maintaining a sense of purpose and mental well-being (eg, balance work life, stress, depression, burnout, and more) among residents [49-51]. Our study extended the prior results by identifying that poor mental health moderates the relationship between distance learning and competency among radiology residents. During the COVID-19 pandemic, physicians experienced more mental health disorders [52] with negative impacts (eg, higher turnover intention and lower work performance) [53,54]. However, good mental health may help trainees to receive distance learning consistently [55]. When trainees are in a suboptimal mental status, they tend to have negative attitudes toward learning and are discouraged from receiving distance learning continuously [55]. Health workforce is the backbone of health systems in response of pandemics [56]. In addition to the structural changes required for the improvement of health systems' resilience, it could also be necessary to provide long-term psychological support for the health workforce to help them overcome psychological distress [57]. In summary, several recommendations can be drawn from this study: (1) distance learning can be used for transferring knowledge to residents particularly when challenges exist in the traditional offline approaches; (2) clinical skills have a crucial role in offline training, which should be noted and well used by training institutions; (3) instructors could use a scientific and caring approach with a special focus on learners' psychological well-being when preparing material and organizing courses; and (4) physicians who have engaged in distance learning could enhance their learning experience through an enhancement of their offline learning environment. This promotes a better psychological state for learning to become more effective.

Health system resilience is critical in training the required competencies of the health workforce [49]. In addition to competency-based education, the COVID-19 pandemic highlighted the application of digital interprofessional education [58]. In the future, distance learning may help physicians gain knowledge and skills in public health, interprofessional communication, and teamwork. In this regard, remote residency training should be developed as a holistic educational concept rather than a mere substitution for traditional in-person learning. Distance learning enables physicians to have a flexible schedule, a feasible access to classes, and an opportunity to keep a good balance between work and life [14]. What is more, the facilitation of distance learning contributes to the sharing of

high-quality educational resources in the post–COVID-19 era. In particular, for health professionals in resource-constrained places (eg, rural areas in western China), the provision of high-quality distance learning could help them overcome geographical constraints and thus reduce inequalities in access to education [49,59]. Nevertheless, it is not possible to replace in-person teaching with distance learning completely. An integrated model of the 2 is encouraged to maximize the advantages of different teaching modalities.

Limitations

This study has several limitations. First, we used SEM for the self-evaluation of radiology residents' competencies; results may be influenced by the Dunning-Kruger effect, where participants with lower abilities tend to overestimate their competencies and the potential self-reporting bias [60]. Second, the lower response rate may be subject to selection bias, as our survey is voluntary in nature. However, based on sample size calculations [61], we obtained 1573 valid samples (precision=5%; baseline proportion=0.50), which accurately represent the characteristics of the residents. Importantly, this represents the largest nationally representative sample of radiology residents in China to date, which may help to minimize the potential bias. Third, although mental health status was asked by a single question based on the self-report psychological distress on a Likert scale, this variable is correlated with long-term mental health status (depression and burnout). Other potential moderating factors that may influence learning status, such as the design of the web-based course, courseware, and teaching styles, could be explored in future research. Fourth, the generalization of the results is another limitation of our study [49].

Future Directions

As distance learning is anticipated to be applied across various fields, additional research is warranted to substantiate our findings. Longitudinal studies are recommended for future research to fully assess the long-term effects of distance learning on competence and mental health.

Conclusions

Distance learning helps mitigate the negative impact of the COVID-19 lockdown on the education of health professionals. Meanwhile, attention should be paid to the disadvantages of distance learning and the mental health status of learners, as they may negatively influence the effectiveness and sustainability of distance learning. Our study provides insights into the role of distance learning in residency training during the pandemic.

Abstract

Background: The COVID-19 pandemic challenged medical educators due to social distancing. Podcasts and asynchronous learning platforms help distill medical education in a socially distanced environment. Medical educators interested in providing asynchronous teaching should know how these methods performed during the pandemic.

Objective: The purpose of this study was to assess the level of engagement for an emergency medicine (EM) board review podcast and website platform, before and during the COVID-19 pandemic. We measured engagement via website traffic, including such metrics as visits, bounce rate, unique visitors, and page views. We also evaluated podcast analytics, which included total listeners, engaged listeners, and number of plays.

Methods: Content was designed after the American Board of EM Model, covering only 1 review question per episode. Website traffic and podcast analytics were studied monthly from 2 time periods of 20 months each, before the pandemic (July 11, 2018, to February 31, 2020) and during the pandemic (May 1, 2020, to December 31, 2021). March and April 2020 data were omitted from the analysis due to variations in closure at various domestic and international locations. Results underwent statistical analysis in March 2022.

Results: A total of 132 podcast episodes and 93 handouts were released from July 11, 2018, to December 31, 2021. The mean number of listeners per podcast increased significantly from 2.11 (SD 1.19) to 3.77 (SD 0.76; *t* test, $P<.001$), the mean number engaged per podcast increased from 1.72 (SD 1.00) to 3.09 (SD 0.62; *t* test, $P<.001$), and the mean number of plays per podcast increased from 42.54 (SD 40.66) to 69.23 (SD 17.54; *t* test, $P=.012$). Similarly, the mean number of visits per posting increased from 5.85 (SD 3.28) to 15.39 (SD 3.06; *t* test, $P<.001$), the mean number of unique visitors per posting increased from 3.74 (SD 1.83) to 10.41 (SD 2.33; *t* test, $P<.001$), and the mean number of page views per posting increased from 17.13 (SD 10.63) to 33.32 (SD 7.01; *t* test, $P<.001$). Note that, all measures showed a decrease from November 2021 to December 2021.
