Abstract

Background: Improving the quality of education in clinical settings requires an understanding of learners' experiences and learning processes. However, this is a significant burden on learners and educators. If learners' learning records could be automatically analyzed and their experiences could be visualized, this would enable real-time tracking of their progress. Large language models (LLMs) may be useful for this purpose, although their accuracy has not been sufficiently studied.

Objective: This study aimed to explore the accuracy of predicting the actual clinical experiences of medical students from their learning log data during clinical clerkship using LLMs.

Methods: This study was conducted at the Nagoya University School of Medicine. Learning log data from medical students participating in a clinical clerkship from April 22, 2024, to May 24, 2024, were used. The Model Core Curriculum for Medical Education was used as a template to extract experiences. OpenAI's ChatGPT was selected for this task after a comparison with other LLMs. Prompts were created using the learning log data and provided to ChatGPT to extract experiences, which were then listed. A web application using GPT-4-turbo was developed to automate this process. The accuracy of the extracted experiences was evaluated by comparing them with the corrected lists provided by the students.

Results: A total of 20 sixth-year medical students participated in this study, resulting in 40 datasets. The overall Jaccard index was 0.59 (95% CI 0.46-0.71), and the Cohen κ was 0.65 (95% CI 0.53-0.76). Overall sensitivity was 62.39% (95% CI 49.96%-74.81%), and specificity was 99.34% (95% CI 98.77%-99.92%). Category-specific performance varied: symptoms showed a sensitivity of 45.43% (95% CI 25.12%-65.75%) and specificity of 98.75% (95% CI 97.31%-100%), examinations showed a sensitivity of 46.76% (95% CI 25.67%-67.86%) and specificity of 98.84% (95% CI 97.81%-99.87%), and procedures achieved a sensitivity of 56.36% (95% CI 37.64%-75.08%) and specificity of 98.92% (95% CI 96.67%-100%). The results suggest that GPT-4-turbo accurately identified many of the actual experiences but missed some because of insufficient detail or a lack of student records.

Conclusions: This study demonstrated that LLMs such as GPT-4-turbo can predict clinical experiences from learning logs with high specificity but moderate sensitivity. Future improvements in AI models, providing feedback to medical students' learning logs and combining them with other data sources such as electronic medical records, may enhance the accuracy. Using artificial intelligence to analyze learning logs for assessment could reduce the burden on learners and educators while improving the quality of educational assessments in medical education.

KEYWORDS

large language models; ChatGPT; workplace-based assessment; artificial intelligence; AI

Introduction

Background

To improve the quality of education in clinical settings, it is important to understand what learners experience and how they learn [1,2]. Various workplace-based assessment tools have been developed and used to enable educators to track learners' progress and provide feedback [3]. However, the rigorous management of learners' progress requires frequent observation of learners, frequent evaluations, and feedback from educators. This can impose a high burden on both learners and educators, potentially hindering learning [4,5]. Thus, the challenge is accurately monitoring learning in clinical settings without burdening learners or educators.

Learners in clinical settings often document their learning and practice experiences. If these records can be analyzed to

understand learners' contexts, monitoring their learning without imposing additional burdens may be possible. One such record kept by learners during clinical clerkship is a logbook. The logbook documents the cases encountered, procedures performed, and learners' reflections. It serves as a tool for prompting student reflections and facilitating feedback and dialogue between educators and learners [6-8]. Evaluating these records against curriculum competencies and goals without adding an extra burden on learners can help monitor their progress [9]. However, educators may have to manually match and analyze these records, which may be a significant burden [5].

Artificial intelligence (AI)–assisted text extraction and standard matching could be useful in this context. Previous studies have successfully used natural language processing, a branch of AI, to analyze supervisory feedback comments and predict student performance against competency standards [10]. AI models that integrate multiple information sources to represent student performance have also been developed [11]. Among AI technologies, large language models (LLMs) have gained attention in medical education because of their extensive pretraining on large datasets, allowing them to handle various situations, including multilingual support, with minimal adjustment [12]. Research using ChatGPT, an LLM, has shown that it can apply codes to interview texts using a codebook, suggesting its potential for extracting competency-based evaluations from student descriptions [13]. However, owing to a lack of such research, aggregation accuracy remains uncertain. Determining the extent to which LLMs can aggregate items related to curriculum goals from learner descriptions may open up opportunities to leverage LLMs to monitor learner progress and enhance education quality.

In Japanese undergraduate education, the Model Core Curriculum for Medical Education (MCC) [14] was established to define two-thirds of the undergraduate curriculum and is used as a guideline for undergraduate medical education. The MCC outlines the experiences that medical students should have by the time they graduate, focusing primarily on clinical clerkships [14]. In Japanese clinical clerkships, medical students are partially observed directly by supervisors [15], but it is difficult for busy supervisors to grasp the full scope of experiences that medical students encounter [14]. If experiences could be understood through analysis of learning logs kept by medical students, valuable information for improving the learning environment could be obtained.

Objectives

Therefore, this study focused on undergraduate clinical clerkships in Japan to investigate the accuracy with which LLMs can aggregate goals from records kept for learning. Our research question was as follows: how accurately can an LLM predict experiences related to the goals defined by the MCC from the records that students keep for learning during clinical clerkships?

Methods

Context

This study was conducted as part of the participatory clinical clerkship at the Nagoya University School of Medicine, a program designed to provide medical students with practical experience in clinical settings. During the final year of medical school (sixth year), students participate in this program for 4 weeks, recording their daily experiences and learning activities. A trial to transform these records into an electronic portfolio began in 2024. This study was part of this trial.

Dataset

This study used learning log data from sixth-year medical students to extract their experiences related to core curriculum goals. Learning log data consisted of daily records of experiences and learning activities entered by medical students into an electronic portfolio during a clinical clerkship from April 22, 2024, to May 24, 2024. The data were treated as weekly datasets.

Extraction of Experiences

The template for extracting experiences from the dataset was the MCC [14]. This study used a table of symptoms, examinations, and procedures that medical students are expected to encounter in patients during their clinical clerkship at Nagoya University School of Medicine as the template for experience extraction (Textbox 1).

Textbox 1. Symptoms, examinations, and procedures that medical students are expected to encounter in patients.

Symptoms

- Fever
- General malaise
- Anorexia
- Weight loss
- Weight gain
- Altered mental status
- Syncope
- Seizure
- Vertigo and dizziness
- Edema
- Rash
- Cough and sputum production
- Blood in sputum and hemoptysis
- Dyspnea
- Chest pain
- Palpitations
- Dysphagia
- Abdominal pain
- Nausea and vomiting
- Hematemesis
- Melena
- Constipation
- Diarrhea
- Jaundice
- Abdominal distention and abdominal mass
- Lymphadenopathy
- Abnormal urine output or urination
- Hematuria
- Menstrual abnormality
- Anxiety or depression
- Cognitive dysfunction
- Headache
- Skeletal muscle paralysis or muscle weakness
- Gait disturbance
- Sensory disturbance
- Back pain
- Arthralgia or joint swelling

Examinations

- Full blood count
- Blood biochemistry
- Coagulation or fibrinolysis

- Immunoserology tests
- Urinalysis
- Stool (fecal) examination
- Blood typing (ABO, and RhHD), blood compatibility test (cross-matching), and atypical antibody screening
- Arterial blood gas analysis
- Pregnancy test
- Microbiological tests (bacterial smear, culture, identification, and antibiotic sensitivity test)
- Cerebrospinal fluid
- Pleural fluid analysis
- Peritoneal fluid analysis
- Histopathology and cytology (including intraoperative rapid diagnosis)
- Genetic testing and chromosome analysis
- Electrocardiography (ECG)
- Lung function tests
- Endocrine and metabolic function tests
- Electroencephalography
- Ultrasound
- X-ray
- Computed tomography
- Magnetic resonance imaging
- Nuclear medicine examination
- Endoscopy

Procedures

- Position change and transfer
- Skin antisepsis
- Application of topical medications
- Airway suction
- Nebulizer
- Venous blood sampling
- Peripheral venous catheterization
- Insertion and extraction of nasogastric tube
- Insertion and extraction of urinary catheter
- Intradermal injection
- Subcutaneous injection
- Intramuscular injection
- Intravenous injection
- Urinalysis (including pregnancy test)
- Microbiological testing (including Gram staining)
- Recording of a 12-lead ECG
- Rapid bedside ultrasound (including focused assessment with sonography for trauma [FAST]) for clinical decision-making
- Rapid antigen or pathogen testing
- Blood glucose test
- Aseptic technique

- Surgical hand washing
- Gowning techniques in the operating room
- Basic sutures and suture removal

OpenAI's ChatGPT, Google's Gemini, and Anthropic's Claude were considered for the LLMs used in experience extraction. Trial prompts and randomly selected student records were entered into each web platform, and the extracted results were compared in terms of validity. Validity was evaluated from the perspective of whether the output followed the expected format, whether the output matched the experience items expected from the text, and whether the output was reproducible. ChatGPT by OpenAI produced the most valid outputs, so it was selected for this study.

LLMs, including ChatGPT, receive text data as input and generate subsequent text based on these data. Therefore, the prompt given to the LLM is crucial. In this study, prompts were created using medical students' learning log data, which were provided to ChatGPT to extract their experiences from the logs. Experiences were extracted based on a table of symptoms, examinations, and procedures that students were expected to experience, with ChatGPT outputting a list of symptoms, examinations, and procedures inferred from the text data. To automate this process, a web application using GPT-4-turbo was developed, which allowed medical students to input learning log data and receive the extracted experiences as a list output from GPT-4-turbo (gpt-4-0125-preview). The prompt used for GPT-4-turbo and the web application code are provided in Multimedia Appendix 1.

Evaluation of Extracted Experiences

The extracted experience goals were presented to the medical students via email. Students were asked to compare the list with their actual experiences, including those not recorded in their reflections, and submit a corrected list. The corrected lists were compared with the original learning log data to evaluate the accuracy of the extracted experiences.

Data Analysis

The accuracy of the extracted experience goals was evaluated using the R software (version 4.1.2; R Foundation for Statistical Computing). The agreement rate between the extracted and corrected experience goals was calculated, and the accuracy of the extracted experience goals was assessed based on this agreement rate.

Ethical Considerations

This study was approved by the ethics committee of Nagoya University Graduate School of Medicine (approval 2023-0451 31742). All participants were informed about the study's purpose, methods, risks, and benefits and were allowed to opt out. All data were fully anonymized and handled to prevent the identification of individuals. No compensation was provided to participants in this study.

Results

Study Period, Participants, and Data Characteristics

During the clinical participation-based clerkship at Nagoya University Hospital from April 22, 2024, to May 24, 2024, a total of 61% (20/33) of the sixth-year students who made entries in the e-portfolio participated in the study, yielding 40 data points. All records were written in Japanese, with an average letter count of 446.2 (SD 353.52; range 72-1473). The predicted and actual experiences are shown in Table 1.

Table . Predicted and actual experience items.

Record index	Predicted item	Actual item	Number of matches	Number of experienced items extracted by GPT-4-turbo	Number of items that the students marked as experiences they had
1	Skeletal muscle paralysis or muscle weakness, gait disturbance, and sensory disturbance	Skeletal muscle paralysis or muscle weakness, gait disturbance, and sensory disturbance	3	3	3
2	Endocrine and metabolic function tests	Endocrine and metabolic function tests	1	1	1
3	Fever	Fever	1	1	1
4	Basic sutures and suture removal	Basic sutures and suture removal	1	1	1
5	Seizure, electroencephalography, and MRI[a]	Aseptic technique, electroencephalography, MRI, weight gain, and seizure	3	3	5
6	Skeletal muscle paralysis or muscle weakness, gait disturbance, and sensory disturbance	Skeletal muscle paralysis or muscle weakness, gait disturbance, and sensory disturbance	3	3	3
7	Anorexia, abdominal distention and abdominal mass, and ultrasound	Palpitations and skeletal muscle paralysis or muscle weakness	0	3	2
8	Venous blood sampling	Venous blood sampling	1	1	1
9	Rapid bedside ultrasound (including FAST[b]) for clinical decision-making and ultrasound	Skin antisepsis, rapid bedside ultrasound (including FAST) for clinical decision-making, aseptic technique, surgical handwashing, gowning techniques in the operating room, basic sutures and suture removal, ultrasound, fever, and diarrhea	2	2	9
10	Basic sutures and suture removal	Basic sutures and suture removal	1	1	1
11	Basic sutures and suture removal	Surgical handwashing, gowning techniques in the operating room, basic sutures and suture removal, full blood count, blood biochemistry, coagulation and fibrinolysis, histopathology and cytology (including intraoperative rapid diagnosis), x-ray, CT[c], MRI, general malaise, and weight loss	1	1	12
12	Venous blood sampling and pregnancy test	Venous blood sampling	1	2	1

Record index	Predicted item	Actual item	Number of matches	Number of experienced items extracted by GPT-4-turbo	Number of items that the students marked as experiences they had
13	Surgical handwashing, gowning techniques in the operating room, and basic sutures and suture removal	Surgical handwashing, gowning techniques in the operating room, and basic sutures and suture removal	3	3	3
14	Pregnancy test and basic sutures and suture removal	Position change and transfer, insertion and extraction of a urinary catheter, surgical handwashing, gowning techniques in the operating room, basic sutures and suture removal, histopathology and cytology (including intraoperative rapid diagnosis), MRI, and abdominal distention and abdominal mass	1	2	8
15	Surgical handwashing	Surgical handwashing, gowning techniques in the operating room, basic sutures and suture removal, full blood count, blood biochemistry, histopathology and cytology (including intraoperative rapid diagnosis), ultrasound, and x-ray	1	1	8
16	Microbiological tests (bacterial smear, culture, identification, and antibiotic sensitivity test), nuclear medicine examination, general malaise, cough and sputum production, dyspnea, abdominal pain, nausea and vomiting, and abnormal urine output or urination	General malaise and edema	1	8	2
17	Surgical handwashing	Aseptic technique, surgical handwashing, gowning techniques in the operating room, basic sutures and suture removal, and cough and sputum production	1	1	5
18	Fever, urinalysis, microbiological tests (bacterial smear, culture, identification, and antibiotic sensitivity test), nausea and vomiting, and hematuria	Full blood count, blood biochemistry, immunoserology tests, urinalysis, microbiological tests (bacterial smear, culture, identification, and antibiotic sensitivity test), edema, palpitations, hematuria, and back pain	3	5	9

Record index	Predicted item	Actual item	Number of matches	Number of experienced items extracted by GPT-4-turbo	Number of items that the students marked as experiences they had
19	Blood glucose test and endocrine and metabolic function tests	Blood glucose test and endocrine and metabolic function tests	2	2	2
20	Cognitive dysfunction	Cognitive dysfunction	1	1	1
21	Chest pain	Chest pain	1	1	1
22	Surgical handwashing and basic sutures and suture removal	Aseptic technique, surgical handwashing, gowning techniques in the operating room, and basic sutures and suture removal	2	2	4
23	Cognitive dysfunction, abnormal urine output or urination, and urinalysis	Cognitive dysfunction and abnormal urine output or urination	2	3	2
24	Dyspnea	Dyspnea	1	1	1
25	Gowning techniques in the operating room	Position change and transfer, skin antisepsis, aseptic technique, surgical handwashing, gowning techniques in the operating room, and basic sutures and suture removal	1	1	6

40	Skin antisepsis	Skin antisepsis	1	1	1

[a]MRI: magnetic resonance imaging.

[b]FAST: focused assessment with sonography for trauma.

[c]CT: computed tomography.

The predicted items were experience items extracted using GPT-4-turbo from the students' practice records. The actual items were those that the students marked as experiences they had during that period. The English-translated version of the students' records used by GPT-4-turbo to extract experiences can be found in Multimedia Appendix 1, with the "Index" column in Table 1 corresponding to the "Index" column in Multimedia Appendix 1.

Agreement Between LLM Predictions and Student-Reported Experiences

The Jaccard index was 0.59 (95% CI 0.46-0.71), indicating moderate agreement, and the Cohen κ was 0.65 (95% CI 0.53-0.76), indicating substantial agreement. Sensitivity and specificity were 62.39% (95% CI 49.96%-74.81%) and 99.34% (95% CI 98.77%-99.92%), respectively. The sensitivity and specificity of the LLM for each category were as follows: 45.43% (95% CI 25.12%-65.75%) and 98.75% (95% CI 97.31%-100%) for symptoms, 46.76% (95% CI 25.67%-67.86%) and 98.84% (95% CI 97.81%-99.87%) for examinations, and 56.36% (95% CI 37.64%-75.08%) and 98.92% (95% CI 96.67%-100%) for procedures, respectively. There was no significant variation among the categories. However, when calculating by category, the sensitivity tended to be lower than the overall calculation, likely due to the influence of items that were not extracted at all. The correlation between the number of characters in the students' records and sensitivity and specificity was 0.04 and –0.64, respectively, indicating a negligible correlation with sensitivity and a moderate negative correlation with specificity. The correlation coefficients for the Jaccard index and the Cohen κ were 0.06 and –0.07, respectively, showing negligible correlations with record length.

Patterns of Missed Experiences

There were several patterns in experiences that were not captured by GPT-4-turbo's analysis even though students considered to have had those experiences. In this paragraph, we explain these patterns with examples corresponding to specific entries in Table 1. Due to the large volume of student records, the full texts are provided in Multimedia Appendix 2 rather than Table 1. One pattern was when predictable experiences were not picked up by GPT-4-turbo's analysis. For example, a student (index 19 in Table 1) described encountering a case of hereditary amyotrophic lateral sclerosis, but GPT-4-turbo's analysis failed to capture the student's experience with muscle weakness, a symptom of amyotrophic lateral sclerosis. Another pattern was when insufficient description made prediction difficult. In total, 20% (8/40) of the students (indexes 9, 11, 15, 17, 22, 25, 29, and 32 in Table 1) recorded observing surgery, but it was unclear from the description whether they assisted in the surgery or merely observed, making it difficult for GPT-4-turbo to extract related procedures such as surgical handwashing and gowning techniques. A third pattern was when experiences were not recorded by the students, making prediction impossible. For instance, a student recorded observing a surgery (index 15 in Table 1) but actually performed suturing, an experience not captured by GPT-4-turbo due to lack of record. Similarly, a student (index 30 in Table 1) noted examining a patient with diabetes but did not record performing computed tomography or ultrasound examinations.

Discussion

Principal Findings

In this study, we analyzed the records kept by medical students during their clinical clerkship for learning purposes using GPT-4-turbo to predict the clinical procedures they experienced. The experiences extracted by GPT-4-turbo were evaluated for accuracy after being revised by the medical students. The extraction of experiences by GPT-4-turbo showed a sufficient level of agreement with the items that students actually experienced and demonstrated high specificity. The high specificity suggests that the extracted experiences likely mirror what the students actually encountered. However, the low sensitivity indicates that some experiences that students actually had were not captured by GPT-4-turbo's analysis of the records. There were three main reasons why certain experiences could not be extracted: (1) experiences that could have been predicted by GPT-4-turbo's analysis were not identified; (2) the descriptions were insufficient, making prediction difficult; and (3) there were experiences that students did not record at all.

Implications of Findings

The results of this study suggest that LLMs such as GPT-4-turbo are able to extract experiences from learning records with sufficient accuracy. On the other hand, when the content of the learning records is insufficient or when students do not record their experiences, experience extraction becomes difficult, indicating that improving the accuracy of LLMs alone may not be sufficient.

Comparison to the Literature

Comparison with previous studies suggests that LLMs are making it easier and more accurate to extract experiences from learning records. Unlike previous studies [10,11], which required extensive pretraining on large text datasets, this study was able to extract experiences from learning records using only prompt engineering without additional training. A related study using LLMs investigated how well GPT-3 could extract predefined codes from documents and compared its results to those of human coders [13]. In that study, providing 5 examples for each code resulted in a Cohen κ of 0.61 for some codes, although the Cohen κ for most codes was lower. In contrast, our study used GPT-4-turbo to extract experiences from learning records without providing specific examples, achieving a Cohen κ of 0.65. Although direct comparison is difficult due to differences in study targets, GPT-4-turbo may have achieved higher extraction accuracy. These findings indicate that, with the advent and evolution of LLMs, extracting experiences from learning records is becoming easier and potentially more accurate.

In addition, this study demonstrates that performance monitoring is possible by analyzing narrative records primarily intended for student learning using LLMs rather than aggregating list-based records mainly used for evaluation, as in some previous studies. Previous studies have explored the use of logbooks to monitor learners' progress of learning. Attempts have been made to monitor skills and experiences using logbooks [16], track the progress of entrustable professional activities [8], and count the cases encountered [7]. However, the "logbooks" used in these studies were lists of cases experienced or evaluations rather than detailed descriptions of experiences [7,8]. This format is more useful for evaluation purposes rather than for recording learning, which ultimately adds to the burden on learners. Our study suggests that analyzing reflections purely recorded for learning purposes can also extract

experiences, offering a technique that monitors learning situations while reducing the burden on learners and educators.

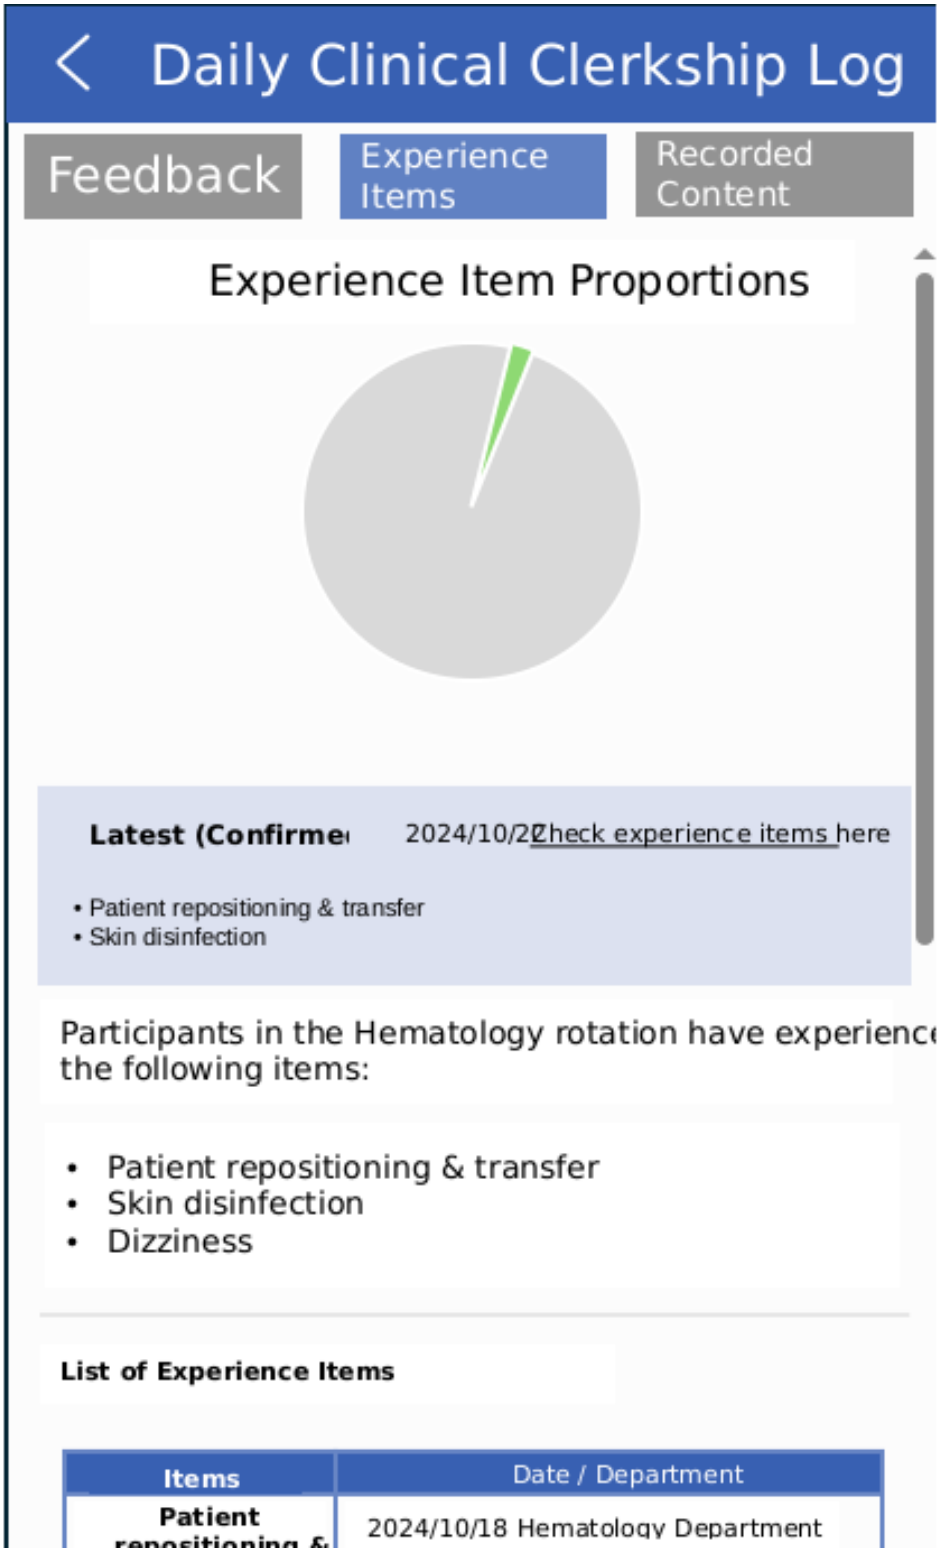
Future Directions

While this study demonstrated the usefulness of experience extraction by LLMs, it also highlighted new challenges. GPT-4-turbo failed to extract some experiences that students actually had. The first pattern involved experience items that could not be extracted despite being predictable from the learning log content. The second pattern involved cases in which descriptions were ambiguous, making inference difficult. The third pattern involved experiences that medical students believed they had but were not recorded in learning logs, making inference impossible. Regarding the first pattern, insufficient reasoning ability of GPT-4-turbo is considered the cause. However, the reasoning ability of LLMs is improving with model evolution [17], and future improvements in LLM accuracy may partially address this issue. Regarding the second and third patterns, insufficient content in medical students' learning logs appears to be the cause, resulting in inadequate information to infer students' experiences. To address these challenges, it may be necessary to enrich students' learning records or extract experiences from other sources.

To enhance the quality of medical students' learning records, providing feedback using the list of experiences extracted by LLMs may be beneficial. Previous studies have shown that logbooks are useful for performance monitoring and improving educational quality, but they have also pointed out that the quality of the records is often insufficient and that feedback is needed [18]. In this study, medical students reviewed the list of experiences extracted from their learning records by GPT-4-turbo and added items that they had actually experienced but were not extracted. Since missing or incomplete records can be a reason for experiences not being extracted, this review process may serve as feedback for students, helping them reflect on what they failed to document in their records. As shown in the development version of the web application in Figure 1, displaying experience items extracted from learning logs might motivate students to improve their learning log documentation.

Combining other data such as electronic health records written by the students might be effective for more accurate monitoring of medical students' performance. Feeding both learning logs and electronic health record descriptions into GPT-4-turbo could enhance the accuracy of experience extraction. Such an approach could lead to more accurate assessment of medical students without increasing the burden on students or faculty. However, since many LLMs, including GPT-4-turbo, are cloud-based, privacy concerns may arise [19,20]. Therefore, new approaches will need to be developed to address these privacy issues in the future.

Figure 1. Development version of the web application.



Limitations

This study has several limitations. First, this study used learning log data from clinical participation-based clerkships at a single university; therefore, its generalizability to learning log data from other universities or clinical clerkships is not guaranteed. In addition, the data collection period was limited to 1 month, which may not capture the full range of experiences or seasonal variations in clinical activities. While the accuracy of the extracted experience content was evaluated by using learning log data recorded by medical students and asking them to make corrections, the quality and quantity of the learning log data recorded by the students could affect the accuracy of the extracted experience content. Large-scale collaborative studies across multiple institutions and over longer periods are needed to ensure broader generalizability. Furthermore, this study used a list of symptoms, examinations, and procedures in the MCC as a template for extracting experience content; however, the

results of using other templates were not examined. Future research is needed to assess performance using other evaluation criteria. Although we confirmed the correlation between record length and extraction sensitivity and specificity, we did not quantitatively evaluate the quality of the records. Future work should investigate the relationship between record quality and extraction performance. In this study, the accuracy of the extracted experience content was evaluated by using learning log data recorded by medical students and asking them to make corrections, but no strict criteria were set for what constitutes "experience" when students made corrections. Moreover, students' judgments about whether they had actually experienced a procedure are subjective, and they may have overreported certain experiences or overlooked ones they truly had. In the clinical clerkship that served as this study's setting, supervising physicians did not continuously monitor students, so only the students themselves could verify their experiences. Therefore, we had to rely on students' subjective reports. In future work, it will be desirable to establish more objective evaluation criteria to reduce potential bias.

Conclusions

In this study, records kept by medical students for learning during clinical clerkships were analyzed using GPT-4-turbo to predict experienced clinical activities. The high specificity of the GPT-4-turbo predictions suggests that the extracted experiences are likely what students actually encountered. However, the low sensitivity indicates that some actual student experiences were not captured by the GPT-4-turbo analysis. Future improvements in AI model performance, providing feedback to medical students on their records and combining learning logs with other data sources such as electronic medical records, may enhance accuracy. Analyzing records using AI may enable detailed assessments while avoiding excessive burdens on learners and educators.

Acknowledgments

ChatGPT (OpenAI) was used in part to create an initial English translation of the Japanese version of this manuscript. This work was supported by Japan Society for the Promotion of Sciences Grants-in-Aid for Scientific Research 23K27816 and 25K06542.

Abstract

Background: Advancements in ChatGPT are transforming medical education by providing new tools for assessment and learning, potentially enhancing evaluations for doctors and improving instructional effectiveness.

Objective: This study evaluates the performance and consistency of ChatGPT-3.5 Turbo and ChatGPT-4o mini in solving European Portuguese medical examination questions (2023 National Examination for Access to Specialized Training; Prova Nacional de Acesso à Formação Especializada [PNA]) and compares their performance to human candidates.

Methods: ChatGPT-3.5 Turbo was tested on the first part of the examination (74 questions) on July 18, 2024, and ChatGPT-4o mini on the second part (74 questions) on July 19, 2024. Each model generated an answer using its natural language processing capabilities. To test consistency, each model was asked, "Are you sure?" after providing an answer. Differences between the first and second responses of each model were analyzed using the McNemar test with continuity correction. A single-parameter *t* test compared the models' performance to human candidates. Frequencies and percentages were used for categorical variables, and means and CIs for numerical variables. Statistical significance was set at $P<.05$.

Results: ChatGPT-4o mini achieved an accuracy rate of 65% (48/74) on the 2023 PNA examination, surpassing ChatGPT-3.5 Turbo. ChatGPT-4o mini outperformed medical candidates, while ChatGPT-3.5 Turbo had a more moderate performance.

Conclusions: This study highlights the advancements and potential of ChatGPT models in medical education, emphasizing the need for careful implementation with teacher oversight and further research.

Introduction

Generative artificial intelligence (AI) represents a branch of AI dedicated to the development of systems that can autonomously generate high-quality digital content on demand, and it can do so across various modalities, such as written text, images, audio, and video [1-3]. Generative AI tools are trained on large datasets, enabling them to produce work that mirrors human-created content [2]. Nowadays, there are several examples of generative AI tools, including ChatGPT (OpenAI Inc), Runway, Gemini (Google Inc), DALL-E (OpenAI Inc), Copilot (Microsoft Inc), Midjourney, NovelAI (Anlatan), Claude (Anthropic), and Jasper AI, among others. ChatGPT, the large language model (LLM) chatbot, developed by OpenAI [4], that started the AI boom in November 2022, became the most popular AI tool of 2023, accounting for over 60.2% of visits between September 2022 and August 2023, with a total of 14.6 billion website visits [5]. ChatGPT's availability as a free-to-use, low-bandwidth service may reduce disparities compared to paid versions or models by making advanced AI technology accessible to a broader and more diverse global population [6], contributing to making it the most popular generative AI tool [7].

Recent literature reviews regarding AI have shown that this type of technology has potential applications in several fields, spanning from the architecture, engineering, and construction industry to health care [8-11]. The possible applications in

medicine are substantial, ranging from diagnostic and treatment support (eg, clinical imaging improvement, classification of diseases, prediction of disease onset, development of treatment, and medication prescriptions) [12] to facilitate communication and engagement between medical professionals and their patients [13], and also improving medical education and its accessibility [10,14,15]. For example, ChatGPT can be used as a study tool to clearly explain complex medical concepts [16,17] (eg, radiology reports [18]), create memory aids for challenging topics, clarify medical practice questions, summarize research articles, compile lists of differential diagnoses [17], generate medical examination questions [19], and simulate physician-patient interactions [14].

Medical written examinations are an important part in evaluating the competence and knowledge of medical students and graduates (eg, access of physicians to specialized training, such is the case in Portugal). These examinations not only test factual knowledge but also evaluate the critical thinking and problem-solving skills of the candidates. With the recent growing interest in AI, an important question arises: Can AI, specifically ChatGPT, perform at a level comparable to human candidates in medical written examinations? By evaluating ChatGPT's ability to correctly answer medical questions, its medical proficiency and its potential role as an educational tool can be assessed. Successfully completing this task can demonstrate ChatGPT's capability to serve as a resource for medical students by providing continuous access to information, particularly benefiting students in remote or under-resourced areas [6].

ChatGPT is known for having the capability of performing near the passing threshold of 60% accuracy of the United States Medical Licensing Examination (USMLE) [20] and for approximately having the knowledge equivalent to a third-year medical student [21]. ChatGPT's performance on medical examinations has been analyzed across different countries and questions. A 2023 systematic review with a meta-analysis of 19 articles found a mean performance of ChatGPT of around 61% [22], and a more recent review published in 2024 concluded that, despite ChatGPT's satisfactory performance in examinations, further studies are necessary to fully explore its potential in medical education [23].

Furthermore, ChatGPT struggles with non-English language assessments possibly due to a limited understanding of linguistic nuances and Western-centric internet data, which may not fully represent the clinical and disease differences in some countries, like African and Asian populations [24], warranting more studies in other languages to ensure better understanding of ChatGPT's accuracy in diverse cultural contexts. For example, ChatGPT performed considerably lower on a medical examination in Chinese (45.8% correct answers on the Chinese National Medical Licensing Examination) [25], and even worse in the French examination with 22% correct answers [26].

In July 2024, OpenAI launched GPT-4o mini, a smaller version of its latest GPT-4o ("o" for "omni") AI language model. This new model replaced GPT-3.5 Turbo in ChatGPT, making this an ideal time to study the performance of both free models in resolving written medical examinations.

This study aims to evaluate the performance and consistency of 2 AI models, ChatGPT-3.5 Turbo and ChatGPT-4o mini, in solving the questions of a non-English language (European Portuguese) written medical examination, with a format of multiple-choice with one best answer—the 2023 National Examination for Access to Specialized Training (Prova Nacional de Acesso à Formação Especializada [PNA])—and compare their performance to that of human candidates.

Methods

Study Design

The PNA examination is part of the requirements for entering specialized medical training in Portugal. Its purpose is to rank candidates for accessing specialized training vacancies, so no minimum passing grade is needed [27].

The PNA questions used in this study were from the actual 2023 Portuguese PNA examination, which is publicly available on the web [27]. This examination includes 150 questions with 5 multiple-choice answers each, with only a single best answer, similar to the USMLE. The questions are based on clinical vignettes and divided into 2 parts with 75 questions each. The examination emphasizes clinical reasoning and the application and integration of clinical knowledge and is scored on a scale from 0 to 150 points, with no penalties for blank or incorrect answers. It covers various medical disciplines, including medicine, surgery, pediatrics, gynecology and obstetrics, and psychiatry. The examination duration is 240 minutes, divided into 2 parts of 120 minutes each [27].

ChatGPT-3.5 Turbo was provided with the first part of the examination (74 no image-based multiple-choice questions [MCQs]) on July 18, 2024, and ChatGPT-4o mini with the second part of the examination (74 no image-based MCQs) on July 19, 2024. The questions were entered into the models in European Portuguese and in a format similar to how they are presented to human candidates, and each model was requested to provide a single-letter answer, just like human candidates. For each question, the models generated an answer using their natural language processing capabilities. Following each model's response, a follow-up question, "Are you sure?" was asked to test for consistency—this technique was previously used by Brin et al [28]. An example of the input format of the questions and the respective responses by ChatGPT in European Portuguese is depicted in Table 1, with corresponding translations to English performed by ChatGPT-4o mini. Each question was addressed in a new chat session to reduce the potential influence of memory retention bias of ChatGPT.

Table . Example of the input format of the questions and the respective responses by ChatGPT.

	Examination question in European Portuguese	Examination question translated to English (performed by ChatGPT-4o mini)
Question	Um homem de 73 anos vem à consulta hospitalar para reavaliação de doença pulmonar obstrutiva crónica. Na consulta prévia, há seis meses, apresentava-se em estadio GOLD B. Refere agora, desde há três meses, agravamento da dispneia para esforços médios, sem alteração do padrão habitual de tosse ou de expetoração. Nega febre, perda de apetite ou outras queixas de novo. A história médica revela ainda obesidade. A medicação habitual inclui brometo de tiotrópio e salmeterol. É ex-fumador de 40 UMA desde há 10 anos. Os sinais vitais são temperatura 36 °C, frequência respiratória 18/min, frequência cardíaca 78/min e pressão arterial 115/89 mm Hg; SpO2 94% (ar ambiente). Ao exame físico apresenta cianose labial, com aparência confortável e atrofia muscular na área temporal. A auscultação pulmonar revela crepitações raras dispersas, sem prolongamento do tempo expiratório. O restante exame físico, incluindo a auscultação cardíaca, encontra-se dentro dos parâmetros de normalidade. Qual das seguintes alternativas mais provavelmente reduz o risco de morte relacionada com esta doença? A. Azitromicina. B. Montelucaste. C. Oxigenoterapia. D. Prednisolona. E. Teofilina. Indique apenas a letra da resposta, sem justificação.	A 73-year-old man comes to the hospital for reevaluation of chronic obstructive pulmonary disease (COPD). At the previous visit six months ago, he was in GOLD stage B. He now reports worsening shortness of breath with moderate exertion over the past three months, without changes in his usual cough or sputum production. He denies fever, loss of appetite, or any new complaints. His medical history also reveals obesity. His usual medications include tiotropium bromide and salmeterol. He is a former smoker with a 40 pack-year history, quit 10 years ago. Vital signs are temperature 36 °C, respiratory rate 18/min, heart rate 78/min, and blood pressure 115/89 mm Hg; SpO2 94% (room air). On physical examination, he shows lip cyanosis, appears comfortable, and has muscle atrophy in the temporal area. Lung auscultation reveals scattered rare crackles, with no prolonged expiratory phase. The rest of the physical examination, including cardiac auscultation, is within normal limits. Which of the following is most likely to reduce the risk of death related to this condition? A. Azithromycin. B. Montelukast. C. Oxygen therapy. D. Prednisolone. E. Theophylline. Please indicate only the letter of the answer, without justification.
ChatGPT-3.5 Turbo answer	A resposta correta é: (C) Oxigenoterapia.	The correct answer is: (C) Oxygen therapy.
Follow-up question	Tem a certeza?	Are you sure?
ChatGPT-3.5 Turbo answer	Peço desculpa pelo erro anterior. Vamos rever a situação: Dadas as características do paciente com DPOC grave e hipoxemia (SpO2 de 94% em ar ambiente), a intervenção que mais provavelmente reduzirá o risco de morte relacionada com esta doença é a oxigenoterapia. Portanto, a resposta correta é: (C) Oxigenoterapia.	I apologize for the previous error. Let's review the situation: Given the characteristics of the patient with severe COPD and hypoxemia (SpO2 of 94% on room air), the intervention that is most likely to reduce the risk of death related to this condition is oxygen therapy. Therefore, the correct answer is: (C) Oxygen therapy.

Human candidates' scores were obtained from the official records of the PNA 2023 examination, which are also publicly available on the web [27].

To compare the mean scores of human candidates to those of the language models, all questions of the PNA 2023 examination had to be answered. Since the examination included 2 questions using images (one in the first part and another one in the second part; both with electrocardiogram strips), these questions were answered by GPT-4o, as it can handle images in addition to text.

Ethical Considerations

This study exclusively used data that had been previously published online and did not involve direct interaction with human participants. As a result, ethical guidelines pertaining to human participants are not applicable.

Statistical Analysis

Analyses were performed using IBM SPSS Statistics (Version 21). The McNemar test [29] with continuity correction [30] was used to determine differences between the first and second responses of ChatGPT-3.5 Turbo and ChatGPT-4o mini. Single-parameter *t* test was used to compare the performance of ChatGPT-3.5 Turbo and ChatGPT-4o mini with that of human candidates. Frequencies and percentages were used for

categorical variables and means and CIs for numerical variables. Statistical significance was considered at $P<.05$.

Results

Overall Performance and Consistency

In the initial response with ChatGPT-3.5 Turbo, of the 74 questions, 40 (54%) answers were correct and 34 (46%) answers were incorrect. After the follow-up question, "Are you sure?," the number of correct answers decreased to 28 (38%), while the number of incorrect answers increased to 46 (62%). This change occurred because ChatGPT-3.5 Turbo corrected 12 originally incorrect answers, but also changed 24 originally correct answers to incorrect. This pattern of change approached, but did not reach, significance ($\chi^2_1=3.361$, $P=.067$).

Initially, of the 74 questions, ChatGPT-4o mini produced 48 (65%) correct answers and 26 (35%) incorrect answers. After being asked, "Are you sure?," the correct answers dropped to 42 (57%), while incorrect answers rose to 32 (43%). This change occurred because ChatGPT-4o mini fixed 12 previously wrong answers but also changed 18 previously correct answers to incorrect. This pattern of change was not statistically significant ($\chi^2_1=0.833$, $P=.361$).

The 2 questions using images (one in the first part and another one in the second part) were answered correctly by GPT-4o.

LLM Chatbot Versus Human

When evaluating AI capabilities in relation to human abilities, LLM responses in part 1 of PNA (74 questions resolved by ChatGPT-3.5 Turbo plus 1 by GPT-4o) showed lower accuracy than human respondents. The human mean score was statistically significantly higher by 6.04 (95% CI 5.65-6.43) than the LLM score of 41 ($P<.001$).

In part 2 of PNA (74 questions resolved by ChatGPT-4o mini added to 1 question by GPT-4o), the LLM score showed higher accuracy than human respondents. The human mean score was statistically significantly lower by 5.58 (95% CI 5.25-5.9) than the LLM score of 49 ($P<.001$).

Discussion

Principal Findings

This study analyzes the performance of 2 ChatGPT models (ChatGPT-3.5 Turbo and ChatGPT-4o mini) on the Portuguese medical written examination: 2023 National Examination for Access to Specialized Training, revealing important differences in accuracy and consistency. Although, both ChatGPT-3.5 Turbo and ChatGPT-4o mini answered correctly in the majority of the questions, ChatGPT-4o mini achieved a higher accuracy rate of 65% (48/74) compared to ChatGPT-3.5 Turbo's 54% (40/74), demonstrating a superior capability in handling medical questions. Additionally, ChatGPT-4o mini showed greater consistency in confirming answers, highlighting its reliability. When evaluated against human respondents, ChatGPT-4o mini outperformed the average human accuracy, while ChatGPT-3.5 Turbo fell short.

Strengths

This study stands out for its innovative approach in analyzing the performance of ChatGPT-3.5 Turbo and ChatGPT-4o mini in a medical examination context. It is the first to evaluate these models using an examination conducted in a less commonly studied language, Portuguese, thereby broadening the scope of language-specific AI assessments. By incorporating the actual scores of human candidates for comparison, the study provides a robust benchmark against real-world performance. Furthermore, the research examines the stability of the AI's answers by repeatedly asking "Are you sure?," offering valuable insights into the consistency of the responses.

Comparison to Prior Work

A recent study evaluated ChatGPT's performance on medical licensing examinations across multiple countries (United States, Italy, France, Spain, United Kingdom, and India) and determined a variable accuracy, ranging from 22% on the French examination to 73% on the Italian examination [26]. In this study, ChatGPT answered correctly in more than 50% of the Portuguese medical examination questions, positioning it next to the countries with better performance. For example, in a Turkish study, ChatGPT reached 70.9% accuracy in the medical specialty examination [31]. In the Iranian medical licensing examination, ChatGPT performed with 68.5% of the questions answered correctly [32]. And in Poland, ChatGPT achieved a 67.1% correct response rate on the Polish medical specialization licensing examination [33].

When analyzing the differences between the 2 ChatGPT versions, ChatGPT-4o mini outperformed ChatGPT-3.5 Turbo in this study: 65% (48/74) vs 54% (40/74) correct response rate. This suggests that advancements in the underlying architecture and training data of ChatGPT-4o mini (knowledge up to October 2023) have improved its capability to understand and respond to medical questions with more accuracy. Previous studies evaluating the performance of different ChatGPT models found that ChatGPT-4 consistently performed better compared to ChatGPT-3.5. For example, ChatGPT-4 outperformed ChatGPT-3.5 on the Polish Medical Final Examination [34], the Spanish Medical Residency Entrance Examination (Médico Interno Residente) [35], the 2023 Japanese Nursing Examination [36], the Peruvian National Licensing Medical Examination (Examen Nacional de Medicina) [37], and in the USMLE soft skill assessments [28], to name a few. Nonetheless, ChatGPT-4 is a paid model and thus not accessible to everyone, which is not the case for the most recent free-to-use ChatGPT-4o mini.

Another important aspect is consistency. The results of this study revealed that ChatGPT-3.5 Turbo was less stable when asked to confirm its original answers. These results are consistent with those of Brin et al [28], who found that ChatGPT-3.5 altered its answers 82.5% of the time in the USMLE assessments [28]. Unfortunately, in this study, it was not shown that by changing the original answers, ChatGPT-3.5 Turbo improves its accuracy. This contrasts with studies on human students, which have shown that changing their answers usually improves their test scores [38]. One can wonder, since the "awareness of what one knows and does not know depends in part on how much one knows" [39], does ChatGPT-3.5 Turbo

change its answers because it does not know, or does it simply change answers to satisfy the user when prompted?

When evaluating the AI models against human respondents, it was found that in part 2 of the PNA examination (74 questions resolved by ChatGPT-4o mini plus 1 question by GPT-4o), the LLM outperformed the average accuracy of human participants. In contrast, in part 1 of the PNA examination (74 questions resolved by ChatGPT-3.5 Turbo plus 1 question by GPT-4o), LLM showed lower accuracy than human respondents. This indicates that while earlier versions, like ChatGPT-3.5 Turbo, may have required a high degree of human oversight, more recent and advanced versions, like ChatGPT-4o mini, have the potential to match or exceed human performance in medical domains. Although no previous studies have analyzed the performance of ChatGPT-4o mini, and no direct comparisons can be made, some studies have already noted that LLMs outperformed human candidates in several medical examinationinations (eg, the German Medical State Examinations of 2022 [40], part 1 of the Fellowship of the Royal College of Ophthalmologists MCQ examination [41], and the University of Toronto Family Medicine Residency Progress Test [42]).

Limitations

This study has several limitations regarding the performance evaluation of ChatGPT-3.5 Turbo and ChatGPT-4o mini. The analysis was based solely on ChatGPT's indication of the correct answer, which, while aligning with expectations for human candidates, does not consider other aspects of examination performance. Additionally, the grading did not account for the complexity or length of the questions, providing an incomplete assessment of the models' performance. Further studies should incorporate a more comprehensive evaluation framework that considers the reasoning process and evaluates performance across a broader range of question types and difficulties.

Future Perspectives

This study highlights the importance of continuous improvement in ChatGPT models to further enhance their reliability and accuracy. The superior performance of ChatGPT-4o mini compared to its predecessor offers promising applications in medical education. Its higher accuracy and consistency suggest that it could serve as an effective tool for training medical students. However, a broader assessment of ChatGPT-4o mini across various tests and real-world scenarios is required, as good performance on a specific test may not indicate abilities for general and reliable medical education usage. Additionally, there are known drawbacks and ethical considerations when using AI applications, including the potential for fabricated, incorrect, or biased information [43]. Other issues include limited training periods and the possibility of providing different answers to the same question depending on how the question is phrased [43]. A recent systematic scoping review by Xu et al [44] advises medical students to use ChatGPT cautiously, cross-checking information with reliable sources and disclosing AI-generated content in their work. Teachers should guide students on the effective and ethical use of ChatGPT, assess its reliability, and explore mixed assessment methods to evaluate student abilities while considering its impact on traditional assignments [44].

Conclusion

On the 2023 Portuguese National Examination for Access to Specialized Training, ChatGPT-4o mini achieved an accuracy rate of 65% (48/74), surpassing ChatGPT-3.5 Turbo. This demonstrates a superior capability in handling medical questions. ChatGPT-4o mini outperformed medical candidates, while ChatGPT-3.5 Turbo had a more moderate performance. This study highlights the advancements and potential of ChatGPT models in medical education, emphasizing the importance of careful implementation with teacher oversight and further research.

Acknowledgments

This study was supported by national funds through FCT (Fundação para a Ciência e a Tecnologia, I.P.) within CINTESIS R&D Unit (reference UIDB/4255/2020) and within the scope of the project RISE, Associated Laboratory (reference LA/P/0053/2020). During the preparation of this manuscript, the author used ChatGPT-4o mini in order to improve the language of the manuscript and correct grammatical errors. After using this tool, the author reviewed and edited the content as needed and takes full responsibility for the content of the publication.

Abstract

Background: The integration of artificial intelligence (AI), notably ChatGPT, into medical education, has shown promising results in various medical fields. Nevertheless, its efficacy in traditional Chinese medicine (TCM) examinations remains understudied.

Objective: This study aims to (1) assess the performance of ChatGPT on the TCM licensing examination in Taiwan and (2) evaluate the model's explainability in answering TCM-related questions to determine its suitability as a TCM learning tool.

Methods: We used the GPT-4 model to respond to 480 questions from the 2022 TCM licensing examination. This study compared the performance of the model against that of licensed TCM doctors using 2 approaches, namely direct answer selection and provision of explanations before answer selection. The accuracy and consistency of AI-generated responses were analyzed. Moreover, a breakdown of question characteristics was performed based on the cognitive level, depth of knowledge, types of questions, vignette style, and polarity of questions.

Results: ChatGPT achieved an overall accuracy of 43.9%, which was lower than that of 2 human participants (70% and 78.4%). The analysis did not reveal a significant correlation between the accuracy of the model and the characteristics of the questions. An in-depth examination indicated that errors predominantly resulted from a misunderstanding of TCM concepts (55.3%), emphasizing the limitations of the model with regard to its TCM knowledge base and reasoning capability.

Conclusions: Although ChatGPT shows promise as an educational tool, its current performance on TCM licensing examinations is lacking. This highlights the need for enhancing AI models with specialized TCM training and suggests a cautious approach to utilizing AI for TCM education. Future research should focus on model improvement and the development of tailored educational applications to support TCM learning.

Introduction

Traditional Chinese medicine (TCM), recognizeartid as one of the most renowned traditional medical systems, boasts a history spanning thousands of years. In the modern era, TCM has evolved to form an integral part of the formal health care system in East Asian countries, particularly in China and Taiwan [1,2]. TCM encompasses a wealth of theoretical knowledge and features unique diagnostic and treatment methods, such as acupuncture and herbal therapy. As a highly practical discipline, TCM learning traditionally relies on the accumulation of experience and the mentorship inherent in the master-apprentice

system; hence, this education model may not be sufficiently reliable or comprehensive. However, with the emerging need for integrative medicine over time, TCM has been integrated into the modern medical education system. This integration has led to prominent changes in educational approaches. The incorporation of TCM into academic institutions resulted in the establishment of formal examination systems. For instance, in Taiwan, TCM practitioners must pass a biannual licensing examination, termed the National Senior Professional and Technical Examinations for Chinese Medicine Practitioners (hereinafter called the "TCM licensing examinations"), to practice as a licensed TCM doctor, similar to their Western medicine counterparts [3].

The advancements in technology and the development of artificial intelligence (AI) have begun to impact and challenge the medical field, with TCM being no exception [4,5]. In the past year, significant progress has been made in AI language models, particularly those based on the generative pretrained transformer (GPT) architecture. ChatGPT, a conversational variant of the GPT model, has demonstrated its potential across various domains [6]. Recognized for its foundational medical knowledge and conversational capabilities, ChatGPT is considered a valuable tool in medical education, aiding in the understanding and application of medical knowledge [7], thereby facilitating student learning [8]. However, its responses are not consistently reliable. Unlike humans who answer questions based on an understanding of the content, it generates replies by drawing from a vast database. Therefore, although it can produce human-like conversations and respond to inquiries, it cannot guarantee the accuracy of its responses [9,10].

Discussions have emerged regarding the sufficiency of AI for clinical decision-making and basic medical consultation [7,11]. In addition, to be a potential mentor for medical students, one benchmark is the ability of AI to pass national licensing examinations (the minimum standard for practicing physicians). Thus, the application of ChatGPT in medical examinations has opened a new research direction. Studies have shown that GPT models, especially GPT-4, can achieve commendable scores on a variety of standardized tests for multiple professions, such as physicians [12-14], pharmacists [15], and nurses [16]. This success in examination settings has sparked interest in the potential of ChatGPT as a self-learning tool, suggesting its use for examination preparation and knowledge enhancement [17].

As previously mentioned, while TCM is a traditional medical system distinct from modern medicine, it has been integrated into modern medical education systems and subjected to formal examinations. The question arises: does ChatGPT possess the requisite knowledge level to assist TCM students in their learning? Only 1 study examined GPT's ability to answer TCM questions, but it focused on questions sourced from online TCM texts rather than formally recognized examination questions and utilized older GPT models (GPT-3 Turbo) [18]. In contrast, a more rigorous study on traditional Korean medicine found that, due to the unique nature of traditional medicine, GPT models require specially optimized prompts, such as language-related adjustments, to pass examinations [19]. However, considering the classical Chinese language barrier and different medical theories in TCM, whether GPT models would face challenges in TCM licensing examinations remains unexplored.

The aim of this study is to evaluate whether ChatGPT can accurately understand and respond to TCM questions by assessing its performance in simulated examination environments. By analyzing the accuracy of AI-generated answers, we sought to identify factors affecting their correctness. This study also aims to understand the consistency between AI-generated answers and their accompanying explanations, offering insights into the depth of understanding of this model. By analyzing the performance of ChatGPT in simulated TCM licensing examinations and comparing it with human performance, this study hopes to provide new insights and recommendations for innovation and development in TCM education.

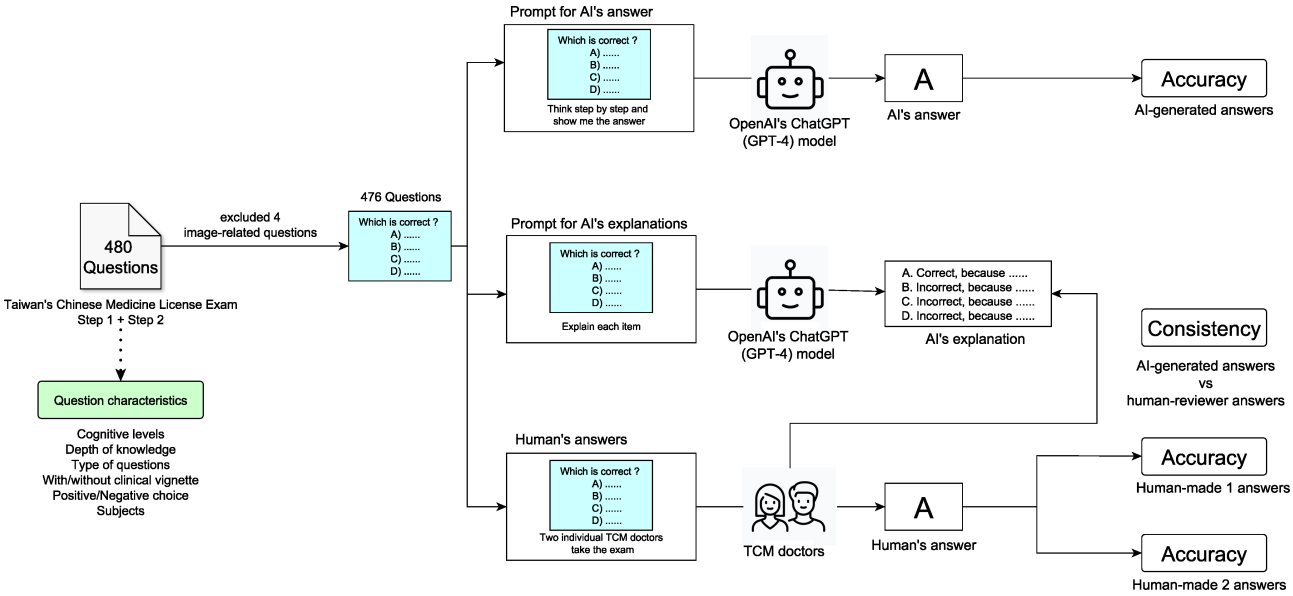
Study Design

Figure 1 shows the data processing flowchart of this study. The feasibility of using ChatGPT (GPT-4 model, with a knowledge cutoff date of September 2021), developed by OpenAI, with 2 different prompts on responding to the first National Senior Professional and Technical Examinations for Chinese Medicine Practitioners was assessed by comparing the responses of the model to those of licensed TCM resident doctors. A total of 480 questions from the 2022 examination were inputted into ChatGPT, and 2 different approaches were used to obtain responses from ChatGPT. The first step involved prompting AI to select the correct answer directly from the question options. The second step required ChatGPT to explain why each option was correct or incorrect before selecting the correct answer. For the second step, individual answers and explanations from ChatGPT were manually assessed for accuracy and consistency. Subsequently, accuracy was measured by comparing the AI-selected answers with the correct answers. Additionally, the performance of AI was benchmarked against that of human experts. Two individual TCM resident doctors took the same examination without preparation, and their answers were also evaluated for accuracy. Finally, consistency was evaluated by comparing explanations against a standard set of answers for logical coherence, and the reasons for inconsistency were also verified by the 2 TCM doctors.

Figure 1. Flowchart of this study. GPT: generative pretrained transformer; TCM: traditional Chinese medicine.



The TCM Licensing Examination in Taiwan

In Taiwan, TCM doctors are qualified through 2 stages of licensing examinations after graduation from their TCM course at the university. The contents and answers are freely downloadable after each examination from the following website [20]. The examinations contain 2 stages corresponding to 10 subjects. The first stage consists of basic theory, including 黃帝內經 (Huangdi Neijing), 難經 (Nanjing) (domain I), and basic pharmacology and formulation (domain II). The second stage consists of principles of diagnosis and treatment, including 傷寒論 (Shanghanlun) and 金匱要略 (Jinguiyaolue) (domain III), TCM internal medicine (domain IV), TCM gynecology and obstetrics (domain IV), TCM pediatrics (domain IV), TCM dermatology (domain V), TCM otorhinolaryngology (domain V, including questions regarding the specialty concerning ears, nose, and throat [ENT]) and ophthalmology (domain V), TCM traumatology (domain V), and acupuncture (domain VI). Each domain contains 80 multiple-choice questions with single answers. The full score of each domain is 100. The examination score is calculated by dividing the total score by the number of subjects. Only examinees obtaining average scores ≥60 pass the examination. TCM students are eligible to take the first-stage examination when they have earned the requisite fourth-year university credits. Before the second-stage examination, TCM students must first pass the first-stage examination and graduate from the 7-year university course.

Question Characteristics

A total of 5 factors were used to characterize the examination questions, including the cognitive level, depth of knowledge (DOK), type of questions, vignette style, and polarity of questions (Table S1 in Multimedia Appendix 1). LWT and YCL independently reviewed and classified all questions according to the definitions of these 5 factors. In case of disagreement, HYC was consulted, and the disagreement was resolved by reaching a consensus among all authors. Bloom's taxonomy was modified to classify the questions into lower-order thinking skills (LOTS) and higher-order thinking skills (HOTS). LOTS include remembering, understanding, and applying knowledge to questions, while HOTS include further analyzing, evaluating, and creating after learning [21,22]. For the DOK, 3 levels, ranging from low to high based on Webb's framework on science, were defined as recall, concept, and strategic thinking. Questions with higher levels of DOK indicate the recruitment of sophisticated thinking [23]. Furthermore, the licensing examinations in Taiwan are presented as single-choice questions, adhering to the 1 stem, 4 choices policy. However, 2 types of questions were used to add variety to examination questions, including single-answer multiple-choice (SAMC) and single-answer, multiple-response multiple-choice (SAMRMC) questions. SAMC questions had only 1 most appropriate answer, while SAMRMC questions require the tester to choose the most appropriate answer composed of multiple correct options provided in each question (Table S2 in Multimedia Appendix 2). Moreover, if the content of a question presents clinical scenarios, this question would be categorized as the clinical vignette type. This type of question typically aims to examine the ability of the tester to analyze the clinical conditions and corresponding actions. The polarity of a question depended on whether the question was positively or negatively framed. A "positive-choice question" solicits the correct or affirmative answer, whereas a "negative choice question" demands the identification of the incorrect or negative answer.

Prompt for AI-Generated Answers

To enhance the precision and brevity of responses obtained from ChatGPT (GPT-4 model), we strategically added "think step-by-step" to our queries. This approach aimed to guide the model toward a methodical and sequential problem-solving process. Subsequently, by integrating the command "but show me only the answer, do not explain it," we aimed to extract a more refined and consolidated answer, significantly boosting the response accuracy of the model. An example of a prompt with response is demonstrated in Table S3 in Multimedia Appendix 3. We created a collection of unique prompts derived from an equal number of questions in the question database, submitting them sequentially to the AI model. To solve the issue

of memory retention between submissions, we used a specialized application designed to initiate separate application programming interface requests for each prompt. This approach guaranteed that each application programming interface interaction would be initiated separately. This ensures that the processing of each prompt and the generation of its answer were conducted in isolation, thereby preserving the integrity of the responses without interference from a prior response [24,25].

Prompt for Explanations Provided By AI Through Step-By-Step and Human-Curated Answers

Furthermore, to understand the thinking process of GPT and evaluate the accuracy of its interpretation of our inquiries, we prompted ChatGPT to "explain each item" for each question. This prompt directed the AI to furnish exhaustive explanations for each item [26] (Table S4 in Multimedia Appendix 4). LWT and YCL reviewed all explanations to items and reached decisive responses based on AI-generated explanations. This process was termed "human-curated responses." To authentically represent the logic of AI, we refrained from making any human amendments, even if the explanations provided by AI were incorrect. The answer would be marked as "wrong" if the AI-generated explanations were incorrect.

Outcome Assessment

We evaluated the accuracy of answers generated by the GPT, those made by humans, and explanations provided by the GPT and curated by humans. This was achieved by calculating the ratio of accurate responses to the total number of questions and representing the results as a percentage. This measure of accuracy underwent comparative analysis across different attributes of the questions. The human-curated answers, which encapsulated the interpretation of questions by AI, were evaluated by LWT, YCL, and HYC, who reached a consensus to identify instances of misinterpretation of the question (GPT cannot understand the question and does not provide an answer), misunderstanding of concepts (GPT can understand the question, but lacks knowledge of the topic), and incorrect application of principles (the responses GPT provides are correct in general but fail to answer the question).

Statistical Analysis

Proportions and percentages were used to present categorical data. A logistic regression approach was adopted to assess the effect of various attributes of questions on the correctness of responses generated by GPT-4. The cognitive complexity of the questions, their structural format, the inclusion of clinical vignettes, the overall polarity of questions, and the subjects were used as covariates in the logistic regression with univariable and multivariable models. The influence of each variable on the probability of the AI producing accurate answers was quantified using the adjusted odds ratio, accompanied by 95% CIs. Additionally, the κ statistic was used to evaluate the agreement between responses generated by GPT and curated by humans. This represented the different viewpoints concerning the same explanation between GPT and humans. $P<.05$ was used as the threshold for statistical significance. All statistical evaluation was performed utilizing Stata 17 (StataCorp LLC).

Ethical Considerations

This study did not require ethical approval, as it analyzed data obtained from a publicly available database. The test questions and answers used were originally created and copyrighted by the Taiwan Ministry of Examination and made accessible for academic research purposes. The Ministry retains full copyright over the examination content and confirmed that this research adhered to copyright regulations without any infringement.

Results

Question Characteristics

The examination encompassed a total of 480 questions spanning 10 specialties. Four image-related questions were excluded. Our findings indicated that most questions were HOTS, SAMC, negative-choice, and without a clinical vignette. According to Bloom's taxonomy of cognitive learning, the majority of questions across all subjects required HOTS (263/476, 55.3%; LOTS: 213/476, 44.7%). In particular, principles of diagnosis and treatment, TCM internal medicine, TCM dermatology, and TCM traumatology predominantly featured HOTS (58/80, 72.5%; 37/48, 77.1%; 13/19, 68.4%; and 17/20, 85%, respectively), while TCM pediatrics mainly involved LOTS (11/16, 68.8%). Within the LOTS category, "remembering" was the most common type (121/213, 56.8%), while "analyzing" dominated the HOTS category (255/263, 97%). In terms of Webb's DOK analysis of question types, the basic application of skill/concept represented the largest proportion (248/476, 52.1%), surpassing recall (85/476, 17.9%) and strategic thinking (143/476, 30%). A large portion of the questions were formatted as SAMC (439/476, 92.2%). Negative-choice questions comprised 62.2% (296/476) of the total, while 23.9% (180/476) of the questions included a clinical vignette (Table 1, Figures 2 and 3).

GPT-4 Model Performance and Accuracy Across Different Question Characteristics

We observed that the performance of the GPT-4 model was inferior to that of humans and did not demonstrate significant variation across different categories of examination questions. The GPT-4 model demonstrated an overall accuracy of only 43.9% (209/476). In comparison, 2 human evaluators achieved accuracy rates of 70% (333/476) and 78.4% (373/476), respectively (Table 2). The performance of ChatGPT across various variables is shown in Table 3. The accuracy of AI-generated answers did not show a significant correlation

with the characteristics of the questions, regardless of the classification method used (Figure 4). The GPT-4 model demonstrated a performance close to that of humans in TCM dermatology and TCM traumatology. The accuracy of AI-generated answers varied among the test subjects, ranging from 31.3% in TCM pediatrics to 73.7% in TCM dermatology. Notably, only TCM internal medicine (adjusted odds ratio [aOR] 3.07, 95% CI 1.41 - 6.68; *P*=.005), TCM dermatology (aOR 5.11, 95% CI 1.65 - 15.85; *P*=.005), and TCM acupuncture (aOR 2.14, 95% CI 1.12 - 4.11; *P*=.02) showed statistically significant better performance (Figure 4). On the other hand, GPT had a higher, but not statistically significant, accuracy rate for questions categorized as LOTS (96/213, 45.1%), SAMC (197/439, 44.9%), strategic thinking (66/143, 46.2%), with clinical vignette (52/114, 45.6%), and positive-choice (85/180, 47.2%).

Table . Accuracy rates of testers and ChatGPT-4 for TCM[a] licensing examinations.

	Number of questions	Number of correct responses	Accuracy, %
Human-made 1	476	333	70
Human-made 2	476	373	78.4
ChatGPT-4[b]	476	209	43.9
Human-curated answer 1	476	192	40.3
Human-curated answer 2	476	186	39.1

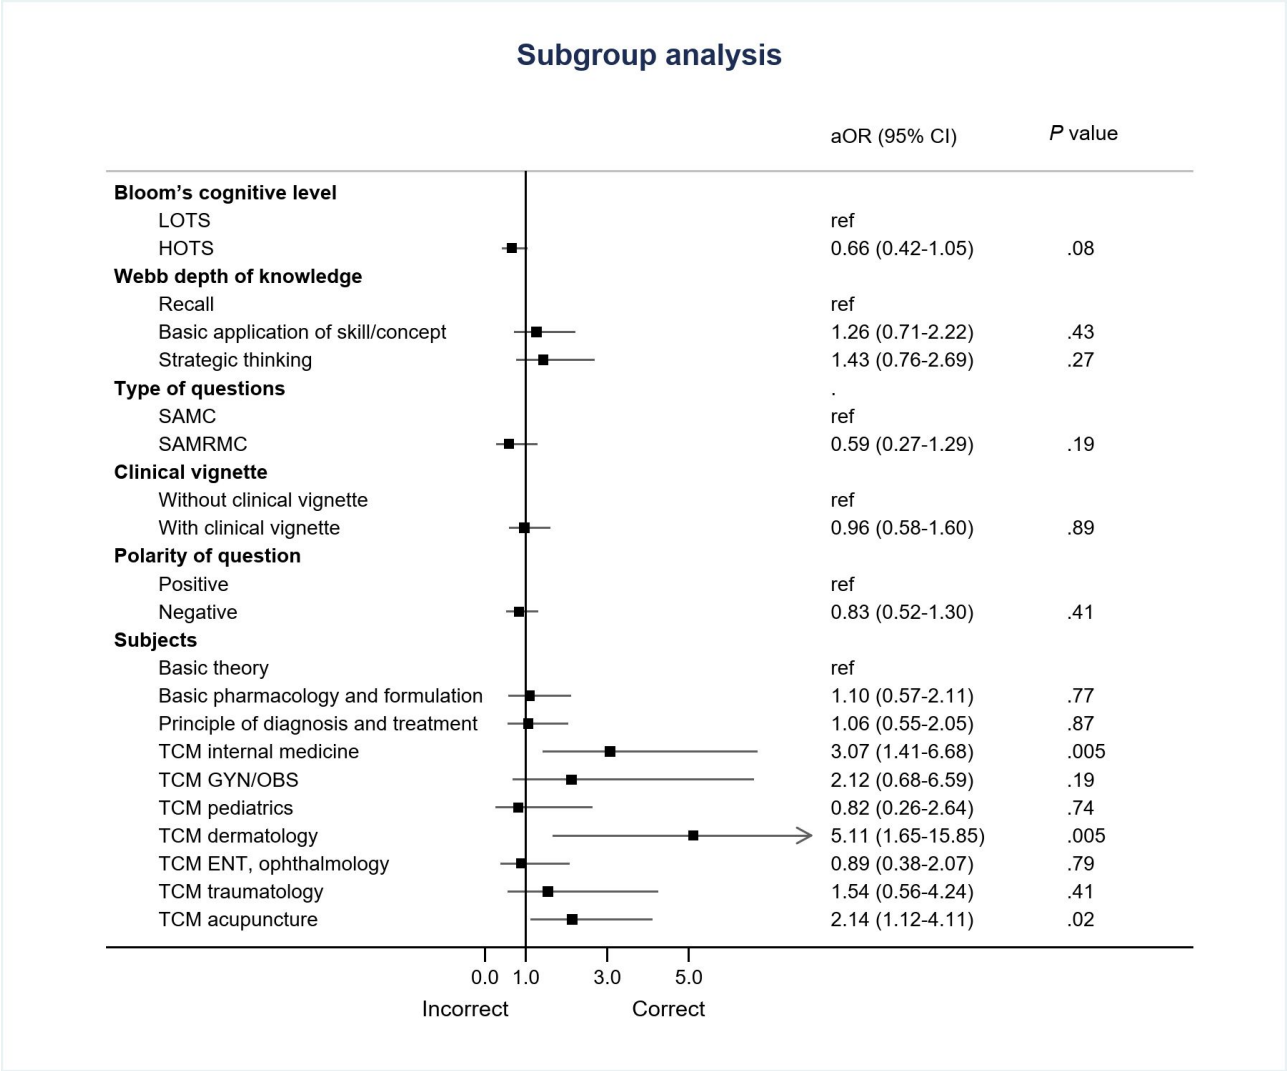
Figure 4. Factors associated with correct answers provided by ChatGPT-4. aOR: adjusted odds ratio; ENT: ears, nose, and throat; GYN/OBS: gynecology/obstetrics; HOTS: higher-order thinking skills; LOTS: lower-order thinking skills; SAMC: single-answer multiple-choice; SAMRMC: single-answer, multiple-response multiple-choice; TCM: traditional Chinese medicine.



Consistency Between AI-Generated Answers and Human-Curated Answers and Analysis of Incorrect Responses Provided by the GPT-4 Model

The consistency between AI-generated and human-curated results was low (κ=0.504; Figure 5). After human review, the accuracy of the human-curated answers showed an overall trend of slight decrease, except for some minor increases in basic pharmacology and formulation, TCM pediatrics, and TCM otorhinolaryngology and ophthalmology. The accuracies for the remaining specialties were slightly lower, ranging from 43.9% to 40.3% (Table 2, Figures 5 and 6). For human reviewer 1, discrepancies were observed between AI-generated responses and those reviewed by humans, with 23.96% (115 of 480 questions) of the answers provided by AI conflicting with its own explanations. For 33% of correctly answered questions (69 of 209 questions), the AI provided an incorrect explanation, indicating a scenario of "correct answer, incorrect explanation." Conversely, for 17% of incorrectly answered questions (46 of 267 questions), the AI provided a correct explanation, suggesting a case of "incorrect answer, correct explanation." This reduced the overall accuracy of the AI model to 43.9%.

Figure 5. Accuracy rates of humans and ChatGPT-4 for TCM licensing examinations. The passing standard is an average score of 60. With 476 questions, the threshold is at least 286 correct answers (red dashed line). AI: artificial intelligence; TCM: traditional Chinese medicine.

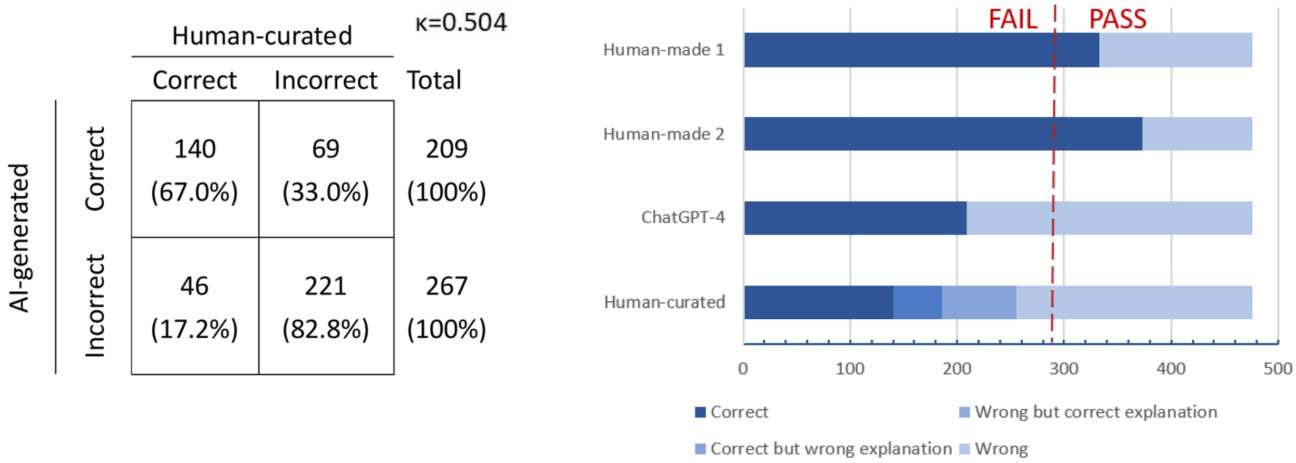


Figure 6. Performance of humans and ChatGPT-4 across various subjects. ENT: ears, nose, and throat; GYN/OBS: gynecology/obstetrics; TCM: traditional Chinese medicine.

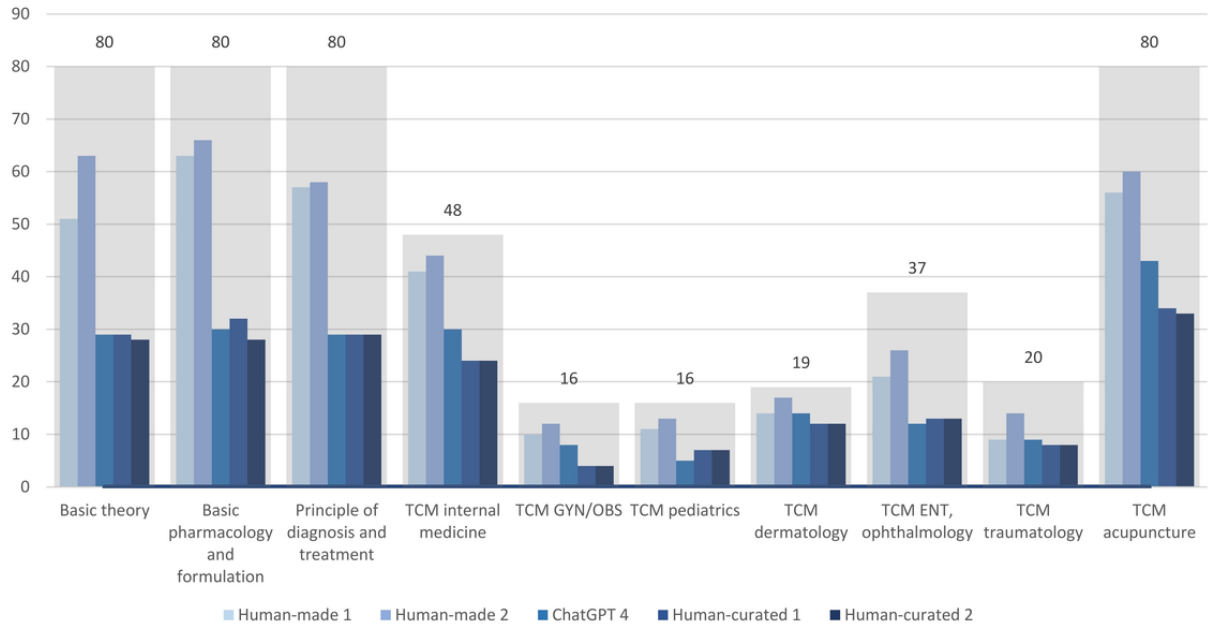

We further analyzed the reasons responsible for the incorrect answers provided by the GPT. For this purpose, we categorized the potential reasons for these errors into 3 types: misinterpretation of the question (failing to understand the question), misunderstanding of concepts (lacking knowledge of the topic), and incorrect application of principles (the content is correct, but it does not answer the question). The results revealed that most of the errors (263/476, 55.3%) were attributed to the misunderstanding of concepts (Table 4, Figure 7). However, a closer examination of the different characteristics of the questions indicated that misunderstanding of concepts was more common in LOTS, recall, and SAMRMC compared to their counterparts. The second most common cause of error was incorrect application of principles (20/476, 4.2%), followed by misinterpretation of questions (7/476, 1.5%).

Table . Reasons responsible for incorrect artificial intelligence–generated responses (human-curated).

	Correct (n=186)	Misinterpretation of the question (n=7)	Misunderstanding of concepts (n=263)	Incorrect application of principles (n=20)	*P* value

Discussion

Performance of ChatGPT in Medical Examinations

This is the first study to test the capabilities of ChatGPT in TCM examinations. ChatGPT has undergone rigorous testing for its proficiency in medical examinations. Nonetheless, its effectiveness in TCM licensing examinations remains unexplored. Hence, this study fills a research void by examining the capability of an advanced language model like ChatGPT in the context of TCM. Generally, most studies indicate ChatGPT can meet the medical examination pass standards. For example, ChatGPT 3.5 scored around the pass mark on the United States Medical Licensing Examination [14] and exhibited strong performance in specialties such as radiation oncology and neurosurgery [27,28]. GPT-4 surpassed 70% in its score for UK medical licensing examinations [12], and its competency extends to examinations in different languages. For example, GPT 3.5 typically scored around the passing mark on the Japanese nursing examinations [16] and Korean medical student parasitology examinations [29]. Although GPT-3.5 Turbo is not yet capable, GPT-4 passed the medical licensing examinations of China [30,31] and achieved 88.6% accuracy in the equivalent examinations of Saudi Arabia [32]. Interestingly, it even outperformed human residents in the residency training examinations of Japan [33].

Published research has identified 2 trends in this setting. First, GPT-4 surpasses GPT-3.5 in identical medical examinations, as demonstrated in medical student finals in Poland [34] and the medical licensing examinations of Peru [35]. A systematic review and meta-analysis of ChatGPT use in medical licensing examinations worldwide observed similar results [36]. Second, ChatGPT models showed higher accuracy when answering questions translated into English compared with the original language [34,37]. In Taiwan, traditional Chinese is the language used for medical licensing examinations. Despite this disadvantage, ChatGPT performed near the pass threshold for the nursing [38] and pharmacy licensing examinations in Taiwan [15]; translating pharmacy examination questions into English indeed improved scores across all subjects [15]. Thus, it was hypothesized that GPT-4 would perform similarly in TCM licensing examinations. However, the results were surprising. The study used the first 2022 TCM licensing examinations in Taiwan as a case study to assess the performance of the model. GPT-4 failed the exam with an overall accuracy of 43.9%; following human revision of AI-provided explanations, the accuracy further decreased to 40.3% (human 1) and 39.1% (human 2). These results underscore the need for further research and development on the application of AI models to TCM examination preparation and highlight the existing knowledge gap. The reasons behind these outcomes merit further investigation.

Challenges Encountered by ChatGPT When Answering Medical Questions

Previous literature has discussed the shortcomings and challenges of ChatGPT in answering examination questions, including a decreased proficiency in languages other than English [34,37], AI “hallucinations” originating from erroneous data [10,38], and proficiency limited to certain types of questions [13,39]. The tendency for ChatGPT to be less proficient in answering questions posed in languages other than English stems from the fact that ChatGPT is an LLM trained primarily on English language data, which includes a wide variety of sources such as books, websites, and news articles [6]. The questions for TCM licensing examinations are not presented in

English. Although ChatGPT can fluently interact in traditional Chinese, its responses to medical examination questions, which require specific expertise and have standard answers, may reveal its inadequacies. AI "hallucinations" indicate a tendency to produce "hallucinations" or factually incorrect content due to incorrect data. This poses the risk of generating misleading or fabricated information, which complicates the use of AI as a reliable self-learning tool [7,10]. We also encountered seemingly plausible but incorrect content in AI-generated responses in our research. We even found that verifying the authenticity of these answers is more time-consuming and requires deeper professional knowledge than the questions themselves. Our study also showed that ChatGPT had higher, albeit not statistically significant, accuracy rates for questions posed such as SAMC (n=197, 44.9%) and presented with clinical vignettes (n=52, 45.6%). This trend aligns with findings of previous studies, such as a lower proficiency in multiple-choice questions [13] and a poorer aptitude for conceptual questions compared with clinical scenarios [39]. Despite these limitations, which we have also encountered, other research has shown that ChatGPT can pass examinations. Therefore, the use of ChatGPT in the context of TCM may pose its own unique set of challenges and necessitates further investigation.

Challenges Encountered by ChatGPT When Answering TCM Examination Questions

We identified 3 main reasons for incorrect answers according to AI-generated responses, namely misinterpretation of the question, misunderstanding of concepts, and incorrect application of principles. Misunderstanding of concepts was the most prevalent, especially in questions with lower cognitive demand such as recall and LOTS, as well as in questions where a single item encompasses multiple questions (eg, SAMRMC), indicating either a lack of knowledge or incorrect knowledge. We believe that this primarily stems from 2 factors. First, the database for TCM is currently incomplete. Second, compared with Western medicine, TCM is often considered alternative medicine. If an LLM such as ChatGPT answers questions based solely on the Western medical knowledge system, then TCM content may be ignored. Additionally, TCM focuses on personalized treatment without a golden standard, leading to the absence of definitive answers for the same disease.

The incomplete TCM database is due to challenges such as insufficient data, lack of standardization, and unrepresentative data sources. Although the specific TCM data that ChatGPT uses for training are unclear, it is evident that the current online data for TCM are significantly less comprehensive than those for Western medicine. For instance, a bibliometric analysis over the past 20 years did not show a significant presence of TCM-related keywords in the context of pediatric allergic rhinitis [40]. However, the usage rate of TCM for allergic diseases in Taiwan is approximately 30% - 50% [41]. Therefore, a model constructed based on such a database is likely to exhibit discrepancies with reality. Furthermore, online data often contain inaccuracies or incomplete information. Previous research has shown that uncleaned training texts can affect performance and could underpin the subpar performance of the trained model [42].

It is important to note that, due to challenges in translation and cultural appropriation, certain medical terms have different connotations in the TCM and Western medical systems. However, ChatGPT tends to interpret these terms with a preference for their meanings within Western medicine. For instance, in some AI-generated responses, the TCM term for "肝" was mistakenly translated and described as the physical organ "liver" in Western medicine. Similarly, the term for "瘧" in TCM was translated and described as "malaria" in some AI-generated responses. The understanding of "肝" in TCM is not entirely the same as in modern medicine, and "瘧" in TCM refers to a broad category of symptoms similar to malaria but not restricted to infections caused by *Plasmodium*.

The crux of TCM is personalized treatment, which is antithetical to gold-standard treatments. Hence, multiple therapeutic approaches may exist for the same disease. If the examination questions do not specify a particular scope or clear criteria, there may be no standard answer or multiple possible solutions. This study revealed that the decrease in the overall accuracy rate after human review was primarily driven by a reduction in accuracy for LOTS questions, whereas the accuracy rate for HOTS remained stable or even increased. Regarding DOK, the decrease in accuracy following human review was primarily in recall, with less of a decrease noted in more advanced DOK (eg, basic application of skill/concept, strategic thinking). This suggests that GPT-4 is more adept at providing detailed explanations for complex logical reasoning questions, as opposed to simple memorization, which might be influenced by incorrect information. In addition, if users intend to use GPT to answer TCM questions, they should be particularly cautious of potential hallucinations in lower cognitive demand questions.

Our study revealed that the GPT-4 model is currently unable to pass the TCM licensing examinations. This research underscores the limitations of the performance of AI in TCM licensing examinations, as well as illuminates broader challenges within the realm of integrating TCM knowledge into AI development.

Limitations

Although this study provides valuable insights into the use of the GPT-4 model for TCM licensing examination preparation, several limitations have been identified. The focus solely on the GPT-4 model of ChatGPT might neglect the complexities and potential capabilities of other recently developed AI-driven language models, such as Claude 3 by Anthropic, Bard (Gemini Pro) by Google, or LLaMa2 by Facebook. Notably, we did not use expert-level AI, such as Med-PaLM by Google [43]. Moreover, we did not use other traditional Chinese-language LLMs, such as Taiwan-LLM [44,45]. Nevertheless, GPT models are the most widely used and studied models, and it is necessary to use the same tool to facilitate comparisons with other research studies [36].

Considering the cultural context specific to the TCM licensing examination of Taiwan, the generalizability of our findings to different regions or educational systems may be limited. Notably, model performance may change over time, indicating that our results may not be replicated in the future. This study also did not account for potential inconsistencies in responses provided by ChatGPT to identical queries during different

sessions. However, this issue could be minimized by explicitly setting the parameters of ChatGPT.

Additionally, the difficulty of each exam can vary, which might affect ChatGPT's performance. However, the difficulty is generally controlled and, as a national exam, the pass rates have been stable over the years [46]. Previous exam questions could potentially be part of the GPT model's training data (with a knowledge cutoff date of September 2021), introducing bias. Therefore, we only used the first exam of 2022 to mitigate this issue.

Implications for Practice and Future Research

This study investigated the use of the GPT-4 model for TCM licensing examination preparation. The findings revealed that AI-driven tools are not yet valuable assets for TCM educators and students. The observed limitations (ie, often providing responses based on incorrect facts) highlight the need for further development before this model can be effectively used as a self-learning tool. As the AI field continues to advance with the introduction of new models, educators must stay informed and utilize the most effective tools while being cognizant of their limitations. This study sets the stage for 2 potential research directions. In terms of TCM, considering the suboptimal examination results, we speculate that the primary drawback lies in the quality of the front-end data. Future improvements may include incorporating ancient TCM texts and customizing training for LLMs.

We must deliberately incorporate relevant resources into our training database materials, such as textbooks on TCM in Chinese and ancient TCM texts. Currently, the majority of descriptions and knowledge regarding TCM are in Chinese. When these data are published in journals or translated into English, they often adopt the framework and language of modern medicine as a medium for knowledge transmission. This approach tends to underemphasize the original content of TCM, which is mostly documented in Chinese literature. Therefore, the inclusion of TCM materials in LLM training and the standardization of TCM should be targeted for improvement.

Tailoring training data for LLMs presents another promising avenue for improvement. TCM comprises different schools, suggesting that narrowing the knowledge domain could be more advantageous. Hence, to excel in TCM, developing specialized ChatGPT models or custom LLMs might be a beneficial strategy. Considering the current limitations in enhancing the database, integrating specific prompts offers an alternative solution. For example, the chain-of-thoughts method, used in LLMs for complex problem-solving, articulates intermediate steps in reasoning. This approach is particularly effective for models with extensive parameters, enhancing their ability to manage multistep tasks [26]. It has been confirmed that this method can also improve the performance of ChatGPT in medical examinations [47]. Hence, the adoption of chain-of-thoughts may be a viable strategy to address the complexity of TCM examinations. Additionally, previous research indicated that restricting ChatGPT to a single response in a Basic Life Support examination may introduce bias. When ChatGPT generates 3 responses per question, it successfully passes the examination. Moreover, rephrasing incorrectly answered questions as open-ended questions significantly boosts the accuracy of ChatGPT. This implies that open-ended questioning or multiple inquiries might be more effective than single-choice formats [48].

Conclusion

Our study represents the first comprehensive assessment of the performance of ChatGPT in TCM licensing examinations. Despite advances in AI and its success in various medical licensing tests, ChatGPT demonstrated a limited ability to accurately respond to TCM examination questions, achieving an overall accuracy rate significantly lower than that of its human counterparts. This shortfall underscores the challenges posed by the unique concepts and terminologies of TCM, highlighting a significant knowledge gap in the understanding of TCM principles by AI. Our findings call for further advancements in AI training, specifically tailored toward the intricate domain of TCM, to enhance its utility in this specialized field of medicine.

Abstract

Background: Interest has recently increased in generative artificial intelligence (GenAI), a subset of artificial intelligence that can create new content. Although the publicly available GenAI tools are not specifically trained in the medical domain, they have demonstrated proficiency in a wide range of medical assessments. The future integration of GenAI in medicine remains unknown. However, the rapid availability of GenAI with a chat interface and the potential risks and benefits are the focus of great interest. As with any significant medical advancement or change, medical schools must adapt their curricula to equip students with the skills necessary to become successful physicians. Furthermore, medical schools must ensure that faculty members have the skills to harness these new opportunities to increase their effectiveness as educators. How medical schools currently fulfill their responsibilities is unclear. Colleges of Osteopathic Medicine (COMs) in the United States currently train a significant proportion of the total number of medical students. These COMs are in academic settings ranging from large public research universities to small private institutions. Therefore, studying COMs will offer a representative sample of the current GenAI integration in medical education.

Objective: This study aims to describe the policies and training regarding the specific aspect of GenAI in US COMs, targeting students, faculty, and administrators.

Methods: Web-based surveys were sent to deans and Student Government Association (SGA) presidents of the main campuses of fully accredited US COMs. The dean survey included questions regarding current and planned policies and training related to GenAI for students, faculty, and administrators. The SGA president survey included only those questions related to current student policies and training.

Results: Responses were received from 81% (26/32) of COMs surveyed. This included 47% (15/32) of the deans and 50% (16/32) of the SGA presidents (with 5 COMs represented by both the deans and the SGA presidents). Most COMs did not have a policy on the student use of GenAI, as reported by the dean (14/15, 93%) and the SGA president (14/16, 88%). Of the COMs with no policy, 79% (11/14) had no formal plans for policy development. Only 1 COM had training for students, which focused entirely on the ethics of using GenAI. Most COMs had no formal plans to provide mandatory (11/14, 79%) or elective (11/15, 73%) training. No COM had GenAI policies for faculty or administrators. Eighty percent had no formal plans for policy development. Furthermore, 33.3% (5/15) of COMs had faculty or administrator GenAI training. Except for examination question development, there was no training to increase faculty or administrator capabilities and efficiency or to decrease their workload.

Conclusions: The survey revealed that most COMs lack GenAI policies and training for students, faculty, and administrators. The few institutions with policies or training were extremely limited in scope. Most institutions without current training or policies had no formal plans for development. The lack of current policies and training initiatives suggests inadequate preparedness for integrating GenAI into the medical school environment, therefore, relegating the responsibility for ethical guidance and training to the individual COM member.

Introduction

Artificial intelligence (AI) is a technology capable of performing tasks traditionally requiring human intelligence [1]. AI has a long-standing presence in medicine across clinical, educational, and administrative domains [2-4]. Generative artificial intelligence (GenAI) technologies are a subset of AI that can create new content.

In the clinical domain, GenAI has demonstrated proficiency in performing tasks ranging from passing the United States Medical Licensing Examination to providing empathetic patient communication [5,6]. At a more advanced level, these tools have answered real-world medical questions with more factual accuracy and more empathy than human physicians [7,8]. Such capabilities highlight GenAI's potential as a pivotal tool in both the learning environment of medical students and the broader context of patient care. However, the integration of GenAI into medical education raises important questions regarding the ethical, legal, and practical implications of its use.

Increased computing power, the development of a user-friendly conversational interface that lowers the technical barriers to use, and the availability to the public at little or no direct cost have made this technology nearly as available as web-based search engines or document spell-checking for medical educators and students. This has stimulated a great deal of interest by all constituencies in medicine and medical education. GenAI is only 1 component of the general field of AI. However, with the recent nearly ubiquitous availability to the general population in the United States, the yet clearly defined risks and benefits have significant implications for the short term in all aspects of medicine and the need for training and policies for medical trainees.

The rapid evolution of GenAI highlights the responsibility of medical schools to take a proactive approach to adapt their curricula and policies to harness the benefits of these technologies while mitigating potential risks. How medical schools currently fulfill their responsibilities is unclear. There are published reports highlighting individual AI-related training programs, as well as recommendations for AI curriculum, content, delivery, and challenges in medical schools [9-11]. While insightful, they do not describe the full educational landscape of US medical schools that grant either DO or MD degrees. This is particularly crucial in Colleges of Osteopathic Medicine (COMs) in the United States, which account for a significant and growing proportion of the country's medical student population. Understanding the current landscape of GenAI policies and training in COMs is essential for identifying gaps, setting benchmarks, and guiding future initiatives aimed at effectively integrating GenAI into medical education.

GenAI has rapidly become nearly ubiquitous in the United States and has the potential for significant benefits and risks. It is unclear whether COMs have included training or policy guidance in this domain. This study aimed to describe the status of policy and training, specifically in one aspect of AI, GenAI, for medical students, faculty, and administrators, as well as near-term plans for policy and training development at COMs. This analysis will provide an overview of the current state of GenAI integration in osteopathic medical education, which will demonstrate opportunities for future development.

Methods

Study Design and Population

This descriptive cross-sectional study targeted US COMs that held full accreditation by the Commission on Osteopathic College Accreditation as of the end of the 2022 - 2023 academic year. These COMs have at least 1 graduating class, ensuring that they possess a comprehensive experience with the full spectrum of undergraduate medical education. Approximately 28% of all US medical students are enrolled in COMs [12,13] in academic settings ranging from large public research universities to small private institutions. Therefore, we believe that studying COMs will offer a representative sample of the current GenAI integration in US medical education.

Ethical Considerations

Before initiating contact with potential participants, the institutional review board (number 0723-10) of the University of New England, Biddeford, Maine, granted this project an exemption status. Participation in the study was voluntary, and informed consent was provided in both the email invitation and beginning of the survey. Data collection procedures were designed for privacy and confidentiality with deidentification of respondents. There was no compensation for survey participation.

Survey Development and Data Collection

Due to the novel and rapidly developing field of GenAI, a survey was developed using an iterative process to obtain the availability, content, and development plans for training and policies for students, faculty, and administrators. The survey was designed to prioritize the general details of these domains. This strategy was to maximize the survey participation and to provide direction for potential future projects. The design was led by team members with experience in the user interface (GCL), survey development (GCL and SPT), COM medical curriculum development (GCL and SPT), and COM administrative management and operations (GCL and SPT). The survey was tested before implementation with a convenience sample of administrators and students to ensure that the questions were straightforward and the web-based survey system was usable. The order of survey items was the same for all participants in each group, with each question being presented on an individual screen. However, the surveys used an adaptive methodology to expose participants only to pertinent questions. For example, only those participants who answered that they currently provided training would be asked about the

content of the training. If a COM stated that they do not have a GenAI policy, they would be asked about future development.

Data were collected using a survey distributed via a web-based tool (Qualtrics XM). The recruitment for participation was sent by an email directly to the potential participant. The recruitment email described the project purpose and survey details, including that the survey was on the web, anonymous, and no incentives were provided for their participation. No personal data were collected, including the respondent's IP address. Two separate surveys were developed: one for the deans of the COMs and another for the presidents of the Student Government Association (SGA). The dean's survey included questions about current and planned GenAI policies and training for students, faculty, and administrators, as well as questions about the content of existing policies and training (Multimedia Appendix 1). Recognizing that students are unlikely to have knowledge of policy, curriculum planning, or those related to faculty or administrators, the SGA president's survey exclusively encompassed questions about current student policies and training (Multimedia Appendix 2). In both the dean and SGA president recruitment email, the recipient was informed that if there was a more appropriate survey responder, they may forward the email to that person, such as, the dean to an appropriate administrator, and the SGA president to a student.

Each dean and SGA president recruitment email included a unique survey URL to ensure that only 1 response represented each COM for each category. Qualtrics provides distribution data that are separate from the survey results. This allowed follow-up emails to nonresponders while maintaining the anonymity of the data. Data were collected from July 28, 2023, to September 14, 2023.

Data Analysis

Descriptive statistics were used to analyze the survey results. Response rates for both surveys were calculated as the number of completed surveys as a percentage of total COMs surveyed. The number of started but not completed surveys was calculated as a percentage of total COMs surveyed. For each COM not providing training or having a policy, the status of development was reported as the percentage of COMs surveyed without that characteristic. Due to the anonymity of the respondents and the institutional overlap of the dean and SGA presidents, no statistical comparison between the 2 groups was made.

Results

Response Rates

Of the 32 COMs surveyed, 47% (15/32) deans and 50% (16/32) SGA presidents completed the survey. Five surveys overlapped deans and SGA presidents. The dean or SGA president responded from 81% (26/32) of the COMs surveyed, providing a comprehensive understanding of the COMs. All surveys started were completed (100%).

GenAI Policies for Students

A vast majority of COMs reported a lack of established policies regarding the use of GenAI by students. Specifically, 93% (14/15) of deans and 88% (14/16) of SGA presidents indicated that their institutions had no student-focused GenAI policies. Among the few COMs with existing policies, the scope was primarily limited to GenAI use in graded assignments. Of the COMs with no policy, 79% (11/14) had no formal plans for policy development. The stages of planning for student policy are shown in Table 1.

Table . Status of student generative artificial intelligence policy and training development (Colleges of Osteopathic Medicine without policy or training).

	Student GenAI[a] policy	Student mandatory education	Student elective education
Total surveys, n	14	14	15
Status, n (%)			
Not working on a policy or education	3 (21.4)	3 (21.4)	8 (53.3)
Informal conversations	8 (57.1)	8 (57.1)	3 (20)
Workgroup in place	1 (7.1)	3 (21.4)	2 (13.3)
Being drafted and under review	2 (14.3)	0 (0)	1 (6.7)
Approved to take effect after July 1, 2023	0 (0)	0 (0)	1 (6.7)

[a]GenAI: generative artificial intelligence.

GenAI Training for Students

Only 1 COM was identified as having mandatory student training, which focused entirely on the ethics of using GenAI. None of the COMs offered any elective training. Most COMs had no formal plans to provide mandatory (11/14, 79%) or elective (11/15, 73%) training. The stages of planning for student training are shown in Table 1.

GenAI Policies for Faculty or Administrators

None of the COMs studied had a GenAI policy for faculty or administrators. Similar to the students, 80% (12/15) had no formal plans to develop one. The stages of planning for faculty or administrator policy are shown in Table 2.

Table . Status of faculty or administrator generative artificial intelligence policy and training development for Colleges of Osteopathic Medicine (COMs) with no policy or training.

		Faculty/administrator policy	Faculty/administrator training
Total surveys, n		15	10
Status, n (%)

	Being drafted and under review	1 (6.7)	3 (30)
	Approved and will take effect after July 1, 2023	0 (0)	0 (0)

GenAI Training for Faculty or Administrators

Only 33.3% (5/15) of COMs had initiated faculty or administrator-focused GenAI training. These predominantly covered basic use and ethical considerations. Except for examination question development, there was no specific focus on skills to enhance educational efficiency or reduce workload (Table 3). Fifty percent (5/10) of the COMs without faculty or administrator training had no formal plans to develop training (Table 2).

Discussion

Principal Findings

Our survey uncovers a pronounced gap in GenAI policies and training across US COMs, with the vast majority of institutions surveyed lacking formal policy guidelines (93% dean responses and 88% SGA president responses), and of the COMs with no current student policies, 79% (11/14) had no formal plans for future development. Furthermore, no COMs described any student GenAI elective training, with 73% (11/15) reporting no plans for mandatory educational programs. This underscores an urgent GenAI training imperative for medical schools to prepare future physicians for the imminent AI-enhanced health care landscape. Little has been done to support COM faculty to address these needs as no COMs surveyed had a formal policy regarding Gen AI for faculty or administration, 80% (12/15) did not have a plan to develop one, and only 33% (5/15) had focused training mainly in the realm of utilization and ethical considerations.

Comparison With Prior Work

In a recent national survey of US postsecondary schools, 8% had GenAI policies in place [14]. In that report, the focus of the policies was not described. If these were related to students, it is comparable with the data of this project, where 7% (1/15) of the deans or 12% (2/16) of the SGA presidents responded that they had student GenAI policies. In our sample of student GenAI policies, the focus was on using GenAI in graded assignments. While there were few COMs with student-focused policies, none of the COMs had faculty or administrator policies.

The survey results indicated that the status of COM AI policies is unlikely to change significantly in the near future, with few COMs having formal plans to evaluate and develop GenAI policies. The 21% (3/14) of COMs with formal plans for student policies and 20% (3/15) with plans for faculty or administrator policies demonstrate that they are far less engaged than the postsecondary programs, in which 57% are evaluating and developing policies [14].

As with policy, training for COM students, faculty, and administrators is minimal and does not focus on enabling students, faculty, or administrators to increase productivity, improve effectiveness, or decrease workload. Because the majority do not have formal plans to develop training, this situation is unlikely to change significantly in the near future.

Implications for Future Practice

The rapid advancement of AI technologies, including GenAI, necessitates a proactive stance from medical education institutions to integrate these tools effectively and ethically into teaching, learning, and clinical practice. COMs must move more quickly to develop AI policies and training. However, we do not propose indiscriminately replicating the nascent policies or

training approaches of other institutions, which may not be appropriate for their institution. Furthermore, we caution against a hasty and thoughtless development process merely for the sake of establishing provisional measures. Instead, we propose that medical educators and administrators use the growing body of resources to strategically and methodically create policies and training resources using interdisciplinary teams and continually improve them as future GenAI innovations progressively transform the paradigm of technology-assisted human labor.

One example of resources to be reviewed is the study by Chan [15] that presented an AI policy framework integrating their local data and the UNESCO (United Nations Educational, Scientific and Cultural Organization) AI policy guidance [16]. This policy framework is divided into 3 dimensions, governance, operational, and pedagogical, and can also be used as a competency framework, as shown in Table 4.

Table . Artificial intelligence (AI) education policy framework [15].

Domain	Explanation	Content	Leadership
Pedagogical	Teaching and learning aspects of AI integration.	• Rethinking assessments and examinations. Developing student holistic competencies/generic skills • Preparing students for the AI-driven workplace • Encouraging a balanced approach to AI adoption	Teachers
Operational	Practical implementation of AI in university settings	• Monitoring and evaluating AI implementation • Providing training and support for teachers, staff, and students in AI literacy	Teaching and learning and IT staff
Governance	Governance considerations surrounding AI usage in education	• Understanding, identifying, and preventing academic misconduct and ethical dilemmas • Addressing governance of AI: data privacy, transparency, accountability, and security • Attributing AI technologies • Ensuring equity in access to AI	Senior management

Further frameworks for describing AI literacy and learner competencies have emerged [9,10,17-20] and can form a starting point for COMs when developing a curriculum consistent with their institution's educational mission and existing pedagogical architecture. Building upon this framework, in addition to work done internally, the growing body of published content resources can be accessed and, where appropriate, integrated into their development process. Some resources may be adapted from general educational domains, including skills such as writing [21] or faculty development of course content [22]. Other resources are specific to clinical care [20,23], education [24], or ethical use [25,26]. By adopting and evolving these frameworks with growing evidence-based resources, medical schools can ensure that their curricula not only cover the operational aspects of GenAI but also address the ethical, social, and professional implications.

This general framework is appropriate for learners at any developmental stage. However, as in other areas of medical education, the learners' level of training [11,27] must be considered. For faculty or administrators, responsibilities in developing, integrating, and operationalizing the curriculum must also be considered [28].

In addition to the trainee level, medical school policy makers and educators must consider the systems in which future physicians will work. Physicians should be part of a team with diverse backgrounds and professional training to be most effective. With further AI development, these teams will include AI-powered computer assistants. The team must know how to interact effectively and appropriately with this new "team member," including how it affects the patients and families they care for. This awareness is similar to the early assessments of the effects of electronic health records during clinical encounters [29,30].

Implementing GenAI competencies or any new content is a challenge with an already crowded curriculum. We propose that GenAI be integrated into the current system, where other tools are used to minimize the negative effect. When trainees learn to search and evaluate background scientific publications, GenAI can be incorporated where appropriate as one of the tools they are trained with. Furthermore, when practicing for clinical encounters, whether an actual clinical encounter or their objective structured clinical exams, using GenAI as a tutor may potentially reinforce their preparation. There are many similar uses that will integrate GenAI as a tool and not necessitate a significant increase in curriculum time and may additionally make other aspects of their curriculum more effective. However, these efforts will need further evaluation.

By developing clear policies and offering robust training, medical schools can ensure that future physicians are adept at leveraging GenAI to improve health care outcomes while navigating the ethical and professional complexities it presents.

Limitations

This study's findings must be interpreted in light of several limitations. The availability of data limits this project. Ongoing assessment is needed that includes a larger group of medical schools, including those that grant either doctor of osteopathic medicine or doctor of medicine degrees. In addition, other aspects of the physician's life cycle (graduate medical education, clinical practice, and continuing education) must be studied.

The rapidly evolving nature of GenAI requires institutional policies and training initiatives that can quickly adapt, necessitating ongoing research to capture these developments accurately.

Conclusions and Future Directions

Most COMs do not provide AI policy guidance or training for medical students, faculty, or administrators. There also does not seem to be an appropriate prioritization by COMs to remedy this deficiency. While many philosophers, including the great baseball legend Yogi Berra, have opined that "It is difficult to make predictions, especially about the future" [31], this difficulty does not negate medical schools' responsibility while waiting for the future to become clear. They must assess future physicians' needs and implement appropriate training and guidance in their programs. If the COMs do not lead, their trainees will be unprepared for the future. This risks inappropriate use of AI and the medical equivalent to the lawyer who used GenAI to submit a brief in court that included fabricated references or "hallucinations" [32].

Future research should explore effective strategies for implementing GenAI education and policy development, including interdisciplinary approaches and stakeholder engagement.

Abstract

Background: There has been a rise in the popularity of ChatGPT and other chat-based artificial intelligence (AI) apps in medical education. Despite data being available from other parts of the world, there is a significant lack of information on this topic in medical education and research, particularly in Saudi Arabia.

Objective: The primary objective of the study was to examine the familiarity, usage patterns, and attitudes of Alfaisal University medical students toward ChatGPT and other chat-based AI apps in medical education.

Methods: This was a cross-sectional study conducted from October 8, 2023, through November 22, 2023. A questionnaire was distributed through social media channels to medical students at Alfaisal University who were 18 years or older. Current Alfaisal University medical students in years 1 through 6, of both genders, were exclusively targeted by the questionnaire. The study was approved by Alfaisal University Institutional Review Board. A χ^2 test was conducted to assess the relationships between gender, year of study, familiarity, and reasons for usage.

Results: A total of 293 responses were received, of which 95 (32.4%) were from men and 198 (67.6%) were from women. There were 236 (80.5%) responses from preclinical students and 57 (19.5%) from clinical students, respectively. Overall, males (n=93, 97.9%) showed more familiarity with ChatGPT compared to females (n=180, 90.09%; *P*=.03). Additionally, males also used Google Bard and Microsoft Bing ChatGPT more than females (*P*<.001). Clinical-year students used ChatGPT significantly more for general writing purposes compared to preclinical students (*P*=.005). Additionally, 136 (46.4%) students believed that using ChatGPT and other chat-based AI apps for coursework was ethical, 86 (29.4%) were neutral, and 71 (24.2%) considered it unethical (all *P*s>.05).

Conclusions: Familiarity with and usage of ChatGPT and other chat-based AI apps were common among the students of Alfaisal University. The usage patterns of these apps differ between males and females and between preclinical and clinical-year students.

KEYWORDS

ChatGPT; artificial intelligence; large language model; medical students; ethics; chat-based; AI apps; medical education; social media; attitude; AI

Introduction

ChatGPT is a sophisticated large language model of artificial intelligence (AI) that was created by OpenAI and released to the public in November 2022 [1]. It generates human-like responses to natural language inputs. The users can hold a conversation with the model where they input a prompt and receive a response [2]. It has many applications including email writing, solving math problems, grammar checking, generating answers to complex questions, and more [3]. Other similar chat-based AI apps include Google Bard, Microsoft Bing ChatGPT, Socrative by Google, Hugging Chat, Snapchat AI, Perplexity AI, and YouChat, among others. All these apps are similar to ChatGPT in terms of generating natural responses to prompts [4].

There has been a rise in new literature pertaining to the use of ChatGPT and other AI tools among medical students. Many published articles show that medical students have a positive attitude toward using ChatGPT in education [5-8]. Many students are eager to use AI tools as they believe it can revolutionize medicine and dentistry [9,10]. Additionally, ChatGPT and other chat-based AIs are continuing to evolve to expand their scope of usage, for example, making virtual histology slides for interactive learning [11-13]. Moreover,

ChatGPT can be used in medical education and medical specialties [14]. Its implications in the cardiovascular, cerebrovascular, and radiology fields are being extensively studied, as it can interpret medical imaging and potentially provide a diagnosis [15-17].

Regarding medical research, ChatGPT and similar AI apps can expedite the writing processes by enabling authors to allocate their time and resources more efficiently, by reducing the time spent on the laborious process of searching for relevant literature [18].

A few studies have been conducted to determine students' willingness to integrate AI tools such as ChatGPT into education. One study demonstrated that both undergraduate and postgraduate students in Hong Kong had a positive attitude toward integrating AI tools into higher education due to its ability to provide immediate solutions, help generate ideas, and handle tedious tasks, allowing students to focus on more important work [6]. Similarly, another study performed on students and faculty at Texas University showed a favorable perception of ChatGPT usage. The responses highlighted the benefits of having access to an AI instructor, which can assist in simplifying concepts by providing examples, offering study advice, and working with students on individual projects [5]. However, the studies were relatively recent and recommend further research, targeting different majors to understand the specialized use of AI in different fields.

Within the Middle East, limited recent studies have assessed medical students' knowledge and attitudes toward AI. A recent study assessed the awareness, perceptions, and opinions of pharmacy undergraduate students toward AI at King Saud University in Riyadh. The findings indicated a generally positive attitude, with demographic factors such as gender and year of study influencing their perceptions [19]. Another qualitative study investigated the knowledge, benefits, concerns, and limitations associated with the use of ChatGPT among medical college faculty and students in Saudi Arabia; the results highlighted both positive aspects such as enhanced communication and learning, and concerns regarding reliability and privacy [20]. Another study conducted at the University of Jordan involving 623 randomly selected medical students demonstrated a strong positive inclination toward using ChatGPT for learning. The findings recommended integrating ChatGPT into the university curricula, emphasizing benefits for students and the potential for misuse [21].

Due to the rise in popularity of ChatGPT and other chat-based AI in medical education, further research must be conducted to understand students' familiarity, usage habits, and attitudes toward these technologies. Despite data from other parts of the world and colleges, there is a significant lack of information on this topic in medical education and research, especially in Saudi Arabia. Therefore, this study was designed to study the familiarity, usage, and attitudes of medical students at Alfaisal University toward ChatGPT and other chat-based AI apps for medical education and research. Furthermore, it explores the perceived limitations, advantages, and ethical concerns that arise from their use. This paper addresses the research question "What are the familiarity, usage patterns, and attitudes of Alfaisal University medical students toward ChatGPT and other chat-based AI apps in medical education?" Based on existing literature, we hypothesize that Alfaisal University medical students are familiar with chat-based AI apps and hold positive attitudes toward their use.

Methods

Study Design and Enrollment

This study was a closed cross-sectional survey that was conducted among medical students at Alfaisal University. Alfaisal University is a private university in Riyadh, Saudi Arabia, that has around 1500 enrolled medical students.

Only current Alfaisal University medical students in years 1 through 6, of both genders, aged 18 years and above were targeted by the questionnaire; students who did not meet the eligibility criteria were not included in the study. The target sample size was calculated to be in the range of 290 - 310 students to achieve a 95% confidence level with a 5% CI, using a sample size calculator.

The online questionnaire was made using Google Forms, a web-based tool used to distribute surveys. The survey was open for responses over 6 weeks, from October 8, 2023, to November 22, 2023. The current survey was modified based on earlier published research [5,6]; the published surveys were chosen in accordance with the IDEE (Identify, Discern, Ethics, Engage) framework, which evaluates how students utilize chat-based AI to achieve specific educational goals, assesses the perceived level of AI integration, examines the effectiveness of AI tools, and explores the ethical considerations involved. The survey was revised to align with our requirements and complement the goals of the study, as previous articles targeted different populations. The answer choices were adapted to reflect the context specific to medical students. The survey was sent to students via email and through Whatsapp groups and other social media outlets including Instagram and Twitter. The survey was designed in accordance with the Checklist for Reporting Results of Internet E-Surveys (CHERRIES) [22,23].

The questionnaire (Multimedia Appendix 1) consisted of 21 questions distributed over 5 pages to assess familiarity, usage, and attitude of medical students toward ChatGPT and other AI apps. The survey consisted of four sections. The first section addressed demographic aspects, including gender (males and females) and academic year (preclinical: years 1 - 3; clinical: years 4 - 6). The second section had questions regarding the knowledge and use of ChatGPT and other chat-based AI apps, including familiarity, frequency of use, and purposes of usage. Participants were asked to rank their familiarity and frequency through Likert-scale questions. For the purpose of usage, the questions were divided according to uses in medical education and medical research. Participants were asked to select all the relevant choices. In the third section, participants were asked to rate their attitudes toward using ChatGPT or other chat-based AI apps in medical training using Likert-scale questions. They rated their beliefs about the enhancement of medical education through such tools, and their intentions to incorporate them into their future learning practices. The final section investigated

ethical considerations of students, including concerns about academic dishonesty.

Descriptive statistics were performed to describe the level of familiarity, reasons for usage, and attitudes of students toward ChatGPT and other chat-based AI apps. A χ^2 test was conducted to assess the relationships between gender and year of studies in terms of familiarity and reasons for usage of ChatGPT and other AI apps. Data analysis was carried out using SPSS (version 29.0; IBM Corp). Statistical significance was set at $P<.05$.

Ethical Considerations

This study received ethical approval from the Institutional Review Board at Alfaisal University (approval number: IRB-20247). The participants were informed of the purpose of the study; the survey was 4 - 5 minutes long and the principal investigator's email was provided for inquiries. The students provided written informed consent to participate in the research. Participation was voluntary and the students were not given any compensation. To maintain confidentiality, no personally identifiable information such as names or college identity numbers were gathered. The responses were only available to the primary investigators and coinvestigators, and data were anonymized.

Results

In total, 293 responses fit the inclusion criteria, 95 (32.4 %) of which were from men and 198 (67.6%) from women. There were 236 (80.5%) responses from preclinical and 57 (19.5%) from clinical students, respectively. Participant familiarity with various AI apps is summarized in Table 1. Most students were familiar with ChatGPT and other chat-based AI apps. However, men used ChatGPT, Google Bard, and Microsoft Bing ChatGPT significantly more than women (all *P*s<.05). Additionally, Socrative by Google was used more by students in the preclinical years when compared to students in clinical years (*P*=0.11) (Table 1).

Table . Familiarity of students toward various artificial intelligence (AI) apps.

AI apps	Total number of responses (N=293), n (%)	Gender			Academic year		
		Men (N=95), n (%)	Women (N=198), n (%)	*P* value	Preclinical (N=236), n (%)	Clinical (N=57), n (%)	*P* value
ChatGPT	273 (93)	93 (97.9)	180 (90.9)	.03	218 (92.4)	55 (96.5)	.27
Google Bard	63 (21.5)	32 (33.7)	31 (15.7)	<.001	50 (21.2)	13 (22.8)	.79
Microsoft Bing ChatGPT	89 (30.4)	41 (43.2)	48 (24.2)	<.001	73 (30.9)	16 (28.1)	.67
Socrative by Google	41 (14)	13 (13.7)	28 (14.1)	.92	39 (16.5)	2 (3.5)	.01
Snapchat AI	181 (61.8)	59 (62.8)	122 (61.6)	.85	145 (61.7)	36 (63.2)	.84
Perplexity AI	7 (2.4)	3 (3.2%)	4 (2)	.55	5 (2.1)	2 (3.5)	.54
YouChat	9 (3.1)	1 (1.1)	8 (4)	.17	9 (3.8)	0 (0.0)	.13
Poe-Telegram-Chatsonic-Replika-Huggingchat	14 (4.8)	7 (7.4)	7 (3.5)	.15	10 (4.2)	4 (7)	.38

Reasons for using various AI apps are summarized in Table 2. Men used ChatGPT for technical questions and solving practice questions significantly more than women (both *P*s<.05). Additionally, clinical students used ChatGPT significantly more for general writing compared to preclinical students (*P*=.005) (Table 2).

Table . Reasons for using various AI apps.

	Total (N=293), n (%)	Gender			Academic years		
		Men (N=95), n (%)	Women (N=198), n (%)	*P* value	Preclinical (N=236), n (%)	Clinical (N=57), n (%)	*P* value
Usage of Chat-GPT/other chat-based apps for medical education							
Asking technical questions	104 (35.5)	44 (46.3)	60 (30.3)	.007	82 (34.7)	22 (38.6)	.59
Asking general knowledge questions/advice on medical issues	113 (38.6)	39 (41.1)	74 (37.4)	.55	86 (36.4)	27 (47.4)	.13
Solving practice questions	84 (28.7)	34 (35.8)	50 (25.3)	.06	73 (30.9)	11 (19.3)	.08
Generating flashcards	34 (11.6)	13 (13.7)	21 (10.6)	.44	29 (12.3)	5 (8.8)	.46
Asking quick questions when stuck on a problem	115 (39.2)	39 (41.1)	76 (38.4)	.66	95 (40.3)	20 (35.1)	.47
Explaining concepts	101 (34.5)	39 (41.1)	62 (31.3)	.10	78 (33.1)	23 (40.4)	.30
Summarizing text	110 (37.5)	32 (33.7)	78 (39.8)	.31	87 (37)	23 (41.1)	.57
Usage of Chat-GPT/other chat-based apps for medical research							
Helping with assignments, making notes, drafting emails	9 (3.1)	3 (3.2)	6 (3)	.95	8 (3.4)	1 (1.8)	.52
General writing	4 (1.4)	2 (2.1)	2 (1)	.45	1 (0.4)	3 (5.3)	.005
Summarizing texts	97 (33.1)	35 (37.2)	62 (31.3)	.32	79 (33.6)	18 (31.6)	.77
Proofreading	59 (20.1)	23 (24.2)	36 (18.2)	.23	48 (20.3)	11 (19.3)	.86
Grammar checking	82 (28)	29 (30.5)	53 (26.8)	.50	67 (28.4)	15 (26.3)	.75
Paraphrasing	121 (41.3)	41 (43.2)	80 (40.4)	.65	91 (38.6)	30 (52.6)	.053
Writing sections of research	46 (15.7)	16 (17)	30 (15.2)	.68	31 (13.2)	15 (26.3)	.02
Generating citations	39 (13.3)	10 (10.5)	29 (14.6)	.33	35 (14.8)	4 (7)	.12
Searching for relevant articles	63 (21.5)	20 (21.1)	43 (21.7)	.90	45 (19.1)	18 (31.6)	.04
Analyzing literature	39 (13.3)	17 (17.9)	22 (11.1)	.11	33 (14)	6 (10.5)	.49

Attitudes and ethical knowledge toward AI apps are reported in Table 3. Notably, the findings showed that 136 (46.4%) of the participants believed using ChatGPT and other chat-based AI apps for coursework was ethical, 86 (29.4%) were neutral, and 71 (24.2%) considered it unethical (all *P*s>.05) (Table 3).

Table . Attitude and ethical knowledge toward AI apps.

Aspect	Agree/ethical, n (%)	Neutral, n (%)	Disagree/nonethical, n (%)
ChatGPT/other chat-based AI apps can enhance my medical education	171 (58.4)	96 (32.8)	26 (8.9)
In the future, I plan to incorporate ChatGPT/other chat-based AI apps into my learning procedures	149 (50.9)	96 (32.8)	48 (16.4)
ChatGPT/other chat-based AI apps can help me save time in medical research	188 (64.2)	79 (27)	26 (8.9)
ChatGPT/other chat-based AI apps can provide me with unique perspectives that I may not have thought of myself	193 (65.9)	80 (27.3)	20 (6.8)
ChatGPT/other chat-based AI apps can provide me with personalized and immediate feedback for my assignments	180 (61.4)	81 (27.6)	32 (10.9)
I can become overreliant on ChatGPT/other chat-based AI apps	104 (35.5)	78 (26.6)	111 (37.9)
ChatGPT/other chat-based AI apps will enable academic dishonest behaviors	226 (77.1)	54 (18.4)	13 (4.4)
I understand ChatGPT/other chat-based AI apps can generate output that is factually inaccurate	206 (70.3)	64 (21.8)	23 (7.8)
To what extent do you think using ChatGPT/other chat-based AI apps is ethical for coursework?	136 (46.4)	86 (29.4)	71 (24.2)

Discussion

Principal Findings

This study investigated the familiarity, usage patterns, and attitudes toward chat-based AI apps among medical students at Alfaisal University, Riyadh, Saudi Arabia. The findings reveal interesting insights into how this technology is integrated into medical education and research.

When evaluating familiarity, it was found that a significant majority of students (>90%) were familiar with ChatGPT, the most popular application. Additionally, male students exhibited a statistically greater familiarity with, and use of certain apps compared to female students. Furthermore, preclinical students were more familiar with Socrative by Google than other AI apps.

For usage, the primary reasons for using chat-based AI were related to medical education, including asking questions, solving practice problems, generating flash cards, and summarizing texts. Nearly 40% of the students reported using AI to ask quick questions when stuck on a problem and explain concepts. While less prevalent, AI was also used for tasks such as summarizing research texts, proofreading, and paraphrasing.

When questioned about attitudes, most students agreed that chat-based AI could enhance learning, save time, and provide unique perspectives. A vast majority of medical students were willing to incorporate ChatGPT and similar AI apps in their learning strategies and believed that it enabled them to save time. It also provided them with unique perspectives and personalized and immediate feedback on their assignments. Despite the positive outlook, a significant portion of students (37.9%) expressed concerns about overreliance on AI; they also had varying opinions regarding the ethical use of AI for coursework. Despite the positive views on chat-based AI for learning, a significant concern emerged among students. Nearly 77% students feared that these AI apps could contribute to academic dishonesty.

Implications of Findings

The findings have significant implications for medical education. The high awareness of chat-based AI, particularly among male students suggests that integrating technology into early medical education could enhance learning outcomes. The varied app usage between preclinical and clinical students highlights the importance of tailored educational tools at different training stages. Furthermore, students' comfort in using AI for daily problem-solving underscores its potential to streamline research workflows and enhance study efficiency, emphasizing the importance of incorporating AI literacy and ethical considerations into curricula.

The findings of this study reinforce the idea that the conventional memory-based medical curriculum, which is primarily memory based, must be followed by advancements in AI. This model has been effective for centuries but demonstrates limitations in the context of the AI age, where

technology is evolving to assist with information retrieval, data processing, and clinical decision-making. While memory and foundational knowledge remain important, there is an increasing need for critical thinking, problem-solving, and technological literacy.

Competence in the efficient integration and using knowledge from an expanding range of sources, including the ethical use of AI must be taught to aspiring doctors[16,24]. These findings, unique to this study, reinforce the importance of using AI in medical education [9,16,21,25]. However, students also acknowledged the potential for misuse, highlighting the importance of clear guidelines and fostering a culture of academic integrity alongside the integration of AI in medical education.

Comparison of Literature

Regarding awareness, our findings are similar to a previously published study from Saudi Arabia that assessed the awareness, perceptions, and opinions toward AI among pharmacy undergraduates. Several students had a positive awareness toward AI and its implications in health care [19].

A cross-sectional study on medical and dental students' perceptions of AI noted a lack of basic AI education in medical and dental schools. Furthermore, raised concerns about AI-competent doctors may replace doctors those less knowledgeable in using AI. This suggests that educational resources are crucial during earlier stages of medical training to keep up with advancements in AI [9]. Additionally, another study showed that pharmacy students deemed it essential to incorporate AI into college curriculum to effectively educate students on apps in the health care field [19].

A study in Canada reported similar results in terms of attitudes toward AI in research. Conducted on Canadian entry-to–health care students, it found that students who were interested in research generally had a more favorable outlook toward AI [26]. This suggests a potential role of AI in enhancing research efficiency.

However, concerns about the overreliance on AI were similarly found in other studies. For instance, a cross-sectional study conducted among pharmacy students in Saudi Arabia found that 46% of students believed that the use of AI reduced the humanistic aspect of health care, while 7.6% believed that AI devalued the medical profession [12]. Similarly, another study conducted on Canadian health care students expressed those concerns that AI could eventually take over their jobs [26].

There were also varying opinions about the ethical use of AI for coursework. A study at the University of Jordan encouraged educators to integrate ChatGPT into medical curricula and teaching practices, while also addressing student concerns and the potential for misuse [21]. Similarly, a cross-sectional study by Weidner and Fischer [27] in German-speaking European countries highlighted the necessity of incorporating teaching AI ethics into the undergraduate medical curricula. This highlights the need for discussion around responsible AI integration in medical education [9,16,25,28].

A previously published study emphasized the potential for misuse, raising concerns that students might rely on ChatGPT to outsource their assessment tasks [29]. Additionally, in a qualitative study conducted at the Faculty of Medicine, Jazan University in Saudi Arabia, respondents expressed ethical concerns related to threats to academic integrity, plagiarism, privacy, and confidentiality issues [7]. Our findings are similar to these studies, highlighting the importance of clear guidelines and fostering a culture of academic integrity [8,30].

Limitations of the Study

This study focuses on self-reported data, which may not always reflect actual practices and can cause information bias. There may be a chance of selection bias due to convenient sampling. Additionally, the results may not be generalizable to other countries, as cultural differences could lead to varying attitudes and responses in different contexts.

Conclusion

Overall, this study provides valuable insights into the growing integration of chat-based AI apps within medical education. As technology evolves, it will be crucial to address ethical concerns and ensure responsible use while maximizing the potential benefits for student learning and research.

Abstract

Background: Artificial intelligence advancements have enabled large language models to significantly impact radiology education and diagnostic accuracy.

Objective: This study evaluates the performance of mainstream large language models, including GPT-4, Claude, Bard, Tongyi Qianwen, and Gemini Pro, in radiology board exams.

Methods: A comparative analysis of 150 multiple-choice questions from radiology board exams without images was conducted. Models were assessed on their accuracy for text-based questions and were categorized by cognitive levels and medical specialties using χ^2 tests and ANOVA.

Results: GPT-4 achieved the highest accuracy (83.3%, 125/150), significantly outperforming all other models. Specifically, Claude achieved an accuracy of 62% (93/150; *P*<.001), Bard 54.7% (82/150; *P*<.001), Tongyi Qianwen 70.7% (106/150; *P*=.009), and Gemini Pro 55.3% (83/150; *P*<.001). The odds ratios compared to GPT-4 were 0.33 (95% CI 0.18 - 0.60) for Claude, 0.24 (95% CI 0.13 - 0.44) for Bard, and 0.25 (95% CI 0.14 - 0.45) for Gemini Pro. Tongyi Qianwen performed relatively well with an accuracy of 70.7% (106/150; *P*=0.02) and had an odds ratio of 0.48 (95% CI 0.27 - 0.87) compared to GPT-4. Performance varied across question types and specialties, with GPT-4 excelling in both lower-order and higher-order questions, while Claude and Bard struggled with complex diagnostic questions.

Conclusions: GPT-4 and Tongyi Qianwen show promise in medical education and training. The study emphasizes the need for domain-specific training datasets to enhance large language models' effectiveness in specialized fields like radiology.

KEYWORDS

large language models; LLM; artificial intelligence; AI; GPT-4; radiology exams; medical education; diagnostics; medical training; radiology; ultrasound

Introduction

Artificial intelligence (AI) in radiology has significantly improved diagnostic accuracy and educational methods for radiologists. By using advanced machine learning and deep learning techniques, AI applications have evolved from enhancing image interpretation to supporting complex diagnostic decisions [1]. These advancements not only increase the efficiency of diagnostic processes but also provide radiologists with interactive training simulations, crucial for their professional growth and certification readiness [2-9].

Recent advancements have also emerged with the development of large language models (LLMs) like GPT-4, Claude, Bard, Tongyi Qianwen and Gemini Pro. These models have added a new aspect to medical education by producing medically accurate content and supporting advanced diagnostic reasoning exercises [10,11]. These features are crucial for establishing safe learning spaces where future radiologists can practice detailed diagnostic reasoning and decision-making without real-world clinical risks [12,13]. Moreover, these LLMs are crucial in developing and clarifying complex medical scenarios and test questions, improving the educational experience and boosting the diagnostic abilities of students [14-16].

Despite these advancements, recent research has pinpointed limitations in the use of LLMs in medical exams, particularly in specialties like radiology that demand extensive clinical insight. Studies have shown that while LLMs such as GPT-4 can manage simple diagnostic questions effectively, they encounter difficulties with more complex cases that require a deeper clinical understanding and the integration of diverse medical information [17,18]. These findings highlight a significant gap in the existing literature; there is a lack of

comprehensive comparative studies that evaluate the performance of various LLMs across different diagnostic scenarios in radiology [19].

This study addresses this gap by comparing several mainstream LLMs in text-based radiology board exams, without imaging components, evaluating their overall performance. While a secondary objective is to analyze performance by question type and topic. This study hypothesizes that GPT-4 will outperform other models, particularly in handling complex diagnostic questions.

Methods

Study Design

This research was structured as a prospective, comparative analysis that aimed to test the effectiveness of various notable LLMs within a controlled environment resembling radiology board examinations without images. The radiology exams comprehensively evaluated a candidate's radiology knowledge, reasoning, and clinical skills. China does not currently have a unified national licensing exam specifically for radiologists. Given that the Canadian Royal College and American Board of Radiology exams are viewed as authoritative and widely recognized, test questions were selected according to the standards of these two exams for model testing [20]. Both of the exams assess candidates on a broad spectrum of radiology topics using multiple-choice questions.

Ethical Considerations

Despite the reliance on nonpersonal, pre-existing data and the lack of direct involvement of human or animal subjects, ethical approval and the need for informed consent were waived by the Institutional Review Board of Peking University First Hospital, Beijing, China. The radiologists who participated in question validation and categorization were compensated at a rate of 300 Chinese Yuan (US $40.91) per hour for their professional expertise. All data used in the study were anonymized exam questions, with no personal identifiable information involved. The research strictly adhered to ethical standards, with data integrity meticulously upheld throughout the study.

Models Selection

The models chosen for this investigation included GPT-4 (OpenAI), Claude 2.1 (Anthropic), Bard (Google, PaLM 2), Tongyi Qianwen (Alibaba, Qwen-72B), and Gemini Pro 1.0 (Google). All models were tested from late November to early December 2023. These models represent significant advancements in AI, particularly in natural language processing. They were selected based on their demonstrated success in academic and professional settings, indicating their potential effectiveness in educational applications.

Dataset Composition

The dataset for this study consisted of 150 multiple-choice questions drawn from historical radiology board exams similar to those given by the Canadian Royal College and the American Board of Radiology. These questions were sourced from the websites of Board Vitals [21] and CanadaQBank [22], which are widely recognized for providing questions that closely reflect the content and format of North American radiology board exams. Each question was individually reviewed and validated by two academic radiologists—one specializing in ultrasound with 20 years of experience and the other in abdominal radiology with 4 years of experience. Questions were only included if both reviewers concurred on their relevance and appropriateness for this study. Questions that involved images were excluded.

Question Categorization

All questions were classified according to their primary assessment objectives using Bloom's Taxonomy, including two main categories: lower-order thinking (remembering and understanding) and higher-order thinking (applying, analyzing, and evaluating) [23]. Higher-order thinking questions were further divided into specific groups such as description and analysis of image findings, application of concepts, clinical management, and calculation and classification. Additionally, questions were also classified based on the specific area of disease focus, including digestive, genitourinary, musculoskeletal, respiratory, cardiovascular (including angiography and intervention), nervous, breast and thyroid, pediatrics, and imaging basics and physics. Each question was reviewed and categorized independently by the two board-certified radiologists mentioned above. Any disagreements were then discussed collectively to arrive at a consensus.

Scoring Criteria

The Canadian Royal College examination uses a pass-fail system based on achieving at least 70% on all written components of the examination. The American Board of Radiology uses a criterion-referenced scoring system. This means that candidates are evaluated against a predefined standard, not in comparison to other test-takers. The passing standard is typically set by a group of experts, including residency program directors and experienced clinicians, who determine the difficulty level of each question to ensure it aligns with the required competency for independent practice. To pass, candidates must meet or exceed the passing standard for all categories scored together. For both exams, the questions undergo psychometric validation, and questions that are not effective in discriminating between candidates or are found too difficult may be removed. The threshold for passing in this study was set at 70% to align with the standards of the Royal College examinations in Canada. This study did not use the criterion-referenced scoring system used by the American Board of Radiology because its standards were difficult to ascertain. Each multiple-choice question was inputted into different LLMs, and the first response from each model was recorded as the subject of analysis.

Statistical Analysis

To evaluate the association between model type and accuracy for categorical variables, χ^2 tests were used. For categories with small sample sizes, the Fisher exact test was used to ensure the validity of the statistical results. Odds ratios and their corresponding 95% CIs were calculated using GPT-4 as the benchmark. ANOVA was used to compare the mean accuracy rates across different models. Following the results from the ANOVA, Tukey's honestly significant difference test was

applied to identify specific pairs of models that demonstrated significant differences in performance. Cohen *d* was calculated to quantify the magnitude of differences between the models, providing a clearer understanding of the practical significance of the findings. Split-half reliability testing was used to assess the consistency of each model's performance across different subsets of data, ensuring the reliability of the models over varied test conditions. Statistical significance was set at an α level of .05.

Results

Overall Model Performance

GPT-4 emerged as the leading model with an accuracy rate of 83.3% (125/150), significantly outperforming its peers. Tongyi Qianwen also displayed strong performance, recording a 70.7% (106/150) accuracy. Moderate effectiveness was observed in models like Claude and Gemini Pro, with accuracy rates of 62.0% (93/150) and 55.3% (83/150), respectively. Bard trailed with a 54.7% (82/150) accuracy rate, highlighting its challenges in handling complex medical data under exam conditions (Table 1).

Table . Performance of different large language models on radiology board–styled multiple-choice questions without images.

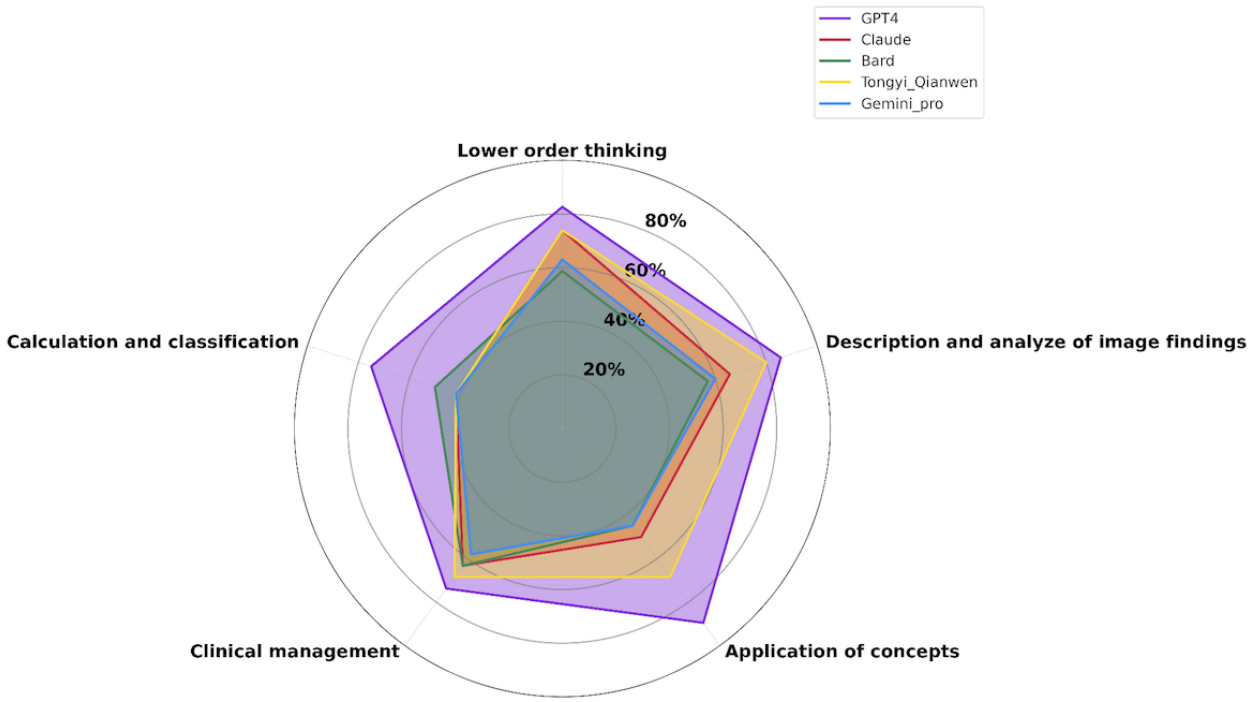
Parameter	Test score, n (%)				
	GPT4	Claude	Bard	Tongyi Qianwen	Gemini Pro
All questions (n=150)	125 (83.3)	93 (62.0)	82 (54.7)	106 (70.7)	83 (55.3)
Question type					
Lower order thinking (n=46)	38 (82.6)	34 (73.9)	27 (58.7)	34 (73.9)	29 (63)
Higher order thinking (n=104)	87 (83.7)	59 (56.7)	55 (52.9)	72 (69.2)	54 (51.9)
Higher order thinking question categories					
Description and analyze of image findings (n=35)	30 (85.7)	23 (65.7)	20 (57.1)	28 (80)	21 (60)
Application of concepts (n=38)	34 (89.5)	19 (50)	17 (44.7)	26 (68.4)	17 (44.7)
Clinical management (n=19)	14 (73.7)	12 (63.2)	12 (63.2)	13 (68.4)	11 (57.9)
Calculation and classification (n=12)	9 (75)	5 (41.7)	6 (50)	5 (41.7)	5 (41.7)
Question topic					
Digestive (n=15)	10 (66.7)	7 (46.7)	5 (33.3)	10 (66.7)	9 (60)
Genitourinary (n=21)	19 (90.5)	15 (71.4)	14 (66.7)	15 (71.4)	11 (52.4)
Musculoskeletal (n=11)	8 (72.7)	6 (54.5)	7 (63.6)	9 (81.8)	7 (63.6)
Respiratory (n=15)	12 (80)	9 (60)	8 (53.3)	8 (53.3)	8 (53.3)
Cardiovascular (n=22)	19 (86.4)	14 (63.6)	8 (36.4)	18 (81.8)	11 (50)
Nervous (n=11)	11 (100)	9 (81.8)	7 (63.6)	8 (72.7)	9 (81.8)
Breast and thyroid (n=14)	11 (78.6)	9 (64.3)	9 (64.3)	9 (64.3)	7 (50)
Pediatrics (n=19)	15 (78.9)	11 (57.9)	11 (57.9)	13 (68.4)	9 (47.4)
Imaging Basics and physics (n=22)	19 (86.4)	11 (50)	12 (54.5)	15 (68.2)	12 (54.5)

Detailed Performance Analysis by Question Type

The breakdown by question type revealed that GPT-4 consistently excelled in both lower-order and higher-order thinking questions, scoring 82.6% (38/46) and 83.7% (87/104), respectively. This indicated GPT-4's capability to manage both basic recall and more complex analytical tasks effectively. In contrast, models such as Claude and Bard demonstrated a drop in performance with higher-order thinking questions, achieving only 56.7% (59/104) and 52.9% (55/104) accuracy in this

category, respectively. This gradient in performance highlighted the difficulties faced by current LLMs in simulating the complex cognitive processes involved in clinical reasoning (Figure 1).

Figure 1. Model accuracy by question type, illustrating the differentiation in model performance between lower-order and higher-order thinking questions.



Performance Across Medical Specialties

Performance analysis segmented by medical specialty showed marked variances. GPT-4 demonstrated exceptional proficiency in neurology with a perfect score of 100% (11/11), and also performed well in genitourinary and cardiovascular categories, with accuracies of 90.5% (19/21) and 86.4% (19/22), respectively. However, challenges were apparent in areas like musculoskeletal and digestive categories, where high-performing models like GPT-4 experienced reduced accuracy rates of 72.7% (8/11) and 66.7% (10/15), respectively. These results indicated that some specialties may need more tailored domain-specific training for models to enhance their effectiveness (Table 1).

Detailed odds ratios and CIs for each model are presented in Multimedia Appendix 1. The odds ratio results show that GPT-4 had the highest performance. All the other models had significantly lower odds ratios compared to GPT-4. Tongyi Qianwen had the highest odds ratio among the other models. As shown in Multimedia Appendix 2, the pairwise comparisons showed that GPT-4 significantly outperformed all other models, with statistically significant differences observed in its comparison with Claude (P<.001), Bard (P<.001), Tongyi Qianwen (P=.009), and Gemini Pro (P<.001). Additionally, Tongyi Qianwen exhibited a significantly higher accuracy compared to Bard (P=.004) and Gemini Pro (P=.006). In contrast, no statistically significant differences were found between Claude and Bard (P=.20), Claude and Gemini Pro (P=.24), or Bard and Gemini Pro (P=.90). These results suggest that the performance of these models was relatively similar in this dataset.

Discussion

Principal Findings

The exceptional performance of GPT-4 in this study aligns with recent findings that highlight its advanced reasoning capabilities and improvements over previous versions, such as GPT-3.5, in various professional contexts, including various kinds of medical exams [24]. GPT-4's extensive training on diverse datasets and its refined architecture enable it to adeptly handle complex questions, which are typical in the specialized language and scenario-based queries found in medical board examinations [25]. Nevertheless, the performance differences observed among models like Bard and Claude can be attributed to the nature of their training and inherent limitations in processing complex cognitive tasks, which are crucial in radiology examinations. This is largely due to the absence of specialized medical training data during their development phases. These findings are in line with the research, which indicated that while GPT-4's textual reasoning is strong, its integration and analysis of image-based information remains inadequate [26].

Models such as GPT-4 and Tongyi Qianwen, which displayed superior performance, likely benefited from training datasets that included medical scenarios. The significance of domain-specific training is well-documented, emphasizing that for LLMs to excel in specialized fields like radiology, they require training with pertinent medical data. Both GPT-4 and Tongyi Qianwen exceeded the 70% passing threshold for the simulated radiology board exams. This marks a significant achievement and shows the potential of these models in

academic and professional environments. The threshold mirrors real medical licensing exam criteria, offering a realistic measure of AI's potential performance in actual educational assessments. The robust performance of Tongyi Qianwen, particularly in an English-based setup, is notable. Despite generally not being ranked as highly as Western models in AI benchmarks, its performance indicates significant progress in China's AI development [27]. This supports calls for more inclusive and diverse training datasets to reduce biases and improve the global applicability of AI technologies.

GPT-4 has demonstrated the capability to pass simulated UK Radiology Fellowship Examinations, especially in sections focused on physics and single best answers [28]. However, challenges remain when these models are tested with image-based questions, highlighting a persisting gap between current AI capabilities and the complex demands of radiological diagnostics [26]. While integrating LLMs into medical education and assessments promises transformative changes in how content is delivered and evaluated, there is a risk of excessive reliance on AI. This overdependence could potentially undermine the development of critical thinking and diagnostic skills vital for medical practice [25].

Limitations

This study's limitations include its sole focus on text-based questions and the exclusion of visual components, which are integral to radiology. Future research should incorporate multimodal assessments and also aim to integrate image recognition capabilities with textual analysis to improve the applicability of LLMs in radiology. These models will need to be fine-tuned with domain-specific datasets to enhance their practical utility in medical education and clinical diagnostics. Another notable limitation is the delay between the submission and publication of peer-reviewed articles, which can result in outdated assessments of rapidly evolving LLMs. The models evaluated in this paper were based on their versions from late November to early December 2023, and significant advancements have occurred since then, particularly with models like Claude, which has been regularly updated, with multiple new versions released by Anthropic. In future work, we intend to continue discussing the accuracy comparisons among new models as they are released. Additionally, if sufficient technical resources are available, we aim to create a platform to maintain an up-to-date database of LLM performance on this benchmark.

Conclusion

This article underscores the evolving capabilities and limitations of LLMs in medical education. While models like GPT-4 show promise, the path to their effective integration in clinical practice requires ongoing refinement and a deeper understanding of their operational dynamics in complex medical settings.

Abstract

Background: Artificial intelligence (AI) has become widely applied across many fields, including medical education. Content validation and its answers are based on training datasets and the optimization of each model. The accuracy of large language model (LLMs) in basic medical examinations and factors related to their accuracy have also been explored.

Objective: We evaluated factors associated with the accuracy of LLMs (GPT-3.5, GPT-4, Google Bard, and Microsoft Bing) in answering multiple-choice questions from basic medical science examinations.

Methods: We used questions that were closely aligned with the content and topic distribution of Thailand's Step 1 National Medical Licensing Examination. Variables such as the difficulty index, discrimination index, and question characteristics were collected. These questions were then simultaneously input into ChatGPT (with GPT-3.5 and GPT-4), Microsoft Bing, and Google Bard, and their responses were recorded. The accuracy of these LLMs and the associated factors were analyzed using multivariable logistic regression. This analysis aimed to assess the effect of various factors on model accuracy, with results reported as odds ratios (ORs).

Results: The study revealed that GPT-4 was the top-performing model, with an overall accuracy of 89.07% (95% CI 84.76% - 92.41%), significantly outperforming the others (P<.001). Microsoft Bing followed with an accuracy of 83.69% (95% CI 78.85% - 87.80%), GPT-3.5 at 67.02% (95% CI 61.20% - 72.48%), and Google Bard at 63.83% (95% CI 57.92% - 69.44%). The multivariable logistic regression analysis showed a correlation between question difficulty and model performance, with GPT-4 demonstrating the strongest association. Interestingly, no significant correlation was found between model accuracy and question length, negative wording, clinical scenarios, or the discrimination index for most models, except for Google Bard, which showed varying correlations.

Conclusions: The GPT-4 and Microsoft Bing models demonstrated equal and superior accuracy compared to GPT-3.5 and Google Bard in the domain of basic medical science. The accuracy of these models was significantly influenced by the item's difficulty index, indicating that the LLMs are more accurate when answering easier questions. This suggests that the more accurate models, such as GPT-4 and Bing, can be valuable tools for understanding and learning basic medical science concepts.

Introduction

Advances in artificial intelligence (AI), machine learning, and large language models (LLMs) have made these tools widely used across a variety of industries. Education and other fields are increasingly using these technologies for decision-making and predictive analysis, using machine learning fed by large databases [1]. Their utility has expanded to a wide range of applications, including speech recognition, image categorization, and language translation [2].

The application of computer technologies to study and create models for decision-making, prediction, and simulation is known as machine learning. Model performance is based on training datasets. The incorporation of AI into traditional health care and medical education has had a substantial impact on medical practices [3]. It has accelerated diagnostic processes in radiography [4], pathology, endoscopy, and ultrasonography, has improved clinical decision-making, and has decreased the workloads of health care personnel. AI has had an impact on pharmaceutical development and management and medical education, resulting in a new paradigm [5].

A study on the accuracy of ChatGPT in answering questions that were contextually similar to those in the United States Medical Licensing Examination (USMLE) reported accuracy rates of 44% - 64% for step 1 and 42% - 57.8% for step 2, depending on the dataset [6]. This research indicated that the model's accuracy in answering questions matched the passing score for third-year medical students, suggesting that further development is required for ChatGPT to meet or exceed the USMLE passing criteria [7]. Additionally, the model has the potential to generate insightful content that could aid human learners in studying medical sciences [8].

Evaluations of ChatGPT's accuracy in answering university-level physiology examination questions have shown it can correctly answer more than 75% of them. Furthermore, it can provide explanations that align with expert assessments [9]. For specialized surgical studies, ChatGPT's GPT-4 model, an evolution of GPT-3.5, has been used to assess surgical question accuracy, revealing an overall accuracy of 76.4%, compared to 46.8% with GPT-3.5, a statistically significant difference ($P<.05$). GPT-4 showed an accuracy range of 63.6% - 88.3% across different topics, outperforming GPT-3.5 in every subtopic [10].

In terms of answering questions for family medicine experts in Taiwan, ChatGPT demonstrated an accuracy of 41.6% in a study that also found that the length of the questions did not affect the model's accuracy. However, the authors noted that the AI's accuracy might depend on the difficulty of the test, the local language, and medical practices, which differ by region and could reduce the model's accuracy [11].

This study investigated the accuracy of responses from widely used LLM AIs, including ChatGPT (with GPT-3.5 and GPT-4), Bing, and Google Bard. Also, we compared their accuracy and determined relationships with the difficulty index for multiple-choice questions closely related to the content of the Thailand Center for Medical Competency Assessment step 1, as well as other factors that may affect the AI's accuracy, such as the length of the question, the presence of negatively worded questions, and the variety of topics across various systems. This research was undertaken to explore these dimensions.

Methods

Study Design and Setting

This study was carried out at the Institute of Medicine, Suranaree University of Technology, Thailand. The curriculum has been accredited by the World Federation for Medical Education since 2021, and the program enrolls 92 medical students annually. Preclinical medical students receive instruction through a collaboration between the School of Preclinic, the Institute of Science, and the Institute of Medicine.

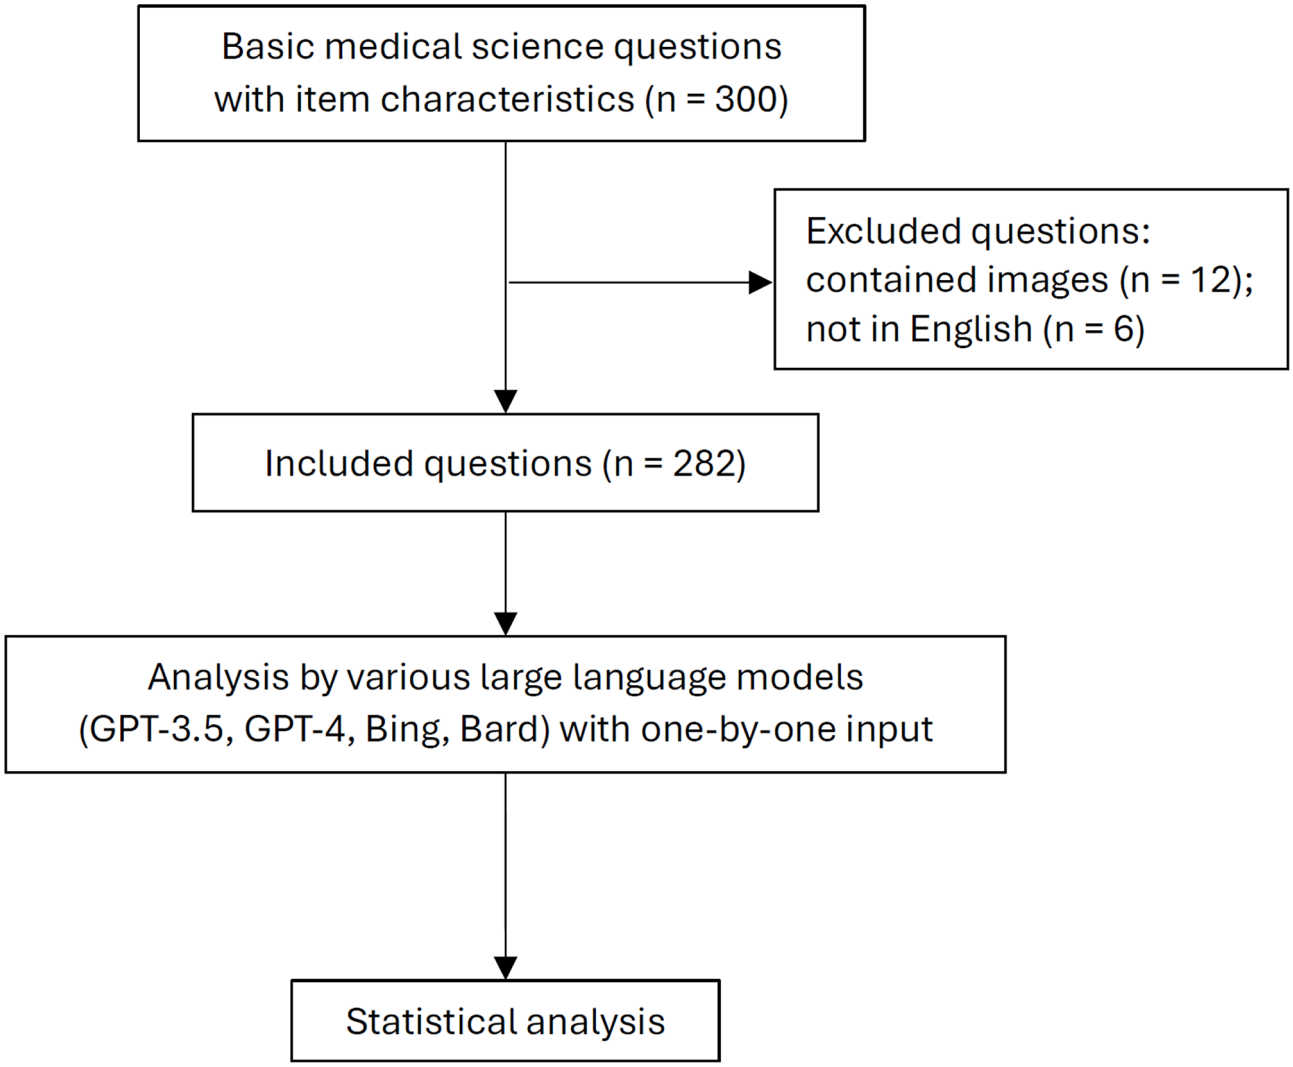
Ethical Considerations

The Human Research Ethics Committee at Suranaree University of Technology approved an exemption (certificate of exemption 117/2566) for this study, which was conducted in accordance with international guidelines for human research.

Data Source

This study used a set of 300 multiple-choice questions that closely matched the content and topic distribution of Thailand's step 1 National Medical Licensing Examination. These questions were voluntarily administered to third-year medical students in February 2021 and 2022. This timing was chosen because the students had already completed courses relevant to the examination. The difficulty index and discrimination index of each question were assessed from the test. The same set of questions was used for both years without any modifications to the content of the exam. The study excluded questions that contained pictures or were not written in English. These exclusion criteria were applied to ensure consistency in the type of questions assessed and to maintain a focus on the textual comprehension and response accuracy of the LLMs (Figure 1).

Figure 1. Study flow chart.



Question Characteristics

Question length was defined as the number of words contained within a question. Negative word questions were identified as those containing the terms "not," "no," "exclude," or "neither." Case scenario questions were characterized by the inclusion of a clinical case scenario, providing a contextual background to the question being asked.

We also used item analyses [12-14], such as the difficulty index, discrimination index, and internal consistency reliability, as independent factors associated with the LLMs' accuracy.

Difficulty index (represented by the letter *p*) is the proportion of examinees who answered a specific question correctly. If a question is easy and every examinee answers it correctly, *p* will be 1. Conversely, if no examinees answer the question correctly, *p* will be 0. This index helps in evaluating the relative difficulty of each question in an examination [12].

Discrimination index (represented by the letter *r*) refers to a question's ability to differentiate between examinees who have high scores and those who do not. Questions with a high discrimination ability are characterized by high scorers typically answering them correctly, while low scorers tend to answer them incorrectly [13]. The most widely used metric for assessing a question's discrimination ability is the point-biserial correlation. The point-biserial correlation coefficient ranges from −1 to 1. A higher point-biserial correlation indicates a question with better discriminatory power.

Internal consistency reliability was measured with Cronbach α. It ranges from 0 to 1, with higher values indicating greater internal consistency. A Cronbach α value above 0.7 is generally considered acceptable, values above 0.8 are considered good, and values above 0.9 are considered excellent.

Prompt Input for LLMs

We used the prompt "Choose the best one answer." Each question was asked to each LLM after inputting the prompt during the same period, from January 18 to 24, 2024. We individually inputted the selected questions into various LLMs, including ChatGPT (with GPT-3.5 and GPT-4), Microsoft Bing, and Google Bard (one session contained one prompt and individual question). The responses from these models were then categorized as either correct or incorrect.

Statistical Analysis

In this study, discrete variables are represented as percentages, while continuous variables are represented as either the mean (SD) or median (IQR). The association between categorical

variables was analyzed using the χ^2 test or Fisher exact test. The relationships between variables and the ability of the LLMs to provide correct answers was examined using multivariable logistic regression, with results reported as odds ratios (ORs) and 95% CIs. Statistical significance was determined at a *P* value of <.05 for all tests. The analysis was facilitated by Stata (version 17; StataCorp), which was used for data analysis and chart creation.

Results

We evaluated the LLMs by using a set of 300 multiple-choice questions that were closely aligned with the content and topic distribution of Thailand's Step 1 National Medical Licensing Examination. According to the exclusion criteria, 12 picture-containing questions and 6 non-English questions were excluded; therefore, 282 eligible questions were included. All eligible questions were concurrently input into various LLMs (Figure 1). The responses were then recorded, categorizing the outcomes as either correct or incorrect.

The questions were categorized according to the block system (Table 1), with distributions as follows: 32.3% on general principles, 5.7% on the hematopoietic system, 8.2% on the nervous system, 3.9% on skin and connective tissues, 4.3% on the musculoskeletal system, 7.8% on the respiratory system, 8.9% on the cardiovascular system, 7.5% on the gastrointestinal system, 6.7% on the urinary system, 7.1% on the reproductive system, and 7.8% on the endocrine system. The average question length was 49.10 (SD 18.94) words, with 24 questions (8.2%) containing negative wording. More than half of the questions, specifically 53.2%, were based on clinical case scenarios (more descriptive statistics for the item analysis for each block are provided in Multimedia Appendix 1). The mean difficulty index was 0.35, indicating moderately difficult to difficult questions. The discrimination index was 0.16, suggesting a poor ability to distinguish between higher and lower performers. Otherwise, the internal consistency reliability, at 0.84, highlighted an acceptable level of consistency across the examination.

Table . Question characteristics (n=282).

Characteristics	Values
Number of questions by block, n (%)	
General principles[a]	91 (32.3)
Hematopoietic system	16 (5.7)
Nervous system	23 (8.2)
Skin and connective tissue	11 (3.9)
Musculoskeletal system	12 (4.3)
Respiratory system	22 (7.8)
Cardiovascular system	25 (8.9)
Gastrointestinal system	21 (7.5)
Urinary system	19 (6.7)
Reproductive system	20 (7.1)
Endocrine system	22 (7.8)
Question length (words), mean (SD)	49.10 (18.94)
Negative-word questions, n (%)	24 (8.5)
Case scenario questions, n (%)	150 (53.2)
Average difficulty index (*p*)	0.35
Average discrimination index (*r*)	0.16
Internal consistency reliability (α)	0.84

[a]"General principle" questions refer to fundamental principles in biochemistry, molecular biology, human development, genetics, normal immune responses, basic pathological processes, laboratory investigations, general pharmacology, epidemiology, and biostatistics.

The overall accuracy of the LLMs in the basic medical science examination was as follows (Table 2): GPT-4 achieved the highest accuracy at 89.07% (95% CI 84.76% - 92.41%), Microsoft Bing had an accuracy of 83.69% (95% CI 78.85% - 87.80%), GPT-3.5 recorded an accuracy of 67.02% (95% CI 61.20% - 72.48%), and Google Bard demonstrated an accuracy of 63.83% (95% CI 57.92% - 69.44%). The Fisher exact test showed that GPT-4 performed more accurately than Microsoft Bing, and that the difference was statistically significant (*P*<.001)

Table . Accuracy of large language models with 95% CIs, compared based on category (n=282).

	GPT-3.5	GPT-4	Microsoft Bing	Google Bard
Number of correct answers	189	251	236	180
Overall accuracy, % (95% CI)	67.02 (61.20 - 72.48)	89.07 (84.76 - 92.41)	83.69 (78.85 - 87.80)	63.83 (57.92 - 69.44)
General principles, % (95% CI)	84.62 (75.54 - 91.33)	90.11 (82.05 - 95.38)	84.62 (75.54 - 91.33)	72.53 (62.17 - 81.37)
Block system, % (95% CI)	61.78 (54.49 - 68.70)	88.48 (83.08 - 92.64)	83.25 (77.18 - 88.25)	59.69 (52.36 - 66.70)

The GPT-4 model demonstrated the highest accuracy among the LLMs in the general principles section for basic science, achieving 90.11% (95% CI 82.05% - 95.38%), as shown in Table 2. GPT-3.5 and Bing exhibited equal accuracy in this section, with the lowest accuracy being 72.53% (95% CI 62.17% - 81.37%) for Bard. Additionally, GPT-4 maintained its position as the top performer in the block system with an accuracy of 88.48% (95% CI 83.08% - 92.64%), whereas Bard again displayed the lowest performance in this segment (Figure 2). Overall, GPT-4 stood out for its superior performance in overall accuracy, general principles, and the block system.

Figure 2. Comparative accuracy with 95% CIs for artificial intelligence models across different question categories.

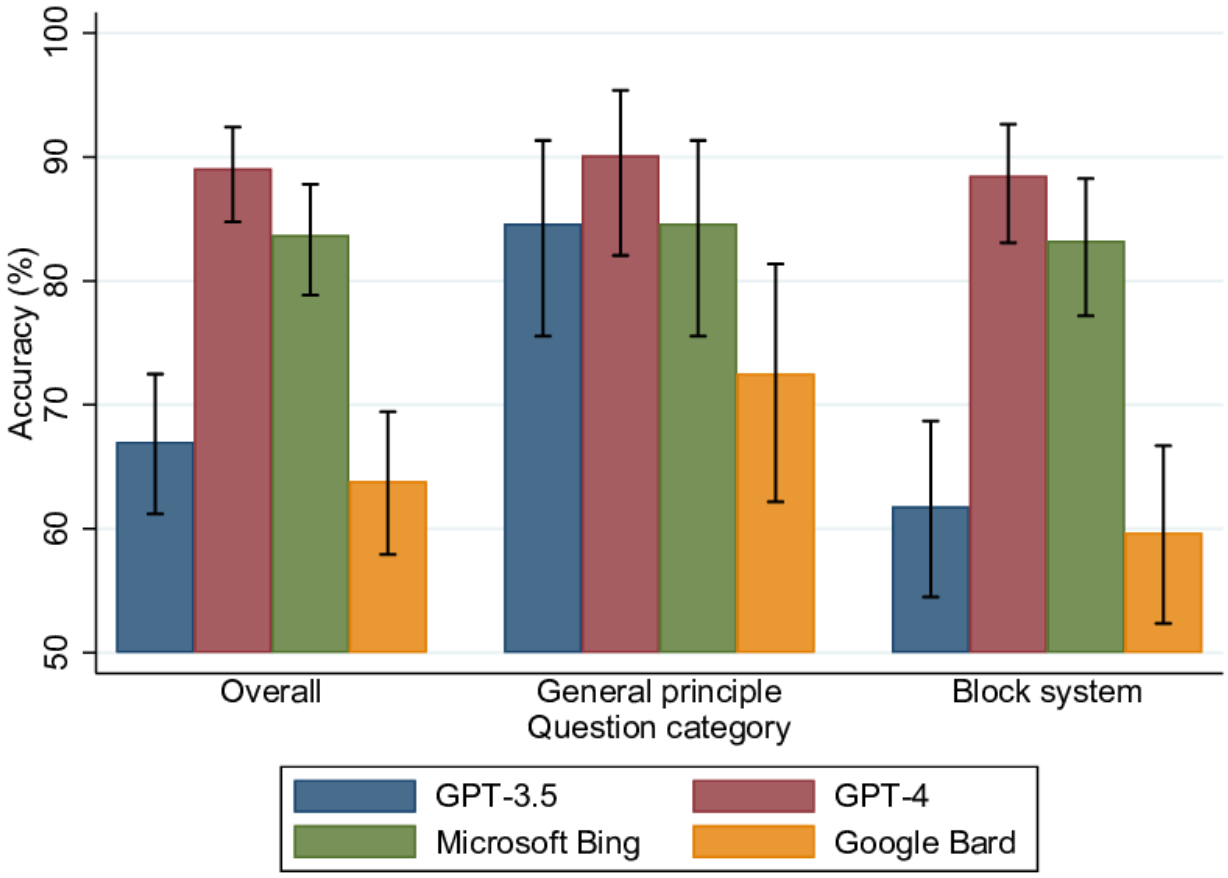


Table 3 presents the number of correct answers stratified by the block system alongside the proportion of correct answers relative to the total number of questions. The GPT-4 model exhibited the best performance, with its accuracy ranging from 84% to 95%. Following GPT-4, the Microsoft Bing model demonstrated block system accuracies between 68% and 91%. The accuracy of GPT-3.5 and Google Bard was comparable in this study, with GPT-3.5 achieving between 53% and 85%, and Google Bard ranging from 53% to 72%.

Table . Number of correct answers stratified by block system (n=282)

Topic	Correct answers, n (%)			
	GPT-3.5	GPT-4	Microsoft Bing	Google Bard
General principles (n=91)	77 (85)	82 (90)	77 (85)	66 (73)
Hematopoietic system (n=16)	8 (50)	14 (88)	13 (81)	11 (69)
Nervous system (n=23)	13 (57)	21 (91)	19 (83)	12 (52)
Skin and connective tissue (n=11)	8 (73)	10 (91)	9 (82)	5 (46)
Musculoskeletal system (n=12)	9 (75)	11 (92)	10 (83)	8 (67)
Respiratory system (n=22)	12 (55)	17 (77)	19 (86)	13 (59)
Cardiovascular system (n=25)	14 (56)	21 (84)	20 (80)	16 (64)
Gastrointestinal system (n=21)	15 (71)	20 (95)	18 (86)	14 (67)
Urinary system (n=19)	10 (53)	17 (90)	13 (68)	10 (53)
Reproductive system (n=20)	13 (65)	18 (90)	18 (90)	12 (60)
Endocrine system (n=22)	16 (73)	20 (91)	20 (91)	13 (59)

Table 4 illustrates the question characteristics associated with correct answers. There was a correlation between the difficulty index and the accuracy in all 4 models, with the strongest association observed in the GPT-4 model (OR 90.13, 95% CI 4.30 - 1887.54; *P*=.004). This was followed by GPT-3.5, which had an OR of 28.03 (95% CI 4.68 - 167.98; *P*<.001). Microsoft Bing and Google Bard demonstrated similar correlations with correct answers, with ORs of 18.9 (95% CI 1.84 - 195.42; *P*=.01) and 18.73 (95% CI 3.12 - 112.45; *P*=.001), respectively, as shown in Table 4. There was no statistically significant correlation between the accuracy of GPT-3.5, GPT-4, and Bing and question length, negative word questions, clinical case scenario questions, or the discrimination index.

Table . Multivariable logistic regression analysis showing question characteristics associated with correct answer of large language model artificial intelligence (n=282).

Variable	GPT-3.5		GPT-4		Microsoft Bing		Google Bard	
	OR[a] (95% CI)	*P* value	OR (95% CI)	*P* value	OR (95% CI)	*P* value	OR (95% CI)	*P* value
Question length (word)	0.99 (0.97 - 1.00)	.07	1.00 (0.98 - 1.02)	.96	1.00 (0.98 - 1.02)	.94	0.98 (0.97 - 1.00)	.02
Negative word question	0.55 (0.22 - 1.35)	.19	0.44 (0.15 - 1.30)	.14	0.46 (0.18 - 1.22)	.12	0.26 (0.10 - 0.69)	.007
Case scenario question	0.94 (0.50 - 1.77)	.85	1.57 (0.63 - 3.93)	.34	0.94 (0.43 - 2.04)	.87	0.56 (0.30 - 1.07)	.08
Difficulty index (*p*)	28.03 (4.68 - 167.98)	<.001	90.13 (4.30 - 1887.54)	.004	18.9 (1.84 - 195.42)	.01	18.73 (3.12 - 112.45)	.001
Discrimination index (*r*)	2.80 (0.34 - 23.32)	.34	4.85 (0.20 - 116.54)	.33	9.66 (0.67 - 140.06)	.10	9.31 (1.02 - 84.68)	.048

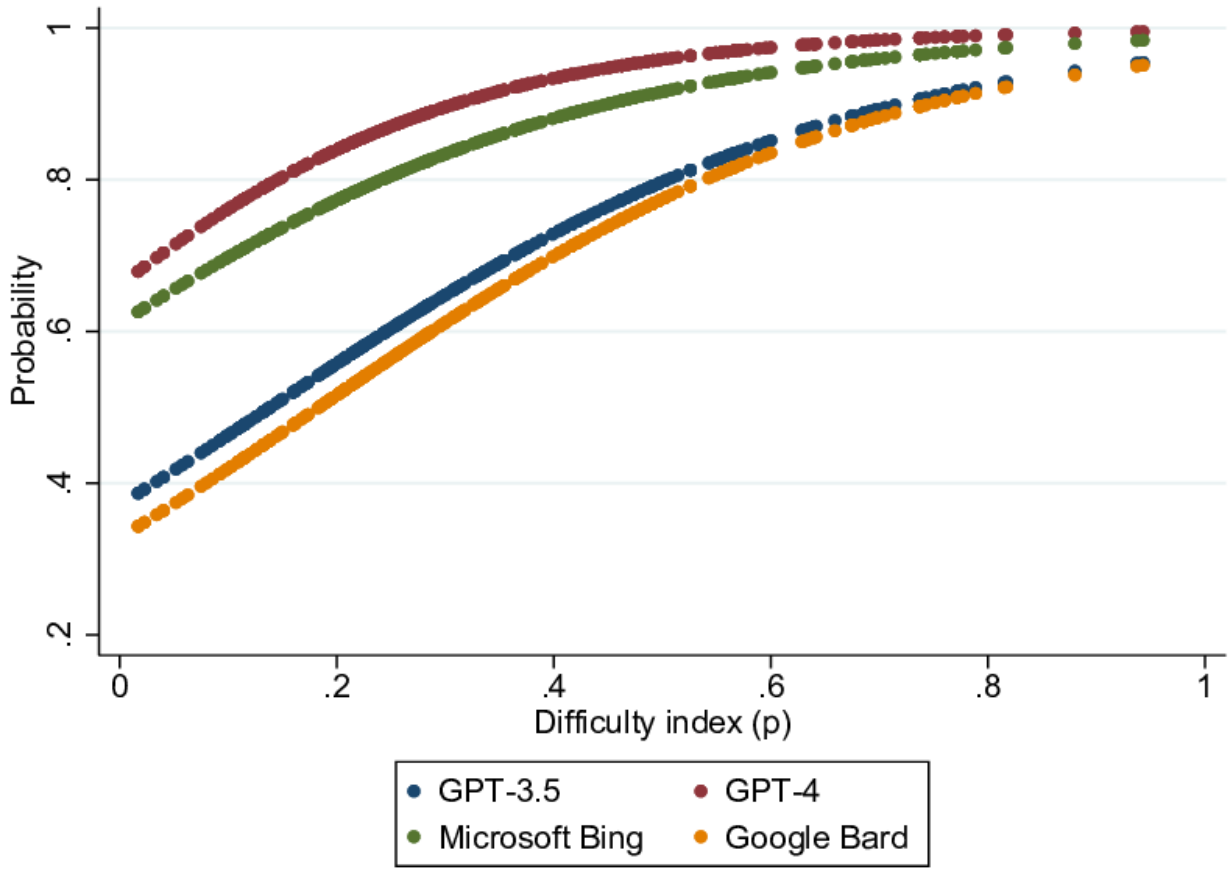
[a]OR: odds ratio.

On the other hand, for Google Bard, longer questions had a higher OR, of 0.98 (95% CI 0.97 - 1.00; *P*=.02), for the model to provide the correct answer than shorter questions. The negative-word questions were less likely to be answered correctly by the model, with an OR of 0.26 (95% CI 0.10 - 0.69; *P*=.007), compared to those without negative words. Furthermore, questions with a higher discrimination index were more likely to be correctly answered with statistical significance by the model, with an OR of 9.31 (95% CI 1.02 - 84.68, *P*=.048), as compared to those with a lower discrimination index. No statistically significant correlation was observed between the accuracy of the AIs in answering clinical case scenario questions, as presented in Table 4.

The correlation between the difficulty index and the estimated accuracy of the various AI models, analyzed with binary logistic regression, is shown in Figure 3. The GPT-4 model consistently demonstrated the highest accuracy across all levels of question difficulty index (Figure 3). Google Bard, on the other hand, had the lowest estimated accuracy. The accuracy of the various

LLMs improved as the difficulty index increased, indicating that these models performed better on easier questions.

Figure 3. Accuracy of various artificial intelligence models estimated based on difficulty index.



Discussion

Accuracy of the LLMs on Basic Medical Science Examinations

This study compared the accuracy of LLMs in answering questions from a basic medical science examination related to the National Medical Licensing Examination, finding that GPT-4 had the highest accuracy, at 89.07%, and Google Bard had the lowest accuracy, at 63.83%, when tasked with answering questions in this context. The most frequently studied AI models were GPT-3.5 and GPT-4.

These results align with the 2023 findings of Yanagita et al [15], who used questions from the National Medical Licensing Examination in Japan, administered by the Japanese Ministry of Health, Labour and Welfare. When inputting Japanese questions into the prompt, they reported an accuracy for GPT-4 of 81.5%, significantly higher than GPT-3.5's accuracy of 42.8%, with GPT-4 surpassing the National Medical Licensing Examination passing standard of 72%.

Our results are similar to those of the study conducted by Gilson et al [6] in 2023, which found that the performance of GPT-3.5 on AMBOSS-Step1 and NBME-Free-Step1 was 44% and 64.4%, respectively. Flores-Cohaila et al [16] conducted a study on the accuracy of LLMs on the Peruvian National Licensing Medical Examination and discovered that GPT-4 had 86% accuracy, following by GPT-3.5 at 77%, with moderately difficult to difficult questions being associated with incorrect answers (the OR for GPT-3.5 was 6.6, 95% CI 2.73 - 15.95; for GPT-4, the OR was 33.23, 95% CI 4.3 - 257.12).

A literature review from China (Wang et al [17]) evaluated the performance of GPT-3.5 and GPT-4 on the China National Medical Licensing Examination and reported 56% and 84% accuracy for GPT-3.5 and GPT-4, respectively, demonstrating GPT-4's superiority over GPT-3.5 in terms of accuracy on basic medical science examinations.

The accuracy of GPT-4 and GPT-3.5 is influenced by the variety within the question dataset. This results in diverse outcomes across different countries, changing according to the environmental context, difficulty level of the examination, and the proportion of subcomponents within the examination question sets, which may vary from one country to another. Consequently, the estimated accuracy of AI models for each dataset is not constant.

Difficulty Index and the LLMs' Accuracy

In this study, we identified factors correlated with the accuracy of AI models in answering questions. We found that for every model, the difficulty index was associated with correctly answering questions. Moreover, across all models, there was a tendency to answer questions correctly as the difficulty index increased (indicating easier questions). Specifically, GPT-4

demonstrated the highest OR at 90.13 (95% CI 4.30 - 1887.54; *P*=.004), followed by GPT-3.5, with an OR of 28.03 (95% CI 4.68 - 167.98; *P*<.001).

This result aligns with findings from Antaki et al [18] showing that question difficulty was the most predictive factor of GPT-3.5's answer accuracy (likelihood ratio 24.05; *P*<.001) and that GPT-4 was more accurate than GPT-3.5. The current research reveals the accuracy of AI models in answering questions across various disciplines, particularly studies focusing on the renowned GPT-3.5 model. However, this study focused on the relationship between the difficulty index, derived from human examination observations, and the accuracy of every simple-to-access LLM that is widely used. There was also a variation in accuracy among all models, with GPT-4 being the most accurate, and there was an obvious correlation with the difficulty index for each model, indicating that easier questions had higher accuracy.

The Implication of LLMs for Medical Education

This study's findings hold significant implications for medical education, particularly regarding the use of LLMs such as GPT-4, Microsoft Bing, GPT-3.5, and Google Bard as educational tools [19]. There are 3 major ways that this study's findings can be applied to augment traditional study methods.

First, enhancing study efficiency: the high accuracy rates of LLMs, especially GPT-4, in answering medical examination questions suggest their utility as effective study aids. By providing immediate and accurate answers with explanations, these models can help students identify areas of weakness and reinforce their learning more efficiently than traditional study methods alone.

Second, supplementing traditional education methods: LLMs can act as supplementary tools in medical education, alongside lectures, textbooks, and clinical scenarios. Integrating LLMs into the curriculum provides students with an additional resource for study and review to enhance the overall educational experience.

Last, preparing for licensing examinations: given the study's focus on medical licensing examinations, LLMs could play a crucial role in preparing students for these critical assessments. The ability of LLMs to accurately answer examination questions, such as those tackled by GPT-4, and explain reasoning processes can assist students in better preparing for the format and content of licensing exams.

LLMs may have a negative impact on medical education. Excessive dependence on LLMs might impede the development of independent critical thinking skills. Students may become reliant on the model's suggestions instead of developing their own reasoning processes. LLMs can sometimes provide incorrect, incomplete, or biased information [20,21]. This can interfere with the development of critical appraisal skills, leading students to accept inaccurate information, which may hinder their critical thinking and medical reasoning abilities [22]. Additionally, reduced peer and mentor interaction can hinder the development of professional judgment, depriving students of diverse perspectives and collaborative problem-solving experiences.

To maximize the benefits while minimizing the negative impact of incorporating LLMs into medical education [23], 4 strategies can be considered. First, structured use: LLMs can be incorporated as supplementary tools in a structured curriculum rather than as primary sources of information. Second, critical appraisal training: the importance of critically appraising information provided by LLMs should be emphasized, and students should be taught how to cross-reference and validate information. Third, independent thought should be encouraged: environments should be fostered that encourage independent thinking and problem-solving, using LLMs to support (not replace) these processes. Fourth, monitoring and evaluation: the impact of LLMs on students' learning and reasoning skills should be assessed, and educational approaches should be adjusted based on these assessments.

Limitations

One significant limitation of this study is the LLMs' ability to accurately respond to complex medical examination questions. Moreover, despite GPT-4's high performance, the study's focus on a single culturally and geographically specific medical licensing examination (Thailand Step 1 National Medical Licensing Examination) may limit the generalizability of the findings to other medical examinations and educational contexts. The exclusion of questions containing images and those not in English restricted the comprehensiveness of the assessment, considering the importance of questions on visual diagnostics. Updates to LLMs can significantly affect their accuracy, leading to a potential increase in the capabilities of the models over time. Furthermore, different LLMs can respond differently to different prompts. They can generate different answers across independent sessions, even with identical prompts. Therefore, a sensitivity analysis of the accuracy of the LLMs' responses should be conducted with a variety of prompt and session settings.

Conclusion

Our results show a significant variation in performance among different LLMs, with the most accurate model being GPT-4. This study has shed light on the role of LLMs as supplementary tools in medical education, as well as the need for more research to increase the generalizability of the findings to different educational settings. We advocate for the ongoing development and modification of LLMs to match the unique demands of medical education internationally, which has important implications for the future integration of AI in medical training and test preparation.

Acknowledgments

This research received funding support from the Unit of Teaching and Learning Development and Research, Suranaree University of Technology.

Authors' Contributions

NK was responsible for the entire project and prepared the initial draft of the manuscript. JP conceptualized the project. GB and NP contributed by proofreading and editing the manuscript. All authors participated in interpreting the results and in preparing the final version of the paper.

Abstract

Background: Medical students often struggle to engage with and retain complex pharmacology topics during their preclinical education. Traditional teaching methods can lead to passive learning and poor long-term retention of critical concepts.

Objective: This study aims to enhance the teaching of clinical pharmacology in medical school by using a multimodal generative artificial intelligence (genAI) approach to create compelling, cinematic clinical narratives (CCNs).

Methods: We transformed a standard clinical case into an engaging, interactive multimedia experience called "Shattered Slippers." This CCN used various genAI tools for content creation: GPT-4 for developing the storyline, Leonardo.ai and Stable Diffusion for generating images, Eleven Labs for creating audio narrations, and Suno for composing a theme song. The CCN integrated narrative styles and pop culture references to enhance student engagement. It was applied in teaching first-year medical students about immune system pharmacology. Student responses were assessed through the Situational Interest Survey for Multimedia and examination performance. The target audience comprised first-year medical students (n=40), with 18 responding to the Situational Interest Survey for Multimedia survey (n=18).

Results: The study revealed a marked preference for the genAI-enhanced CCNs over traditional teaching methods. Key findings include the majority of surveyed students preferring the CCN over traditional clinical cases (14/18), as well as high average scores for triggered situational interest (mean 4.58, SD 0.53), maintained interest (mean 4.40, SD 0.53), maintained-feeling interest (mean 4.38, SD 0.51), and maintained-value interest (mean 4.42, SD 0.54). Students achieved an average score of 88% on examination questions related to the CCN material, indicating successful learning and retention. Qualitative feedback highlighted increased engagement, improved recall, and appreciation for the narrative style and pop culture references.

Conclusions: This study demonstrates the potential of using a multimodal genAI-driven approach to create CCNs in medical education. The "Shattered Slippers" case effectively enhanced student engagement and promoted knowledge retention in complex pharmacological topics. This innovative method suggests a novel direction for curriculum development that could improve learning outcomes and student satisfaction in medical education. Future research should explore the long-term retention of knowledge and the applicability of learned material in clinical settings, as well as the potential for broader implementation of this approach across various medical education contexts.

Introduction

Background

Student and trainee engagement is a critical factor in medical education, influencing outcomes such as academic achievement, overall well-being, satisfaction, and reduced burnout [1,2]. High levels of engagement have been linked to increased motivation and better learning experiences, as active participation encourages deeper understanding and application of complex material [3]. In contrast, traditional lecture-based learning often results in passive absorption of information, limiting student engagement and negatively affecting the ability to interact meaningfully with content [4]. To address this, we developed a cinematic clinical narrative (CCN), an interactive multimedia learning experience designed to enhance student engagement by integrating cinematic storytelling and narrative-based learning techniques. This method builds upon the principles of

cinemeducation, a teaching approach that uses film to create emotional connections and foster active learning [5]. By using generative artificial intelligence (genAI) tools, we have further enhanced the learning experience and decreased the barrier to entry for instructors, making it more immersive and adaptable to current educational needs. GenAI has been recognized as a transformative tool in reshaping medical education, offering new opportunities for interactive, technology-driven learning environments that promote active student engagement [6,7].

The target audience for our CCN comprises first-year medical students learning pharmacology related to the immune system. Medical students often face a knowledge gap in understanding complex pharmacological interactions and the intricacies of immune responses largely due to the difficulty of the material [8,9]. Furthermore, there is speculated to be a skill gap in medical and other professional health science students in applying theoretical knowledge to clinical scenarios [10] and the real problem of burnout due to many factors, one of which is the large amount of knowledge required to retain in a short amount of time [11]. The CCN aims to address these issues by enhancing comprehension, clinical application skills, and empathy toward patients with autoimmune diseases.

The CCN used a unique instructional approach by merging cinemeducation [5] with multiple genAI platforms, tailored for first-year medical students in pharmacology. This method addresses the challenge of enhancing engagement and knowledge retention in complex subjects such as immune system pharmacology. Unlike traditional didactic teaching, our approach, supported by others advocating for innovative teaching strategies, uses storytelling to deepen understanding and empathy [12-14]. Use of genAI in medical training, particularly in personalizing learning experiences and competencies for genAI-based tools, is also a current area of active research [15,16]. This aligns with other researchers who highlight the importance of interactive and engaging content in medical education [17]. Our project also leverages the effectiveness of narrative-based learning, which offers an experiential learning environment over conventional teaching methods and is more accurate to real-world situations [18].

Medical students often struggle to engage with and retain complex pharmacological concepts, especially in preclinical education, where traditional teaching methods can lead to passive learning and poor knowledge retention. To address this challenge, we developed and implemented a novel instructional approach, CCNs, which leverages multimodal genAI tools to create immersive, engaging learning experiences. The aim of this study is to evaluate the effectiveness of these genAI-enhanced CCNs in increasing student engagement, interest, and knowledge retention in medical pharmacology concepts. We tested this intervention by assessing student interest using the Situational Interest Survey for Multimedia (SIS-M) and measuring examination performance on content covered by the CCNs. We hypothesize that students exposed to CCNs will report higher levels of engagement compared with traditional case-based learning and have passing examination grades on questions related to the CCN.

Theoretical Framework

The instructional method in the CCN uses contemporary educational theories emphasizing active, learner-centered approaches. Drawing inspiration from the Constructivist Learning Theory, which advocates for knowledge construction through experience [19], our approach uses an adaptation of cinemeducation to create an immersive learning environment [5]. This also aligns with Mayer's Cognitive Theory of Multimedia Learning, which suggests that learning is enhanced through multimodal presentations [20]. Furthermore, our multimodal use of various genAI platforms for content development is informed by the Technological Pedagogical Content Knowledge (TPACK) framework [21], ensuring an effective integration of technology in teaching. This methodology responds to identified needs in medical education for more engaging and effective teaching strategies, bridging theory and practice in a novel and impactful way.

Methods

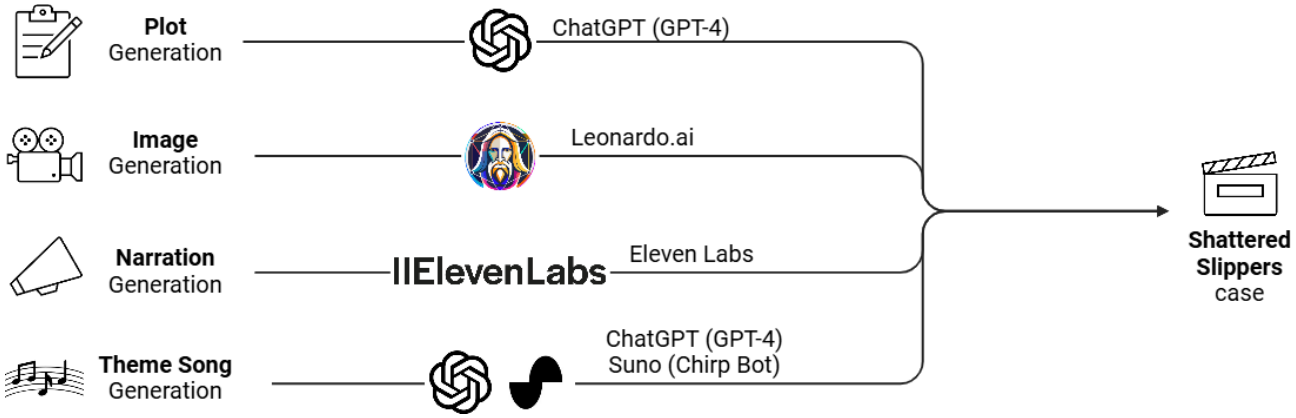
Participants and CCN Design Overview

This study was conducted at the University of Idaho WWAMI Medical Education Program, which is part of a collaborative University of Washington School of Medicine program serving Washington, Wyoming, Alaska, Montana, and Idaho. The WWAMI program provides medical education to students across these states, offering them the opportunity to complete their first 2 preclinical years of medical school in their home states before transitioning to clinical training. The target learners for this study were first-year medical students in the WWAMI program enrolled in a 6-week foundational infections and immunity course, which included topics covering immune system pharmacology. Students in this course attend pharmacology lectures that culminate in clinical cases, allowing them to apply their newly acquired knowledge of medications to real-world patient scenarios.

We decided to reimagine one of these cases into "Shattered Slippers," a CCN that was presented as a fictional sequel to the movie "Another Cinderella Story" (Multimedia Appendices 1 and 2). This fictional sequel features the star from the original movie, Selena Gomez, which was purposeful, given her real-life battle with lupus and her experience receiving a kidney transplant. This choice not only provides a strong thematic link connecting the CCN to the source material but also serves to humanize and demystify the conditions under study.

The development of "Shattered Slippers" used a suite of genAI platforms to create an immersive and engaging learning experience (Figure 1). The plot was crafted using GPT-4, known for its language understanding and generation capabilities. For visual imagery, Leonardo.ai and Stable Diffusion were used to generate high-quality, contextually relevant images. Narration was produced using Eleven Labs, ensuring a coherent and captivating storytelling experience. Furthermore, the theme song, integral to setting the tone of the educational module, was composed using the combined efforts of GPT-4 and Suno.

Figure 1. Multimodal generative artificial intelligence (genAI) case generation approach. Each portion of the case used a different genAI platform for material generation. These included ChatGPT (GPT-4), Leonardo.ai, Eleven Labs, and Suno.



These artificial intelligence (AI)–generated materials were all integrated into 2 PowerPoint presentations. Part I of the CCN was presented at the end of a 1-hour pharmacology lecture on immunomodulatory drugs with specific focus on nonsteroidal anti-inflammatory drugs, glucocorticoids, and innate immune system inhibitors. Part II of the CCN was presented 4 weeks later at the end of a 1-hour pharmacology lecture on immunomodulatory and transplant drugs with specific focus on cytokine inhibitors, cytotoxic drugs, and antimetabolites. Both lectures were presented in-person with >90% of students attending both lectures. The combined CCN is provided as a supplemental file (Multimedia Appendix 2).

At the conclusion of the course, students were informed about Selena Gomez's actual medical journey. This revelation effectively bridged the gap between the fictional narrative of "Shattered Slippers" and real-world medical scenarios, thereby enhancing the educational impact and relevance of the clinical cases discussed.

Plot Development

The process of developing the plot for "Shattered Slippers" began with a reimagining of a clinical case initially presented in the first-year medical school curriculum. This original case centered around a ballerina struggling with rheumatoid arthritis, where students were tasked with diagnosing the sources of her pain and inflammation and selecting suitable immunomodulatory medications.

Using ChatGPT (GPT-4) [22], a large language model (LLM), we transformed this clinical scenario into a compelling narrative for "Shattered Slippers." The sequential steps of the medical case were input into GPT-4, with instructions to adapt these into a fictional storyline (Figure 2 and Multimedia Appendix 3). To enhance thematic resonance and real-world connection, the ballerina's diagnosis in the plot was altered from rheumatoid arthritis to lupus, mirroring the real-life medical condition of Selena Gomez, who stars in the CCN.

Further expanding the scope of the narrative, the plot incorporated a kidney transplant storyline. This addition served a dual purpose. First, it aligned with the second lecture on immunoregulatory pharmacology focusing on organ transplant pharmacology. Second, it resonated with Selena Gomez's personal medical history, as she has undergone a kidney transplant. This incorporation not only ensured continuity with the educational objectives of the course but also added depth and authenticity to the fictional narrative, making it more engaging and relatable for the students.

Figure 2. Excerpt of plot generation. The initial prompt in the conversation covered the development of a separate CCN. Prompt engineering techniques in this initial prompt included Persona Prompting [23,24] and a modified version of Zero-Shot CoT [25]. Excerpts of the first prompt and output related to the Shattered Slippers CCN are provided. CCN: cinematic clinical narrative; CoT: Chain of Thought; LLM: large language model.

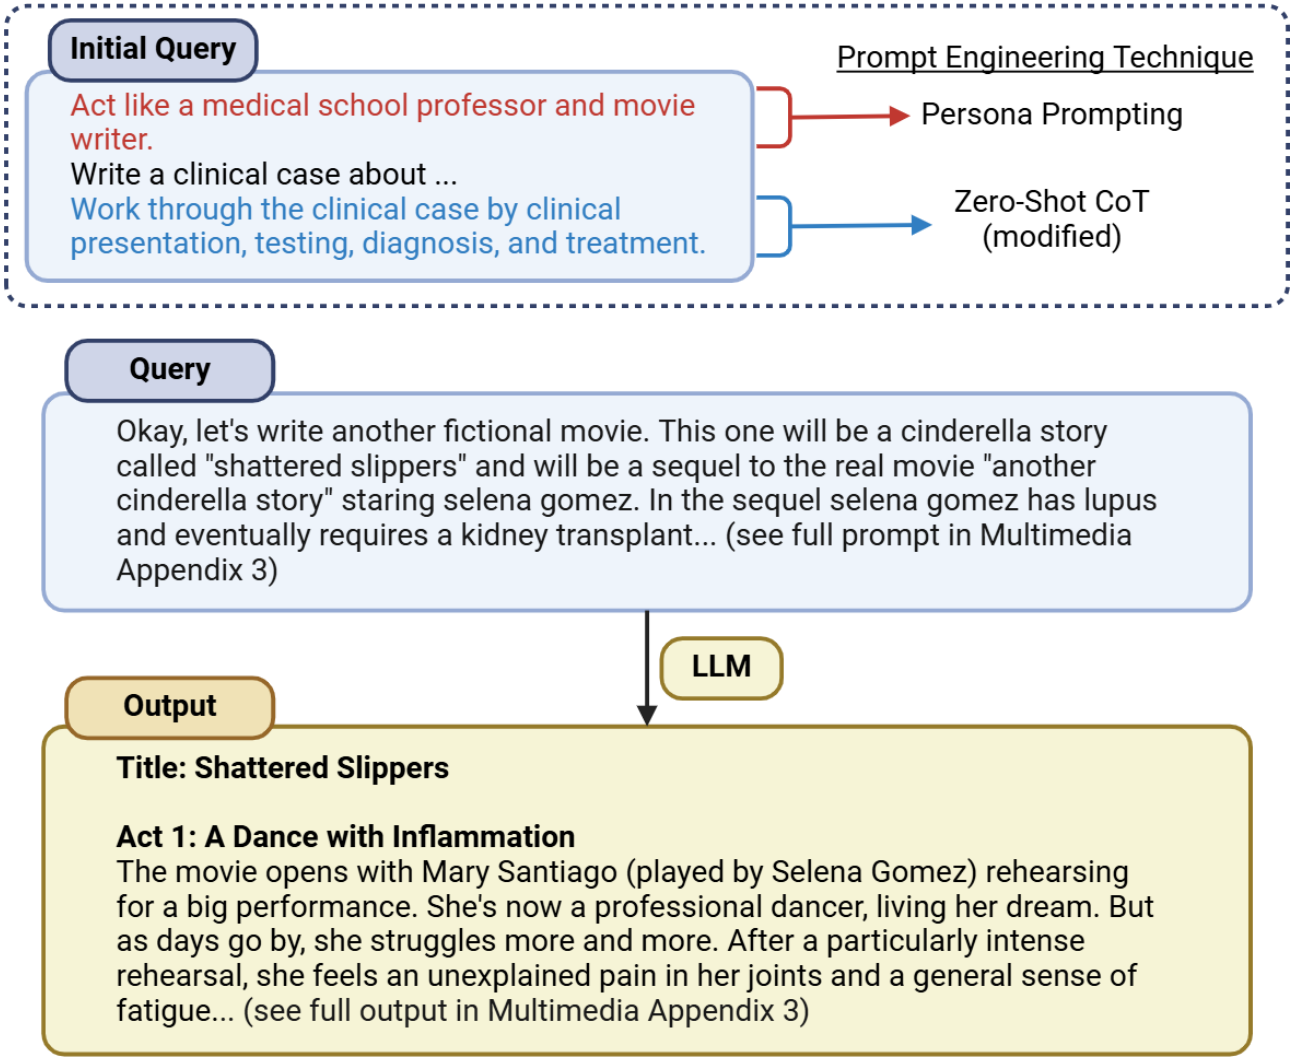


Image Generation

In order to create a more immersive educational experience, fictional images were integrated into the “Shattered Slippers” case study. These images were generated using the Leonardo.ai platform [26], which harnesses the capabilities of the Stable Diffusion XL image–generating technology (Figure 3 and Multimedia Appendix 4).

In an effort to maintain transparency and distinguish between real and AI-generated content, all images depicting real people were marked with an “AI-generated image” icon. This icon, chosen for its symbolic significance, is the spinning top from the movie “Inception.” The selection of this particular icon was purposeful; it serves as a metaphor for the increasingly blurred lines between reality and artificial constructs, mirroring the movie’s thematic exploration of distinguishing reality from illusion. This concept was explained to the students prior to their engagement with the case, setting the stage for a thoughtful consideration of the role and impact of genAI in content creation. This iconography not only helped in identifying AI-generated images but also subtly underscored the advanced capabilities of genAI in creating hyperrealistic images.

Figure 3. Artificial intelligence (AI)-generated image of Selena Gomez singing with Justin Bieber. The prompt used was "adult Selena Gomez and Justin Bieber singing together." The spinning top in the bottom right corner was added as a watermark to denote an AI-generated image. Generated with Leonardo.ai.

Narration Generation

Enhancing the immersive aspect of the CCN, an audio narration was incorporated to accompany the text on the PowerPoint slides. This element was designed to emulate the experience of listening to a movie narrator, thereby bringing the story of "Shattered Slippers" to life in an auditory format. To achieve this, the finalized script of the plot was submitted to the Eleven Labs platform [27], which specializes in converting text into lifelike audio narration (Multimedia Appendix 5).

Each of these audio narrations were incorporated into their corresponding PowerPoint slides. As each slide was presented during the course, the audio narration played automatically, further synchronizing the visual and auditory elements of the learning experience. This integration of audio narration with the visual content not only enriched the storytelling aspect of the module but also supported diverse learning styles, facilitating a more engaging and multisensory educational experience for the students.

Theme Song Generation

Although not directly educational, a theme song for "Shattered Slippers" was created to complete the immersive experience. The inclusion of a theme song aimed to add an additional layer of engagement and context to the fictional movie, contributing to a more comprehensive and cinematic learning environment.

The lyrics for the theme song were generated using GPT-4 [22]. Following the lyric generation, Suno Chirp Bot, a genAI tool for music composition [28], was used to create the melody and vocals for the theme song. This genAI-driven process allowed for a harmonious blend of lyrics and music, resulting in a fully rendered theme song (Multimedia Appendix 6).

Once completed, the theme song was embedded into the PowerPoint presentation. This musical addition served as a capstone to the multisensory educational module, further enriching the student's experience by providing a unique auditory element that complemented the visual and textual components of "Shattered Slippers."

Data Collection

The "Shattered Slippers" CCN was integrated into 2 distinct pharmacology lectures, both of which focused on medications used in immune system modulation. The target audience for this CCN was a class of 40 first-year medical students (n=40). This approach aimed not only to enrich their understanding of immunomodulatory pharmacology but also to engage them in a unique and memorable learning experience.

To evaluate student interest in the CCN as an educational tool, at the conclusion of the course, students were invited to participate in a feedback process using the SIS-M [29-31] (Table 1) of which 18 students responded (n=18). The SIS-M was developed by Dr Tonia Dousay, a professor in instructional design and educational technology, to assess various constructs of situational interest in multimedia-based learning environments. Originally created for the educational field, the SIS-M focuses on adult learners and measures constructs such

as triggered situational interest (initial engagement with multimedia), maintained interest, and value interest (perceived usefulness of the content). The survey was originally used to evaluate the effectiveness of multimedia in promoting engagement and motivation in higher education and adult learning settings [29,30] and has recently been used in medical education research [31], making it an appropriate tool for assessing learner engagement in this study. This survey was used to capture their views and opinions on the "Shattered Slippers" case, providing insights into student engagement, interest, and the overall impact of the CCN on their learning experience. The survey includes items to rank on a 1 - 5 scale (1=strongly disagree, 5=strongly agree), a question asking for preference of clinical case format, and an open-ended question asking, "Why do you think this is your preference." The CHERRIES report for this survey is supplied (Multimedia Appendix 7).

Table . SIS items.

SIS[a] type	Survey item
SI-triggered	The multimedia presentation was interesting.
SI-triggered	The multimedia presentation grabbed my attention.
SI-triggered	The multimedia presentation was often entertaining.
SI-triggered	The multimedia presentation was so exciting, it was easy to pay attention.
SI-maintained-feeling	What I learned in the multimedia presentation is fascinating to me.
SI-maintained-feeling	I am excited about what I learned in the multimedia presentation.
SI-maintained-feeling	I like what I learned in the multimedia presentation.
SI-maintained-feeling	I found the information in the multimedia presentation interesting.
SI-maintained-value	What I studied in the multimedia presentation is useful for me to know.
SI-maintained-value	The things I studied in the multimedia presentation are important to me.
SI-maintained-value	What I learned in the multimedia presentation can be applied to my job.
SI-maintained-value	I learned valuable things in the multimedia presentation.

[a]SIS: Situational Interest Survey.

Data Analysis

The research team used Microsoft Excel for the analysis of the SIS-M survey results. The average class pharmacology examination grades (n=40) from questions covered by the "Shattered Slippers" case study (n=2) were analyzed for achievement data. These included a multiple-choice question, selected by the course lead (not the study author) from a pool of questions that tested pharmacology content covered in each pharmacology lecture. The questions were administered during the students' weekly examinations, scheduled for the week immediately following the presentation of the material. Importantly, these questions were modeled after USMLE-style step 1 board questions, which assess students' ability to apply their pharmacological knowledge in a clinical context. Using this format provides a rigorous and standardized measure of student understanding of the material, ensuring that the assessment reflects the type of knowledge and critical thinking required for success on future board examinations.

The SIS-M survey's analysis focused on various dimensions of situational interest: triggered interest, maintained-value (MV), maintained interest, and maintained-feeling (MF). Thematic analysis was conducted using ChatGPT (GPT4o and o1-preview) and Claude 3.5 Sonnet. This involved generating initial codes and identifying themes, followed by the researcher combining and refining these themes for overlap and relevancy between the 3 LLMs [31]. Prompt engineering techniques used included Persona Prompting [23,24], Zero-Shot Chain of Thought (CoT) [25], and Self-Criticism [32]. The Zero-Shot Chain of Thought prompting was not used with the ChatGPT o1-preview model, as it has built-in Tree-of-Thought functionality in every output. The initial prompt was the following:

> *Act like a brilliant medical education researcher. I am doing a study on a Cinematic Clinical Narrative (CCN) which is an educational tool that combines clinical case studies with storytelling techniques typically seen in movies or TV shows. By embedding medical information within a compelling fictional storyline, CCNs help medical students retain complex medical concepts in an engaging, memorable way. The CCN in the study was called "Shattered Slippers," was a fictional sequel to the movie "Another Cinderella Story," and stars Selena Gomez. It covered the topics of immunomodulatory medications for treating lupus, and kidney transplants. I surveyed the participants on their preference of the CCN over traditional clinical cases and asked them to explain their preference. Please perform a thematic analysis on the below participant responses marked between <response> </response>. Let's work this out in a step by step way to be sure we have the right answer.*
>
> *<response>*
>
> *Participant responses here*
>
> *</response>*

This was then followed by the following Self-Criticism prompt: "Please reflect on your previous answer for any errors."

Ethical Considerations

This educational research was approved as exempt by the institutional review board of the University of Idaho (21-223). As the CCN incorporated references to real celebrities and included AI-generated images of actual people, we consulted legal counsel to ensure compliance. The counsel advised that, given the educational context and the clear labeling of images as AI-generated rather than real, the usage was permissible. Furthermore, we end the CCN with a brief description of the real-life health struggles of the celebrities, which is all public information. However, since this remains a legally gray area, we recommend exercising caution in future projects that use similar techniques. The SIS-M was conducted anonymously to ensure the confidentiality of participants' responses. No identifying information was collected, allowing students to provide honest feedback without concern for personal attribution.

Results

The quantitative assessment of the "Shattered Slippers" CCN using the SIS-M is summarized in Table 2. The results indicated high levels in participants' interest with the "Shattered Slippers" CCN, with the majority of students (14/18) indicating a preference for the CCN over traditionally presented clinical cases, only 1 student preferring the traditional approach, and 3 expressing no preference (Table 3).

Table . Situational Interest Survey for Multimedia results (N=18): scores.

Question	Minimum[a]	Maximum[a]	Mean[a]	SD	Variance
The Shattered Slippers case was interesting.	4.00	5.00	4.61	0.49	0.24
The Shattered Slippers case grabbed my attention.	4.00	5.00	4.72	0.45	0.20
The Shattered Slippers case was often entertaining.	3.00	5.00	4.67	0.58	0.33
The Shattered Slippers case was so exciting, it was easy to pay attention.	3.00	5.00	4.33	0.58	0.33
What I learned from the Shattered Slippers case is fascinating to me.	4.00	5.00	4.39	0.49	0.24
I am excited about what I learned from the Shattered Slippers case.	4.00	5.00	4.39	0.49	0.24
I like what I learned from the Shattered Slippers case.	3.00	5.00	4.39	0.59	0.35
I found the information from the Shattered Slippers case interesting.	4.00	5.00	4.33	0.47	0.22
What I studied in the Shattered Slippers case is useful for me to.	4.00	5.00	4.50	0.50	0.25
The things I studied in the Shattered Slippers case are important to me.	3.00	5.00	4.28	0.56	0.31
What I learned from the Shattered Slippers case can be applied to my major/career.	3.00	5.00	4.44	0.60	0.36
I learned valuable things from the Shattered Slippers case.	4.00	5.00	4.44	0.50	0.25

[a]Rated on a 5-point scale (1=Strongly disagree, 5=Strongly agree).

Table . Situational Interest Survey for Multimedia results (N=18): preferences for case type.

Which case type do you prefer?	Count
Traditional case studies	1
Shattered Slippers case study	14
No preference	3

Participants indicated a high average triggered situational interest in the CCN (mean 4.58, SD 0.53), as well as high maintained interest scores indicated by the students (mean 4.40, SD 0.53).

The results for MF interest indicated high MF in students receiving the CCN (mean 4.38, SD 0.51). A feeling of educational value by the participants was supported by high scores for MV interest (mean 4.42, SD 0.54).

Bridging quantitative data with qualitative insights, the survey conducted among participants also provided an open-ended question for students to reflect on their opinion of the CCN. Thematic analysis of the responses revealed the following:

- *Enhanced engagement through storytelling and entertainment*: The combination of storytelling and entertainment in the CCN heightened student engagement, making the learning process more enjoyable and effective compared with traditional methods.
- *Improved memorability and recall of medical concepts*: The CCN's engaging narrative and multimedia elements enhanced memory retention, making complex medical information more accessible and memorable.
- *Relatability through pop culture and personal connection*: Leveraging familiar pop culture icons such as Selena Gomez helped students form a personal connection with the material, enhancing engagement and motivation to learn.
- *Preference for interactive and detailed learning*: Some students value interactive learning environments and detailed information, suggesting that while the CCN is engaging, it could be further enhanced by incorporating active learning elements and comprehensive content.
- *Suggestions for improvement*: Attention to technical elements, such as the use of genAI voice narration, could improve the overall effectiveness and reception of the CCN.

The thematic analysis reveals that the CCN "Shattered Slippers" was preferred over traditional case studies due to its engaging storytelling, enhanced memorability, and relatability through pop culture references. While students appreciated the innovative approach, some expressed a desire for more interactive learning methods and provided suggestions for technical improvements. Incorporating these insights can further refine the CCN as a valuable tool in medical education.

In addition to the survey feedback from the SIS-M, the success of the "Shattered Slippers" CCN was further demonstrated academically. Students displayed strong comprehension and knowledge of the material covered, achieving an average score of 88% on examination questions pertaining to the case study content. This high performance underscores the effectiveness of the CCN as a teaching tool, suggesting that it may also be useful in promoting academic performance as well as student preference and interest.

Discussion

Principal Findings

The "Shattered Slippers" CCN supports the pedagogical value of integrating innovative genAI-driven methods and culturally resonant themes into medical education. Our study shows the capacity of this approach to not only enhance student interest but also promote their understanding and retention of complex subject matter. Furthermore, it adds very little to no extra time to the lecture material, as it basically reskins the existing material into a more cinematic experience. This is particularly important, as many new active learning teaching methodologies either extend the amount of time students spend with the material or cause instructors to remove large amounts of material in order to incorporate novel active learning activities. We considered it ethical to clearly mark AI-generated images of real individuals to avoid confusion but did not deem it necessary to label AI-generated material such as text or audio that was not mimicking a real-world person. As genAI models continue to improve in generating realistic images and cloned voices, it will become increasingly important to label AI-generated materials that mimic real-world individuals to prevent confusion with reality and avoid potential legal issues.

This study shows the importance of engaging students beyond conventional didactic methods, suggesting that the inclusion of elements such as plot development, multimedia, and popular culture can make learning more relatable and impactful. The feedback from the SIS-M supports that this approach can effectively address the initial problem of student disengagement and the need for more effective educational strategies as identified in the introduction.

The process of creating CCNs with genAI tools is highly efficient and cost-effective. Designing the case outline took about a day, while plot and narration generation were completed in seconds using GPT-4 and Eleven Labs. Image and theme song generation took under an hour each, with slight delays due to iterative refinement. Overall, the time investment was minimal compared with traditional methods. The required technical skills are basic, involving familiarity with genAI platforms for text, image, and audio generation and standard project management skills to integrate these elements into a PowerPoint slide deck. In terms of cost, the only expense was a US $20 per month subscription to ChatGPT; other platforms were used on free tiers. This low cost, combined with fast production times, makes migrating to this format highly accessible and efficient for educators, offering significant time and cost savings compared with traditional content creation methods of this caliber.

Future directions of this work will explore how similar immersive educational experiences can be scaled and adapted for diverse student populations and learning environments. The versatility of genAI-enhanced CCNs extends beyond pharmacology, offering potential applications in other areas such as anatomy, pathology, and clinical skills. This pedagogical strategy can be adapted to various medical disciplines, making abstract topics more engaging and accessible to diverse learners. It also asks questions on how educational policies might evolve to integrate this type of AI-generated material into curricula systematically. As genAI becomes more integral to education, policies must address both the ethical use of genAI and the need for genAI literacy among educators and students. Personalized, genAI-driven learning experiences could revolutionize how content is delivered, providing flexibility and tailored learning opportunities. There is an opportunity to explore interdisciplinary collaborations, merging medical education with fields such as AI, storytelling, and multimedia design. These collaborations could further refine educational tools and help bridge the gap between traditional learning and modern health care technologies, fostering genAI literacy in future medical professionals. This promising pilot study shows potential for scalability and broad applicability of genAI-enhanced CCNs. The strategy offers a model for

transforming how complex medical topics are taught, providing a scalable, engaging solution that can be adapted across different medical content areas to meet evolving educational needs.

Limitations

Our project has limitations in terms of cultural adaptability due to its reliance on specific cultural references and celebrity figures, which may not resonate with all audiences. Furthermore, the use of genAI technologies presents challenges in environments with varying levels of technological resources and differing instructor familiarity with these platforms. While the skills required to effectively use genAI can vary depending on the model, these challenges are mitigated by the increasing availability of more user-friendly genAI platforms. These platforms are simplifying AI integration in educational contexts, expanding the potential for their broader application. For instance, prompt engineering, which is crucial for optimizing output from LLMs, is becoming less essential with newer versions such as ChatGPT's o1-preview model, which incorporates many of these strategies into the system itself. This reduces the need for advanced user expertise and lowers the barrier to efficient LLM use.

Another limitation of our study is the process of validity checking for AI-generated content. Although the materials were reviewed by medical professionals, including physicians, PhDs, and PharmDs, to ensure accuracy, the use of genAI introduces potential risks in content reliability, especially as AI-generated content may produce subtle inaccuracies or lack the nuanced context that a human expert might provide. Future implementations of this approach would benefit from a formalized validation process to ensure that the clinical and educational integrity of AI-generated materials is maintained.

The evaluation methodology, focusing on immediate reactions via the SIS-M, provides a single time point of the resource's impact but does not capture the longevity of knowledge retention or the applicability of the learned material in clinical settings. Furthermore, the study included a limited sample size, with only 18 respondents to the SIS-M survey, which may not provide a comprehensive view of the broader student population. Future research could explore longitudinal studies to measure the lasting educational benefits of such methodologies with a larger participant population.

Furthermore, our study lacked a control or comparison group, a common challenge in medical education research. All students in the study were exposed only to the CCN case, and without a traditional case-based learning comparison, it is difficult to isolate the exact impact of the CCN on student performance. While we acknowledge that a control group could provide valuable insights, the integration of such comparisons is often logistically difficult in medical school settings. Future studies could address this by designing more controlled experimental conditions or through the use of quasi-experimental designs to better understand the differential effects of various educational interventions on learning.

Conclusions

The "Shattered Slippers" CCN demonstrates the effectiveness of combining cinemeducation with genAI in medical education. This approach enhanced student engagement, promoted knowledge retention, and offered a novel perspective on complex pharmacological clinical cases. The application and positive student feedback suggest that this multimodal genAI approach to educational content creation has potential for broader application in medical education. Our project also highlights the need for continuous innovation and adaptation in teaching methodologies to meet the evolving demands of health care education. Future research and development in this area could further transform medical education, making it more engaging, effective, and aligned with modern technological advancements.

Acknowledgments

The author would like to extend his heartfelt gratitude to his students for their participation and invaluable contributions to the "Shattered Slippers" project. Their engagement and feedback were essential in shaping this educational endeavor and its success.

Abstract

Background: With the rapid development of artificial intelligence technologies, there is a growing interest in the potential use of artificial intelligence–based tools like ChatGPT in medical education. However, there is limited research on the initial perceptions and experiences of faculty and students with ChatGPT, particularly in Saudi Arabia.

Objective: This study aimed to explore the earliest knowledge, perceived benefits, concerns, and limitations of using ChatGPT in medical education among faculty and students at a leading Saudi Arabian university.

Methods: A qualitative exploratory study was conducted in April 2023, involving focused meetings with medical faculty and students with varying levels of ChatGPT experience. A thematic analysis was used to identify key themes and subthemes emerging from the discussions.

Results: Participants demonstrated good knowledge of ChatGPT and its functions. The main themes were perceptions of ChatGPT use, potential benefits, and concerns about ChatGPT in research and medical education. The perceived benefits included collecting and summarizing information and saving time and effort. However, concerns and limitations centered around the potential lack of critical thinking in the information provided, the ambiguity of references, limitations of access, trust in the output of ChatGPT, and ethical concerns.

Conclusions: This study provides valuable insights into the perceptions and experiences of medical faculty and students regarding the use of newly introduced large language models like ChatGPT in medical education. While the benefits of ChatGPT were recognized, participants also expressed concerns and limitations requiring further studies for effective integration into medical education, exploring the impact of ChatGPT on learning outcomes, student and faculty satisfaction, and the development of critical thinking skills.

Introduction

Artificial intelligence (AI) is a computer-based technology invented as a digital system to imitate and aid human intellect and skills. The wide use of AI technology is changing the medical field considerably, aiming for more efficient patient management. Medical education is one of the vital domains of health care practice, in which AI has a promising contribution by providing an alternative and efficient means of information access, achieving teaching goals and skills development. As an example, the integration of AI in simulated surgical skills learning showed comparable results compared to remote expert instructions [1], but it led to unintended outcomes in another study, which affected trainees' efficiency metrics on the cost of safer skills development [2]. Case-based learning is another potential field harnessing AI technology in medical education, which has shown promising results [3]. AI technology has also been used in teaching clinical examination skills, such as breast self-examination, yielding mixed results: high levels of student satisfaction paired with increased anxiety [4]. Such AI-driven interventions will be leading health care practice in the future, such as the introduction of machine-based surgical treatment with robotic surgery, which has effectively promoted diagnostic accuracy, achieving treatment goals and saving health care professionals' workload [5-7]. AI technology integration in medical education and medical research will not only contribute to patients' care but also improve if not revolutionize the medical education system [8,9]. All these changes of AI integration into the medical practice need to be accompanied by evolution in the medical teaching and training curricula [8,9], facing significant interest among educators and researchers recently on AI's rapid involvement in medical education [10-13].

One of the pioneer and popular generative AI-based tools is ChatGPT, a language model developed by OpenAI that uses natural language processing to generate humanlike responses to queries, with many potential applications in health care [14,15]. ChatGPT was perceived by health care workers to positively impact the future of health care systems by 76.7% in a recent study [16]. However, little is known specifically about the perceptions and experiences of faculty and students or trainees against the use of ChatGPT in the context of medical education within Saudi Arabia.

The health care sector in Saudi Arabia is experiencing dramatic growth and reformatting, with a strong emphasis on prioritizing medical education and digitizing the health systems. Therefore, using AI technology in the health care system is a promising strategy for substantial investments in medical, nursing, and other specialized educational disciplines [17]. As medical education evolves, the use of AI-based tools like ChatGPT could potentially transform the way medical education is delivered [18]. Literature has a gap in assessing the perceptions and attitudes of medical education stakeholders regarding integrating AI technology in curricula, clinical teaching, and simulation skills development. Most literature addressed specific AI technology adoption in medical practice or certain educational domains but did not assess it collectively in multiple domains related to medical education. Therefore, it is crucial to explore the medical faculty staff and students' knowledge, perceived benefits, concerns, and limitations of ChatGPT application in medical education.

This qualitative study seeks to explore the perception on the use of newly introduced AI chatbots, like ChatGPT3.5, in medical education from the perspective of faculty and medical students. By deepening our understanding of faculty and students' knowledge about ChatGPT and its applications in medical education, this study identifies both the facilitators and barriers to its use. The research offers valuable preliminary insights into the acceptance of AI-based tools in medical education and informs the development of effective strategies for integrating such tools within medical education systems in Saudi Arabia and similar contexts, as more AI models evolve.

Methods

Study Design

This study was conducted using a focus group technique at the College of Medicine, King Saud University, a leading university in Saudi Arabia [19]. The study included faculty and students from different levels.

The study aims to preliminarily explore and understand participants' perceptions of ChatGPT, a newly introduced large language model. A qualitative methodology was chosen, as it is well suited to exploring experiences, meanings, and perspectives from participants' viewpoints [20-22]. Examining the perceptions of both faculty and students enables a comparative head-to-head analysis of their viewpoints. Qualitative methodology provides a deep explanation of different viewpoints participants may have about ChatGPT use in medical education. It can also allow the authors to propose probing questions to understand and explore users' perceptions. Although individual interviews would elicit a more detailed picture of an issue, focus group discussion was used, as the aim

of the study is to explore different viewpoints using participants' dynamics and thought sharing to enrich the discussion [23]. Data source triangulation was applied to support the trustworthiness of the findings and allow prelude comparison.

Participants were recruited from the College of Medicine through purposive sampling. As a small number of faculty and students used ChatGPT at the time of data collection, a purposive sample was applied. A student was asked to announce the need to interview students who have ever used ChatGPT. Another announcement to faculty was made, and an invitation was sent to random faculties from 3 departments who use or want to share their ideas about ChatGPT in medical education. The sample included 6 medical faculty members (2 associate professors and 4 professors) and 6 medical students (2 second year, 2 third year, 1 fourth year, and 1 fifth year). Two focus group discussions were conducted in April 2023 on the Zoom platform (Zoom Video Communications), one with faculty members and the other with students, and each group consisted of 6 participants. The discussions were conducted in English language as preferred by the participants. Two of the authors (NA and MHT) served as moderators, and each discussion lasted for approximately 1 hour.

Using the Zoom platform in data collection facilitated gathering participants at the same time after working hours. As the team acknowledged that nonverbal cues may not be detected as participants refrained from opening their cameras, follow-up questions and probing were used to minimize subjectivity in understanding participants' responses. Not all participants knew each other; hence, the setting was more private to freely share opposing views.

A topic guide was prepared by the author (NA) to cover aspects such as participants' familiarity with ChatGPT, its uses, facilitators, and limiting factors of its incorporation in medical education. Probing and follow-up questions were allowed depending on participants' responses. The themes were saturated at that time after the second interview possibly due to the limited experience of participants in the early stages of ChatGPT launch. Thematic analysis was used to analyze the data using a priori themes and allowing new themes to emerge from the data [24]. The discussions were transcribed using Zoom's automatic transcription feature. This feature had the advantage of identifying the name that the participants chose for themselves in the discussion and linking it with the speaker.

The transcripts were revised and read multiple times to identify patterns and themes that emerged from the data. A coding framework was developed from the data by each coder (NA and MHT) and applied using NVivo software (version 12; QSR International) [25]. Themes were identified and refined through an iterative process of coding, reviewing, and discussing the data among the research team until a consensus was reached [24]. Initial codes were developed by 2 different authors (NA and MHT) and then, comparison and discussion were made to agree on the coding framework. Coding themes were similar, and no major changes were made in the thematic framework.

Ethical Considerations

This study received ethics approval from the Institutional Review Board at King Saud University (approval 23/0155/IRB). All participants provided verbal informed consent prior to their inclusion in the study, including consent for the audio recording of interviews. Participants were fully informed about the purpose of the study, the voluntary nature of their participation, and their right to withdraw at any time without any consequences. To ensure participant privacy and confidentiality, pseudonyms were assigned, and no identifying information was included in the transcripts or final report. The data were securely stored and accessible only to authorized members of the research team. No compensation was provided to participants for their participation in the study.

Results

Overview

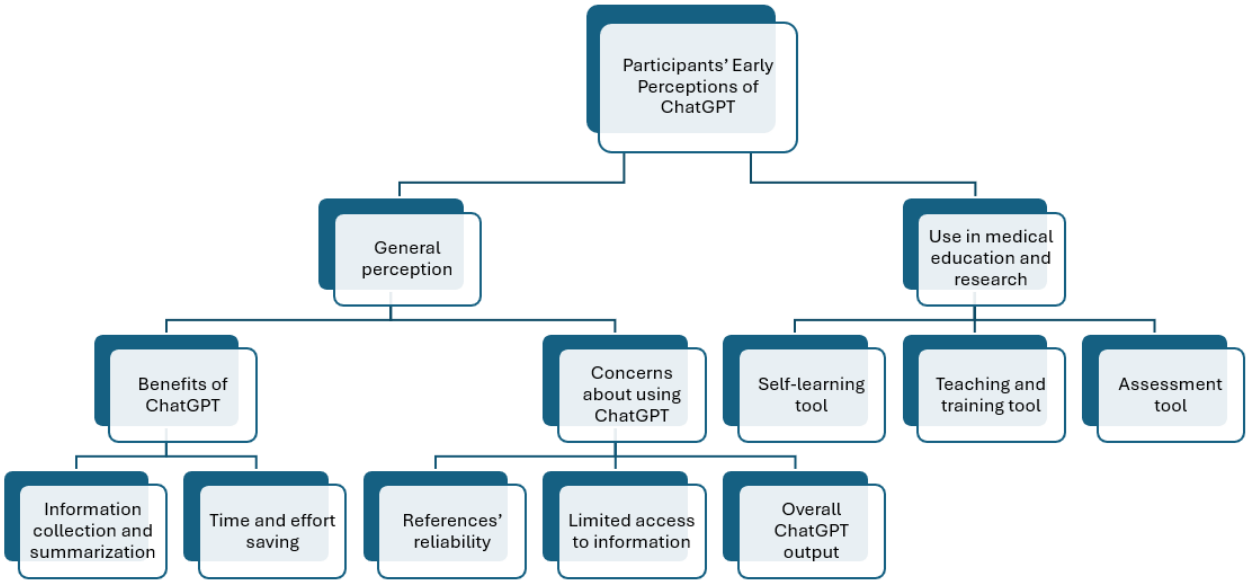
In total, 6 medical faculty staff and 6 medical students with different experiences with ChatGPT participated in the study. Table 1 shows their demographic data. Figure 1 displays the thematic framework used to assess participants' perception of ChatGPT in general and in medical education.

Analysis of the data from the discussion generated two main themes: (1) participants' general perception of ChatGPT and (2) ChatGPT use in medical education and research.

Table 1. Participants position, department, and frequency of ChatGPT use.

Participant code	Position	Department	Age (years) and sex	Using ChatGPT
Participant 1	Faculty	Critical Care Department, College of Medicine	44 and male	Regular user in medical education
Participant 2	Faculty	Ear, Nose, and Throat department, College of Medicine	56 and male	Regular user in medical education
Participant 3	Faculty	Family medicine, College of Medicine	60 and female	Not a user
Participant 4	Faculty	Pediatrics department, College of Medicine	38 and male	Not a user
Participant 5	Faculty	Pediatrics department, College of Medicine	41 and male	Regular user in medical education
Participant 6	Faculty	Medical Education Department, College of Medicine	58 and female	Not a user
Student 1	Student	College of Medicine	20 and male	Regular user for general search
Student 2	Student	College of Medicine	22 and male	Regular user for general search
Student 3	Student	College of Medicine	21 and male	Regular user for general search
Student 4	Student	College of Medicine	21 and male	Regular user for general search
Student 5	Student	College of Medicine	19 and male	Regular user for general search
Student 6	Student	College of Medicine	20 and male	Regular user for general search

Figure 1. Thematic framework of participants' perception on using ChatGPT.



Participants' General Perception of ChatGPT

Overview

All participants expressed good knowledge of ChatGPT's main goal and functions. One participant noted:

> *The idea from this software is that it will chat with you regarding any topic you will ask about...it chats with me in a human like manner, and collect for me the answers from all over resources, and display them.* [Participant 1]

One student described ChatGPT as an "assistant," and others elaborated:

> *Artificial intelligence helps me execute the command that I'm asked to execute.* [Student 2]

> *It's another way of searching for highly accurate information, depending on what I search for and how I search for it.* [Student 5]

Participants were challenged about ChatGPT compared to other traditional search engines: "It is not at similar to Google, even Google started invention of AI application to enrich its platform" (Participant 2). Most participants supported the use of ChatGPT but were not concerned about its information sources.

Benefits of ChatGPT

Two main subthemes emerged from the focus group discussions about the benefits of using ChatGPT.

Collects and Summarizes Information

The majority of the participants believed that searching for information through ChatGPT is more efficient compared to

standard search engines, as the former saves time by summarizing and textualizing the raw information output from the search: "ChatGPT is beautiful in collecting information and presenting it to me in a simplified text that I can easily comprehend" (Participant 2).

Few participants used ChatGPT to review scientific papers or provide ideas for new papers: "I used it to study limitations of studies and the future recommendations for studies I was asked to review...it gives me ideas" (Participant 2).

Students also noted:

> *I find ChatGPT more directive towards what I ask, and to the point, mostly because when I look for something on classical search engine, such as Google...I have to go into some sub web pages which has an answer and look between all the thousands of answers to find one. While ChatGPT will give it to me concisely like this is option A, option B, option C.* [Student 3]

Another faculty added, "It will do the search for me; then even with critically appraise it and give me the final result" (Participant 1). However, one faculty participant was more conservative in her comments about using AI in collecting data and did not perceive the information displayed by ChatGPT as reliable because it lacks the "critical thinking" skill to enable it to reach a final scientific plausible conclusion, "The problem of collecting all the information in one place is that collecting the information and giving it in a nutshell, in one place. This machine is not critically thinking" (Participant 3).

Saves Time and Efforts

Opinions varied in terms of whether using ChatGPT saves time and effort, considering the perceived benefits. One faculty mentioned: "It saves time when I'm stuck in generating exam question" (Participant 2). A student added: "It's not accurate, but at least it saves me time. This is the most important point" (Student 4).

On the other hand, another faculty participant subtly disclosed her denunciation about the functionality of ChatGPT. She believed that ChatGPT helps partly in performing tasks, but that advantage is contradicted by paying time to verifying and authenticating the ChatGPT output.

> *Me as a researcher. When I search for information I'm putting it together, ChatGPT tries to put it for me. So far, I can't see it superior to the human mind...It does some of the work for me, but I have to take it with a bunch of salt.* [Participant 3]

Concerns About Using ChatGPT

When the participants discussed the drawbacks of using ChatGPT, they mentioned expressions such as "hallucination" and "blinding euphorically." The following subthemes emerged as perceived drawbacks of ChatGPT.

References Reliability

While few participants were not sure about the source of ChatGPT information, most participants believed that it is the internet: "It's the same data retriever as Google" (Participant 3). Other participants had a deeper view: "ChatGPT generated references, and citations have to be taken with caution" (Participant 2).

Faculty experienced situations where they doubted the reference of the information provided by ChatGPT. For example, one faculty noted: "I'm not sure what are the sources used to extract information, even if I ask for references, it might not mention them...or at least it will not volunteer in mentioning them" (Participant 1). While others defended that: "If it doesn't have access to the reference, it will tell that it doesn't have access, but if the reference is online, it can refer to that" (Participant 2).

Similarly, a student commented: "It is multitasking, rather than searching for the source of information, it presents the answer and references" (Student 5). One participant pointed that the unreliability of ChatGPT sources supports her view of not relying on ChatGPT.

Limited Access to Information

Several participants acknowledged ChatGPT's limitation in accessing all available information, driving caution while using ChatGPT:

> *One of the restrictions regarding medical search, it's restricted to certain resources like PubMed...there are some other medical websites that it cannot access yet.* [Participant 4]

> *We don't know the algorithm behind the search nor exactly how it looks for information.* [Participant 6]

One of the participants elaborated that ChatGPT is invented by humans; therefore, they may manipulate or restrict its search and output.

> *It's not free of bias. If I am asking for something morally wrong or illegal. It will not answer because it is constrained. So, it is not fully free from human constraints.* [Student 3]

Some faculty participants raised an ethical concern that may affect the trust in ChatGPT information. One participant explained:

> *Can drug company pay ChatGPT to display answers that are in favour of certain medication? Could ChatGPT be manipulated? ChatGPT inventors are for sure looking for money somehow by anyway!* [Participant 1]

Overall ChatGPT Output

All participants believed that ChatGPT users should not fully trust the information presented and practice caution, while others elaborated that it is ideal for new topics as a jumpstart:

> *I should not take it (information from ChatGPT) for granted; I have to review what's there, but it gives me a nice idea, very excellent ideas...It sheds the light on some certain angles that I was not looking for.* [Participant 2]

Some participants pointed that trusting ChatGPT output depends on your previous background about the topic:

> *I should have the ability to differentiate between what is reliable and what is not reliable...Myself, I am not well-versed in medical education. For example, I am highly qualified in research, but regarding education I take for granted whatever output from ChatGPT in that regard, while I can filter information regarding research and judge it well.* [Participant 3]

One student agreed:

> *It depends on what I am looking for. Sometimes it's very accurate. Sometimes it's not...But as a human mind I have an idea about what I am looking for, therefore, I can judge if its accurate or doubt the answer.* [Student 4]

All participants agreed that the unfamiliarity of ChatGPT users with its search algorithm enforced the participants' trust issue.

A faculty explained:

> *Do we know the ChatGPT searching methodology? is it scientific methodology? How it extracts the information from the paper, how it appraises it? What are the sources that this engine has access to? All this will augment the reliability of my experience.* [Participant 1]

One participant mentioned that ChatGPT cannot be used for critical thinking in certain contexts; thus, it cannot be fully trusted:

> *It cannot give me what is relevant to me, my community and population and my students...It might be dangerous to put ChatGPT superior to human intellect!* [Participant 3]

Another faculty participant defended the ChatGPT's reliability, noting that it declares its level of expertise and specialty ahead of each information presented:

> *If I ask ChatGPT about something in geology, it will start with "I am not a geologist" and then move on with the dialogue...and it finishes the response by "it is very important to refer to those sources."* [Participant 2]

ChatGPT Use in Medical Education and Research

Participants discussed ChatGPT use in medical education from 3 aspects as discussed below, but in general, they raised concerns about using it without appropriate and dedicated training.

Self-Learning Tool

The majority of faculty participants supported using ChatGPT in the teaching process. A faculty participant commented:

> *Students are no longer enjoying the usual long lectures, or didactic lectures but they enjoy more challenging aspects exploring a new experience, and living it...I think the ChatGPT could be used as a very good trigger for the students to go and read and find out more, discuss among themselves and go explore this with their seniors, with their educators.* [Participant 5]

Another faculty added that it should be used to get an idea about a topic, but further reading is important for students:

> *ChatGPT is like a short fast access to a topic, it helps to get the most important information...they (students) need to read the references.* [Participant 1]

However, another faculty participant raised concerns using ChatGPT for concluding opinions and summing debates:

> *If they (students) use ChatGPT just for recalling information then no problem...But if they want to make inferences, they should not use it.* [Participant 3]

ChatGPT methodology was raised by another faculty participant who did not support using it in learning at all because of its unclear methodology and unverified information sources.

On the other side, the majority of student participants did not support using ChatGPT to obtain information and felt the traditional search engines are more reliable and easier to use:

> *I do not perceive it as a search engine. I don't look up medical information on it, or anything, because I find the classic search engines easier.* [Student 2]
>
> *I know exactly where the reliable sources are. Then I can take the information from other sources with confidence, and more simple steps.* [Student 1]

Some participants, while supportive of ChatGPT's use in medical practice, emphasized its role in clinical medicine education. They raised concerns about its impact on decision-making, particularly due to ChatGPT's inadequate or unclear strategy for disclosing information sources:

> *If I look at the other search engines for which support medical information, they present like up-to-date information...ChatGPT is very complex, and the methodology and the algorithm it uses is not clear so, it is not a reliable source of information for decision making and for serious information.* [Participant 1]

The issue of updated sources in ChatGPT was also raised:

> *We need to be cautious about using the information...the medical field information is changing very quickly, so we have to be careful about this point.* [Participant 4]

Other participants debated that the information accuracy depends on user searching and prompt engineering skills:

> *Prompt questions will make the difference in getting the response, and I recommend digging into the prompts technology to get more accurate answers, and doing this is important to acquire the right answer.* [Participant 2]
>
> *You get the response according to the precision of the search.* [Student 1]

Interestingly, a faculty participant raised the concern of students and faculty losing their critical thinking skills if they depend on ChatGPT:

> *It is dangerous...because we are replacing critical thinking. We are prioritizing this thing over human intellect.* [Participant 3]

A student participant who expressed poor research skills was concerned about such skills being affected or even weakened by dependence on ChatGPT in research. In general, students did not support the use of ChatGPT as the primary source of information, especially for new topics, but as a collateral resource.

Teaching and Training Tool

Some participants believed that teaching modalities should change after the introduction of AI technology. They expressed optimism of more teaching methodology shifting from memorization to critical thinking; however, this aim was not perceived achievable through ChatGPT so far:

> *We must invest more in the skills of our medical students and problem-solving critical thinking analysis. These are the areas that is lacking in the ChatGPT, and that we need to focus more on.* [Participant 4]

Faculty participants raised concerns about students' replacement of traditional lectures with AI applications like ChatGPT, which might be risky in general, especially in the current stage of unverified and undedicated AI applications for medical education.

Another concern raised from one faculty regarding the lecturers and trainers:

> *Do our faculty have enough knowledge to use and recommend ChatGPT for their students and instruct them how to use it and get maximum benefit from it?* [Participant 3]

However, all students did not see themselves relying on ChatGPT for learning: "We just need to be familiar on how to use ChatGPT and use it as a tool that supports our search rather than completely relying on it" (Student 2).

Faculty participants differentiated between the needs of postgraduate and undergraduate students and their use of ChatGPT. One faculty (Participant 3) felt that using AI in training postgraduate trainees would be difficult because postgraduate training depends on building skills, while undergraduate depends on memorization as per him.

ChatGPT might be a tool to generate clinical scenarios and draw a framework for discussions with the students:

> *One problem would take weeks from our team and long hours of sitting together and creating the medical problems that we teach in the problem-based learning sessions. So, it would be interesting to see how ChatGPT deals with this.* [Participant 4]

An interesting point mentioned by some faculty is the inability of ChatGPT to teach students human, emotional, and social skills: "Using AI is not designed to help in teaching some skills such as Humanity and the communication, the teamwork" (Participant 4).

Assessment Tool

Most faculty participants mentioned using ChatGPT for academic assessment like examination questions generation:

> *I asked ChatGPT to generate questions for me with scenario and without scenario...it was good to Very good. It's not reaching to excellent level. I have to review and modify.* [Participant 2]

In addition, most faculty participants mentioned using ChatGPT for medical problems, clinical scenarios, and bedside teaching. Some faculty participants raised the idea of using AI applications like ChatGPT to assess the quality and objectives of examinations in order to guide certain questions to assess critical thinking rather than recall knowledge only. Cheating and plagiarism were one of the raised concerns by the faculty during the discussion: "We have to be very careful about cheating and misuse of ChatGPT by our medical students in medical assignments" (Participant 4).

In line with the former comment, one student defended his use of ChatGPT, raising a debatable point of using AI applications for academic assignments is ethical or not:

> *I mainly use it for writing, and then I just review it and edit it...mainly for research or some essays...for example I'd give it some data, and I ask it to write a paragraph that summarizes this data, or an introduction to something for example (Disease X).* [Student 2]

Another student mentioned that his use of ChatGPT in assignments is mainly for summarization. Others use it to collect information resources: "It can make my job way easier. For example, if I have a research assignment to just collect the resources about a topic" (Student 3).

Overall, all participants reached a conclusion of being open-minded and accepting for the ChatGPT intrusion into our lives: "I think it's coming in the near future, and we need to live in the reality to adjust and take the best out of it" (Participant 4).

Discussion

Principal Findings

This paper presents a general snapshot of the faculty and undergraduate medical students' perceptions of ChatGPT and its use in medical education. All participants demonstrated a good understanding of ChatGPT and its functionalities; some described its role as assistive, while others found it as a mere information search tool. Almost all participants were impressed by ChatGPT's ability to provide a concise summary of search results compared to traditional search engines, which is in line with the literature [26]. On the other hand, few students in our study perceived Google as a better tool for learning.

In line with other publications [27], our participants believe that ChatGPT provides a more user-appealing and faster solution for busy users by delivering a summarized, high-caliber textual output. One of the major challenges they mentioned regarding ChatGPT use is its sources of information, which is in line with previously published similar studies showing that students and

faculty are aware of the limitations of ChatGPT that influence its accuracy [26,27]. In a comparative study between platforms, ChatGPT-generated responses were considered to be reliable and beneficial, while others deemed them potentially risky [28]. For example, a study showed that there were concerns about ChatGPT advice regarding antimicrobial stewardship, general course lengths were accurate but the duration varied, and source control was either incorrectly cited as justification for prolonging therapy or ignored entirely [29]. Therefore, ChatGPT output should be dealt with skeptically and selectively, as poor users' baseline knowledge might lead to risky, dangerous, or suboptimal conclusions. Previous literature has shown that in comparison with Google, the majority of the participants tend to doubtfully trust ChatGPT output for reasons related to the novelty of AI and users, lack of understanding of its algorithm, and information sources as studied previously [14,30]. Notably, only 40% of these experts concluded that the perceived value of ChatGPT's responses outperformed those from Google [31].

Therefore, participants tend to trust ChatGPT responses if they have a previous background about the search topic. Participants suggested that while ChatGPT might be helpful in certain aspects of medical education, users should approach the information with caution and apply their medical judgment.

The participants' concerns about ChatGPT output also stemmed partly from the observed phenomenon of references' hallucinations, which raised serious concerns about its reliability and validity [32-34]. In addition, they stressed on the point of ChatGPT's limited access to updated medical literature. A previous study had cautioned authors regarding references generated by ChatGPT [35]. To overcome these limitations, developers should work on expanding the access of ChatGPT's resources, improving its search methodology, and ensuring a more comprehensive and reliable source of information.

Faculty participants explored the potential of ChatGPT in generating examination questions and clinical scenarios, enhancing bedside teaching, and reviewing assessments. Still, they emphasized the need for reviewing and modifying AI-generated content as well as the importance of developing policies and strategies to tackle potential academic misconduct related to ChatGPT use. Previous studies showed ChatGPT's excellent performance as it passed the American Heart Association examination with 84% accuracy, but it failed Taiwan's family medicine examination and fared poorly on the urology self-assessment examination [36-38]. A study concluded that ChatGPT responses were frequently incomplete and sometimes misleading [26]. However, a recent expletory review showed that ChatGPT has a potential impact on medical education, scientific research, and medical writing [14]. Thus, the ChatGPT's generated questions need to be carefully examined and revised especially regarding scientific content. Other research highlighted that generated output in that regard is not highly different among different AI platforms, as the multiple-choice question–based examination performance of ChatGPT was marginally better than that of Google's Bard [39].

Both faculty and students appreciated the time-saving advantage of ChatGPT and its fast access to information. Therefore, faculty used it in preparing lecture materials and examination questions. While students used it in their academic assignments, this mirrors a previous study about ChatGPT perception among students who used it for generating academic content, brainstorming ideas, and writing texts [40,41].

Faculty in our study and previous research raised concerns about students' ChatGPT overuse [13,27,42]. According to our participants, using it by students may interfere with their critical thinking, writing, and information retrieval skills. Faculty highlighted the students' need to critically review and modify the AI-generated content, ensuring it aligns with academic standards and expectations. Banerjee et al [11] reported that postgraduate trainee doctors have an overall positive perception of the impact of AI on clinical training; however, they found that AI will eventually reduce the trainees' clinical judgment and practical skills. In line with that, the faculty participants were concerned about students' self-reliance on AI applications on the cost of traditional teaching methods, which might deprive them from skills best learned in person or group teaching. One study listed the following as disadvantages: lack of originality, inaccurate content, or unknown data sources [14]. It is also uncertain how ChatGPT handles offensive material, false information, or plagiarism [34].

Ethical concerns, such as potential manipulation by pharmaceutical companies, were raised by participants. Maintaining transparency and integrity in AI-generated information is vital to address these concerns. Implementing measures such as third-party audits, strict guidelines, data transparency, and continuous monitoring of ChatGPT's information sources can help ensure the unmanipulated ethical use of ChatGPT in medical education [43-45].

We recommend creating guidelines for students on the appropriate use of AI applications, specifying tasks they should complete independently and the extent to which AI tools can assist. Additionally, we propose incorporating teaching sessions to help students critically evaluate AI-generated outputs. At this early stage of AI adoption [46], group teaching sessions comparing the critical appraisal of medical topics using AI tools versus traditional search methods would be beneficial. We also emphasize leveraging AI applications primarily as advanced search engines and using their summarization capabilities rather than relying entirely on their final outputs.

Participants emphasized the importance of being open-minded and adopting new technologies like AI chatbots including ChatGPT. As AI chatbots could have cultural bias, addressing cultural differences in learning styles is vital [46,47].

The potential implications of using ChatGPT in medical education include improved efficiency, streamlined information gathering, and time-saving benefits. However, future research is needed to explore the impact of AI-based tools on medical education in terms of quality, student and faculty satisfaction, and the development of critical thinking skills. Ongoing research and evaluation are essential to ensure the effective integration of AI-based tools like ChatGPT into medical education while addressing potential concerns and limitations.

In preparation for the future of medical education, educational institutions should be proactive in integrating AI technologies

like ChatGPT into their curricula and teaching methodologies [48,49]. Educators and policy makers need to remain vigilant about reliability concerns and actively take steps to be ready to address the ethical challenges and possibilities arising from the use of AI in health professions education [37,45]. This process should involve regular evaluations, ongoing improvements, and a strong emphasis on maintaining the essential human aspects of medical education, such as critical thinking, communication, and empathy.

Strengths

One of the strengths of this study is the qualitative design, which allowed for an in-depth exploration of participants' experiences, perceptions, and concerns related to the use of ChatGPT in medical education, revealing diverse viewpoints and generating valuable insights into the potential benefits and challenges of integrating ChatGPT into medical education [50]. Moreover, the study involved participants with varying levels of experience with ChatGPT, ensuring a comprehensive understanding of the perspectives of both novices and experienced users. The identification of themes and subthemes has laid a solid foundation for further research and exploration of AI-based tools like ChatGPT in medical education.

Limitations

There are some limitations to our study. The sample size was relatively small, and the participants were primarily drawn from a single institution, which may limit the generalizability of some findings to other medical education settings. The study did not quantitatively assess the impact of ChatGPT on learning outcomes, satisfaction, or other measurable aspects of medical education, which could in the future provide valuable data to supplement the qualitative findings. Additionally, since the study's focus was on understanding the perception of faculty and students, the perspectives of other stakeholders, such as administrators and policy makers, were not captured, and this could be explored in future research [51-53]. Furthermore, the study, which was conducted in the early phase of ChatGPT launching, did not explore the long-term implications and potential changes in perception and use of ChatGPT over time, as participants' experience with the tool may evolve, altering their views on its benefits and limitations [54].

Therefore, future research should incorporate larger and more diverse samples from multiple institutions as well as conduct quantitative studies to measure the impact of ChatGPT on various aspects of medical education in Saudi Arabia specifically and globally. Longitudinal studies could be conducted to assess the changes in perception and use of ChatGPT over time and evaluate the long-term effects of its integration into medical education.

Conclusions

Participants praised the advantages of ChatGPT, such as time-saving and excellent summarizing skills. However, concerns were raised regarding the accuracy and critical appraisal of information provided by ChatGPT and the need to approach the information with caution. ChatGPT-delivered information and cited references' hallucination were concerns seriously raised by participants, which needs urgent assessment and solution in addition to limited access to certain medical databases. This study highlights the need for ongoing research and evaluation to ensure that AI-based tools like ChatGPT are effectively integrated into medical education while addressing potential concerns and limitations. Educators and students must also maintain a strong foundation in critical thinking and judgment. As medical education continues to evolve, the integration of AI technologies like ChatGPT has the potential to transform the way medical education is delivered but must be done with a thoughtful and ethical approach.

Acknowledgments

We have used ChatGPT [55], an artificial intelligence chatbot developed by OpenAI, to improve some readability and language of this work, without replacing researchers' tasks. This was done with human oversight, and the authors then carefully reviewed and edited the generated text. We assure that the authors are ultimately responsible and accountable for the originality, accuracy, and integrity of their work. We would like to acknowledge the efforts in data curation in the focus groups, namely (listed with their permission): Abdulaziz Alomar, Faisal Alomri, Hadi Alhemsi, Homoud Algadhib, and Ibrahim Alhezam. The authors are grateful to Princess Nourah bint Abdulrahman University Researchers Supporting Project number (PNURSP2025R148), Princess Nourah bint Abdulrahman University, Riyadh, Saudi Arabia.

Data Availability

The preprint of this research is available [56]. The datasets generated and analyzed during this study are not publicly available due to institutional review board privacy regulations but are available from the corresponding author on reasonable request after obtaining institutional review board approval.

Conflicts of Interest

None declared.

Abstract

Background: Large language models, exemplified by ChatGPT, have reached a level of sophistication that makes distinguishing between human- and artificial intelligence (AI)–generated texts increasingly challenging. This has raised concerns in academia, particularly in medicine, where the accuracy and authenticity of written work are paramount.

Objective: This semirandomized controlled study aims to examine the ability of 2 blinded expert groups with different levels of content familiarity—medical professionals and humanities scholars with expertise in textual analysis—to distinguish between longer scientific texts in German written by medical students and those generated by ChatGPT. Additionally, the study sought to analyze the reasoning behind their identification choices, particularly the role of content familiarity and linguistic features.

Methods: Between May and August 2023, a total of 35 experts (medical: n=22; humanities: n=13) were each presented with 2 pairs of texts on different medical topics. Each pair had similar content and structure: 1 text was written by a medical student, and the other was generated by ChatGPT (version 3.5, March 2023). Experts were asked to identify the AI-generated text and justify their choice. These justifications were analyzed through a multistage, interdisciplinary qualitative analysis to identify relevant textual features. Before unblinding, experts rated each text on 6 characteristics: linguistic fluency and spelling/grammatical accuracy, scientific quality, logical coherence, expression of knowledge limitations, formulation of future research questions, and citation quality. Univariate tests and multivariate logistic regression analyses were used to examine associations between participants' characteristics, their stated reasons for author identification, and the likelihood of correctly determining a text's authorship.

Results: Overall, in 48 out of 69 (70%) decision rounds, participants accurately identified the AI-generated texts, with minimal difference between groups (medical: 31/43, 72%; humanities: 17/26, 65%; odds ratio [OR] 1.37, 95% CI 0.5-3.9). While content errors had little impact on identification accuracy, stylistic features—particularly redundancy (OR 6.90, 95% CI 1.01-47.1), repetition (OR 8.05, 95% CI 1.25-51.7), and thread/coherence (OR 6.62, 95% CI 1.25-35.2)—played a crucial role in participants' decisions to identify a text as AI-generated.

Conclusions: The findings suggest that both medical and humanities experts were able to identify ChatGPT-generated texts in medical contexts, with their decisions largely based on linguistic attributes. The accuracy of identification appears to be independent of experts' familiarity with the text content. As the decision-making process primarily relies on linguistic attributes—such as stylistic features and text coherence—further quasi-experimental studies using texts from other academic disciplines should be

conducted to determine whether instructions based on these features can enhance lecturers' ability to distinguish between student-authored and AI-generated work.

Introduction

The rapid development of artificial intelligence (AI) and the emergence of large language models (LLMs), such as ChatGPT, have increasingly blurred the lines between human-written and AI-generated text. This has created a significant challenge in identifying the authorship of written work, especially as the use of AI has become ubiquitous since chatbots have become freely available [1,2]. Consequently, critical concerns have arisen in the educational and academic sectors, where the reliability and authenticity of written work are fundamental.

According to a recent nationwide survey, nearly two-thirds of the German students reported using AI-based tools for their studies, with ChatGPT being the most commonly used chatbot [3]. ChatGPT, developed by OpenAI, an American AI research laboratory, is a state-of-the-art AI chatbot capable of assisting users with a wide range of tasks, from text generation to problem-solving [4,5]. Its capabilities have opened up significant opportunities for educational and academic contexts. For example, AI-based tools like ChatGPT can support tasks such as text analysis, translation, and proofreading for research purposes [6]. They also can provide support to students by enhancing their understanding of scientific methods, improving and refining written work, and assisting with examination preparation [3,7].

However, the widespread use of such tools raises concerns about their impact on students' development of critical and independent thinking skills [8,9]. In addition, it is possible that ChatGPT could provide incomplete or inaccurate information, potentially leading to misunderstandings of academic concepts and topics [10,11]. Further concerns arise from the potential for academic dishonesty and plagiarism, particularly in the context of written assignments and academic essays [9,12].

The lack of clarity on how to handle such cases is putting universities in a quandary, leading to the first court cases and, more recently, to the University of Munich being vindicated in its decision to reject such written work [13]. In this case, an essay submitted as part of a Master's application was rejected because it was "too well written," raising suspicions that the text was likely generated by an AI tool such as ChatGPT [13]. This case highlights that AI-generated texts are often characterized by their seemingly perfected style of formulation that refers to the linguistic level [13,14], a characteristic that is known to be particularly pronounced and even more nuanced in English output texts compared with other languages such as German [15-18].

The relevance of the problem for medical studies is not obvious at first glance because medical students generally do not have to write long scientific texts on a regular basis during their studies, but usually only for their doctoral thesis. However, the increasing use of AI tools such as ChatGPT also poses challenges in the medical field, where assessments rely not only on linguistic quality but also on content accuracy. The potential misattribution of authorship in medical texts—such as research articles, patient information, or promotional materials—has particularly serious implications, as errors or inaccuracies in these contexts can have grave consequences. It can be assumed that medical texts do not fall as much within the scope of ChatGPT and are therefore more difficult to reproduce accurately, especially because AI authors have no "moral scruples" about concealing ignorance and replacing verified sources with falsified ones [19-22]. However, a few studies have addressed the problem of AI-generated content on medical texts [21-26], reporting that ChatGPT has, at times, managed to mislead medical professionals [26], which may suggest that familiarity with content plays a minor role in authorship identification.

Existing research on LLM-based text generators such as ChatGPT frequently focuses on their role in assisting the writing process rather than evaluating the quality and detectability of longer scientific texts [27-29]. In addition, studies often investigate the detection of texts written by chatbots using automatic tools or even detectors specifically designed for this purpose [18,25,27-30]. The detection rate of these detectors is often higher than that of human reviewers, but the accuracy can vary greatly depending on the text genre and the classifier used [14,31]. Moreover, linguistic features appear to be the most important subset of features influencing the performance of feature-based classifiers [2,5]. In the academic domain, educators still face the challenge of qualitatively assessing the authenticity of student texts, often without the aid of automated detection tools.

It is therefore of particular interest to determine how well human readers from the academic field can detect differences when directly comparing 2 texts on the same topic—an original student text and an AI-generated text—and which features stand out as particularly conspicuous and decisive for them. To better distinguish between the relevance of content-related and text-analytical attributes, we assembled a group of language experts from the humanities field alongside a group of medical experts specializing in pediatrics and neurology. Another key novelty and prerequisite of our study is the use of fully reproduced, longer scientific texts on medical topics written in German by medical students.

Therefore, we conducted a study to determine whether medical experts and humanities lecturers could distinguish between texts written by medical students and those generated by ChatGPT

(specifically ChatGPT version 3.5, March 23). Unlike the interactive "Turing Test" [32], this task was not performed through a dialogue with a machine but rather through an internal, personal evaluation of 2 texts. We hypothesize that, in line with the Turing prophecy [32], the correct identification rate for AI-generated texts within a German medical sample is approximately 70%, with content familiarity playing a secondary role, while formal and linguistic features exert a greater influence.

Through a prospective analysis of longer German-language scientific texts written by students in the specialized health-related field of medicine, this study aims to provide new insights into AI-generated texts and the influence of content familiarity and linguistic expertise. The findings are intended to inform the development of guidelines to help lecturers (and others) recognize AI-generated texts, even in the absence of a comparable "original" text, and to contribute to future projects addressing the challenges posed by AI tools in academia.

Methods

Recruitment Process

This semirandomized controlled trial was conducted between May and August 2023 at the University Hospital of Pediatrics and Adolescent Medicine, St. Josef-Hospital, Ruhr University Bochum (RUB), Germany. To recruit participants, an open call was issued to the Department of Pediatrics and Adolescent Medicine and the Department of Neurology at the University Hospital Bergmannsheil (both RUB). Senior physicians and members of scientific working groups were invited to participate, ensuring the involvement of clinical experts familiar with the content of the texts. Participation was voluntary, with clinical employment or medical expertise serving as key inclusion criteria, along with an interest in scientific texts. In the next phase of recruitment, a call was made to the Faculty of Humanities at Ruhr University to include participants with experience in text reception and analysis, with teaching experience as an additional inclusion criterion.

Design

Each participant received 2 pairs of texts, totaling 4 printed texts. Each pair consisted of 1 of 18 available term papers written by a medical student and a corresponding text generated by ChatGPT (version 3.5, March 2023), with the order of presentation randomized. The medical experts received 1 pair of texts on a topic closely related to their specialty and another pair on a less familiar topic. For example, a pediatrician received the text "Autoantibodies in Diabetes Mellitus," while a neurologist received "Measurement of Aδ and C Fibers in Electrophysiology." The second pair of texts covered a topic less directly related to their field of expertise.

Given the exploratory nature of the study, it became increasingly evident—only after completing the experimental phase with the medical experts—that the extent to which content familiarity influences the identification process needed further examination, particularly in comparison to formal and linguistic aspects.

As a result, a second phase of the study was initiated, involving a new group of experts with greater expertise in formal and linguistic analyses. This allowed for a comparison of results and evaluations across groups. In this group of humanities experts, each participant received the same 2 pairs of texts to ensure better comparability and verification of subject unfamiliarity. The first pair addressed a more general topic also familiar to nonmedical fields: "Iodine Deficiency." The second pair analyzed a more specialized medical topic: "Autoantibodies in Diabetes Mellitus."

Participants were asked to read a pair of texts and, based on their personal experience with student-written texts, decide within a week—without extensive research—which of the 2 they believed was generated by ChatGPT. To ensure the blinding of both interviewers and participants, the headers of the texts contained only a randomly generated 3-digit number and a "chatbot or student" checkbox. Before the subsequent interview, participants documented their decision by ticking the corresponding box for their chosen text version. They were also instructed not to discuss the task or the texts with one another.

About 1-2 weeks after the texts were distributed, participants were invited to a semistructured interview—conducted in person, by telephone, or via Zoom (Zoom Communications/Qumu Corporation)—to discuss their decisions, reasoning, and evaluations of the texts. Unblinding occurred after the interviews.

Creation of the ChatGPT-Generated Versions

Eighteen German-language medical essays served as templates for the ChatGPT-generated texts. These essays were written by doctoral students from the University Pediatric Clinic and the Clinic for Neurology at Bergmannsheil University Hospital, RUB, Germany. They originated from the Doctoral Colloquium pool at the University Hospital of Pediatrics and Adolescent Medicine in Bochum. As part of the colloquium, each doctoral student is encouraged to write a scientific essay thematically related to their announced dissertation topic. To provide an initial experience with scientific research and writing—and to give the reviewing study coordinator a first impression of their academic level and skills—students do not receive specific instructions. For this study, all available German texts from this pool that were written before the general introduction of ChatGPT were considered, provided their authors consented to their use.

We used ChatGPT version 3.5, March 14 to replicate the texts. To generate a version with the same title and outline as the original papers while avoiding text breaks, 2 separate prompts were required to produce a continuous text from the introduction to the conclusion (Table 1).

For the main part, depending on the type of original paper, several commands were necessary. For example, see Table 2.

We then merged the individual sections to create a complete term paper, supplementing it with a bibliography that listed the sources provided by ChatGPT in sequential order. To ensure consistency, we harmonized the formatting of both ChatGPT-generated and student-written texts as much as possible, using the Arial font (size 11 for body text and size 12 for headings) with justified alignment. Sections or sentences specific to a student's individual dissertation project were

removed to maintain general applicability. However, we did not alter the choice of words, sentence structure, punctuation, spelling, or citation style.

Table 1. Prompts used to create ChatGPT text.

German (original prompt)	English (translation)
• "Schreibe bitte einen Abschnitt über das Thema [TITEL DES TEILTHEMAS] der [wissenschaftlichen/medizinischen] Hausarbeit [TITEL DER HAUSARBEIT]." • "Belege Deine Aussagen mit Quellen, die bei Pubmed auffindbar sind."	• "Please write a section on the topic [NAME OF SUBTOPIC] of the [scientific/medical] term paper [NAME OF TERM PAPER]." • "Support your statements with sources that can be found on PubMed."

Table 2. Additional instructions used to create ChatGPT text.

German (original prompt)	English (translation)
"Schreibe einen Abschnitt zum Thema 'Potenziell reversible Pathomechanismen als mögliche Ursachen von Hyposmie oder Anosmie bei Kindern' der wissenschaftlichen Hausarbeit 'Ursachen und Diagnostik von Riechstörungen bei Kindern und Jugendlichen', der an den vorherigen Abschnitt anknüpft."	"Write a section on the topic 'Potentially reversible pathomechanism as possible causes of hyposmia or anosmia in children' of the scientific paper 'Causes and diagnostics of olfactory dysfunction in children and adolescents', which ties in with the previous section."

Data Assessment During the Interview

The medical expert group was interviewed by 2 blinded interviewers (BD and JSB), while the humanities expert group was interviewed by a partially blinded interviewer (CM). Initially, participants provided demographic information, including age, experience in academic and student teaching, academic qualifications, publication history, and prior experience with ChatGPT. They were then asked to assess how well the following questions were addressed in each text, using the German grading system from 1 (very good) to 6 (unsatisfactory) (see Multimedia Appendix 1 for details). How would you rate (1) linguistic fluency, (2) scientific quality (eg, are the re-definitions scientifically derived and are studies cited that lead to certain conclusions?), (3) internal logic, (4) description of the limitations of current knowledge, (5) future research questions, and (6) citations and references of the text? Participants were then asked to identify which text version, using the corresponding 3-digit number, they had categorized as being generated by ChatGPT and to list the key reasons for their decision, which the interviewer recorded using keywords. Next, they rated their confidence in their decision on a scale from 1 (very confident) to 6 (not confident at all). After this initial assessment, participants were unblinded and informed which text had been written by a student and which by ChatGPT. In cases of misidentification, they were asked about their suspected reasons, which the interviewer also documented using keywords.

Construction of Categories

Beyond the identification rate and the text evaluations by each group, a qualitative analysis of participants' statements regarding their reasoning for assigning authorship proved essential. This deeper analysis aimed to examine the influence of content-related versus formal-linguistic aspects and to better attribute global features to either student or chatbot authorship. For this purpose, the free-text responses (recorded by interviewers using keywords) were first thematically clustered based on the terms mentioned (see sample statements in the *Free-Text Analysis* section). Subsequently, through multiturn discussions between medical and linguistic experts, these thematic clusters were refined into distinct, nonoverlapping categories that encompassed all interviewee statements while reducing redundancy and multiple classifications.

Many of these categories align with standard text-analytical frameworks, which typically cover a broad range of attributes, including morphology, syntax, style, structure, coherence and cohesion, content quality, form, and even sociolinguistic aspects [33-35]. However, the categories derived in this study are directly based on the text types used in the experiments. As a result, they provide a more precise representation of the emerging and still undefined text type "AI-generated" and are therefore preferable (see Multimedia Appendix 2 for an overview of the categories).

Statistical Analysis

Data were analyzed using Microsoft Excel, SPSS version 29.3 (IBM Corp.), and R-4.1.2 (R Foundation). Descriptive statistics are presented as numbers (n) and percentages or as means (SD), where appropriate. Univariate odds ratios and 95% CIs from the Fisher exact test were used to examine the association between demographic markers, participants' field (medicine or humanities), and their expertise with the likelihood of correctly identifying a text's source. The relationship between interview scores and response accuracy was assessed using the 2-sided Wilcoxon signed rank test for paired values. Additionally, correlations among all 5 responses were tested using a Friedman 2-way analysis of variance for ranks with Bonferroni correction.

To analyze how participants attempted to identify the machine-generated text, we modeled the association of the derived categories (items) from the interviews based on their likelihood of being mentioned in the context of a chatbot-generated text. For each participant and interview, we recorded whether an item was cited in reference to a perceived chatbot text or a perceived student text. This association was analyzed using repeated-measures logistic regression, incorporating a random participant and sequence effect. The

model was further adjusted for age group, the expert group (medical vs humanities), and prior experience with ChatGPT (binary).

Ethical Considerations

An application for the study project was submitted to the Ethics Committee of the Medical Faculty at RUB (reference number 23-7837; April 2023). As the study did not involve direct research on human participants or patient data, the committee informed us that ethical approval was not required.

Results

Interviewee Sample

The biographical data of the 22 participating physicians (14 pediatricians, 3 nutritionists, 4 neurologists, and 1 neuroscientist) and 13 humanities scholars (8 literary scholars, 3 Germanists or linguists, 1 classical philologist, and 1 Romance philologist) are presented in Table 3.

As there were more participating experts than available term papers, 3 pairs of texts were each assessed by 3 or 4 medical experts.

At the time of the survey, only one-fifth of the participants reported having prior experience with ChatGPT. As the number of participating experts exceeded the number of available term papers, 3 pairs of texts were each assessed by 3 or 4 medical experts.

Table 3. Interviewee sample.

Detection Rate

With 35 participants evaluating 2 text pairs each—excluding 1 misaligned and omitted case—a total of 69 decision rounds were conducted. In 48 out of 69 (70%) decision rounds, participants correctly identified the authorship of the texts. Medical and humanities experts showed a slight but nonsignificant difference in detection rates, with medical experts correctly identifying 31 out of 43 (72%) decision rounds compared with 17 out of 26 (65%) decision rounds by humanities experts (odds ratio 1.37, 95% CI 0.5-3.9). Among the 35 participants, 21 (60%) misidentified the authorship of at least one text pair, including 12 medical experts. Additionally, 5 (14%) participants, including 3 physicians, misidentified both text pairs.

Notably, familiarity with the topic did not significantly impact identification accuracy (Table 4), nor did personal characteristics such as age, academic qualifications, or years of teaching experience. However, younger participants without advanced academic titles showed a slight tendency to better identify ChatGPT-generated texts. Confidence in participants' own judgments did not differ significantly across groups (odds ratio 0.6, 95% CI 0.2-1.79).

Table 4. Characteristics of the participants with correct and incorrect decisions about the authorship of the respective text.

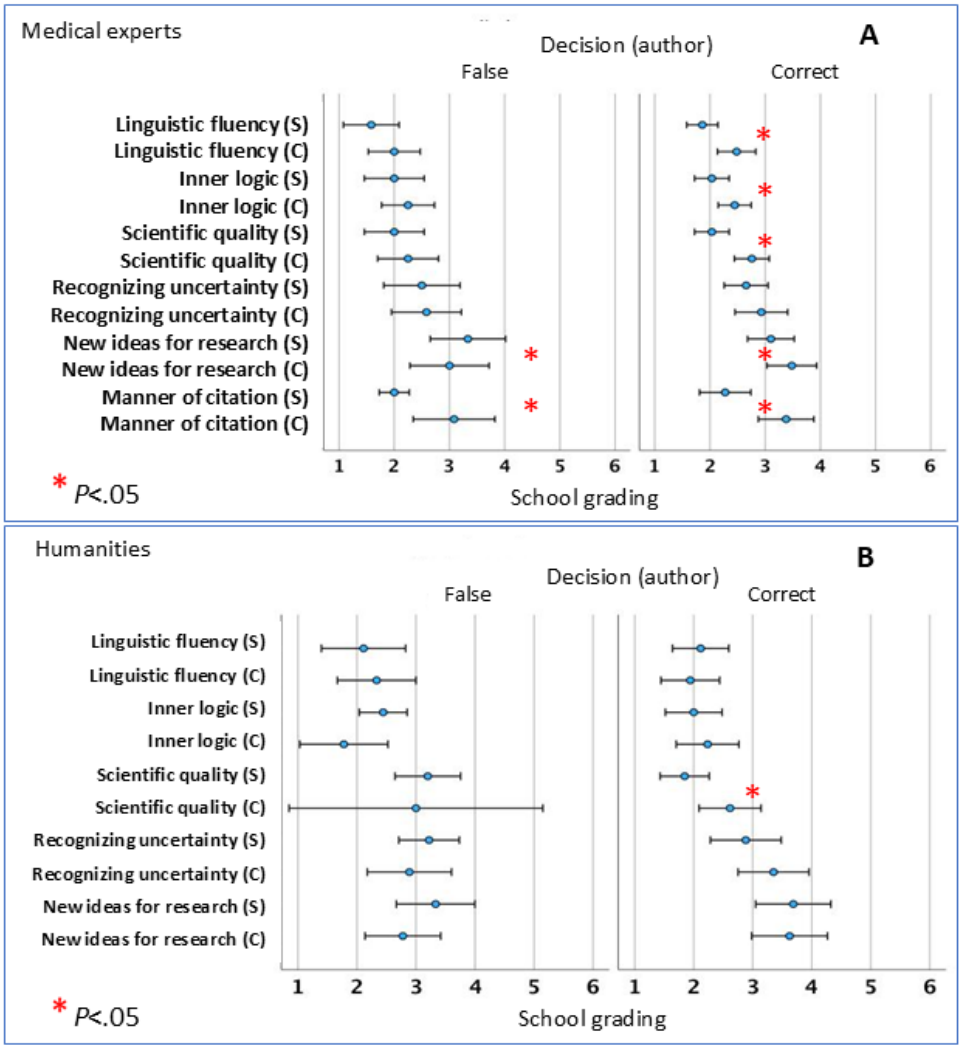
Interview Analysis

When authorship was correctly identified, texts written by medical students received notably higher ratings for stylistic fluency, the internal logic of argumentation, and scientific quality (see Figure 1A, right-hand side). These differences were less pronounced in the assessment of knowledge limitations and future research directions. Regardless of correct identification, the way sources were cited was consistently rated higher in student-authored texts (Figure 1). Among humanities experts, score differences between correctly and incorrectly classified texts were minimal, though the academic quality of student-written texts was still rated significantly (r=0.336, P=.009) higher overall (Figure 1B, right-hand side). Many participants who misidentified the authorship attributed their errors to either underestimating the quality of student work or overestimating ChatGPT's capabilities—particularly in terms

of logical coherence, the presentation of scientific knowledge limitations, and the formulation of new research ideas.

Figure 1. Association of mean school grade (using German school grades 1=very good to 6=unsatisfactory) and correctness of authoring identification in (A) medical experts and (B) humanities experts. Participants were not yet unblinded at the time of assessment (see Multimedia Appendix 1 for details). Left side: incorrect attribution, right side: correct attribution of authorship. *P<.05 (2-sided Wilcoxon signed rank test). C: chatbot-generated text; S: student text.



Free-Text Analysis

We categorized the 187 freely formulated reasons participants provided for their decisions into 1 of 12 derived categories (see Multimedia Appendix 2). Three categories were excluded from statistical analysis due to their low frequency: inconsistency of writing style (n=4), other issues (n=4), and errors in content (n=3). Notably, all 3 content-error attributions came from the medical expert group. Of the remaining 176 statements, 88 (50%) were contributed by medical experts and 88 (50%) by humanities scholars (Table 5).

The experiment revealed that significantly more statements were made about (suspected) ChatGPT-generated texts (130/176, 73.9%) than about student-written texts, regardless of whether the suspicion was correct (Table 5). Sample statements from both groups are provided in Tables 6 and 7. Medical experts' explanations were often concise, frequently critiquing a "superficial" style with "unnecessary additional information." By contrast, humanities experts tended to provide more detailed justifications, describing characteristics such as "smooth style" and "redundancies."

We analyzed the likelihood of specific categories being mentioned in reference to texts suspected to be generated by ChatGPT. The results indicate that "redundancy" (12/14, 86%, associated with GPT vs 2/14, 14%, with student texts), "repetition" (20/22, 91% vs 2/22, 9%), and "common thread and coherence" (21/24, 88% vs 3/24, 13%) were the most frequently cited characteristics (Figure 2).

Table 5. The remaining 9 categories and item frequency by presumed nature of the text (for a detailed explanation in German and English, see Multimedia Appendix 2).

Item	Category	How often mentioned				
		Overall, n (%)	Humanities		Medical experts	
			Chatbot, n (%)	Students, n (%)	Chatbot, n (%)	Students, n (%)
		176 (100)	59 (33.5)	29 (16.5)	71 (40.3)	17 (9.7)
1	Differentiated content	16 (9.1)	4 (6.8)	4 (13.8)	4 (5.6)	4 (23.5)
2	Superficial content	13 (7.4)	2 (3.4)	2 (6.9)	8 (11.3)	1 (5.9)
3	Redundancy	14 (8.0)	7 (11.9)	2 (6.9)	5 (7.0)	N/A[a]
4	Monotonous structure of sentences	14 (8.0)	6 (10.2)	4 (13.8)	4 (5.6)	N/A
5	Repetition	22 (12.5)	8 (13.6)	1 (3.4)	12 (16.9)	1 (5.9)
6	Common thread coherency	24 (13.6)	10 (16.9)	2 (6.9)	11 (15.5)	1 (5.9)
7	Distinctive literature style	16 (9.1)	3 (5.1)	2 (6.9)	8 (11.3)	3 (17.6)
8	Form	25 (14.2)	6 (10.2)	6 (20.7)	9 (12.7)	4 (23.5)
9	Distinctive Wording	32 (18.2)	13 (22.0)	6 (20.7)	10 (14.1)	3 (17.6)

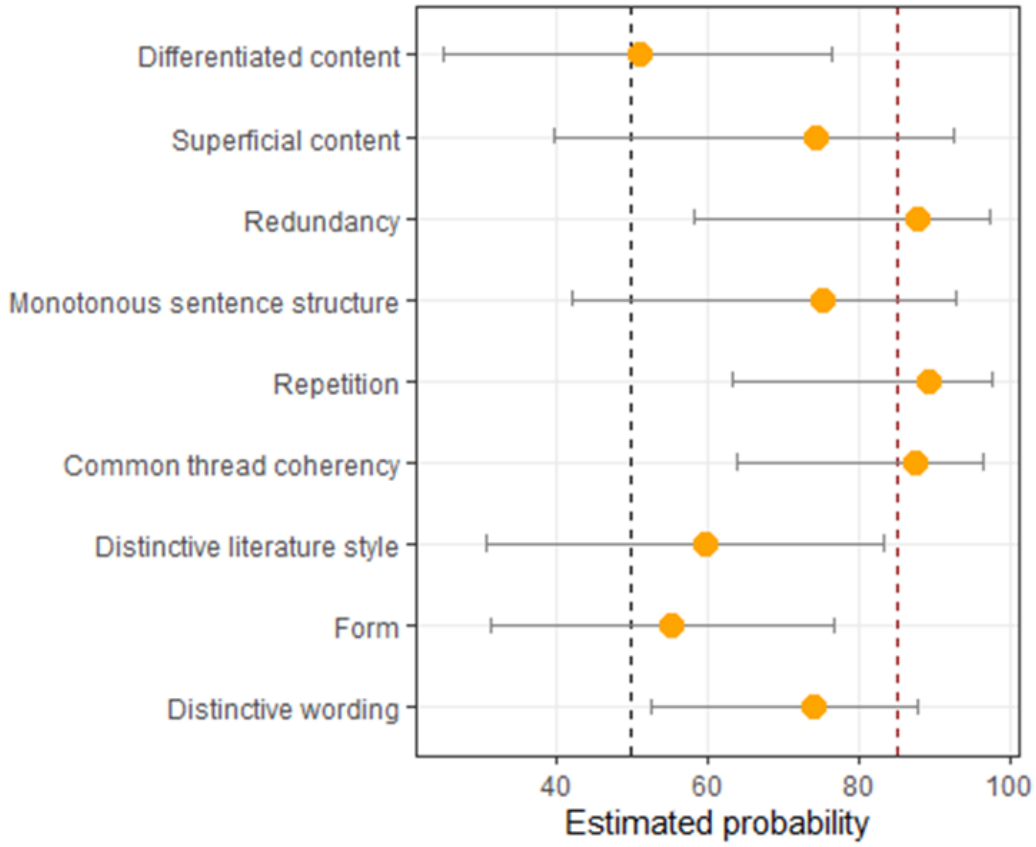
Table 6. Excerpt from the statements of the medical expert group on the main reasons for choosing ChatGPT as the author.

German (original statement)	English (translation)
“‚erschien zu perfekt geschrieben, oberflächlich‘”	“‚seemed too perfectly written, superficial’”
“‚unnützes Wissen, Zusatzinfos, die nicht notwendig für die Arbeit wären‘”	“‚useless knowledge, additional information that is not necessary for the work‘”
“‚fehlender roter Faden, fehlende Kontinuität der Logik’”	“‚lack of common thread, lack of continuity of logic’”

Table 7. Excerpt from the statements of the humanities expert group on the main reasons for choosing ChatGPT as the author.

German (original statement)	English (translation)
“‚fehlende Kohärenz, Redundanz, Monotonie […] ist sehr redundant, wiederholt Formulierungen teils mehrfach in Variationen. Der Definitionsteil wirkt reihend, stilistisch homogen, […] teils erfährt man, was man sich hätte denken können, […]. Der letzte Absatz wiederholt in etwa, was vorher da stand - was so wirkt, als hätte er diesen schon 'vergessen'.”	“‚lack of coherence, redundancy, monotony [...] is very redundant, repeats formulations sometimes several times in variations. The definition section appears to be sequential, stylistically homogeneous, [...] partly one learns what one could have imagined, [...]. The last paragraph roughly repeats what was there before - which makes it seem as if he had already 'forgotten' it.”
“‚Smooth, fließende Übergänge, aber übertextlich schlechter, d.h. gesamt Kohärenz schlechter (Wiederholung), habe nichts gelernt‘.”	“‚Smooth, fluent transitions, but overtextually worse, i.e. overall coherence worse (repetition), 'haven't learned anything'.”
“‚Wiederholung vieler Sätze und Inhalte; ausgeprägte Tendenz zu bestimmten schablonenartigen Formulierungen im Sinne einer ‘Anmoderation’, z.T. phrasenhaft ohne Inhalt. Optisch gute Gliederung (vorgegeben durch die Überschriften), jedoch roter Faden nicht gut erkennbar, vieles wirkt lediglich wie aufgelistete Einzelformationen. […] Nennung vieler Quellen, deren Zuordnung zu einzelnen Aussagen ist oft nicht konkret.”	“‚Repetition of many sentences and contents; pronounced tendency towards certain template-like formulations in the sense of a ‘presentation’, sometimes phrase-like without content. Visually well structured (given by the headings), but a common thread is not easily recognizable, many things appear to be merely a list of individual formations. [...] Mention of many sources, their assignment to individual statements is often not concrete.”

Figure 2. Estimated probability of thinking of ChatGPT as authorship.



Discussion

Overview

This analysis offers insights into the current identification rate of AI-generated texts and their evaluation compared with medical student texts by 2 different expert groups. It also provides an initial overview of the decision-making processes of medical and humanities experts during these assessments. Our findings suggest that both medical and humanities experts can effectively identify ChatGPT-generated texts in medical contexts and that linguistic and stylistic features play a significant role in distinguishing AI-generated from human-written texts, regardless of content familiarity. This supports the broader notion that linguistic analysis is crucial in identifying AI-generated text, aligning with foundational theories in human-robot interaction, such as Turing's predictions [32].

Identification Rate

In the 1950s, Alan Turing [32] predicted that within 50 years, AI would advance to the point where the likelihood of identifying a machine as nonhuman in a dialogue or an "imitation game" would be no more than 70% [32]. With a slight delay of about 20 years, his prediction was almost precisely fulfilled in an online game inspired by the Turing Test [5]. Unlike Turing's method and the large-scale Israeli study, our research did not involve direct dialogue between humans and machines [5,32]. However, when participants were presented with 2 texts of different authorship, an internal dialogue was essential for making an authorship determination. Ultimately, our study's main finding aligns almost exactly with Turing's prediction: only in 48 out of 69 (70%) decision rounds, participants correctly identified the ChatGPT-generated text. This accuracy rate remained consistent regardless of whether participants were experts in the content of the text or in linguistic analysis, and irrespective of their prior experience with ChatGPT. Notably, familiarity with the subject matter did not appear to be a decisive factor, as humanities experts performed similarly to medical experts who specialized in the respective topics. Moreover, at the individual participant level, no significant differences were found between the 2 expert groups in terms of their proximity to the text's subject matter.

A Chinese study by Ma et al [2], which also examined the identification rate of chatbot-generated texts, reported similar findings, with approximately 66% of texts correctly identified. This study analyzed around 40 scientific texts, including 20 scientific paper abstracts and 20 wiki item descriptions, assessed by 2 PhD students with a background in computer science [2]. Ma et al [2] also highlighted notable differences in writing style between AI-generated and human-written scientific texts, a conclusion that aligns with our findings. In our study, participants primarily based their decisions on text-analytical features, while content errors influenced their judgment in only 3 instances.

The study by Waltzer et al [36], which closely resembles our research in design, reported similar findings. In their study, 140 college instructors were presented with pairs of essays and correctly identified the ChatGPT-generated text 70% of the time. Like our results, Waltzer et al [36] found that neither prior

experience with ChatGPT nor subject-specific expertise—measured by self-reported familiarity with the topic—significantly improved identification accuracy [36]. However, a key difference is that their study analyzed English-language essays written for a psychology program, whereas our research focused on German-language texts authored by medical students [36].

Performance

The evaluation of a text can focus on different levels and aspects, often emphasizing either content or linguistic features. Currently, AI programs such as ChatGPT are recognized for their seemingly perfected linguistic style [13,14]. A notable case at a German university (TU Munich) illustrates this: an essay submitted as part of a Master's application was rejected—and this decision was upheld by a court—on the grounds that it was "too well written," strongly suggesting AI authorship [13]. However, it is important to note that this essay was written in English [13]. While ChatGPT is also proficient in translating languages such as German and Chinese [15], its performance in German differs from English. Research suggests that AI-generated texts tend to be more nuanced and varied in English than in German [16,17]. This discrepancy is likely due to the greater availability of digital data in English, which results in more refined and contextually accurate outputs. Nevertheless, AI language models continuously improve as they interact with users, enhancing their capabilities in non–English languages over time.

Interestingly, the humanities group, despite their focus on linguistic features, identified ChatGPT-generated texts less accurately than the medical expert group—though this difference was not statistically significant. Notably, humanities experts rated the linguistic quality of ChatGPT texts higher than those written by medical students, a contrast that was significant compared with the evaluations of the medical experts. The decision-making process behind text identification revealed key patterns: participants were more likely to suspect a human author when encountering spelling and grammatical errors, greater variation in sentence structure, medical-specific terminology, a writing style aimed at a professional readership, or shifts in citation style.

An "AI author," by contrast, was suspected if there was a monotonous sentence structure, partly "English" grammar, a "smooth" wording style, that is, good readability/understandability, but overall more superficial, an intended less professional readership, better overall formal structure of the text (derivation, outline, weft), frequent repetitions, and a lack of supra-textual coherence of the argumentation in contrast to the coherent and easily comprehensible sequence of arguments within individual paragraphs.

Many studies explored the identifiability of chatbot-generated text using machine learning–based detectors, a subset of AI technologies [27-29]. These detectors often achieve higher identification rates than human evaluators. However, direct human comparison is rarely included, and accuracy and F_1-scores vary significantly depending on the text genre and the specific machine learning classifier used. For instance, when various LLM-based classifiers are applied to different data sets, their accuracy ranges from 70% (DetectGPT classifier on Wikipedia articles) to 97% (GPT-Pat classifier on COVID-19–related question-answer data sets). Similarly, perplexity-based classifiers achieve around 70% accuracy on ACL paper abstracts, whereas RoBERTa (Robustly Optimized BERT Pretraining Approach)–based classifiers reach up to 97% on COVID-19–related data sets [37].

Another challenge is that while these tools are generally reliable in detecting AI-generated text, they are not always sufficiently accurate in identifying human-authored text. This suggests that the tools may struggle with the complexity of human writing while also highlighting a key limitation—especially in cases where a lecturer, for example, must evaluate a single piece of writing without comparison [14,31].

Our study also compares the performance of medical students and ChatGPT. Notably, the texts written by medical students received higher professional evaluations. However, the humanities experts specifically rated the linguistic quality of ChatGPT-generated texts more favorably. Additionally, when comparing ChatGPT's performance with that of medical students in an examination setting—such as in the study by Huh [38]—ChatGPT performed worse than medical students [31]. In a parasitology examination, ChatGPT correctly answered 60.8% of the questions, whereas the average score among 77 medical students was significantly higher at 90.8% [38]. In comparison, a German study by Friederichs et al [39] found that ChatGPT correctly answered two-thirds of all multiple-choice questions at the level of the German state licensing examination in the Progress Test Medicine. It even outperformed most medical students in their first 3 years and performed comparably to students in the later stages of their studies [39]. Our study also revealed that participants who overestimated ChatGPT's writing capabilities and underestimated those of the students were more likely to misidentify the author. This misconception was particularly evident in cases where participants misclassified texts in both sessions, suggesting that their biased perception significantly influenced their decisions.

Interpretation

Our study demonstrates that the identification rate predicted by Turing holds within a group primarily engaged in student teaching and academic writing. Our findings confirm the expectation that linguistic features play a more significant role in identifying AI-generated texts than content familiarity or specialized expertise. In both expert groups, text-analytical features were the primary factors influencing their decisions. This aligns with the emerging field of stylometric analysis, which is increasingly being applied to the detection of AI-generated content [40]. ChatGPT-generated text, especially in comparison to authors from the (fictional) literature domain, exhibits limited stylistic variety [41]. Notably, there was no significant difference in the identification rate between the 2 expert groups, despite 1 being more familiar with the subject matter. Higher proximity to the topic was also not a predictive factor at the individual participant level. Instead, certain linguistic characteristics played a key role in the

decision-making process and were consistently associated with AI-generated texts. In particular, redundancy, repetition, and a lack of coherence were distinctive features attributed to ChatGPT-generated texts. While these traits influenced the perception of AI authorship, they ultimately did not prove to be reliable predictors for correct identification. The linguistic features of ChatGPT-generated texts are often perceived as superior due to their smoother wording and better structural organization. This aligns with findings from [42], which indicate that AI-generated texts tend to exhibit relatively low lexical density, high reading ease, and frequent use of the simple present tense. Whether these linguistic characteristics, if systematically outlined in a manual and provided to participants beforehand, could enhance identification accuracy remains an open question. However, this presents an intriguing avenue for future research.

Limitations

While numerous studies are currently investigating the performance of LLM-based text generators such as ChatGPT, many focus primarily on their assistive role in the writing process rather than assessing the quality of fully generated long-form scientific texts. A key contribution of our study is that it examines complete, AI-generated scientific texts rather than partial outputs. Additionally, instead of relying on specialized AI detection tools, we analyze how individuals working in academia recognize such texts without assistance and how they evaluate their performance while identifying distinct linguistic features. This study enables the compilation of categorical features that could aid in identifying AI-generated text in both academic and everyday reading. However, limitations in generalizability arise due to the relatively small sample size and the exclusive use of a single AI model, ChatGPT version 3.5. Nevertheless, for an exploratory study, we do not consider this a critical issue. Additionally, participants were aware that 1 of the texts had to be AI-generated, raising the question of whether they would have identified an AI-authored text without this prior knowledge. A further limitation arises from the use of different interviewers for the 2 expert groups, who also differed methodologically in terms of blinding. However, it should be noted that the decision to identify the authors was always made before the interview process. Additionally, the interview was transcribed in bullet points, so some information may have been lost in this process. Finally, the dynamic nature of development should also be acknowledged, as ChatGPT, like other AI programs, is continuously being developed and improved.

Conclusion

Our study shows that linguistic and text-analytical features, in particular, play a role in the decision-making process for correctly identifying a chatbot author. In our sample, both nonspecialists and specialists identified AI-generated texts with an accuracy rate of approximately 70% (48/69). Further quasi-experimental studies using texts from other academic disciplines should be conducted to determine whether instructions based on these features can enhance lecturers' ability to distinguish between student-authored and AI-generated work.

A follow-up study could be conducted in a few years to track the evolution of AI-generated text identification and examine whether identification success changes as AI technology and tools advance.

Acknowledgments

The authors thank the students for providing their work. We also extend our gratitude to our colleagues at the Paediatric and Neurological University Clinics of the Ruhr-University of Bochum, as well as the teachers at the Department of Philology, for their voluntary participation, contributions, and suggestions. Additionally, we thank the Medical Dean of Studies, Prof. T. Schäfer, for the initial exchange, and Dr. A. Lucke for her critical endorsement of our work.

Authors' Contributions

BD and JSB contributed equally to conceptualization and data acquisition, with BD leading the qualitative analysis and the original draft writing. CM played a leading role in conceptualization, supervision, and writing—review and editing—while contributing equally to formal analysis and data acquisition. TL and MB shared equal responsibilities in supervision and writing—review and editing. JS contributed equally to conceptualization, qualitative analysis, and writing, whereas EEK was involved in writing—review and editing on an equal basis. SH took the lead in proofreading and contributed equally to review and editing. MT led the formal analysis while sharing equal responsibilities in supervision and writing—review and editing. All authors have reviewed and approved the final manuscript.

Conflicts of Interest

Abstract

Background: As health care moves to a more digital environment, there is a growing need to train future family doctors on the clinical uses of artificial intelligence (AI). However, family medicine training in AI has often been inconsistent or lacking.

Objective: The aim of the study is to develop a curriculum framework for family medicine postgraduate education on AI called "Artificial Intelligence Training in Postgraduate Family Medicine Education" (AIFM-ed).

Methods: First, we conducted a comprehensive scoping review on existing AI education frameworks guided by the methodological framework developed by Arksey and O'Malley and Joanna Briggs Institute methodological framework for scoping reviews. We adhered to the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses extension for Scoping Reviews) checklist for reporting the results. Next, 2 national expert panels were conducted. Panelists included family medicine educators and residents knowledgeable in AI from family medicine residency programs across Canada. Participants were purposively sampled, and panels were held via Zoom, recorded, and transcribed. Data were analyzed using content analysis. We followed the Standards for Reporting Qualitative Research for panels.

Results: An integration of the scoping review results and 2 panel discussions of 14 participants led to the development of the AIFM-ed curriculum framework for AI training in postgraduate family medicine education with five key elements: (1) need and purpose of the curriculum, (2) learning objectives, (3) curriculum content, (4) organization of curriculum content, and (5) implementation aspects of the curriculum.

Conclusions: Using the results of this study, we developed the AIFM-ed curriculum framework for AI training in postgraduate family medicine education. This framework serves as a structured guide for integrating AI competencies into medical education, ensuring that future family physicians are equipped with the necessary skills to use AI effectively in their clinical practice. Future research should focus on the validation and implementation of the AIFM-ed framework within family medicine education. Institutions also are encouraged to consider adapting the AIFM-ed framework within their own programs, tailoring it to meet the specific needs of their trainees and health care environments.

(JMIR Med Educ 2025;11:e66828) doi:10.2196/66828

KEYWORDS

artificial intelligence; family medicine; curriculum; framework; postgraduate education

Introduction

The College of Family Physicians of Canada (CFPC) establishes standards for postgraduate family medicine training and its accreditation [1]. It promotes a competency-based curriculum model known as Triple C (comprehensive, continuous, and centered in family medicine) [2] based on the Canadian Medical Education Directives for Specialists (CanMEDS)—Family Medicine framework [3] and on assessment objectives for certification in family medicine [4]. To ensure that medical curricula respond to new developments in health care, education, and societal trends, they must undergo periodic review, modification, and renewal [5-9]. Accordingly, a number of new content areas have been introduced in the recent past into the family medicine curricula. They include leadership [10], social determinants of health [11], ethics [12], global health [13-15], and physician wellness and burnout [16-18]. The increasing complexity of the medical needs of an aging population, the exponential growth in medical knowledge, and an increasingly digitalized environment suggest the need for digital-mediated solutions to support medical practitioners.

Artificial intelligence (AI) and its applications have made a rapid impact on many segments of society, including medicine [19] and notably, in primary health care [20]. While there is no universal consensus on the definition of AI, the World Health Organization [21] describes it as "the performance by computer programs of tasks that are commonly associated with intelligent beings." The introduction, integration, and implementation of AI-based tools and systems into family medicine education and practice assume an adequately trained cohort of users, but to date, training of family physicians on relevant aspects of AI to ensure effective and safe implementation has been absent or inconsistent [20,22]. As such, the CFPC's Outcomes of Training project has identified digital care and health informatics as a training gap and an area for educational enhancement requiring priority attention across the 17 family medicine postgraduate programs in Canada [23,24]. There have been efforts to include AI education globally within each level of medical training. These efforts are led by national medical associations such as the UK National Health Service, the US American Medical Association, and Canada's Royal College of Physicians and Surgeons. They have released documents recommending policies for integrating AI within their respective medical educational institutions [25-27].

Initiatives of AI teaching directed at physicians already in practice include the development of a continuing professional development 3-module CFPC Learn e-course titled, "Artificial Intelligence for Family Medicine" [28]. The first module of this course reviews the basic functionality of AI with applications in family medicine, while the second module focuses on core terminology and related concepts as well as potential harms or risks associated with AI. The last module reviews the concepts of the first 2 and focuses on learning how to tell if an AI-based tool is working well [28].

Competency about a particular subject has been described as the ability to carry out a certain task or action at a basic or acceptable level [29]. Liaw et al [30] have recently proposed six competency domains for family medicine training in AI: (1) foundational knowledge (What is this tool?), (2) critical appraisal (Should I use this tool?), (3) medical decision-making (When should I use this tool?), (4) technical use (How do I use this tool?), (5) patient communication (How should I communicate with patients regarding the use of this tool?), and (6) awareness of unintended consequences (What are the "side effects" of this tool?)." These authors suggest that such competencies can be integrated within current residency training during existing sessions on health informatics or evidence-based medicine but emphasize that these competencies are a "point of departure" and must be further worked on [30].

A curriculum framework can be described as "a core policy document that describes a range of requirements, regulations and advice which should be respected by all stakeholders in the education system, and which should guide the work of schools, teachers and the developers of other curriculum documents" [31]. Curriculum frameworks allow for a visual and detailed roadmap to develop and implement a curriculum [32]. Input from an interdisciplinary team of medical educators, AI experts, end users, researchers, and curriculum designers [33] can effectively support the development of a curriculum framework for teaching AI in family medicine postgraduate training programs. Our comprehensive review of the available curriculum frameworks [34,35] highlighted that there is no framework designed specifically for family medicine residency and no paper that described a systematic approach to design one. From the 2 frameworks uncovered, one framework was incomplete, while the other framework was brief and focused on ophthalmology [34]. The ophthalmology curriculum framework lacks adaptability, as it may prove inadequate for family medicine residency due to the diverse, community-based nature of family medicine, which differs significantly from the highly technological and hospital-based focus of ophthalmology.

Considering the gaps mentioned previously and the foundational importance of curriculum frameworks in the creation of new educational structures, our objective was to design and develop a curriculum framework for AI family medicine education, that is, Artificial Intelligence Training in Postgraduate Family Medicine Education (AIFM-ed), ensuring alignment with current competencies and educational goals. To achieve this, a combination of validated methods including 2 national expert panel discussions were conducted, supplemented by a previous comprehensive systematic scoping review [34]. Developing a framework based on expert insights would help address gaps in AI education and provide an adaptable guide for family medicine educators, curriculum designers, postgraduate residency program directors, medical education researchers, and policy makers in health care education. Due to the systematic approach in designing this framework, audiences can adopt this framework to other fields and specialties, considering that our review did not find any systematically developed frameworks.

Methods

Study Design

For the construction of an AIFM-ed framework, we followed the analysis, design, development, implementation, and evaluation model for instructional design, using the first 3 activities to guide our work. We followed a two-step approach suggested by Redwood-Campbell et al [36] for framework development, wherein (1) a review of the literature was made focusing on curriculum frameworks and core competencies for AI education in medicine [34,35] and (2) a working group used qualitative or consensus methods for final development of the framework.

Our scoping review aimed to synthesize knowledge from the literature on curriculum frameworks and current educational programs that focus on the teaching and learning of AI for medical students, residents, and practicing physicians, and adhered to PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses extension for Scoping Reviews) guidelines. Details of this comprehensive study have been published elsewhere [34,35]. Our review specifically identified several AI educational curricula programs (eg, courses, workshops, webinars, and projects) and 2 curriculum frameworks for AI education, one outlining a broad framework for any level of education [37], while the other described a complete framework for ophthalmology residency education [38].

The outcome of our review was the identification of early concepts that could be applied to elements of the curriculum framework for family medicine and AI [34,35]. This initial curriculum framework was later used during the panel discussion as part of the co-development and redesigning of the framework. This discussion applied the curriculum framework structure described by Obadeji [39], which examines six common elements: (1) the need and the purpose of a curriculum or a program, (2) learning objectives and outcomes, (3) course content that will facilitate the accomplishment of the objectives or learning outcomes, (4) organization of the content, (5) implementation of curriculum, and (6) curriculum evaluation and refinement. This study examined all elements except the final element (curriculum evaluation and refinement). The initial framework was deemed successful by the expert team based on the following indicators: relevance to medical educators and curriculum designers, alignment to current family medicine competencies and educational goals, clarity of AI-specific content, and its potential for further validation. However, we acknowledge that further studies are needed.

Qualitative Methodology

The expert panel methodology follows the SRQR (Standards for Reporting Qualitative Research) checklist [40]. Expert panels help to attempt to reach consensus on controversial subjects [41,42] such as the risk of AI tools leading to reduced proficiency in independent critical thinking and clinical judgment among physicians. The use of qualitative consensus methods for curriculum development facilitates input from a wide range of stakeholders (eg, physicians and curriculum developers) in order to assess and validate expert knowledge [43]. The use of expert panel discussions to assist in creating curricula has become established in pedagogical research and development [44]. Examples within the field of medicine include discussions around social determinants of health for undergraduate medical education [45], telemedicine opportunities for postgraduate medical education [46], and geriatric oncology in continuing medical education [47].

Participant Recruitment and Sampling Strategy

Our panel size fell within the recommended average of 8 members or a median of 6 [48]. The definition of an expert in our case is flexible due to the limited knowledge and experience on this emerging topic; this is emphasized by Duncan et al [49], who state that, “[t]oo narrow a definition, however, can restrict the number of potential participants.” In our case, we chose experts according to the definitions of Fink et al [41], which state that they must be, “representative of their professional group, with either sufficient expertise not to be disputed or the power required to instigate the findings.” This was reinforced by Mead and Mosely [50], which state that, “experts can be defined in a number of ways, such as their position in a hierarchy [...] or as recommended by other participants in a study.” Therefore, from these definitions, we selected panelists based on their academic qualifications, their number and relevance of AI-related publications, professional experience within the development, implementation or research of AI, and finally, any participation in AI-specific projects or conferences.

For panel 1, we reached out to family medicine (clinical) educators from affiliated universities and professional organizations across Canada via email. Snowballing by this initial group generated the names of others known as family medicine educators. For panel 2, family medicine residents were invited from an initial group of residents who were knowledgeable and aware of AI, and that initial group helped to recruit relevant residents for this study.

Each participant voluntarily participated in the study by providing their explicit consent and agreement, which was confirmed through email correspondence. To uphold confidentiality, data were safeguarded through limited, secure data access, the disposal of audiotapes after transcription, and the anonymous analysis of transcripts.

Ethical Considerations

This study involved a panel discussion with experts, which does not require formal ethics board approval under the Economic and Social Research Council Framework for Research Ethics guidelines [51]. According to these guidelines as well as Canada’s Tri-Council Policy Statement on Ethical Conduct for Research Involving Humans, research that presents minimal risk and does not involve sensitive information may be exempt from formal ethics review [52]. This study adhered to these recognized guidelines, ensuring that all participants were treated in accordance with principles of research integrity, voluntary participation, and informed consent.

Participant Eligibility Criteria

Input from 2 different types of panelists was desired, and they were included as participants within 2 distinct expert panels.

The first included family medicine educators practicing in Canada who were somewhat knowledgeable or have expertise in AI education. No limitations were placed on years of practice experience, years of knowledge or experience in AI, language proficiency, work setting, or the types of patients for whom they provided care. The second expert panel included participants who were at the time of the study family medicine residents at McGill University, and who were somewhat knowledgeable in AI. No limitations were placed on language proficiency, years of knowledge or experience in AI, work settings, or the types of patients they provided care for.

Data Collection

We conducted a recorded session of each expert panel via Zoom (version 5.16.10; Zoom Video Communications). The use of a web-based expert panel minimizes costs associated with travel; it also mitigates potential biases linked to panelists [53]. Each web-based expert panel discussion was approximately 2 hours long, followed the same format, used congruent discussion guides, and was facilitated by 2 members of the research team (RT and SAR). The discussions began with a brief presentation given by RT on the results of the first step of the project, that is, the comprehensive scoping review in the field [34,35]. Following the presentation, each of the five elements of the curriculum framework: (1) the need and the purpose of a curriculum or a program, (2) learning objectives and outcomes, (3) course content that will facilitate the accomplishment of the objectives or learning outcomes, (4) organization of the content, and (5) implementation of the curriculum were discussed sequentially and at length. When presenting each element, participants were invited to respond and discuss their opinions and thoughts related to each element, allowing for the co-development and redesigning of the framework together.

Data Analysis

Expert panel discussion data were analyzed using content analysis strategies [54,55] as previously used in a study developed for a training model for nurses using a literature review and expert panel discussions, in which data were analyzed using a descriptive qualitative approach that includes content analysis [56]. In our work, the preparation phase included transcribing the data, immersing in the data, and obtaining a sense of whole through reading the transcript multiple times. In our study, once the recordings from the expert panel discussions were received, one of the authors (RT) listened to the entire recording and subsequently transcribed it verbatim. The next stage of data analysis was the organizing phase, in which open coding and the creating of categories were conducted along with the grouping of codes under higher-order headings. These were carried out by one of the authors (RT) and verified by the senior author (SAR).

As the analysis of data used an inductive approach, no prior coding systems were used, such that coded categories were derived directly from the data [55]. Sentences and phrases from the panelists were captured. In vivo coding was used to prioritize participants' language and perspectives, while descriptive coding aided in categorizing key themes. Two independent coders reviewed the data (RT and SAR), with discrepancies resolved through discussion between coders and the research team. Saturation was achieved when no new themes emerged during the coding of the final transcript. The final step included the presentation of the final curriculum framework, which resulted from the incidence of codes and categories and its relation to the literature. Codes and categories derived were prioritized and highlighted with how frequently they appeared during the panel discussion as well as the overlap between both groups. These highlighted findings were then compared with existing literature to either support or challenge them. If these codes and categories were supported by the literature, they were subsequently integrated into the framework.

Results

Panelists Characteristics

A total of 37 educator and resident experts were invited, 14 for the educator group and 23 for the resident group. Ultimately, 8 from the former and 6 from the latter group participated, for a total of 14 participants. Scheduling problems were the most common reasons for nonparticipation. The characteristics of those included in the expert panel discussion are displayed in Table 1.

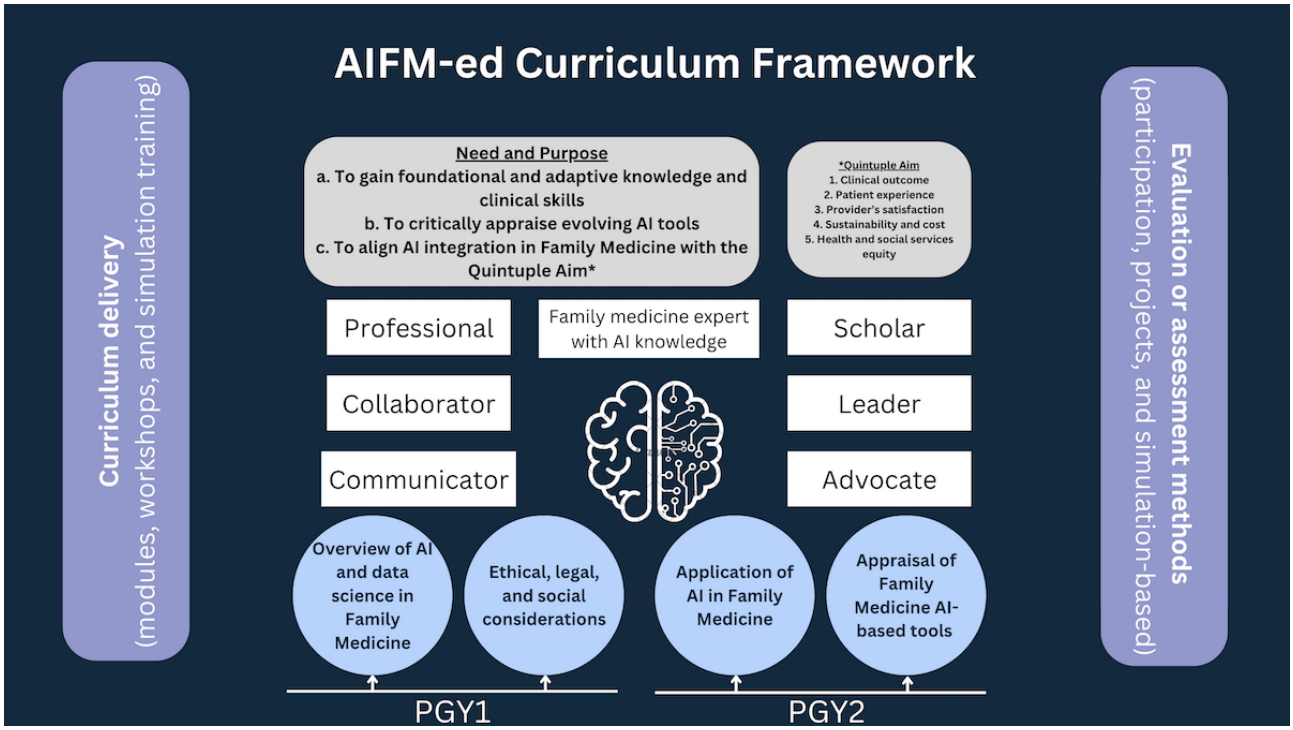
Curriculum Framework for AIFM-ed

Overview

Our project has identified five elements of the curriculum framework for AI training in postgraduate family medicine education: (1) need and purpose of the curriculum, (2) learning objectives, (3) curriculum content, (4) organization of curriculum content, and (5) implementation of the curriculum. A condensed visual representation of the AIFM-ed curriculum framework is displayed in Figure 1, while each element is discussed in detail below.

Figure 1. Representation of the AIFM-ed curriculum framework. AI: artificial intelligence; AIFM-ed: Artificial Intelligence Training in Postgraduate Family Medicine Education; PGY: postgraduate year. * refers to the Quintuple Aim.



Element 1: Need and Purpose of the AIFM-ed Curriculum

When modifying a curriculum in family medicine postgraduate training, it is important to understand why it must be changed and for what purpose. Both panels discussed the current low priority of AI curricula. Residents emphasized a lack of exposure in training and practice. Both panels agreed that the integration of an AI curriculum will inevitably become imperative, recognizing its potential as an essential toolset in practice. One educator summarized this thought by saying, “AI will continue to evolve quickly, so a curriculum must be built for the future.”

To describe the need and purpose for AI education in family medicine, we co-developed the following: “The purpose of an AI curriculum for family medicine residents is for future family physicians to: (a) gain foundational and adaptive knowledge and clinical skills, (b) to critically appraise evolving AI tools, and (c) to align AI integration in Family Medicine with the quintuple aim for health care improvement (i.e., improving population health, improving the provider and patient experience, reducing costs, and advancing health equity [57,58]).”

Using various definitions of AI, the educator panel debated what constitutes AI specifically in family medicine. The term “AI-based tools” is used throughout the results of this paper as a way of describing technologies empowered or enabled with AI algorithms to support clinical practice. This term has been used in previous literature on AI in the context of family medicine training [20,30].

Element 2: AIFM-ed Learning Objectives

Learning objectives are statements that describe significant and essential learning that learners need to be familiar with and reliably demonstrate at the end of a course or educational program [59]. The following outlines the learning objectives for AI training, aligning with CanMEDS and family medicine roles. Table 2 presents each CanMEDS role on the left column [3], with their affiliated learning objectives for AI family medicine education as structured by participants during the panel on the right column. Although the learning objectives are comprehensive and their practical application for most family doctors may be limited, they are ideal for advancing the knowledge and skills of AI-empowered family physicians.

Table 2. Learning objectives discussed during panels about artificial intelligence (AI) in relation to Canadian Medical Education Directives for Specialists (CanMEDS) roles.

CanMEDS roles	The learner engaged in AI education will be able to
Family medicine expert with AI knowledge	
Family physicians are skilled generalists who should be able to understand and use technology including AI tools to provide high-quality, responsive, community-adaptive care across the lifecycle, from prevention to palliation, in multiple settings, and for diverse populations.	• Explain a basic understanding of AI and basic concepts in relation to family medicine. • Demonstrate the use of AI-based tools for family medicine by showing how to use the tool and understand the output. • Critique and decide on when to use an AI-based tool over another health care resource. • Recognize AI-based tools' perceived biases and discriminatory behavior (eg, an AI-based tool diagnosing skin conditions mainly trained on images of lighter skin tones may be less accurate in detecting conditions in individuals with darker skin tones) and the results demonstrated by AI-based tools where the learner will be able to solve and prevent further effects.
Communicator	
Family physicians foster life-long therapeutic relationships with patients and their families. This incorporates the dynamic exchanges that occur before, during, and after the medical encounter that facilitates gathering and sharing essential information for effective patient-centered health care [3].	• Explain to patients the current AI-based tool they are using and its results. • Address relevant gaps of understanding of AI tools among patients such as differing cultural perspectives and digital health literacy.
Collaborator	
Family physicians work with patients, families, communities, and other health care providers to provide safe, high-quality, patient-centered care [3].	• Practice a collaborative team-based approach, including establishing positive and continuing working relationships with relevant stakeholders in relation to developing, implementing, and improving the quality of AI-based tools.
Leader	
Family physicians must actively contribute to implementing and maintaining a high-quality health care system and take responsibility for delivering excellent patient care. This includes prioritizing and using health care resources efficiently, executing tasks collaboratively with colleagues, and contributing to ongoing quality improvement initiatives within their own practice and its management [3].	• Identify which AI-based tools are appropriate for the clinical practice of family physicians. • Allocate AI-based tools, when available, to specific tasks (eg, administrative work) in order for optimal patient care and practice management. • Analyze incidents of use of AI-based tools, appraise AI-based tools, and resolve any issues to avoid patient injury.
Advocate	
Family physicians leverage AI-driven insights to advocate for patients and communities, using their expertise to identify health needs, drive meaningful change, and mobilize resources for improved care outcomes [3].	• Extend AI-based tools and resources, when available and known, with other family physicians and family medicine communities. • Advocate for established AI-based tools, when available, to patients with the aim of improving their health outcomes.
Scholar	
Family physicians demonstrate a lifelong commitment to excellence in practice through continuous learning and teaching others; gather, combine, and evaluate evidence; and contribute to the creation and dissemination of knowledge [3].	• Participate in scholarly activities related to AI that benefit professional growth, clinical practice, and patients. • Maintain or enhance one's own knowledge and skills through professional educational activities related to AI and ongoing self-directed learning.
Professional	
Family physicians are committed to the health and well-being of their patients and society through competent medical practice; accountability to their patients, the profession, their colleagues, and society; profession-led regulation; ethical behavior; and maintenance of personal well-being [3].	• Recognize and appropriately respond to ethical, legal, and social issues encountered in practice, as it relates to AI-based tools and family medicine by communicating to the proper channels and resources (eg, AI and data experts, information technology specialists, ethics boards, and lawyers).

Element 3: AIFM-ed Curriculum Content

When developing a curriculum, a crucial task is to identify relevant subject knowledge, skills, attitudes, and behaviors that will help form the learning objectives [39]. Currently, there is no required AI education in Canadian undergraduate medical education. However, both educators and residents in our study agreed that for AI to be efficiently introduced in family medicine residency, it must be preceded by education in undergraduate

medical education. This earlier introduction of principles and concepts of AI will facilitate learning the more difficult material that is to come. The panels envisaged a basic stream of education in residency for those who had no exposure in undergraduate years. This would address fundamentals and basic knowledge of AI (eg, history, AI model development process, and core algorithms). A more advanced stream of AI education for residents would summarize the fundamentals and focus on how to use AI-based tools (applications) along with how to decide when to use and evaluate them (critical appraisal).

Residents noted that understanding how AI-based tools are used in clinical practice was the preferred content area for study, with less attention devoted to ethical, legal, and social considerations of AI. A resident put this in context, noting that they "do not need or want to learn the history of ChatGPT, but rather how to write effective prompts within this natural language processing chatbot." Table 3 summarizes the key concepts and areas of interest that family physicians should learn and content to include in the curriculum, as viewed by the participants.

Table 3. The curricular concepts and topics of relevance to family physicians.

Main curricular topic	Subtopics
Overview of AI[a] and data science in family medicine	
Providing an overview of AI definitions and concepts including machine learning as well as topics related to data science (eg, mathematics and statistics) and clinical epidemiology for family medicine.	• Review of AI (definitions and concepts) as it relates to family medicine • Introduction to AI and fundamentals of data science in family medicine • Strength and limitations of AI-based tools
Ethics, legal, and social considerations	
Understanding the ethical, legal, and social concerns of AI as it impacts family medicine clinical practice.	• Ethics, patient rights, data security, and confidentiality • Liabilities and regulatory and policy considerations • Equity, diversity, and inclusion of AI
Application of AI in family medicine	
Understanding how to choose and engage with AI-based tools in clinical settings and workflows with the ability to understand, interpret, and apply results of AI systems in clinical practice.	• Clinical practice management and operation • Preventative care and risk profiling (eg, mental health and chronic disease) • Patient self-management • Physician decision support • Physician wellness and resilience • Social determinants of health
Appraisal of family medicine AI-based tools	
Assessing and reviewing AI-based tools to ensure safe and effective integration and use in clinical practice.	• Identification of potential AI adverse effects and potential solutions • Quality improvement

[a]AI: artificial intelligence.

Element 4: Organization of AIFM-ed Curriculum Content

Family medicine postgraduate training is 24 months long in Canada. Given that the current curriculum is considered very heavy, educators and residents emphasized that the addition of another competency could be a burden to both educators and resident learners. They nonetheless agreed that AI curricula will eventually need to be added to that and an organized teaching structure would need to be established. Residents favored incorporating the teaching within the existing, already tight, 24-month core teaching, so that the benefits of longitudinal learning could be taken advantage of. The educators saw AI knowledge–based training during the first postgraduate year, followed by the development of AI-based clinical skills in the second postgraduate year. Educators proposed that if deeper AI education is needed, an additional third-year training program could be introduced for a select group of interested trainees to develop advanced AI skills in family medicine.

Element 5: Implementation of AIFM-ed Curriculum

Curriculum implementation will require the identification of appropriate resources (eg, educators and materials) along with educational strategies that will facilitate teaching activities and learner evaluation.

Curriculum Delivery

Residents highlight that AI education must be longitudinal, as it must be built upon throughout the medical education continuum. Furthermore, educators emphasized that residency is student-centered with learners coming from diverse backgrounds where they must replicate the actual tasks performed during in practice. Therefore, the learning theory of constructivism appears to be a sound and advantageous choice. This learning theory posits that learners actively construct their own learning by drawing upon their prior experiences [60].

There are several methods to implement an AI education curriculum to family medicine residents; however, there are

certain methods that are recommended by both educators and residents. In terms of learning about the knowledge and background of AI (eg, review of AI concepts or the ethical, legal, and social considerations of AI), hybrid (web-based and in-person) courses with asynchronous web-based modules, and in-person workshops, problem-solving sessions could be applied. Residents emphasized that didactic large group lectures especially in regard to a novel topic such as AI would be less engaging. The learning of such content should be considered a refresher with emphasis on the context of AI in family medicine. Both educators and residents then suggest that the in-person sessions would serve as a space for questions and answers and problem-solving activities.

To execute these educational methods, human resources (eg, AI medical educators) and material resources (eg, existing AI-based tools) are pertinent. Educators and residents highlighted that experts in the field of AI and family medicine would be ideal; however, educators emphasized that the faculty challenges such as the current number of experts are limited to provide this education. To overcome this, residents suggested that once an AI curriculum is established, further educators could be sourced from recently graduated residents who completed the AI in family medicine curriculum. With respect to material resources such as family physician–focused AI-based tools, both groups emphasized that they must be validated before use in educational settings.

Assessment and Evaluation Methods

Residents emphasize that the assessment and evaluation methods for the curriculum should be simple in context and focus on learners' participation and exposure. More specifically, learners should be able to have the capacity to demonstrate how to use AI-enabled tools and techniques in a health care setting. This can be seen through the completion of projects and problem-based and simulation-based assessments. Educators on the other hand emphasized taking into account Kirkpatrick's 4 levels of training evaluation model [61], where assessments should be directly related to the activity's learning objectives.

Discussion

The First Curriculum Framework for AI in Family Medicine (AIFM-ed)

In this study, we introduced a novel and evidence-based initial curriculum framework, that is, AIFM-ed developed for AI literacy education in family medicine postgraduate training. This systematically co-developed framework used a combination of validated methods including a comprehensive scoping review, resident and educator panel discussions, and the involvement of interdisciplinary experts in the field. During the development and cocreation of this framework, several key findings emerged. These include the crucial role of multiple resource partners and innovative practices when integrating AI educational content in family medicine education. For example, AI technology vendors specializing in health care, upcoming startups, and AI-focused organizations.

Furthermore, educators and residents stressed the importance of learning about the application of AI-based tools and simulating their use as a method of learning. Several innovative practices have already been implemented including case-based learning and flipped classroom models. Moreover, the adoption of AI-based tools can be diverse depending on its context (eg, teaching and learning and clinical practice) with several barriers and enablers. Additionally, the study identified several challenges in effectively integrating an AI curriculum framework into existing educational structures. These include the lack of AI definition standardization, the reduced urgency in practice due to the lack of time and resources, as well as the capacity to balance theoretical and practical curricular content.

Interprofessional Collaboration and Resources

During the development of the AIFM-ed curriculum framework, several resource partners were identified when discussing the implementation of AI education in family medicine. Interprofessional collaboration within multidisciplinary teams is essential in order for an AI curriculum to be effective [62]. Other researchers emphasize this sentiment when listing their recommendations of ensuring a responsible integration of AI technologies in medical education [63]. This multidisciplinary team and resource partners may include several stakeholders such as nurses, social workers, epidemiologists, AI experts, data engineers, software developers, and patients [64]. Other resource partners identified included AI technology vendors specializing in health care, upcoming startups, and AI-focused organizations. Residents brought up the concept that AI-based tools and AI in general will substantially change in the future (eg, improved tools, systems, and integrations) and thus stressed the importance of continuous partnerships with other professionals in order for relevant information and AI tools.

Educators emphasized that they were unaware of many AI-based tools for patient support and were thus apprehensive in advocating for AI-based tools. Therefore, family physicians and other primary care team members (eg, administrative staff and nurses) should share AI-based tools and resources, when available and known, with other family physician and family medicine communities. Additionally, residents have suggested that before advocating or suggesting AI-based tools, a list of recommended AI-based tools must be developed and released from a medical organization such as the CFPC. Currently, there is a scoping review and inventory that has identified and evaluated published studies that have tested or implemented AI in primary care settings [20,65]. This can be a starting point for such a list of recommended AI-based tools.

Application and Simulation of AI-Based Tools

Both educators and residents emphasize that a curriculum should focus on how to use AI-based tools (application) along with how to decide when to use and evaluate them (critical appraisal). Residents are already doing this comparatively as seen through their discussions of using ChatGPT, an AI-based chatbot launched by OpenAI that can be used as a digital consultant (eg, simple inquiries about diagnoses and treatment plans). One resident stressed that although they use ChatGPT at times for inquiries related to patient care, they are cautious of the information, as they are aware that ChatGPT can make mistakes and always consult other resources. As ChatGPT rises in

prominence, its impact on medical education has been evident through the resident panel discussion and the literature [66,67].

The incorporation of AI content in medical education has already begun with innovative practices, which include case-based learning and flipped classroom models. Case-based learning incorporates real-world AI use cases, where AI is used in clinical practice as examples for physicians [68]. Through this learning approach, students have a better understanding of the technical aspects of AI, as it allows physicians to compare their thought processes with other students and critically reflect or challenge their assumptions and biases of AI and clinical practice [68]. One study assessed the capabilities of ChatGPT within the framework of a preclerkship case-based active learning curriculum. Although the AI chatbot is not comprehensive enough to serve as a textbook, it was shown to answer questions, generate test questions, and appropriately respond to prompts in case-based learning scenarios [69]. According to a scoping review of teaching AI ethics in medical education, 5 publications reported in using case-based learning when understanding ethical challenges [70]. Resident panelists believe that simulation of these tools is beneficial, as it allows residents to enjoy the learning process and realize how these AI-based tools would operate in actual clinical settings. During these simulation sessions or case-based learning approaches, educator panelists highlighted reviewing the capabilities and basic functions of AI-based tools.

Another practical example of incorporating AI content through innovative practices is the flipped classroom model approach. Flipped classroom models can consist of web-based content supplemented by in-person classroom sessions [71], a key observation reinforced by residents of the panel discussion. One study designed and evaluated a novel AI course for medical students using a flipped classroom model, and they found that attending the course can increase self-perceived AI readiness in medical students [71]. In addition, educators have also commented on facilitating AI learning by integrating family medicine AI-based tools in quality improvement projects, which has been emphasized and recommended by other researchers [72].

Adopting AI in Education and Clinical Practice

Family physicians use AI, when implemented, primarily for diagnosis, detection, or surveillance purposes [20]. Although educators have flexibility in choosing from a wide range of AI tools, certain tools have proven to be particularly essential for effective integration. These include AI-enabled chatbots, clinical documentation support, and diagnostic decision support, which have shown to improve physicians' efficiency and accuracy in their work [73-75]. However, there have been several barriers identified in previous reviews, which have made the adoption of AI-based tools difficult [76-78]. These issues include a lack of trust among educators, students, and clinicians; insufficient training and digital literacy; and resistance to change [77].

Additional challenges include data privacy and patient safety concerns, ethical and legal issues, interoperability issues, lack of funding, and inequities in access to AI tools—particularly between rural and urban settings [79]. In contrast, several strategies and enablers have been identified in order to better facilitate the adoption of AI and its continued use. These strategies include strategies fostering interdisciplinary collaboration between educators, clinicians, and AI developers; providing targeted training programs to build AI literacy; developing high-quality datasets for diverse use cases; and creating supportive regulatory frameworks [77]. Establishing national or local community networks to share resources and best practices, while leveraging trusted relationships within these networks, can also significantly enhance confidence in and adoption of AI-based tools. To identify relevant enablers and barriers to AI adoption of a certain audience, a comprehensive, stakeholder-centered approach is essential. For example, researchers in Canada conducted in-depth interviews with primary health care and digital health stakeholders and were able to ascertain their current barriers and potential facilitators of AI [80].

It is important to note that AI systems exist in diverse contexts and content with distinct implications, risks, and ethical and legal challenges depending on their application and domain. For example, in education, AI-enabled tools using large language models may offer personalized education, but biases may be propagated, inaccurate information may be generated, or students may overrely on AI, undermining their critical thinking skills [63,81]. In addition, there is potential for the exacerbation of inequities in accessing AI tools as well as the misuse of AI-generated content. In comparison, AI-enabled tools in clinical practice, such as decision-support systems, could carry risks of incorrect or biased recommendations that may directly impact patient outcomes [82,83], thus, raising ethical concerns about patient autonomy and safety as well as legal liability in cases of harm. Therefore, the differences of AI in each domain are important to understand in order to identify appropriate safeguards. Future research should conduct comparative analyses of AI's risks, implications, and ethical and legal dimensions in educational versus clinical settings, examining factors such as accuracy, equity, accountability, and trust. These studies can inform best practices and policies to optimize AI's potential while mitigating domain-specific risks.

Curriculum Framework Challenges

During the development of this curriculum framework, there were several challenges in effectively integrating an AI curriculum framework into a family medicine residency training program. During the expert panel discussions, many experts emphasized the issue regarding the lack of standardization with the definition of AI. Although a definition of AI was chosen for the purpose of the panel, a specific and committed definition of AI within medical education has not been established [84-86]. Panelists argued that an AI definition must be properly explained to avoid confusion or misrepresentation. In relation to family medicine, a recent primer for AI in primary care was published, which provided the definition, "The field of AI is broad and rapidly expanding. The field is centred on how computers might be able to perform humanlike 'intelligent tasks,' such as summarizing large amounts of information or making inferences about a situation" [87]. The discussions regarding this framework highlight the necessity of a standardized AI definition for better development of teaching and learning content. This is especially true when specializing in different

fields of medical education, including family medicine and primary care.

There is a need to introduce AI education within family medicine; however, the low urgency and priority to integrate this type of education at the moment were noted throughout the discussions. This can be due to the lack of AI-enabled tools for family physicians currently being developed, tested, and implemented in practice [88,89]. Furthermore, some residency programs lack the appropriate AI tools or are in lower-resource settings. As a result of the minimal exposure family physicians have with AI, their motivation to learn about the topic can also be reduced. This reduced priority of AI education competes with the CFPC's 105 topics of family medicine curricula [4]. This is exacerbated by the fact that Canada is in a unique position, in which the length of residency training is only 2 years. In addition, the rapid advancement of AI introduces an extra layer of complexity. As new AI-based tools emerge and existing ones advance, educators and family physicians must frequently reassess and update their knowledge and skills. For example, the recent introduction of generative AI and generative AI tools such as ChatGPT has gained widespread popularity in medical and academic settings [90]. Thus, it is difficult to maintain a robust framework due to the inevitable rapid changes of AI in health care. Therefore, the eagerness to integrate this type of education within the curriculum should be met with caution to manage the expectations of both educators and learners.

A key observation made throughout the panel discussion was about the AI content and how much should a family physician know about AI. During the discussions, many of the participants voiced support on the application and appraisal of AI-enabled tools. This is especially challenging when residency is only 24 months, and there are no required AI educational programs presented in the Canadian undergraduate medical education system. Therefore, within the learning objectives, in regard to how much a family physician should know about AI remains undetermined. Further research must be conducted to investigate the level of AI education a family physician should be aware of. Overall, the aforementioned challenges must be addressed in order for this curriculum framework to be effectively implemented.

Future Studies

Following the analysis, design, development, implementation, and evaluation model process, researchers may move forward to the implementation and evaluation of the AIFM-ed framework. During the implementation step, an educational program such as a course or workshop can be developed with the main concepts originating from the curriculum framework. The training for family medicine is already packed; thus, the implementation of this framework will depend on several factors including the current use of AI-enabled tools in family medicine training, previous training in AI (eg, the undergraduate foundation of AI), and the capacity of experienced teachers. However, once implemented, certain success indicators will need to be evaluated to understand its impact as well as any areas for improvement. Future studies could explore indicators such as the perceived impact of the framework, degree of implementation, as well as knowledge and skill apprehensions. These indicators can be evaluated through the framework-derived educational training program according to the Kirkpatrick model [61].

Strengths and Limitations of This Study

This study had several strengths, including the formation of a national, multidisciplinary panel of family medicine educators. This diverse panel facilitated enriching discussions with varied expertise and insights, allowing for a comprehensive understanding of practical implications and current perspectives on AI education in family medicine postgraduate training. Additionally, by involving both educators and residents, the AIFM-ed curriculum framework ensures the representation from key stakeholders involved in the teaching and learning process of AI education. This co-design approach enhanced the relevance and applicability of the AIFM-ed curriculum framework. Regarding the overall development of this framework, a multi-method systematic approach was used, which includes a comprehensive systematic scoping review and multiple expert panel discussions. This approach allowed us to identify and build on existing AI curriculum topics and resources while also creating new ones. Furthermore, this structured and reproducible methodology ensures a robust foundation that can be used by other educators and researchers to develop training programs (eg, courses) following the established framework.

Despite the strengths, this study also had few limitations. First, the study was developed for programs in Canada, which limits its applicability to other countries due to the different medical education structures globally and their current relationships with AI. However, this could be a starting guide for other researchers to adapt it to their own context. Additionally, expert panel diversity was limiting, where the resident panel came from a single institution, which may further limit the generalizability of the framework. Furthermore, as the participants for the panel discussion were not randomized and were purposively recruited, the results may be subject to selection bias.

Conclusions

We co-developed an AIFM-ed framework for family medicine residency training that outlines its curricular purpose, learning objectives, AI curricular topics, delivery methods, and evaluation strategies to be used by medical institutions. The AIFM-ed curriculum framework ultimately aims to enhance the education of future family physicians, equipping them to effectively integrate AI-enabled tools into their practice and patient care. It is hoped that this framework will provide further advocacy, productivity, and gradual change within the area of curriculum development and AI medical education. Overall, medical institutions are encouraged to begin equipping future physicians with the knowledge, skills, and confidence to effectively use AI-enabled tools, as these technologies will continue to grow within the field of health care and family medicine.

Acknowledgments

The authors would like to thank the panelists for their support, time, and contributions to this research. The authors would also like to acknowledge Dr Pierre Pluye who provided key guidance to the development of this project prior to his passing in August 2023. SAR is Canada Research Chair (Tier II) in artificial intelligence and Advanced Digital Primary Health Care, received salary support from a Research Scholar Junior 1 Career Development Award from the Fonds de Recherche du Québec-Santé during part of this project, and her research program is supported by the Natural Sciences Research Council Discovery (grant 2020-05246).

Authors' Contributions

Conceptualization was led by SAR and RT, who established the study's goals, design, and research questions and obtained the funding for the project. The methodology was developed by SAR and RT. The data collection was done by RT and SAR. Data curation was managed by RT. A formal analysis was conducted by RT. The original draft was written by RT. SAR, FH-E, and MY provided critical revisions. Reviewing and editing were a collaborative effort with all authors. Supervision and overall project leadership were provided by SAR.

Conflicts of Interest

None declared.

Abstract

Background: Competency-based medical education relies heavily on high-quality narrative reflections and feedback within workplace-based assessments. However, evaluating these narratives at scale remains a significant challenge.

Objective: This study aims to develop and apply natural language processing (NLP) models to evaluate the quality of resident reflections and faculty feedback documented in Entrustable Professional Activities (EPAs) on Taiwan's nationwide Emyway platform for otolaryngology residency training.

Methods: This 4-year cross-sectional study analyzes 300 randomly sampled EPA assessments from 2021 to 2025, covering a pilot year and 3 full implementation years. Two medical education experts independently rated the narratives based on relevance, specificity, and the presence of reflective or improvement-focused language. Narratives were categorized into 4 quality levels—effective, moderate, ineffective, or irrelevant—and then dichotomized into high quality and low quality. We compared the performance of logistic regression, support vector machine, and bidirectional encoder representations from transformers (BERT) models in classifying narrative quality. The best performing model was then applied to track quality trends over time.

Results: The BERT model, a multilingual pretrained language model, outperformed other approaches, achieving 85% and 92% accuracy in binary classification for resident reflections and faculty feedback, respectively. The accuracy for the 4-level classification

was 67% for both. Longitudinal analysis revealed significant increases in high-quality reflections (from 70.3% to 99.5%) and feedback (from 50.6% to 88.9%) over the study period.

Conclusions: BERT-based NLP demonstrated moderate-to-high accuracy in evaluating the narrative quality in EPA assessments, especially in the binary classification. While not a replacement for expert review, NLP models offer a valuable tool for monitoring narrative trends and enhancing formative feedback in competency-based medical education.

KEYWORDS

competency-based medical education; entrustable professional activities; otolaryngology; residency; workplace-based assessment; reflection; feedback; Emyway platform

Introduction

Medical education has undergone a fundamental transformation, with competency-based medical education (CBME) emerging as a central paradigm [1]. In contrast to traditional time-based models that focus on the completion of predetermined curricula over fixed durations, CBME emphasizes the direct assessment of learner's abilities to perform core professional activities safely and effectively in authentic clinical environments [2,3]. This outcomes-oriented approach aims to ensure that physicians are not only knowledgeable but also clinically competent, adaptable, and equipped to address the evolving complexities of patient care [4-6].

The field of otorhinolaryngology–head and neck surgery underscores the urgency of this educational shift, given its demand for proficiency in complex surgical procedures and nuanced clinical decision-making [7,8]. In response, the Taiwan Society of Otorhinolaryngology–Head and Neck Surgery (TSO-HNS) launched a structured competency framework in 2020, introducing 11 Entrustable Professional Activities (EPAs) as benchmarks for assessing resident performance (TSO-HNS Entrustable Professional Activities Assessment Framework for Resident Physician Training, second edition; see Multimedia Appendix 1). To support the systematic implementation of these EPAs, the Emyway digital platform was adopted in 2021, enabling more structured, transparent, and objective competency evaluations [9]. Central to Emyway is the integration of workplace-based assessment (WBA), which promotes continuous learning through direct observation, self-reflection, formative feedback, and performance appraisal in real-world clinical settings [10,11]. Unlike traditional assessments, WBAs offer dynamic, individualized insights that inform both clinical decision-making and technical skill development [9].

A key challenge in CBME is bridging the gap between assessment and learning. Reflection and feedback play complementary roles in this process. When aligned, feedback shapes the focus of reflection, and reflection deepens engagement with feedback, turning assessments into learning opportunities. However, prior studies show that reflections often remain descriptive, and feedback lacks specificity, limiting their combined educational value [12,13]. Evaluating the quality of both processes is therefore essential to understanding how WBAs contribute to learning. A growing body of evidence underscores the role of high-quality reflections and feedback in reinforcing core competencies and enhancing learning outcomes [14,15]. However, the quality of these narrative components within WBAs—particularly in otolaryngology residency programs and in multilingual training environments—remains insufficiently studied.

A major challenge in the implementation of CBME is managing the substantial volume of narrative data generated through WBAs [11]. On digital platforms such as Emyway, thousands of EPA evaluations are recorded, rendering manual review impractical. Traditional assessment methods that rely on human interpretation are time-consuming, resource-intensive, and susceptible to variability, limiting their ability to yield consistent and meaningful insights from large datasets [16]. Overcoming this challenge requires innovative strategies to ensure that narrative reflections and feedback remain relevant, specific, and actionable—supporting continuous learning and improvement in residency training [17,18].

This study aims to address the challenge of evaluating narrative data in CBME by applying natural language processing (NLP) to systematically assess the quality of resident reflections and faculty feedback recorded within the Emyway platform. To capture these distinct but interrelated processes at scale, we applied NLP models to evaluate reflection and feedback separately, allowing for a clearer analysis of their respective contributions to CBME. We hypothesize that NLP can provide an objective, consistent, and scalable method for evaluating the effectiveness of narrative assessments, offering valuable insights into how feedback contributes to residents' competency development [16,19]. By leveraging NLP, this study seeks to improve the relevance, specificity, and actionability of reflections and feedback, thereby enhancing the guidance residents receive for their professional growth [19-22]. Resident reflections and faculty feedback are distinct constructs: reflections involve personal self-assessment, while feedback represents external evaluation from faculty. Although different, they occur simultaneously within the same WBA encounter. This study therefore examines both while ensuring that the NLP models and evaluation rubrics for reflections and feedback were developed and analyzed independently. Ultimately, this approach aims to bridge the gap between assessment and learning, strengthen CBME implementation, and support the development of a more robust otolaryngology residency training system.

Methods

Ethical Considerations

This study adheres to established ethical standards for medical education research. Informed consent was obtained actively. Participants were required to read the "Training-Related Data Collection and Privacy Information" and click an "I agree" button before accessing the Emyway platform. The participants did not receive any compensation for their participation. The system includes built-in data protection mechanisms to prevent confidential information from being displayed. All data were deidentified prior to analysis, with personal identifiers removed, and access was restricted to the research team through secure, password-protected servers. The study protocol was reviewed and approved by the institutional review board of Cardinal Tien Hospital (CTH-112-2-1-002).

Study Design and Setting

This cross-sectional study examines the quality of resident reflections and faculty feedback recorded in the Emyway platform of TSO-HNS between 2021 and 2025. Emyway is a nationwide digital platform designed to support CBME by systematically collecting workplace-based EPA assessments from otolaryngology residency programs across Taiwan [9]. Basic clinical information, encounter descriptions, resident reflections, and subsequent faculty feedback and ad hoc entrustment decisions were collected within a single standardized electronic form on the Emyway platform [9]. The primary objective of this study was to evaluate the narrative quality of resident reflections and faculty feedback by using NLP algorithms, with the goal of improving assessment reliability and enhancing the educational value of feedback in clinical training.

Data Collection and Sample Selection

We selected 300 EPA assessment entries from the Emyway national database, covering the period from 2021 to 2025. Each entry included structured fields such as the EPA title, clinical diagnosis, and narrative components authored by both residents and faculty [9]. To ensure diversity and representativeness, we employed stratified random sampling across training years, resident levels, and EPA categories. To reduce potential bias related to temporal improvements in narrative quality, we used cross-validation and ensured a balanced distribution of entries across earlier and later phases of implementation. Only complete assessments containing both resident reflections and faculty feedback were included in the final analysis.

Narrative Quality Assessment

Two medical education experts—one a physician-educator specializing in otolaryngology residency training and the other a senior faculty developer with expertise in educational measurement and feedback assessment—independently evaluated the quality of resident reflections and faculty feedback by using a structured rubric based on the core principles of CBME. Narratives were evaluated using established rubrics developed by Solano et al [17] and Ötleş et al [18], which have been previously validated in surgical residency programs and were adopted in our study without modification to ensure consistency with the existing literature. The rubric assesses 3 key dimensions: relevance, specificity, and either reflection content (for resident narratives) or actionability (for faculty feedback). Relevance evaluates the alignment of the narrative with the EPA and the clinical context. Specificity measures the clarity and detail with which strengths, weaknesses, or areas for improvement were identified. Reflection content assesses the presence of self-directed learning goals in resident narratives, while actionability examines whether faculty feedback provided clear, constructive guidance to support resident development. The analysis of interrater reliability showed a fair to moderate agreement in the 4-level classification and a substantial to almost perfect agreement in the 2-level classification (Table S1 in Multimedia Appendix 2). In cases where the 2 expert raters had discrepancies in their ratings, a third reviewer (the corresponding author) adjudicated and made the final decision to ensure consistency and accuracy in the gold standard dataset.

Based on the evaluation criteria, narratives were categorized into 4 quality levels (Table 1): effective, moderate, ineffective, and irrelevant. Effective narratives were both relevant and specific; resident reflections demonstrated meaningful insight, and faculty feedback included actionable guidance. Moderate narratives maintained relevance but demonstrated only one additional element—either specificity or reflection content for residents or actionability for faculty. Ineffective narratives were superficially related to the EPA but lacked depth, with vague language and an absence of both specificity and meaningful reflection or guidance. Irrelevant narratives were off-topic, superficial, or disconnected from the clinical context. In this study, "high quality" refers to the combined category in the 2-level classification (encompassing both effective and moderate narratives) and "low quality" refers to ineffective and irrelevant narratives, whereas "effective" denotes the highest category within the 4-level classification.

Table 1. Classification of the quality levels in residents' reflections and faculty feedback.

Characteristics according to the 4-level classification[a]	Quality of narrative content				
	Effective[b]	Moderate[b]	Moderate[b]	Ineffective[c]	Irrelevant[c]
Relevance	Yes	Yes	Yes	Yes	No
Specificity	Yes	Yes	No	No	N/A[d]
Reflection content in residents' reflections	Yes	No	Yes	No	N/A
Action plan in faculty feedback	Yes	No	Yes	No	N/A

[a]In the 4-level classification, the categories are effective (highest quality), moderate, ineffective, and irrelevant.

[b]The combined group of effective and moderate narratives was classified as high quality per the 2-level classification.

[c]Ineffective and irrelevant narratives were classified as low quality per the 2-level classification.

[d]N/A: not applicable.

NLP Framework

To enhance the scalability and objectivity of narrative assessment, NLP techniques were applied to analyze resident reflections and faculty feedback. Two independent NLP models were developed and trained separately for reflections and feedback, ensuring that the classification processes remained independent while allowing both dimensions to be examined within the same WBA encounter. Three supervised machine learning models were implemented for classification: logistic regression (LR) [23], support vector machine (SVM) [24], and bidirectional encoder representations from transformers (BERT) [25], which is a state-of-the-art deep learning model for natural language understanding.

Data Preprocessing and Feature Extraction

For traditional machine learning models such as LR and SVM, text preprocessing included tokenization using CKIPtagger for Chinese language segmentation, followed by transformation into term frequency–inverse document frequency feature vectors. In contrast, the BERT model processed raw text inputs directly, structured as a combination of context, EPA title, diagnosis, and either reflection or feedback. This approach leveraged BERT's ability to generate contextualized embeddings without requiring additional preprocessing.

Model Training and Evaluation

To evaluate model performance, the dataset was randomly divided into a training set (80%) and a validation set (20%). Both fine-grained (4-level) and binary (2-level) classification models were developed to assess the impact of classification granularity. LR and SVM models were implemented using the *scikit-learn* library, while the BERT model was fine-tuned using the *simpletransformers* library with the pretrained BERT-base-multilingual-uncased model. BERT was trained for 10 epochs with a learning rate of 2e-5. The code used for training all the models is provided in Multimedia Appendix 3.

Performance Metrics and Narrative Quality Trend Analysis

We evaluated model performance by using standard metrics, including accuracy, precision, recall, and F_1-score. We generated confusion matrices to visualize classification outcomes and identify patterns of misclassification. The analysis aimed to assess the accuracy of distinguishing high-quality and low-quality reflections and feedback, compare the performance across different machine learning models, and explore longitudinal trends in the narrative quality by using the best performing model throughout the study period from 2021 to 2025.

Results

Overall Model Performance

Across the study period, the majority of EPA assessments were complete, containing both resident reflections and faculty feedback. Specifically, 90.1% (1422/1580) were complete in the pilot year (2021-2022), 95.1% (9939/10,447) in 2022-2023, 96.7% (10,601/10,966) in 2023-2024, and 97.1% (12,139/12,497) in 2024-2025. In total, 34,101 out of 35,490 assessments (96.1%) were complete and included in the final analysis. Table 2 presents the expert-assessed quality distribution of 300 randomly selected EPA entries, comprising resident reflections and faculty feedback, used for developing and validating the NLP models.

Table 3 summarizes the prediction outcomes from the 3 models evaluated in the study. The NLP-based classification models demonstrated substantial accuracy in assessing the quality of both resident reflections and faculty feedback, with the BERT model consistently outperforming the LR and SVM models. Specifically, for resident reflections, the BERT model achieved an accuracy of 85% for the 2-level classification and 67% for the more granular 4-level classification. Performance was even stronger for faculty feedback evaluation, where the BERT model attained an accuracy of 92% in the 2-level classification and maintained a 67% accuracy for the 4-level classification. Additionally, precision, recall, and F_1-scores showed consistent patterns across these evaluations, supporting the robustness and reliability of the BERT model.

Table 2. Distribution of expert-assessed quality of 300 randomly selected Entrustable Professional Activity entries (resident reflections and faculty feedback) for natural language processing model development and validation.

Classification/quality rating	Resident reflections (n=300), n (%)	Faculty feedback (n=300), n (%)
4-level classification		
Effective	134 (44.7)	168 (56)
Moderate	86 (28.7)	28 (9.3)
Ineffective	49 (16.3)	24 (8)
Irrelevant	31 (10.3)	80 (26.7)
2-level classification		
High-quality	220 (73.3)	196 (65.3)
Low-quality	80 (26.7)	104 (34.7)

Table 3. Prediction results of the residents' reflections and faculty feedback by the 3 models in the study.

Narrative content, model	4-level classification				2-level classification			
	Accuracy (%)	Precision (%)	Recall (%)	F_1-score	Accuracy (%)	Precision (%)	Recall (%)	F_1-score
Resident reflections								
LR[a]	63	66	63	64	80	83	80	81
SVM[b]	60	63	60	60	85	85	85	85
BERT[c]	67	67	67	65	85	85	85	85
Faculty feedback								
LR	63	55	63	59	78	78	78	78
SVM	63	54	63	54	78	81	78	76
BERT	67	65	67	64	92	92	92	92

[a]LR: logistic regression.

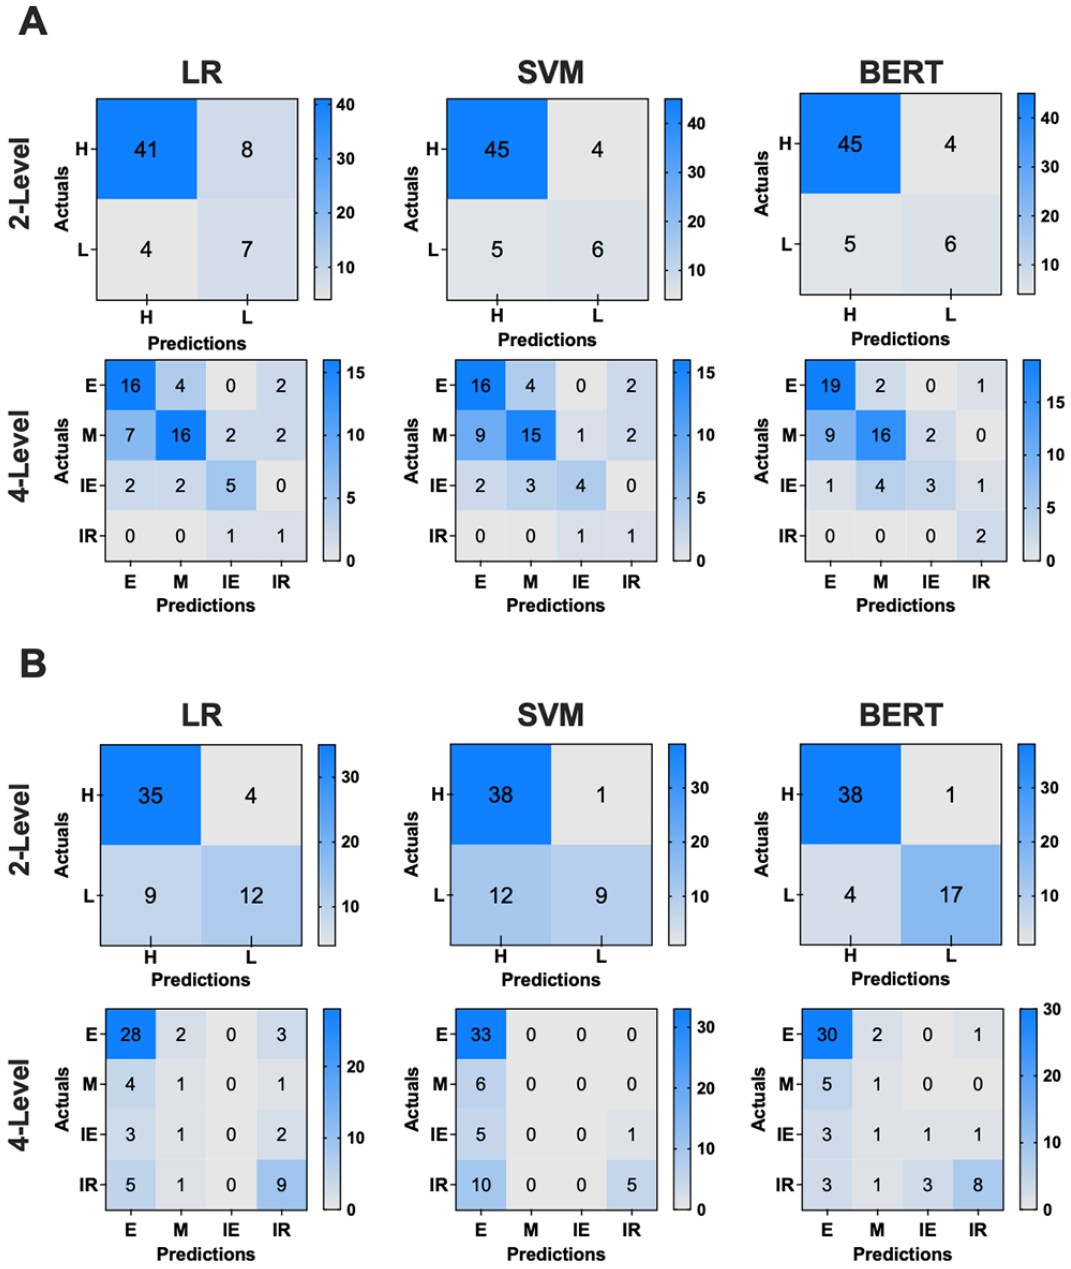
[b]SVM: support vector machine.

[c]BERT: bidirectional encoder representations from transformers.

Confusion Matrix Analysis

To further assess model performance, confusion matrices were generated (Figure 1). The BERT model exhibited fewer misclassifications than LR and SVM, particularly in distinguishing between effective and moderate narratives. In contrast, LR and SVM frequently misclassified effective narratives as moderate or irrelevant, reflecting their limitations in detecting subtle contextual cues. Notably, BERT's superior classification capability was most evident in faculty feedback, where its accuracy surpassed 90%, demonstrating its potential to improve automated assessment reliability in competency-based education frameworks. To illustrate the model's interpretability and limitations, Table S2 in Multimedia Appendix 4 presents anonymized examples of correctly classified and misclassified narratives.

Figure 1. Confusion matrices illustrating the classification performance of 3 natural language processing models—LR, SVM, and BERT—in evaluating the quality of resident reflections (A) and faculty feedback (B). The x-axis represents predicted categories, and the y-axis represents actual expert ratings. For the 2-level classification, narratives were categorized as high quality (H) or low quality (L). For the 4-level classification, the categories are effective (E), moderate (M), ineffective (IE), and irrelevant (IR). Numbers within each cell indicate the count of narratives, while shading intensity reflects frequency (darker=higher count). Compared with LR and SVM, BERT demonstrated fewer misclassifications and stronger performance in distinguishing between adjacent categories, particularly for faculty feedback. BERT: bidirectional encoder representations from transformers; LR: logistic regression; SVM: support vector machine.

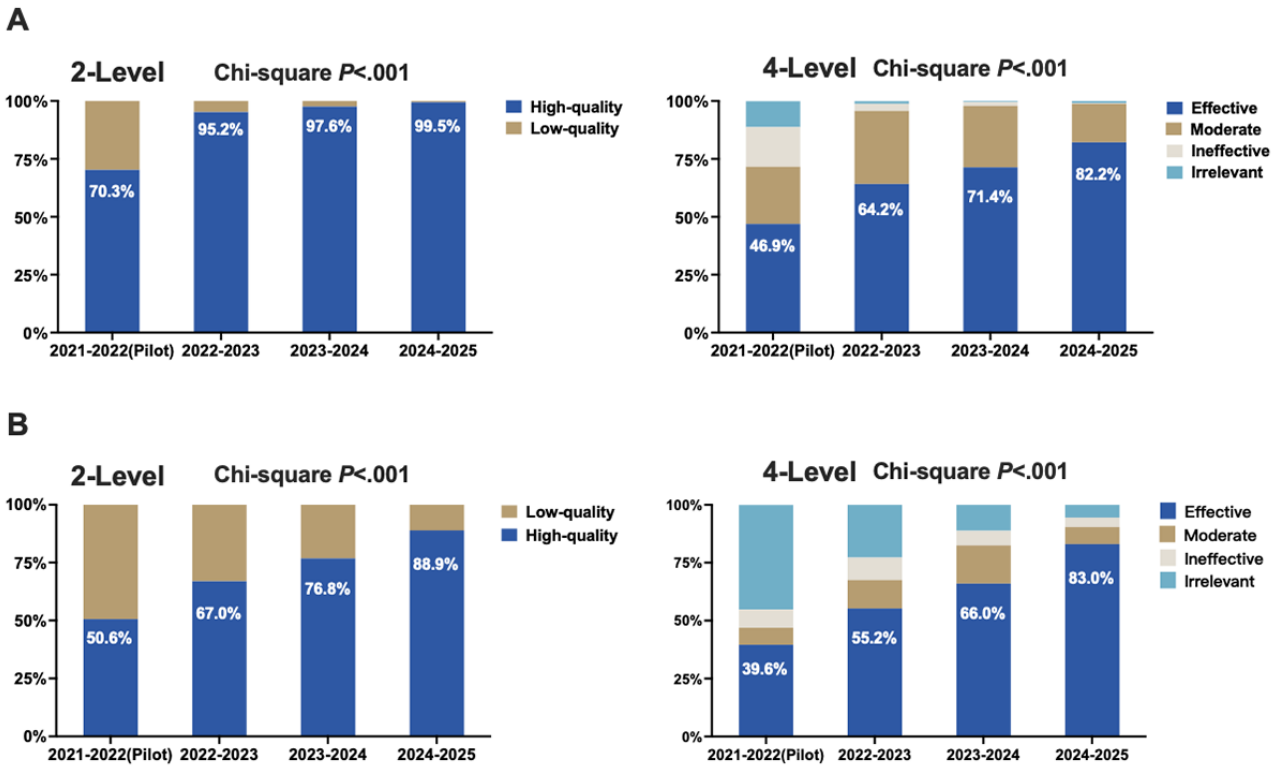


Two-Level and Four-Level Quality Classification Outcomes in the Emyway Platform

Figure 2 illustrates the longitudinal trends in the narrative quality of resident reflections and faculty feedback, as classified by the BERT model using both 2-level and 4-level rating algorithms, across 4 academic years: the pilot year (2021-2022) through 2024-2025. Detailed distributions of frequencies and percentages are presented in Table S3 of Multimedia Appendix 5.

In the 2-level classification, the proportion of high-quality resident reflections increased from 70.3% to 99.5%, while high-quality faculty feedback increased from 50.6% to 88.9% over the study period. Chi-square analyses confirmed that these improvements were statistically significant (P<.001 for both groups), reflecting meaningful enhancement in the quality of narrative documentation. Similarly, in the 4-level classification, the proportion of "effective" resident reflections increased from 46.9% to 82.2%, and "effective" faculty feedback increased from 39.6% to 83%. These gains were also statistically significant (P<.001), suggesting a sustained and substantive improvement in narrative quality over time, likely associated with the ongoing implementation of structured EPA frameworks and digital feedback systems.

Figure 2. Longitudinal trends in the quality of narrative assessments from 2021 to 2025, as classified by the bidirectional encoder representations from transformers model. Panel A displays resident reflections; panel B displays faculty feedback. In each panel, the left graph shows the 2-level classification (high quality vs low quality), and the right graph shows the 4-level classification (effective, moderate, ineffective, irrelevant). The x-axis represents academic years, with 2021-2022 as the pilot year, followed by 3 full implementation years. The y-axis indicates the percentage distribution of the narratives. Over time, both resident reflections and faculty feedback showed a significant increase in the proportion of high-quality and effective narratives.



Discussion

Principal Findings

This study demonstrates the utility of NLP, specifically the BERT algorithm, in evaluating the narrative quality within WBAs in otolaryngology residency training. The BERT model achieved high accuracy in the binary classification—85% for resident reflections and 92% for faculty feedback—supporting its potential as a scalable, objective adjunct to manual evaluation. Notably, narrative quality improved significantly over the study period, with high-quality reflections increasing from 70.3% to 99.5% and high-quality faculty feedback from 50.6% to 88.9%. These findings highlight the potential of NLP to enhance quality assurance and longitudinal monitoring in CBME.

Compared to traditional manual qualitative analysis, NLP offers unique advantages [26]. Although human raters can capture contextual nuance and interpret implicit meaning, their assessments are time-intensive and subject to interrater variability. In contrast, NLP enables consistent, rapid, and scalable evaluation across large datasets [27,28]. Prior research by Akbasli et al [29] has demonstrated the feasibility of applying fine-tuned language models to non-English and multilingual medical texts. Our findings further support this approach, showing that integrating structured contextual inputs such as EPA titles, clinical diagnoses, and narrative components substantially enhance model accuracy. With adequate structured contextual inputs, BERT approximates human interpretive depth while retaining the efficiency and objectivity of automation.

This approach should also be interpreted through the lens of the educational assessment theory. Beyond its statistical performance, the application of NLP algorithms in this study aligns closely with established educational assessment theories and feedback quality frameworks. The structured rubric used to generate the gold standard—encompassing relevance, specificity, and either having reflection content or actionability—reflects the core principles found in frameworks such as the Feedback Quality Instrument [30-32] and the R2C2 model (relationship building, exploring reactions, exploring content, coaching for change) [14,33,34]. These frameworks emphasize that effective feedback and reflection must be contextually relevant, sufficiently specific, and actionable to promote self-regulated learning and professional growth. By incorporating these dimensions into the training data, BERT's decision-making process operationalizes these theoretical constructs, mapping narrative text to empirically validated quality indicators. In this way, the model does not merely classify text based on linguistic patterns but also embeds the pedagogical priorities of CBME and EPA assessment. This alignment ensures that automated scoring supports the same developmental goals as expert human raters, enabling the model to serve as a theoretically grounded, scalable complement to manual evaluation.

However, it is important to clarify that the R2C2 model is a coaching framework designed to structure feedback

conversations rather than an evaluation rubric for written comments. In this study, R2C2 was referenced as a conceptual lens to underscore the coaching potential embedded in high-quality narrative feedback and not as a scoring tool. Recent literature has emphasized its role in facilitating meaningful faculty–learner interactions in WBAs [35,36]. Our findings on the quality of written reflections and feedback should therefore be viewed as complementary to, rather than substitutive of, coaching frameworks such as R2C2, providing a stronger foundation for effective feedback dialogue.

In addition to methodological contributions, our findings suggest practical applications for residency programs. NLP outputs could be integrated into dashboards that track reflection and feedback quality over time, enabling program directors to identify gaps and design targeted faculty development workshops. At the same time, residents could receive timely, formative, reflective prompts into the quality of their reflections. By embedding these tools into CBME frameworks, narrative data can serve not only as an assessment record but also as a resource to strengthen feedback culture and support continuous coaching.

Comparison With Previous Studies

The superior performance of BERT relative to traditional machine learning models such as LR and SVM is a key contribution of this study. For instance, previous work by Ötleş et al [18] reported a mean accuracy of 0.64 by using SVM for the 4-level classification of surgical feedback, which improved to 0.83 when simplified to binary classification. Similarly, Solano et al [17] achieved an overall accuracy of 0.83 by using NLP but noted limitations in sensitivity (0.37), suggesting challenges in detecting lower quality feedback. In contrast, our BERT-based model achieved 85% accuracy for resident reflections and 92% for faculty feedback in binary classification, with balanced precision and recall scores. These results highlight BERT's superior ability to contextualize text and detect nuanced linguistic patterns. Unlike traditional models, BERT effectively interprets the complex, often implicit nature of reflective narratives, validating its use in educational quality assessment within clinical training contexts [37]. This capacity is particularly valuable, as reflective writing in medical education is typically layered, context-sensitive, and difficult to assess using rule-based or shallow models [38,39].

Although the 4-level classification achieved only moderate accuracy, its outputs can still inform educational practice. Even without perfect distinction between adjacent categories, the model can highlight patterns of lower quality narratives that may warrant attention. For instance, faculty development dashboards could flag programs or individuals generating a higher proportion of ineffective or moderate entries, prompting targeted coaching or workshops. These applications position the model as a supportive tool for monitoring and guiding feedback culture, complementing human judgment rather than replacing it.

Unlike prior studies that emphasized cross-sectional performance [17,18], this research provides longitudinal evidence of NLP's ability to track and support improvements in feedback quality over time. Consistent with earlier findings, the model maintained high specificity, particularly in identifying low-quality narratives—a valuable feature for faculty development and system-level monitoring. Although the 4-level classification performance remained moderate (67% accuracy), this aligns with known challenges in distinguishing subtle qualitative gradations and highlights areas for future enhancement.

The sustained improvement in the reflection quality across the study period underscores the value of structured WBA systems such as those implemented through the Emyway platform. These systems provide clear expectations and guidance, promoting deeper engagement, self-awareness, and professional development [40]. This observation aligns with literature indicating that structured reflection fosters clinical reasoning, self-regulated learning, and long-term growth [41-44].

Faculty feedback quality also improved substantially, increasing in specificity, relevance, and actionability. While still trailing resident reflections in overall quality, the upward trajectory from 50.6% to 88.9% suggests growing familiarity with EPA-based frameworks and greater faculty engagement. These findings reinforce the importance of structured systems in supporting effective feedback practices. NLP tools, in this context, can function as educational dashboards—tracking feedback quality across programs and timeframes, flagging low-quality entries, and informing faculty development and institutional policy.

It is important to note that reflection quality and feedback quality were not conflated in this study; rather, they were modeled separately using independent rubrics and NLP training processes. Presenting them together highlights how these complementary elements of the same assessment encounter can be studied in parallel to inform faculty development and resident learning.

We selected BERT over commercial large language models such as ChatGPT for both practical and performance-based reasons. As an open-source model, BERT is accessible to academic institutions without licensing constraints, facilitating integration into resource-limited settings. Moreover, internal comparisons indicated that ChatGPT, while powerful, lacked discriminative precision in this context and frequently defaulted to mid-range classifications (Multimedia Appendix 6). In contrast, BERT demonstrated greater reliability and accuracy, particularly when provided with structured contextual information.

Generalizability

Although our findings highlight the utility of BERT-based NLP within Taiwan's structured otolaryngology training system, their generalizability to other specialties, languages, and international contexts remains uncertain. Narrative style, cultural norms, and feedback practices vary widely across training environments, potentially affecting model performance. To ensure validity in non-Chinese language settings, rubric recalibration would be needed to align evaluation criteria with local educational practices and expectations. Furthermore, although multilingual pretrained models such as BERT provide a strong foundation, language-specific fine-tuning with locally

generated narrative data would be required to capture semantic nuances and ensure accurate classification. These adaptations highlight the importance of international replication and validation, which will be essential to confirm generalizability and extend the impact of NLP-assisted evaluation across medical specialties and cultural contexts.

The use of open-source NLP tools such as BERT also carries important ethical and practical implications. Although these models provide scalability, accessibility, and adaptability for educational use, they raise concerns about confidentiality, data security, and potential bias. To ensure responsible application, future implementation should include secure data management, careful local fine-tuning, and ongoing evaluation of fairness so that such tools enhance rather than compromise educational integrity.

Limitations

Despite encouraging results in binary classification, several limitations should be noted. First, the model's 67% accuracy in the 4-level classification reflects the inherent difficulty of distinguishing subtle qualitative differences in narrative assessments. Overlap in language used across adjacent categories—such as moderate and ineffective—poses challenges for both human raters and machine learning models. This limitation is common in educational NLP research and underscores the need for larger, more diverse training datasets, domain-specific model fine-tuning, and potentially incorporating contextual metadata (eg, resident level or case type). Although model performance stabilized during cross-validation, suggesting that the sample was adequate for the study objectives, larger datasets could further strengthen robustness. Moreover, the limited sample size may have contributed to weaker performance in the 4-level classification. Future strategies to address this limitation include expanding the dataset as the Emyway platform accumulates more entries, exploring data augmentation and domain-adaptive pretraining, and pursuing cross-institutional collaborations to increase sample diversity. These steps would strengthen model robustness and improve its ability to support nuanced educational decision-making. Although 4-level predictions should be interpreted with caution, they can still offer valuable insights for faculty development and formative assessment when combined with human judgment.

Second, as with all text-based evaluations, important nonverbal cues and dynamic interpersonal interactions are not captured. Future work could extend beyond text-based analysis by integrating audio and video data with NLP. Multimodal inputs would capture tone, pacing, and nonverbal cues, complementing narrative content and offering a more holistic view of feedback interactions. This approach could strengthen competency-based medical education by providing richer insights to guide faculty development and resident learning.

Third, although improvements were observed in the narrative quality, this study did not directly measure faculty engagement or sustained educational change. Future research should examine how NLP-generated insights might be incorporated into faculty development initiatives and longitudinal assessment strategies to determine whether they enhance faculty participation and support lasting improvements in feedback and reflection quality.

Finally, the possibility of a Hawthorne effect should be considered. The awareness of being evaluated may have influenced improvements in reflection and feedback quality [45,46]. Complementary qualitative research such as interviews or focus groups with residents and faculty could elucidate underlying motivations and perceptions, providing a richer perspective on behavioral change.

Conclusions

This study demonstrates that BERT-based NLP, when applied with structured contextual inputs, can effectively evaluate the quality of multilingual resident reflections and faculty feedback in WBAs. The model achieved moderate to high accuracy, particularly in binary classification, suggesting its utility as a scalable adjunct to human evaluation. While not a substitute for expert judgment, NLP can facilitate large-scale monitoring of narrative quality and enhance the analysis of formative feedback in CBME. The progressive improvement in the narrative quality over 4 years highlights the value of structured EPA frameworks and digital platforms such as Emyway in promoting reflective practice and faculty development. Future research should explore the generalizability of this approach across medical specialties and investigate the integration of multimodal data to further enhance assessment validity and educational outcomes.

Acknowledgments

The authors are grateful to Taiwan Society of Otorhinolaryngology-Head and Neck Surgery and all its faculties and resident physicians for utilizing the Joint Commission of Taiwan's Emyway platform. The authors also thank the information technology team of Dalin Tzu Chi Hospital for their support with the platform. Additionally, the authors are grateful for the administrative assistance provided by Chiu-Ping Wang, Shu-Hwei Fan, Uan-Shr Jan, and Wan-Ning Luo in this project. They received no additional compensation for their contributions. This study was supported by the National Science and Technology Council of the Republic of China (Taiwan) under grants NSTC 109-2511-H-567-001-MY2, NSTC 110-2511-H-567-001-MY2, NSTC 112-2410-H-567-001-MY3, and in part, funded by Cardinal Tien Hospital under grants CTH110AK-2220 and CTH111AK-2221. The funders had no role in the design and conduct of the study; collection, management, analysis, and interpretation of the data; preparation, review, or approval of the manuscript; and decision to submit the manuscript for publication.

Data Availability

The datasets used and analyzed during this study are available from the corresponding author on reasonable request.

Abstract

Background: Artificial intelligence (AI) is increasingly being integrated into medical education. As AI technologies continue to evolve, they are expected to enable more sophisticated student tutoring, performance evaluation, and reforms of curricula. However, medical education entities have been ill-prepared to embrace this technological revolution, and there is anxiety concerning its potential harm to the community.

Objective: To explore research trends in the field and identify future directions for AI-enabled medical education, we conducted a systematic bibliometric analysis focusing on temporal trajectories in the field.

Methods: Documents were collected from the Web of Science and Scopus databases covering the period from 2000 to 2024. A multistep search strategy combining information retrieval, a definitive journal list, and cocitation analysis was used to identify relevant publications. Journal and author impact were assessed using both publication and citation metrics. Research trends and hot spots were examined through citation burst detection, frequency analysis, and co-occurrence networks, with a color gradient used to indicate the average occurrence year of keywords. The citation lineage structure of the field was evaluated using a k-means clustering-based analysis of cocitation networks to trace influential references.

Results: Our analysis revealed a significant increase in publications since 2021, with foundational works emerging as early as 2019. Influential journals in this domain included *JMIR Medical Education*, *Anatomical Sciences Education*, and *Medical Education*. The evolving research trajectory exhibited a shift from conventional computer-assisted learning tools toward generative AI platforms. Earlier applications of AI in medical education were predominantly concentrated at the undergraduate level, indicating substantial potential for expansion into graduate and continuing medical education. Furthermore, limited cocitation connections were observed between recent generative AI research and conventional medical AI studies, and investigations into medical students' attitudes toward generative AI remain scarce.

Conclusions: There are critical needs for (1) interdisciplinary studies that intentionally integrate generative AI with foundational medical AI work and (2) involving medical educators and students in AI development. Future research should focus on building theoretical frameworks and collaborative projects that connect these currently separate domains to foster a more cohesive knowledge base.

KEYWORDS

artificial intelligence; AI; medical education; bibliometric analysis; research trends; generative artificial intelligence; generative AI

Introduction

The integration of artificial intelligence (AI) into medical education is not just a passing trend but a transformative leap that promises to revolutionize the quality, efficiency, and accuracy of medical learning and practice. This integration not only addresses the challenges posed by the sheer volume and complexity of medical knowledge but can also offer personalized learning experiences tailored to individual students' needs and abilities [1]. Nevertheless, there is still concern about AI's role in the future of medical education. Ethical issues, including student privacy; bias inherent in the data or algorithms; and model explainability, transparency, and accountability, are legitimate concerns [2]. The possibility of being replaced by AI or losing control over machines also generates distrust among stakeholders in medical education [3]. While advanced, AI tools often focus on the technical aspects of education delivery, neglecting the nuanced intricacies of human cognition and learning [4].

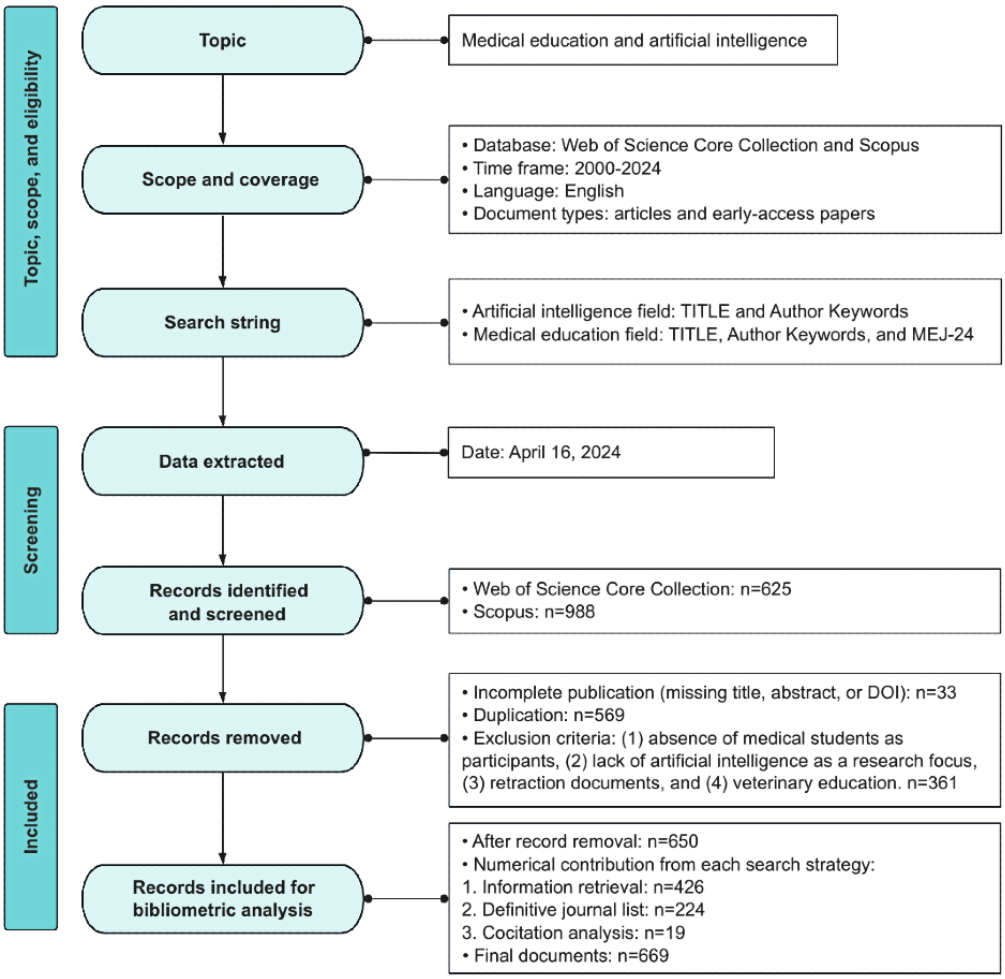
While the scholarly conversation on this topic is growing rapidly, the existing literature lacks a comprehensive, data-driven map of its intellectual structure and evolution. Narrative reviews and bibliometric studies in adjacent fields such as general AI in health care or digital education tools exist [5,6], but a dedicated analysis that tracks the evolution of research hubs within this specific domain is missing. Key questions remain unanswered: What are the foundational papers that have shaped this field? How have research themes evolved over time? What are the current dominant clusters of knowledge, and where is the frontier heading?

This study conducted a systematic bibliometric analysis to delineate the structural and temporal dynamics of medical education technology research. Adopting the methodological framework by Maggio et al [7], we systematically analyzed journal and author impact through publication and citation metrics; identified research trends and hot spots using citation burst detection, keyword frequency analysis, and co-occurrence networks supplemented by average occurrence year; and traced influential reference lineages via k-means clustering of cocitation networks. The objective was to provide an evidence-based map of the field's evolution, highlighting key areas of impact and emerging thematic directions to inform strategic research and educational planning.

Methods

This was a systematic bibliometric analysis, and the study selection process is illustrated in Figure 1 [7], which shows the identification, screening, and inclusion and exclusion criteria of documents.

Figure 1. Study flowchart. *The Medical Education Journal List 24 (MEJ-24) was proposed by Maggio et al [7] and is provided in Multimedia Appendix 1.



Ethical Considerations

This study did not involve human or animal participants and did not require patient consent. The ethics committee of Peking Union Medical College Hospital waived the ethical application because only published data were used. Patients or the public were not involved in the design, conduct, reporting, or dissemination plans of our research.

Data Extraction

Documents were extracted from the Web of Science and Scopus databases. To refine the strategy, we used 3 complementary approaches to delineate the field of AI in medical education following the framework established by Maggio et al [7].

The first approach was information retrieval. Initially, search terms were identified by reviewing existing systematic reviews and key publications in the fields of AI and medical education [7,8]. This process established a baseline set of keywords, including "artificial intelligence," "machine learning," and "medical education." The preliminary search string was then evaluated by a medical librarian and domain experts to ensure its appropriateness and was refined based on their feedback. This refinement involved incorporating more technical terms (eg, "deep learning," "natural language processing," and "transformer models") to better capture emerging trends. Furthermore, Boolean operators and truncation (eg, "educat* OR curricul* OR teach*") were applied to enhance search breadth. The revised search string was deployed using field searching techniques, specifically within the title and author keyword fields. The detailed search strategy is provided in Multimedia Appendix 2.

The second approach was definitive journals. Core medical education journals were identified using the Medical Education Journal List 24 (MEJ-24), an empirically derived set of journals validated through collaboration between medical education researchers and bibliometric experts [7]. For the search strategy, we conducted field searches across the 24 journals of the MEJ-24 using the journal source field. For AI-related terms, we searched the author keyword and title fields following the same information retrieval approach detailed previously. The MEJ-24 journals can be found in Multimedia Appendix 1.

The third approach was journal cocitation analysis. The journal cocitation analysis was conducted using the document pool retrieved through the 2 search strategies described previously (ie, information retrieval and the definitive journal list). Following data selection (as detailed in the Data Selection section), 650 documents were identified. A reference co-occurrence matrix was then constructed (see the Bibliometric Analysis section for details), and the top 30 most cited references among these articles were quantified. Notably, 63% (19/30) of these highly cited references had not been captured by the

original search string. These 19 articles were subsequently added to the cohort.

Documents were collected from January 1, 2000, to April 16, 2024. Only articles in English, reviews, and early-access papers were included.

Data Selection

The extraction approach yielded 1613 documents (n=625, 38.75% from Web of Science and n=988, 61.25% from Scopus). Documents lacking titles, abstracts, or digital object identifiers (DOIs) were removed, as were duplicates identified across the document pools using DOI matching. The inclusion criteria required that documents focus on the application of AI or computer-assisted techniques within medical education and present educational interventions or evaluations of AI tools in medical training contexts. Exclusions comprised retracted publications and documents addressing specific off-topic technical or noneducational themes. These included machine learning methods with nomenclature overlaps but no substantive educational relevance (eg, "teacher-student curriculum learning algorithm"), medically focused topics unrelated to AI in education (eg, "computer vision syndrome"), general online or remote education literature without specific AI components, and publications related to veterinary education. Our literature screening and selection process was conducted by 2 independent reviewers. Interrater reliability was quantified using the Cohen κ, which yielded a value of 0.85 based on 38.56% (622/1613) agreed inclusions, indicating strong agreement between reviewers. Discrepancies in inclusion decisions were resolved through consultation with 2 domain experts. Of the 107 articles over which there was initial disagreement, 28 (26.2%) were selected for inclusion after expert review, resulting in a total of 650 articles. A subsequent cocitation analysis of these 650 articles identified the 30 most cited references, 19 (63%) of which were not captured in the original search. These 19 articles were added to the cohort, bringing the final total to 669 articles (Multimedia Appendix 3). Information retrieval from databases contributed 63.7% (426/669) of the articles, the definitive journal list method contributed 33.5% (224/669) of the articles, and cocitation analysis contributed 2.8% (19/669) of the articles.

Data Processing

We imported raw export files in CSV format from both Scopus and Web of Science into the R environment (version 4.4.2; R Foundation for Statistical Computing) and standardized column names across datasets to ensure compatibility. Formatting inconsistencies in titles, abstracts, keywords, and author lists were resolved to create consistent records across both databases. Following the data selection process (as described in the Data Selection section), the preprocessed dataset was manually screened by 2 independent reviewers using Microsoft Excel. Discrepancies regarding inclusion were resolved through consultation with domain experts.

During keyword normalization, terms were standardized by converting them to lower case, reconciling plural and singular forms, expanding abbreviations, and removing special characters. For example, variants such as "3d computer-models," "3d models," and "3d reconstruction" were merged into the unified term "3d model." Keywords such as "artificial intelligence," "medical students," "computer," and "technology" were removed due to their limited analytical value. A complete mapping of these keyword transformations is provided in Multimedia Appendix 4.

Finally, we constructed a comprehensive analysis-ready dataset containing standardized fields for DOI, title, abstract, keywords, citation counts, authors, journals, publication year, and references. This final matrix formed the basis for all subsequent bibliometric analyses.

Bibliometric Analysis

Quantitative assessments of authors, journals, countries, and keywords were conducted using all available data under an inclusion threshold of 1. Collaboration networks between countries and keyword co-occurrence networks were constructed using VOSviewer (version 1.6.19; Centre for Science and Technology Studies, Leiden University) [9]. To enhance interpretability and network clarity, stricter thresholds were applied for network visualizations: keywords were retained only if they occurred at least 4 times, and country coauthorships were included only with a minimum of 5 occurrences. A keyword tree map was generated using the R package *Bibliometrix* (version 4.1.2) [10], with box sizes proportional to the keyword occurrence frequency. Keyword burst detection was conducted using CiteSpace (version 6.3.R1) [11] with the following parameters: g-index scale factor=2000, gamma=1, and minimum duration=1. The gamma parameter regulates the weight distribution in the burst strength calculation. A value of 1 ensures a balanced weighting scheme that neither overemphasizes recent citation spikes nor discounts significant earlier activity. The minimum duration parameter set to 1 requires that any identified citation burst persist for at least 1 year.

To evaluate journal impact, we considered both publication volume and citation metrics, and visualized the results using bubble plots. The x-axis represented $\log_{10}$(total publications+1), whereas the y-axis corresponded to $\log_{10}$(total citations+1). Bubble size reflected the average number of citations per publication, and color indicated the mean publication year, together providing a multidimensional perspective on journal influence.

To assess the influence of authors, we applied fractional counting to both publication and citation counts. For each author *A* who published *k* articles, we defined the following metrics:

(1)

(2)

where *mi* denotes the number of authors for article *i* and *ci* represents the citation count for article *i*. This fractional counting approach prevents the inflation of metrics for authors who frequently publish in large collaborations, thereby ensuring a

more equitable representation of individual scholarly contributions compared to whole-counting methods.

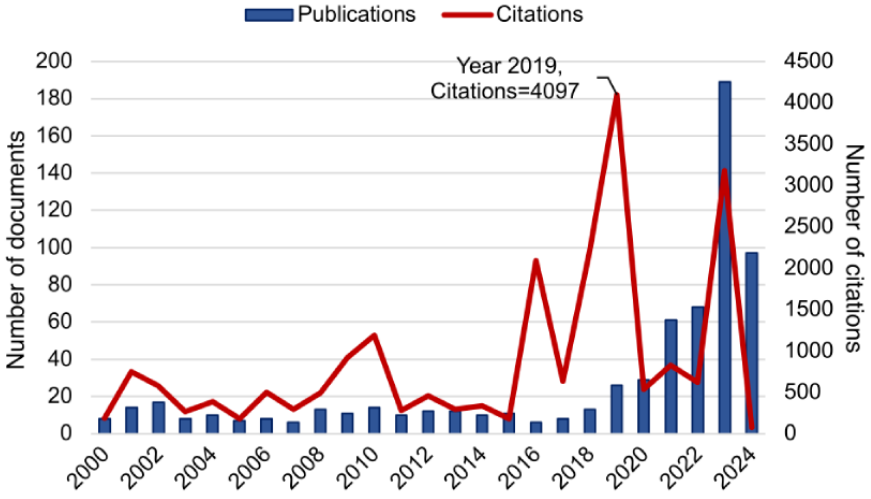
The cocitation clustering analysis was conducted using the R package *ComplexHeatmap* (version 2.12.1) [12]. A reference matrix was constructed, with rows representing cited references and columns representing citing documents. To focus on the most influential references, two inclusion criteria were applied: (1) cited references must be among the top 30 most frequently cited based on citation counts, and (2) citing documents must reference at least 2 of these top 30 cited references. This approach ensured the identification of meaningful cocitation patterns rather than isolated references. K-means clustering (k=3) was applied to the citing documents, with the algorithm repeated 500 times to ensure stability. The choice of 3 clusters was empirically determined to balance interpretability and granularity. Clusters were interpreted by examining cocitation patterns (which references frequently appeared together) and temporal trends (how citation networks evolved over time).

Results

Influential Documents, Journals, and Authors in the Field of AI in Medical Education

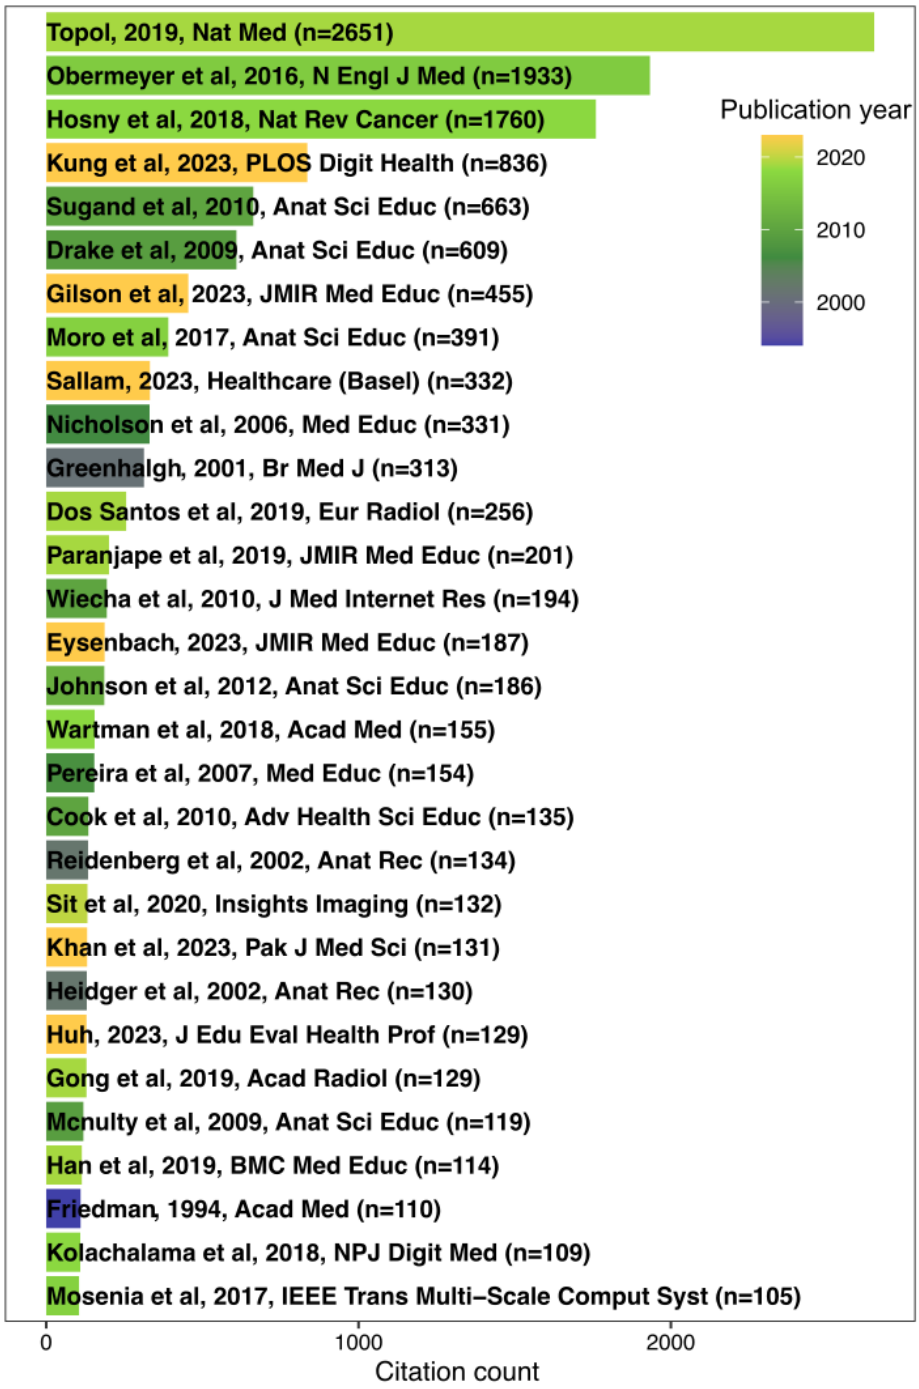
Our bibliometric analysis encompassed 669 documents from 269 journals authored by 3296 individuals across 295 countries, highlighting the global scope of research in this field. Figure 2 shows a notable increase in publications on AI in medical education since 2021. It is worth noting that, although publications from 2019 were relatively limited in number, they received substantial citations, suggesting that key conceptual foundations were proposed during this period. Figure 3 shows the top 30 most cited documents. Several highly influential works were published in 2019, most prominently the landmark article "High-Performance Medicine: The Convergence of Human and Artificial Intelligence" by Topol [13], which garnered 2651 citations. Other notable contributions included "Medical Students' Attitude Towards Artificial Intelligence: A Multicentre Survey" by Pinto Dos Santos et al [14] (cited 256 times) and "Introducing Artificial Intelligence Training in Medical Education" by Paranjape et al [15] (cited 201 times), further underscoring that 2019 marked the emergence of critical discussions on AI integration. More recent highly cited works reflected growing interest in generative AI models, such as "Performance of ChatGPT on USMLE: Potential for AI-assisted medical education using large language models" by Kung et al [16] (cited 836 times) and "How Does ChatGPT Perform on the United States Medical Licensing Examination? The Implications of Large Language Models for Medical Education and Knowledge Assessment" by Gilson et al [17] (cited 455 times).

Figure 2. Trends in publication and citation numbers.



Next, we evaluated the contribution of journals, authors, and countries within the field of AI in medical education (Figure 4). Relying solely on citation metrics may overlook journals that make consistent and foundational contributions to the field. To address this limitation, we applied a log-transformation to both citation and publication counts, allowing for a more balanced and comparable assessment across journals. Our analysis identified the following as the most influential journals in AI in medical education: *JMIR Medical Education* (publications: 67/669, 10%; citations: n=1575), *Anatomical Sciences Education* (publications: 48/669, 7.2%; citations: n=3317), *Medical Education* (publications: 35/669, 5.2%; citations: n=1467), *BMC Medical Education* (publications: 36/669, 5.4%; citations: n=456), *Academic Medicine* (publications: 23/669, 3.4%; citations: n=669), and *Medical Teacher* (publications: 28/669, 4.2%; citations: n=326).

Figure 3. Top 30 most cited documents.

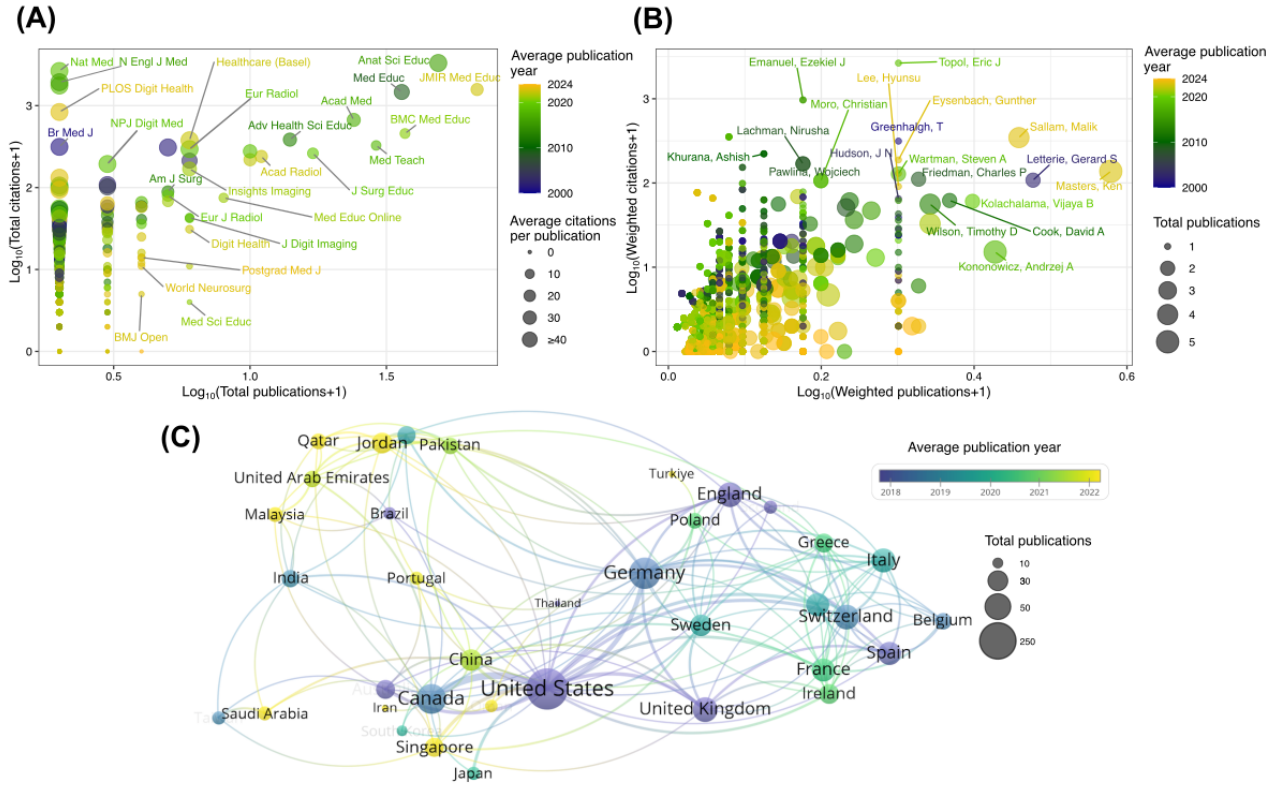


To assess the scholarly impact of authors while preventing the inflation of metrics for authors who frequently publish in large collaborations, we applied weighted counting to both publication and citation counts. Analogous to the normalization applied in journal-level analysis, we also used a $\log_{10}$ transformation to weighted citation and weighted publication counts at the author level. The results indicated that the following authors achieved high weighted publication and citation scores, reflecting their substantial contributions to the AI in medical education research field: Ken Masters (publications: 5/669, 0.7%; citations: n=140), Malik Sallam (publications: 4/669, 0.6%; citations: n=389), Gerard Letterie (publications: 2/669, 0.3%; citations: n=107), Steven Wartman (publications: 2/669, 0.3%; citations: n=254), Charles Friedman (publications: 2/669, 0.3%; citations: n=110), Kolachalama Vijaya (publications: 2/669, 0.3%; citations: n=114), Timothy Wilson (publications: 4/669, 0.6%; citations: n=176), David Cook (publications: 2/669, 0.3%; citations: n=151), and Andrzej Konowicz (publications: 5/669, 0.7%; citations: n=50).

To examine global collaboration patterns in the field, we constructed a country-level collaboration network, which revealed a central role for researchers based in the United States. The United States not only produced the highest volume of publications but also formed the most extensive collaborative ties with other countries. Similarly, several European nations—including Germany, the United Kingdom, and

France—emerged as major contributors. By incorporating temporal information through the average publication year for each country, we observed that non-Western countries such as China, Qatar, and Malaysia are increasingly active in the field, reflecting its expanding global engagement.

Figure 4. Journal, author, and country contributions visualized through bubble plots and a collaboration network. (A) For journals, bubble size reflects average citations per publication. (B) For authors, bubble size shows total publications. (C) In the country collaboration network, node size shows total publications, and line thickness represents partnership strength. Bubble and node colors reflect average publication year.



Identification of Research Hot Spots Using Keyword Analysis

To identify research hot spots over time, a keyword citation burst analysis was conducted. This method reveals when specific keywords become popular, how long they stay important, and the point at which their influence declines [18]. Figure 5 illustrates the top 10 keywords with the strongest citation bursts. Early bursts around 2010 featured terms such as "computer-assisted instruction" and "computer simulation," largely within the context of gross anatomy courses, particularly in undergraduate education. Subsequent trends highlighted the expansion of AI-enabled techniques into computer-assisted surgery. In 2023, research attention shifted toward "machine learning" and "large language models," with the generative pretrained transformer model standing out as one of the most promising developments likely to shape the future of the field.

A keyword tree map was constructed to visualize the frequency of keywords across the collected documents (Figure 6). The most common keywords included "ChatGPT," "computer-assisted instruction," and "machine learning." Frequent applications for AI in medical education were associated with anatomy, curriculum design, simulation, and image analysis. In addition, topics such as ethics, health care, and digital health also emerged as focal areas within AI-based educational research.

To gain deeper insights into conceptual relationships and their evolution, we developed keyword co-occurrence networks. Temporal evolution of the co-occurrence network aligned with the burst citation analysis (Figure 7). Computer-assisted learning was linked to various teaching techniques, including virtual microscopy, patient simulation, and 3D models. More recently, with the development of machine learning approaches, research interest shifted toward wider applications, such as curriculum reform, big data analysis, health care practice, and surgical training. The network further highlights natural language processing and large language models as current research hot spots, particularly in applications such as answering multiple-choice tests in medical licensing examinations, providing feedback systems, and serving as conversational agents. We then compared co-occurrence patterns across undergraduate education (occurrence: n=29; average occurrence year 2013, SD 7.8), graduate education (occurrence: n=9; average occurrence year 2016, SD 8.5), and continuing medical education (occurrence: n=10; average occurrence year 2016, SD 7.2). The results revealed that anatomy education, examinations, and problem-based learning were prominent in undergraduate medical education; graduate education emphasized communication, innovation, and decision support; and continuing medical education focused on clinical practice and digital health. Notably, large language models such as ChatGPT permeated all 3 educational stages.

Figure 5. Keyword burst citation detection analysis indicating the year of emergence, burst strength, and the start and end years of each keyword's citation surge.

Figure 6. Tree map of author keywords sized by their frequency of occurrence in the literature.

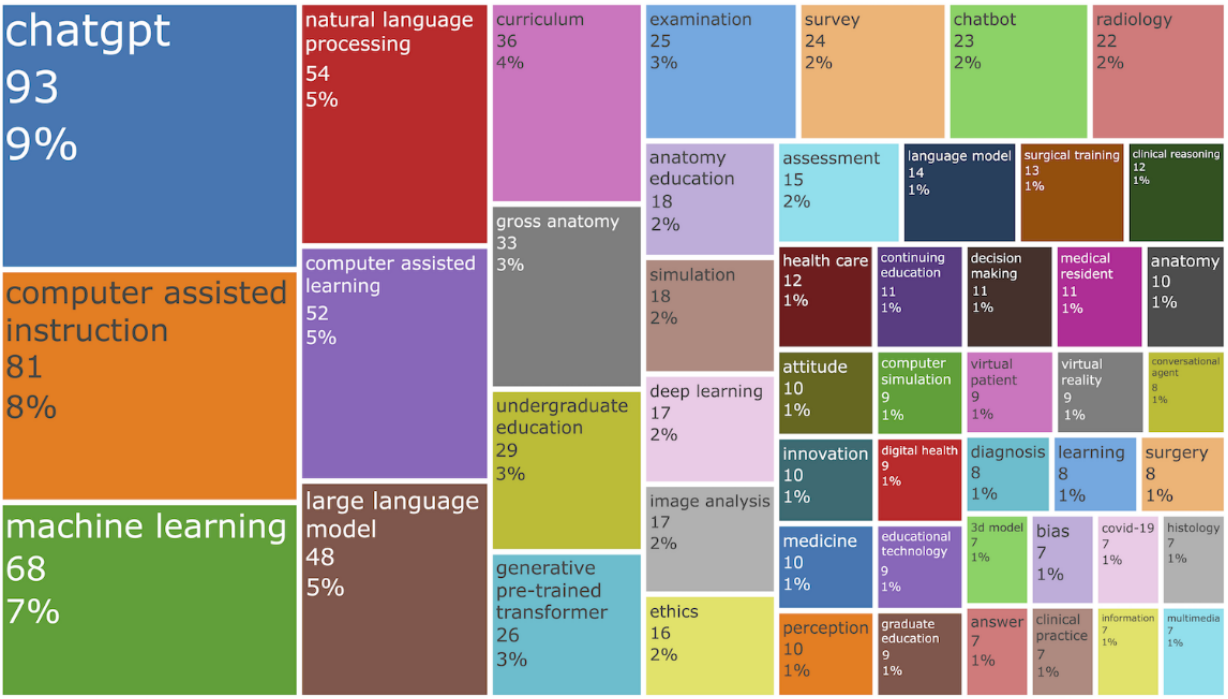


Figure 7. Keyword co-occurrence network. (A) Node size corresponds to keyword frequency, and node color represents the average occurrence year (blue represents older terms; yellow indicates more recent terms). (B) Magnified view of the network highlighting keywords associated with undergraduate, graduate, and continuing medical education.

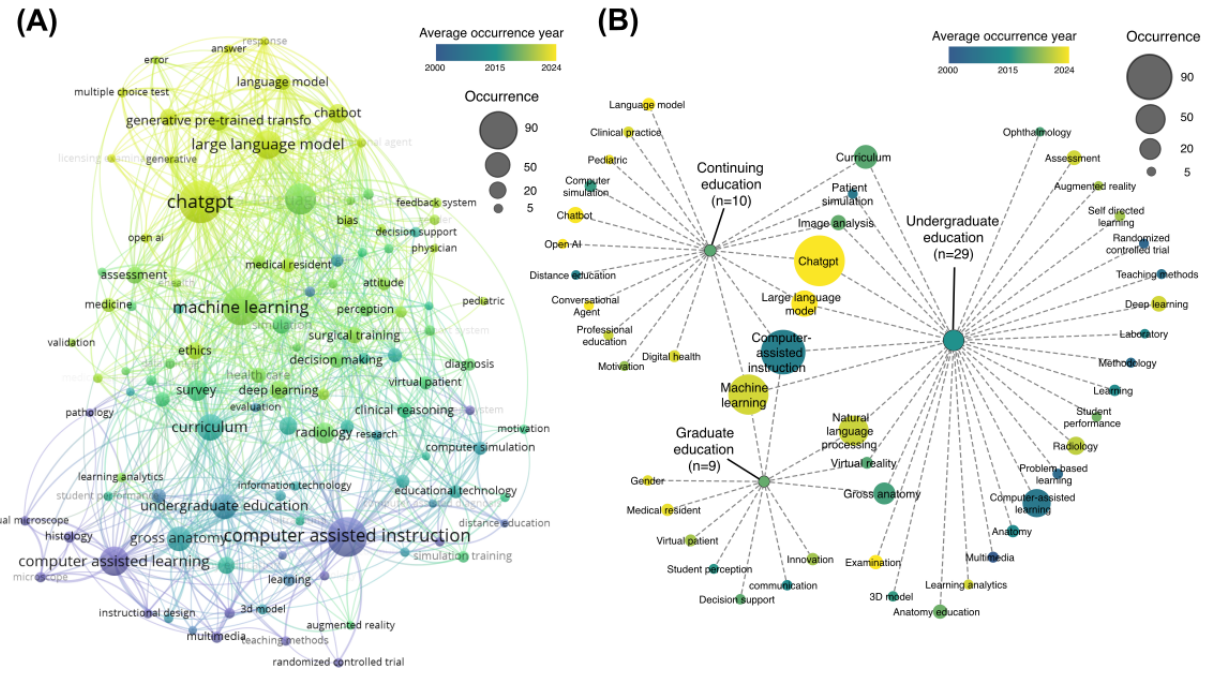
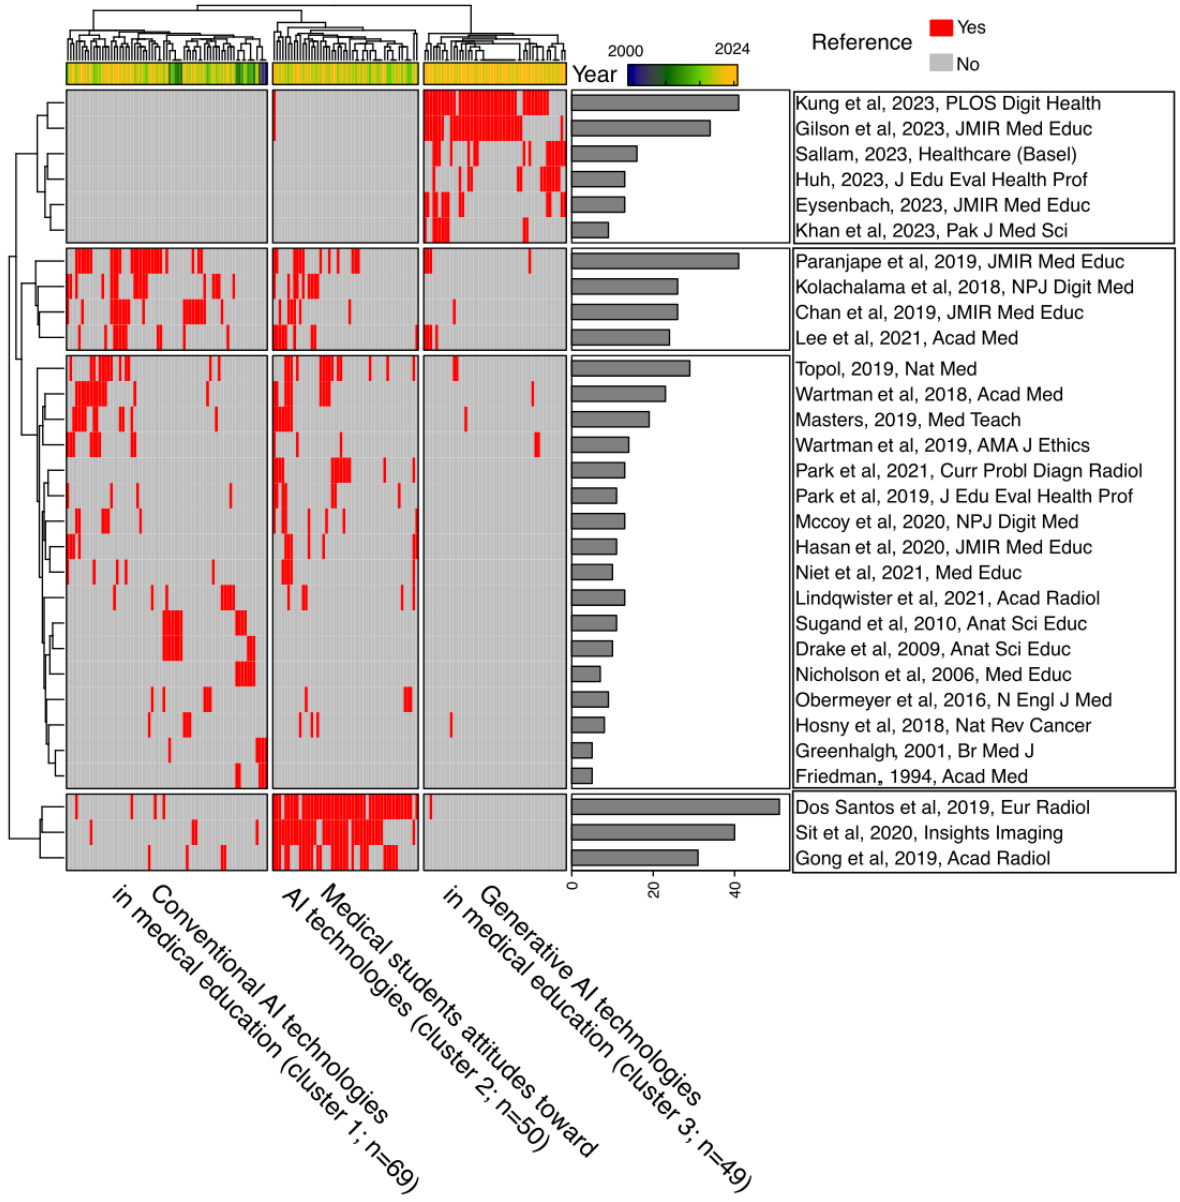


Cocitation Analysis of References

Next, we examined the cocitation structure among the documents. Studies with shared research interest tended to cite similar foundational references, revealing their intellectual lineages [11]. A reference co-occurrence matrix was constructed, where rows represented cited references and columns represented citing articles. To capture meaningful cocitation patterns rather than isolated references, we included only the top 30 most frequently cited references and required that citing documents reference at least 2 of these highly cited works. After applying these criteria, 25.1% (168/669) of the articles remained for subsequent analysis. This approach identified 3 principal thematic clusters within the literature (Figure 8). The first was conventional AI technologies in medical education (cluster 1; citing documents: 69/168, 41.1%). References in this cluster advocated for structural innovations in medical training, with an emphasis on integrating computational thinking and AI literacy (Paranjape et al [15], Chan and Zary [2], Kolachalama and Garg [19], Topol [13], Wartman and Combs [20,21], and Masters [22]). The second thematic cluster was medical students' attitudes toward AI technologies (cluster 2; citing documents: 50/168, 29.8%). Studies in this cluster used quantitative surveys and qualitative methods to evaluate learner engagement with emerging tools (Pinto Dos Santos et al [14], Gong et al [23], and Sit et al [3]). The third thematic cluster was generative AI technologies in medical education (cluster 3; citing documents: 49/168, 29.2%). A rapidly growing cluster, it addressed implementation challenges and validation frameworks for generative AI models (Sallam [1], Huh [24], Kung et al [16], and Gilson et al [17]). Notably, while recent publications showed substantial emphasis on generative AI applications (cluster 3), few studies comparatively evaluated generative AI technologies against earlier conventional AI education reforms (cluster 1) or prioritized investigating student attitudes (cluster 2) toward these new tools.

Figure 8. The cocitation structure of the literature. Rows represent cited references, whereas columns denote citing articles. Red cells indicate the presence of a cocitation relationship, and the temporal gradient (blue represents older terms; yellow indicates more recent terms) highlights the chronological evolution of citation patterns. The accompanying bar plot reflects the cumulative citation frequency of each reference (Multimedia Appendix 3). AI: artificial intelligence.



Discussion

Emerging Trends and Global Contributions in AI-Driven Medical Education Research

The analysis of influential works in AI-based medical education revealed that 2019 was a critical turning point for the field. Seminal publications by Topol [13], Pinto Dos Santos et al [14], and Paranjape et al [15] laid the conceptual foundation for AI integration into medical training, sparking sustained scholarly dialogue. Their high citation rates reflect broad recognition of issues such as digital competency development, curricular reform, and learner attitudes toward AI—themes that remain relevant today. The more recent surge in citations for works on large language models (eg, Kung et al [16] and Gilson et al [17]) highlights a shift toward generative AI applications, particularly in knowledge assessment and adaptive learning platforms. This pattern aligns with global trends in AI adoption, where emerging technologies rapidly influence educational paradigms.

Our journal-level analysis further demonstrates the importance of using normalized metrics to evaluate influence. While journals such as *Nature Medicine* and the *New England Journal of Medicine* achieved high citation counts per article—often due to overarching prestige or coverage of breakthrough topics—specialized journals such as *JMIR Medical Education*, *Anatomical Sciences Education*, and *Medical Education* provided consistent intellectual contributions that shaped the field structurally. This result is consistent with previous literature findings that *JMIR Medical Education* and *Medical Teacher*, among others, are ranked as the top most productive journals

[25]. The log-transformation approach helped mitigate biases toward low-output, high-impact journals, offering a more equitable assessment of sustained influence.

At the author level, weighted counting methods revealed key contributors without overrepresenting researchers involved predominantly in large collaborations. Scholars such as Ken Masters, Malik Sallam, and Steven Wartman produced focused yet high-impact work, suggesting that quality and thematic consistency can achieve significant scholarly recognition even with modest publication numbers.

Geographically, the United States and Western European nations currently lead in output and collaboration reach. However, the rising activity from countries such as China, Qatar, and Malaysia signals a broadening of research capacity and interest beyond traditional hubs. This decentralization may foster diverse perspectives and context-specific AI applications in global medical education.

Evolution of Thematic Focus and Implications of AI in Medical Education

The integration of AI into medical education has undergone distinct thematic shifts over the past 2 decades, reflecting both technological advancements and evolving pedagogical priorities. In the early 2000s, efforts centered on computer-assisted instruction, leveraging multimedia, 3D models, and virtual reality to enhance anatomy instruction and patient simulation [26,27]. These tools initially focused on cognitive skill development but often overlooked social and psychomotor competencies essential to clinical practice. Our keyword analysis validated this trajectory, showing early citation bursts around 2010 for terms such as “computer-assisted instruction” and “computer simulation,” particularly within undergraduate anatomy education. Subsequent developments saw AI applications expand into computer-assisted surgery and more integrated educational supports, including systems for personalized learning and clinical reasoning simulation [15,19]. Our co-occurrence network analysis further delineated these thematic alignments across different training stages. The undergraduate education phase, with an average keyword occurrence year of 2013, emphasized foundational topics such as anatomy, examinations, and problem-based learning. In contrast, graduate education, with an average keyword occurrence year of around 2016, reflected a shift toward communication skills and clinical decision support. Meanwhile, continuing medical education, also centered around 2016, focused strongly on clinical practice and digital health. Together, these patterns illustrate AI’s expanding role in supporting the entire continuum of medical training.

A significant shift occurred around 2023, as observed in both our burst detection and co-occurrence networks, with research attention toward “machine learning” and “large language models.” Keywords such as “ChatGPT” and “generative AI” now dominate the literature, reflecting a new wave of innovation aimed at conversational agents, feedback systems, and assessment tools, particularly in answering multiple-choice questions and simulating tutor-learner interactions. Notably, large language models have permeated all levels of medical education, suggesting their transformative potential across undergraduate, graduate, and continuing training contexts [17,28].

Challenges in AI-Driven Medical Education and Future Directions

AI can automate routine tasks, alleviating the cognitive load on learners’ working memory. This process of “cognitive off-loading” enables students to dedicate more mental resources to mastering higher-order, complex skills [29]. Consequently, modern medical curricula should transition from rote memorization to emphasizing higher-order skills such as computational thinking and AI literacy [21]. However, keyword analysis indicates that current AI in medical education remains predominantly focused at the undergraduate level, with keyword frequencies of 29 for undergraduate education compared to only 9 for graduate education and 10 for continuing medical education. This disparity suggests significant potential for expanding AI integration into both graduate and continuing medical education [30]. Proposed reforms include providing foundational training in statistics, offering hands-on experience with open-source tools, and integrating AI components into existing courses [2,31]. A structured, stage-specific educational approach is recommended across all training levels: premedical education should introduce AI concepts in entrance examinations, medical training should require coursework in data science and AI ethics, clinical rotations should incorporate AI decision support tools (eg, radiology AI), and postgraduate training should include continuing education modules on emerging AI applications [13,15]. Nevertheless, overreliance on AI carries the risk of eroding fundamental medical skills among students [29]. A balanced approach is essential to ensure that AI serves as a complement to rather than a replacement for core clinical competencies.

Cocitation analysis revealed that cluster 1 corresponded to curriculum reforms and recommendations proposed by medical education experts for structural innovations in medical training [2,13,15,19-22], whereas cluster 2 comprised studies exploring students’ attitudes toward AI applications in medical education [3,14,23]. However, there is a noticeable gap between recent research on generative AI (cluster 3) and the earlier AI in medical education studies (clusters 1 and 2), indicating that integrative frameworks incorporating learning theories and user feedback remain underdeveloped. Future research should prioritize the development of unified theoretical models that incorporate diverse learning perspectives into generative AI systems, as well as establish assessment frameworks to evaluate the effectiveness of generative AI in achieving intended educational outcomes. Moreover, the perceptions and attitudes of both teachers and students are critical for technological advancement, underscoring the importance of a co-design approach in developing educational tools [20]. Therefore, it is essential to evaluate the efficacy of AI integration into existing curricula using multidimensional metrics, including surveys and learning analytics [14,32].

We also observed that the keyword “ethics” (occurrence: n=16) represented a significant theme in AI in medical education, frequently co-occurring with terms such as “big data,” “bias,” and “privacy.” Data privacy and model reliability remained

major concerns, especially when processing a large volume of sensitive information [2]. Furthermore, skepticism persists due to issues such as potential algorithmic bias and AI's limited adaptability to diverse cultural and contextual settings within medical education [33]. To address these challenges, AI systems should emphasize explainability and incorporate human oversight, enabling educators to review and override unjustified decisions [34]. Robust data governance and ethical guidelines must form the foundation of AI deployment, whereas interdisciplinary collaboration helps ensure that AI solutions are aligned with educational goals, whereas interdisciplinary collaboration helps ensure that AI solutions are aligned with educational goals [19]. Involving both instructors and students in the development and validation of AI tools can lead to more adaptive and context-aware systems that effectively complement human expertise and deliver targeted, AI-enhanced educational support.

Limitations

Potential methodological limitations should be considered, including language bias, the exclusion of gray literature, and the artificial temporal boundary set for the analysis (2000-2024). Due to the inherent constraints of bibliometric methods, our findings should be interpreted as exploratory in nature. It is also important to note that the identified trends and research hot spots are derived from publication keywords. To address these limitations, future studies should use a more comprehensive content analysis framework. This approach will facilitate a deeper exploration of broader trends in AI applications, such as their objectives, methodologies, and major outcomes, thereby yielding richer insights than those of traditional bibliometric techniques.

Comparison With Prior Work

Previous bibliometric studies have explored AI applications in medical education [6,25]. Many of their findings can be reproduced, such as author impact, identification of influential journals, international collaboration patterns, and keyword frequency analyses. However, our study introduced several novel methodological approaches. First, by using the search strategy proposed by Maggio et al [7], we identified a broader corpus of literature in the domain of AI in medical education. Second, we investigated the temporal shift in the average publication year across journals, authors, and countries, as well as the evolution in research themes. This approach allowed for dynamic tracking of knowledge contributions and thematic trends over time. Third, while Wang et al [6] summarized the top 10 most cited references in their dataset, a list that shows considerable overlap with our reference matrix, we extended this analysis by visualizing the cocitation network structure using a clustered heat map. This revealed distinct clustering among citing articles, offering deeper structural insights into the intellectual foundations of the field. Our cocitation methodology is designed to be generalizable and applicable to other bibliometric research domains.

Conclusions

As AI technologies continue to evolve, they are likely to enable more sophisticated simulations, personalized learning experiences, and data-driven insights that may transform medical education. Our bibliometric analysis provides an exploratory overview of current research trends and collaborations in this emerging domain, offering preliminary insights that can guide future, more in-depth investigations. Future research in AI-based medical education should prioritize expanding into graduate and continuing medical training, bridging the disciplinary gap between generative AI and established medical AI research through integrated frameworks, and deepening inquiry into learner and educator perceptions to ensure the responsible and effective implementation of these technologies.

Abstract

Background: Digital tools are increasingly used to support clinical decision-making in dental education. However, the accuracy and efficiency of different support tools, including generative artificial intelligence, in the context of dental trauma management remain underexplored.

Objective: This study aimed to evaluate the accuracy of various information sources (chatbot, textbook, mobile app, and no support tool) in conveying clinically relevant educational content related to decision-making in the primary care of traumatically injured teeth. Additionally, the effect of the input strategy on the chatbot's output response was evaluated.

Methods: Fifty-nine dental students with limited prior experience in dental trauma were randomly assigned to one of 4 groups: chatbot (based on generative pretrained transformer [GPT]-4o, n=15), digital textbook (n=15), mobile app (AcciDent app 3.5, n=15), and control group (no support tool, n=14). Participants answered 25 dichotomous questions in a digital examination format using the information source allocated to their group. The primary outcome measures were the percentage of correct responses and the time required to complete the examination. Additionally, for the group using ChatGPT-4o, the quality of prompts and the clarity of chatbot responses were independently evaluated by 2 calibrated examiners using a 5-point Likert scale. Statistical analyses included nonparametric analyses using Kruskal-Wallis tests and mixed-effects regression analyses with an α level of .05.

Results: All support tools led to a significantly higher accuracy compared with the control group (P<.05), with mean accuracies of 87.47% (SD 5.63%), 86.40% (SD 5.19%), and 86.40% (SD 6.38%) for the textbook, the AcciDent app, and ChatGPT-4o, respectively. The groups using the chatbot and the mobile app required significantly less time than the textbook group (P<.05). Within the ChatGPT-4o group, higher prompt quality was associated with greater clarity of the chatbot's responses (odds ratio 1.44, 95% CI 1.13-1.83, P<.05), which in turn increased the likelihood of students selecting the correct answers (odds ratio 1.89, 95% CI 1.26-2.80, P<.05).

Conclusions: ChatGPT-4o and the AcciDent app can serve dental students as an accurate and time-efficient support tool in dental trauma care. However, the performance of ChatGPT-4o varies with the precision of the input prompt, underscoring the necessity for users to critically evaluate artificial intelligence–generated responses.

KEYWORDS

decision–making support tool; dental trauma education; large language model; mobile app; prompting strategy

Introduction

Dental trauma is defined as an acute mechanical injury to teeth and surrounding structures, commonly resulting from accidents or falls. With a global prevalence of 25%-30%, dental trauma represents a significant public health issue, affecting approximately 1 billion individuals and ranking as the fifth most common type of injury worldwide [1,2]. The incidence of dental trauma has shown an upward trend in recent years, leading to considerable health care expenditures [3]. In Germany alone, the estimated annual costs related to dental trauma range between €200 and €550 million (€1=US $1.03) [4].

Immediate and appropriate treatment is crucial to prevent long-term complications and to reduce treatment-related costs [4]. Inadequate or inappropriate initial care is a major contributing factor to poor outcomes following dental trauma. Therefore, timely and accurate diagnosis combined with evidence-based primary treatment is essential to optimizing functional and aesthetic prognoses [5,6]. To standardize the management of dental trauma, several clinical practice guidelines have been published [7]. Among these, the guidelines developed by the International Association of Dental Traumatology (IADT) provide clearly structured recommendations, which, when followed, have been associated with improved clinical outcomes and a reduced incidence of complications [8-10]. Unfortunately, it has been shown that there is substantial evidence of educational shortcomings in the field of dental trauma [11,12], which is further underscored by studies reporting varying, partly insufficient knowledge among dental professionals [13,14].

According to a recent systematic review, mobile health approaches have gained increasing popularity among both patients and health care professionals [15]. Mobile health refers to the emerging field of health care that uses mobile-based technologies, such as smartphone apps, social media platforms, and artificial intelligence (AI), for disease prevention, health education, and clinical decision support [15,16]. To date, several mobile apps have been developed, including 3 based on the IADT guidelines (ToothSoS, AcciDent, and Injured tooth) [15]. Given the growing availability and integration of health care technologies, it appears likely that students tend to compensate for knowledge deficits in dental trauma management by turning to digital solutions [17].

Moreover, AI-driven systems have gained increasing relevance in medical and dental practice in recent years [18-20]. Advances in AI have accelerated the development of large language models (LLMs), such as generative pretrained transformer (GPT) [21], which are increasingly recognized for their potential to assist in medical practice [22]. However, when using chatbots based on LLMs, obtaining high-quality answers largely depends on how users interact with the chatbot [23,24]. For this purpose, the emerging field of prompt engineering aims to systematically develop prompts to enhance the performance of LLMs [23,25]. Nevertheless, awareness among practitioners regarding the importance of effective prompting and the potential impact of various prompting techniques on the quality of generated output remains limited [23].

Previous research in dental traumatology has evaluated the accuracy of chatbot-generated responses in simulated dental trauma scenarios. Ozden et al [26] reported that the performance of such models varied significantly depending on the specific algorithm. In their evaluation, ChatGPT-3.5 demonstrated an accuracy of 51%, whereas Google Bard achieved a slightly higher accuracy of 64% [26]. More recent findings, however, suggest substantial advancements in the performance of newer LLMs. A recently published study assessing the emergency management of tooth avulsion found that ChatGPT-4 attained an accuracy of up to 96.3% in responding to dichotomous (yes/no) clinical questions [27].

Although AI apps in health care are expanding rapidly, further research is necessary to evaluate their reliability and clinical applicability in dentistry [28]. Given their ability to provide rapid, accessible information, LLMs may represent a valuable resource for managing dental trauma in emergency settings. Moreover, they are likely to be used by students as a supplementary tool during exam preparation. Nevertheless, as previously noted, the effectiveness of chatbot responses remains highly dependent on the specificity and clarity of user input. Therefore, the primary objectives of this study were to evaluate the accuracy of 3 different support tools compared with a control group by assessing the percentage of correct responses and to record the total time required. The null hypotheses stated that there would be no significant differences among the 4 groups in terms of response accuracy or time efficiency. As a secondary objective, the study examined whether the precision of the input prompt submitted to the chatbot influenced the clarity of its responses (output), and whether this output clarity affected the students' likelihood of selecting the correct answer.

Methods

Ethical Considerations

The study was approved by the local ethics committee of the University Medical Center Göttingen, Germany (number 28/10/24) and conducted in accordance with the Declaration of Helsinki (Registration on OSF Registries osf.io/xw62j). Dental students in their final academic year were asked to participate in the study. All of them had signed informed consent prior to participation. The researchers had no access to personal information such as sex, age, or prior academic performance. All data were pseudonymized before being subjected to statistical analysis. Participants did not receive any financial compensation. As an incentive, the 5 best-performing students in each group were awarded a book prize.

Study Design

A consecutive randomization procedure was applied to dental students in their final academic year, comprising participants from the 9th (n=26) and 10th semesters (n=33), resulting in a total sample of 59 students. Selection was conducted in a blinded manner, ordered by ascending matriculation numbers. Students were pseudorandomly allocated into 4 groups, ensuring that each group included an equal number of students from the 9th and 10th semesters. This approach ensured allocation concealment and minimized potential selection bias. None of the students had received formal education in dental

traumatology, ensuring a homogenous baseline knowledge across groups. They were not informed about the study content or its design until shortly before the start of the study, in order to prevent individual preparation. At this point, informed consent was required for participation. Based on group allocation, each student was granted access to one specific support tool: control (no tool, n=14), a digital textbook (n=15) [29], a mobile app (AcciDent app 3.5, n=15), or a GPT-4o-based chatbot (OpenAI, n=15). Students using the digital textbook [29] were instructed to use the keyword-based search function. Using a computer-based assessment tool (CAMPUS version 1.4 Rev 7090; IMS-3, Institut für Kommunikations-und Prüfungsforschung gGmbH), all students completed 25 questions presented as declarative statements, which they were instructed to classify as either true or false, using only their assigned support tool (Table S1 in Multimedia Appendix 1).

To ensure standardization and minimize potential bias, all participants in the GPT-4o chatbot group were provided with newly created accounts that had no prior usage history. Each assessment session was initiated with a fresh login and no prior interactions, effectively eliminating session memory effects. Students accessed the chatbot via a browser-based interface under supervised conditions. No other prompts or unrelated queries were entered during the assessment. This setup ensured that all responses were generated based solely on the test items and not influenced by prior context, history, or personalized adaptation of the model.

The 25 dichotomous assessment questions were developed by one specialized endodontist and one general dentist with clinical expertise in endodontics. The questionnaire was based on current IADT guidelines [5,6,9], which provide evidence-based recommendations for dental trauma management.

To eliminate time-related variability within the chatbot group, the assessment was conducted simultaneously for all study participants on December 11, 2024. During the experiment, the total time required to complete the questionnaire was recorded for each student. Participants were informed that their working time would be recorded, but no time limits were imposed in order to prevent influencing their performance. All answers were pseudonymized and transferred to an Excel spreadsheet (Microsoft Corp) for statistical analysis.

Item Analysis and Scoring Criteria

To ensure content validity, the items were reviewed by 5 dental education experts prior to the experiment. All questions were reviewed to confirm they could be answered using one of the assessed supporting tools. For the item quality analysis, all items were evaluated using the difficulty index (P), the discrimination index (D), and internal consistency reliability (Kuder Richardson formula 20; KR-20). In addition, group-specific difficulty and discrimination rates for the control group were calculated in order to better reflect the discriminatory power of the items in relation to baseline student knowledge. The difficulty index ranges between 0% and 100%, with the latter representing the lowest difficulty. Based on established guidelines in educational measurement [30,31], the ideal difficulty of items should be at a point on the difficulty scale midway between 100% and the chance level difficulty (50% for true-false items). This means the ideal difficulty index (P) value should be about 0.75 for dichotomous questions [31]. The discrimination index is the ability of an item to differentiate between students of higher and lower abilities and ranges between 0 and 1 [32]. The KR-20 reliability coefficient is a measure of reliability for a test with binary variables, ranging from 0 to 1, where 0 is no reliability and 1 is perfect reliability. In general, a score of more than 0.5 is usually considered reasonable.

A prompting strategy analysis was conducted within the chatbot group. For this purpose, all chat transcripts were exported and subsequently stored in pseudonymized form as PDF files. Based on previous publications, 2 independent raters evaluated each interaction using a 5-point Likert scale (1=strongly disagree, 2=disagree, 3=neutral, 4=agree, and 5=strongly agree) [33,34]. In cases of disagreement between the 2 raters, a consensus was achieved by reevaluation. This process ensured the achievement of a unanimous result while maintaining the integrity and objectivity of a dual-rater system. The scale was specifically developed in alignment with established prompting techniques, including role prompting, chain-of-thought prompting, knowledge-guided prompting, and output format specification. The following aspects were assessed: (1) the extent to which the student's prompt was focused, specific, and aligned with effective prompting strategies (input evaluation), and (2) the clarity and persuasiveness of the chatbot's response (output evaluation; Table 1). Furthermore, the Flesch Reading Ease was used to assess the readability and complexity of the answers provided by ChatGPT-4o, with results presented as a numerical value ranging from 1 to 100 [35].

Table 1. Predefined criteria for evaluating the input prompt and the output response given by the chatbot. For each applicable criterion, one point was assigned, and the corresponding value on the Likert scale was applied.

Evaluated element	Predefined criteria for chat evaluation
Input prompt	Focused question, inclusion of context or domain-specific details, precise requirements for the output (such as format), reasoning, reference to evidence
Output	Content-related, clear and persuasive, with justification, use of specific medical terms, and reference to guidelines

Statistical Analysis

As the data were not normally distributed, Kruskal-Wallis tests were applied to analyze potential differences between groups in terms of the percentage of correct responses and the total time required. Multiple post hoc pairwise comparisons were performed (using Dunn tests), and the resulting *P* values were adjusted using the Bonferroni-Holm method. To assess the internal agreement within each group, Fleiss κ coefficients were computed [36].

Regarding the prompting strategy, interrater agreement was calculated using weighted Cohen κ. Based on the evaluations of input and output quality, 2 regression analyses were carried out. (1) An ordinal regression model with a random intercept was applied to analyze the effect of the input prompt on the ordinal outcome variable output response. The student was included as a random effect to account for interindividual variability. Confidence intervals were computed using profile likelihood estimation. (2) A logistic regression model with a random intercept for the student was applied to examine the effect of the output response on the students' likelihood of selecting the correct dichotomous answer. Confidence intervals were estimated using profile likelihood methods.

All statistical analyses were performed using the software R (version 4.4.2; R Foundation for Statistical Computing). The predetermined α level was .05.

Results

The participant flow diagram is shown in Figure 1. Regarding the item analysis, the KR-20 reliability coefficient was 0.59. The results of the item difficulty index and the discrimination index are summarized in Table 2 and presented in greater detail in Table S2 in Multimedia Appendix 2.

Figure 1. Research design and participant allocation into the groups.

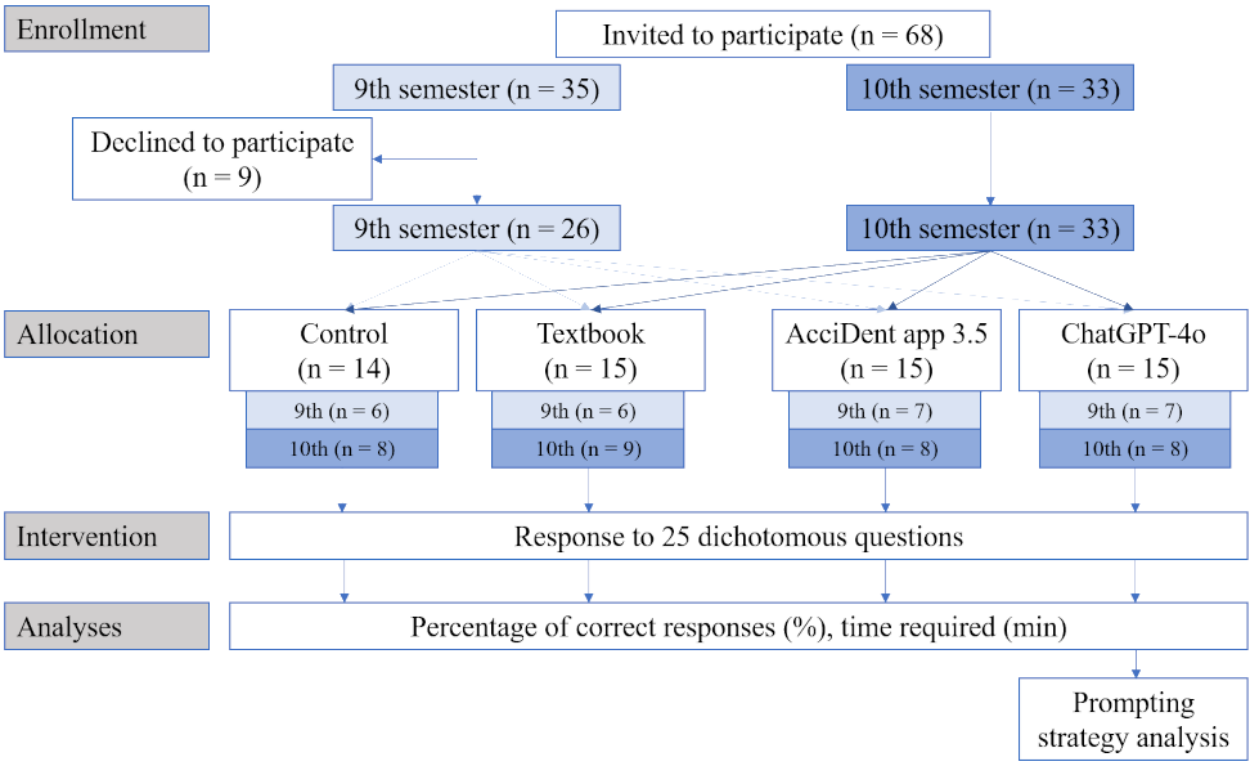

Table 2. Mean and SD and median and range of item difficulty and discrimination indices among all groups and for the control group across all 25 items.

	Total		Control group	
	Mean (SD)	Median (range)	Mean (SD)	Median (range)
Difficulty index	0.84 (0.16)	0.92 (0.47 to 1.0)	0.77 (0.25)	0.86 (0.29 to 1.0)
Discrimination index	0.18 (0.18)	0.12 (0.01 to 0.56)	0.20 (0.29)	0.07 (–0.20 to 1.0)

The control group achieved the lowest percentage of correct responses, with statistically significant differences compared with all 3 groups having used an information source ($P_{Textbook}$=.006, P_{App}=.02, $P_{Chatbot}$=.008; Figure 2, Table 3). In terms of time required, the control group demonstrated the fastest performance, when compared with all groups using a support tool ($P_{Textbook}$<.001, P_{App}<.001, $P_{Chatbot}$=.005). Of these, the textbook group required the most time on average, with significant differences to the AcciDent app group (P=.02) and the chatbot group (P=.001). The latter showed no significant difference between each other (P=.37). Internal agreement was highest within the chatbot group, followed by the AcciDent app group, both showing moderate agreement. (Figure 3 and Table 3).

Figure 2. Boxplots illustrating the percentage of correct responses among the 4 experimental groups. Small letters indicate statistically significant differences among groups.

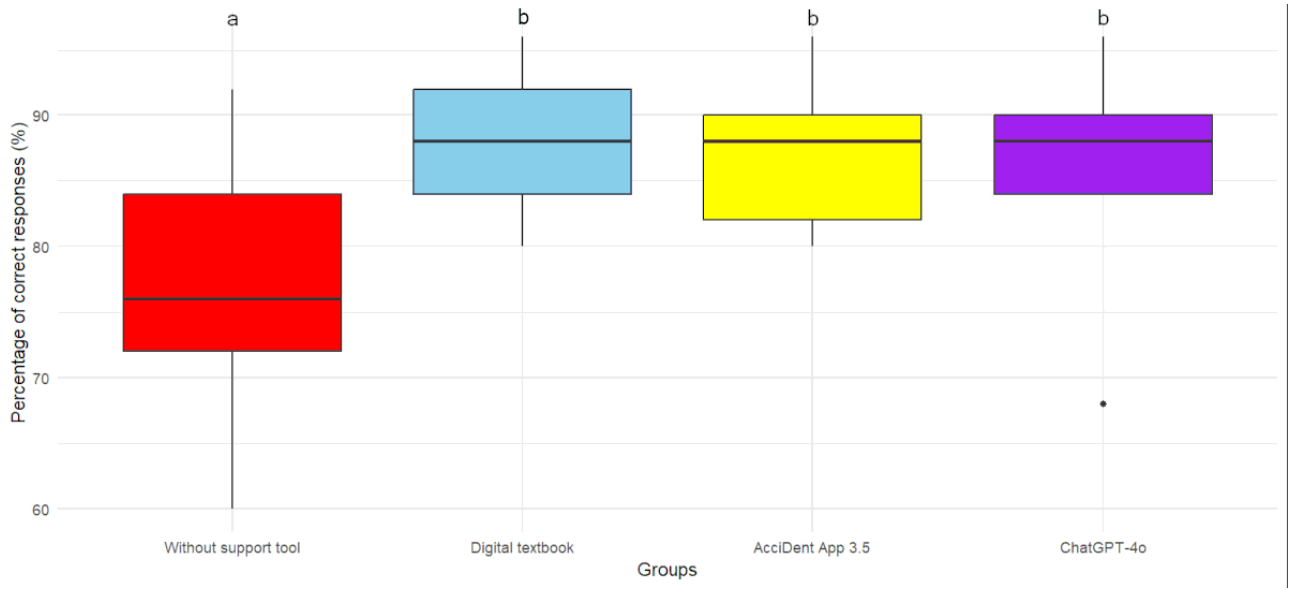

Table 3. Statistics regarding the percentage of correct answers and the total time required, as well as the Fleiss κ coefficient for the experimental groups. Small letters indicate statistically significant differences among groups.

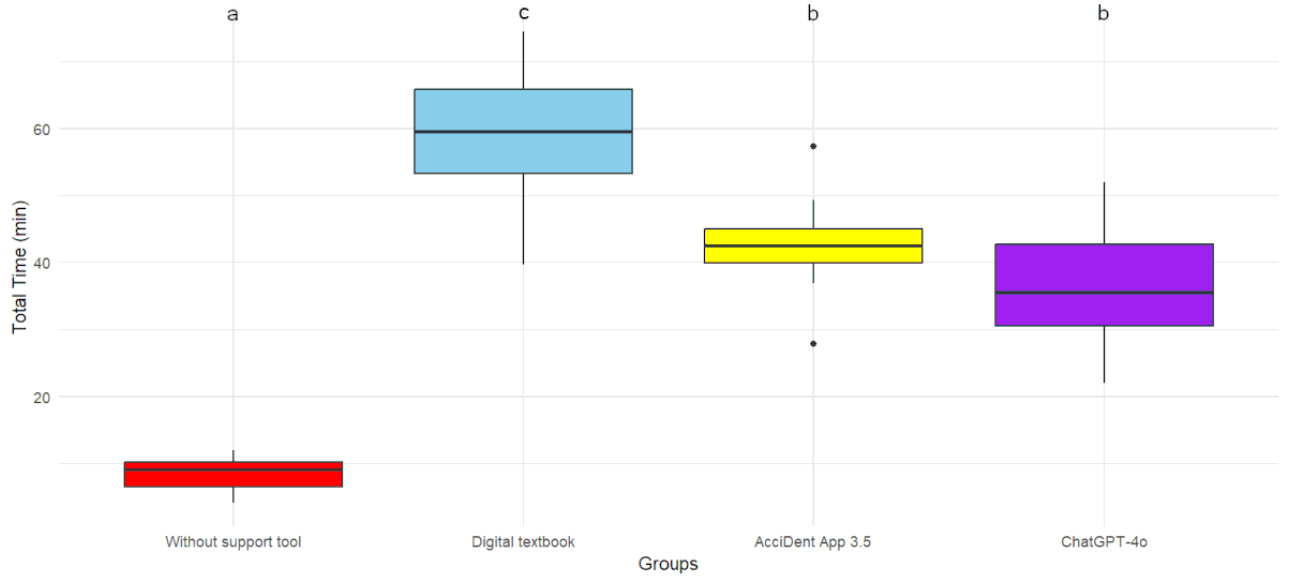
	Percentage of correct responses		Time required (min)		Fleiss κ
	Mean (SD)	Median (IQR)	Mean (SD)	Median (IQR)	
Control	76.57 (8.71)	76 (72-84)[a]	8.54 (2.45)	9.03 (6.55-10.20)[a]	0.28
Textbook	87.47 (5.63)	88 (84-92)[b]	59.60 (10.39)	59.50 (53.62-65.90)[c]	0.24
AcciDent app 3.5	86.40 (5.19)	88 (82-90)[b]	42.65 (6.44)	42.52 (39.89-45.03)[b]	0.41
ChatGPT-4o	86.40 (6.38)	88 (84-90)[b]	36.56 (10.03)	35.53 (30.58-42.78)[b]	0.47

[a,b,c]Statistically significant differences among groups.

Figure 3. Boxplots illustrating the time required to complete the questionnaire among the 4 experimental groups. Small letters indicate statistically significant differences among groups.



In the quality analysis, the input prompts posed by the students received a median rating of 2 (IQR 2-3, range 1-5), while the chatbot's output responses were rated with a median of 4 (IQR 3-4, range 1-5). Cohen κ indicated a high level of interrater agreement, with values of 0.98 and 0.82 for the input prompts and the output responses, respectively.

The ordinal regression analysis revealed a significant effect of the input prompt on the output response with an effect estimate of 0.3647 (P=.003). The estimated (odds ratio 1.44, 95% CI 1.13-1.83) suggests that for each unit increase in prompt precision, the odds of being in a higher category for the output response increased by 44%.

The logistic regression model demonstrated a significant effect of the chatbot's output response on the selection of the correct answer (effect estimate=0.6345, P=.002). The odds ratio of 1.89 (95% CI 1.26-2.80) indicates an 89% increase in the odds of correctness for each unit increase in clarity of the output response.

According to the Flesch Reading Ease, the answers given by ChatGPT-4o had a mean value of 36.20 (SD 9.13), classifying them as rather difficult to read.

Discussion

Choice of Support Tools and Principal Findings

Despite the availability of regularly updated clinical practice guidelines [5,6,9], studies report substantial variation in dentists' knowledge regarding appropriate treatment approaches [13,14], which may, at least in part, be attributed to insufficient education on this topic during undergraduate training. It is likely that such knowledge gaps are increasingly being addressed through the use of digital tools, as they offer rapid access to relevant information and align with modern learning habits. Accordingly, the primary aim of this study was to compare different support tools in terms of their accuracy in clinical decision-making situations. Considering the upward trend of digital health technologies while still accounting for students' preferences, we included 2 technologically advanced support tools (mobile app and chatbot) and a digital textbook representing a more traditional information source. To the best of our knowledge, this is the first study to compare different support tools specifically addressing emergency treatment questions related to dental trauma. Overall, the results indicated that the use of a support tool significantly increased accuracy compared with the control group, with no significant differences observed among the 3 sources. In recent years, the mobile health approach has gained increasing popularity, not only in daily clinical practice among health care professionals, but also as a means of delivering educational content [15,17]. In the field of dental traumatology, several mobile apps have been introduced. However, information regarding the dental trauma management according to the type of injury varied among the mobile apps [37]. Three of the apps were based on the widely accepted IADT guidelines, with the AcciDent app being the most popular and commonly used in Germany. Therefore, it was selected for inclusion in this study. In line with our results, previous studies have demonstrated that the use of a dental trauma app as a decision support tool significantly improves dental students` accuracy in answering multiple-choice questions related to the management of injured primary teeth, compared with a control group without access to informational resources [38,39].

Although this study indicated that the use of any of the evaluated support tools increases performance, the time required to get an answer differed significantly. Students using the mobile app and the chatbot completed the questionnaire within a mean time of 42.65 and 36.56 minutes, respectively, whereas those using the digital textbook required significantly more time (59.60 min). Moreover, it is important to note that the digital textbook included a keyword-based search function, which facilitates information retrieval. Consequently, it can be assumed that the use of a paper-based textbook would likely have resulted in even longer completion times.

Item Quality

For the purpose of the study, students of the final academic year were asked to answer 25 dichotomous questions. The item quality analysis revealed an internal consistency (KR-20) of 0.59. While this value is below the commonly accepted threshold of 0.70 for high reliability, it may still be considered acceptable in the context of this exploratory study. The value likely reflects the intentional heterogeneity of the item content, which was designed to cover a broad range of clinically relevant topics regarding the emergency treatment of traumatic dental injuries. Since the primary aim was not to measure a single underlying construct, but rather to assess the accuracy of different support tools across a variety of question types, a lower internal consistency is expected and does not compromise the interpretability of the results. In terms of discrimination appropriateness, a difficulty analysis was conducted. While many items in the full dataset fell into the "easy" category (P_{mean}=0.84, D_{mean}=0.18), several still demonstrated substantial variation between groups, underscoring their discriminatory utility at the group level. To better reflect the discriminatory power of the items in relation to baseline student knowledge, difficulty, and discrimination indices were also calculated exclusively for the control group without support tool. Within this subgroup, the values were more balanced (P_{mean}=0.77, D_{mean}=0.20), suggesting that item performance was more aligned with typical student knowledge and less confounded by tool-specific effects. Moreover, since the purpose of the assessment was not to achieve maximum discrimination among individuals but rather to evaluate the accuracy of information derived from different sources, the inclusion of items reflecting clinically relevant knowledge, even when classified as "easy," is justifiable.

Performance of LLM-Based Support Tools

Recent advances in AI have accelerated the development of LLMs [21]. As these models continue to develop and become more accessible, their integration into health care settings has expanded considerably. Numerous studies have investigated LLMs as an assistive tool in medicine and dentistry regarding various domains, including treatment recommendations [34], emergency treatments [40], radiological and clinical diagnostics [41-43], education [24,44-46], and decision-making [47,48]. In the context of dental traumatology, several chatbots have been examined with regard to their accuracy in answering topic-specific questions [26,49-52]. These studies either simulated patient-initiated queries or potential questions posed by dental professionals. Moreover, methodological differences among these studies are evident in the type of question analyzed: patient-initiated questions were predominantly open-ended or

case-related [49,50], while questions directed to professionals were assessed using multiple-choice or dichotomous formats [26,51,52]. With respect to the latter, reported accuracies for dichotomous questions varied widely (ranging from 10% to 80.81%) depending on the chatbot used (Google Bard, Google Gemini, Copilot F, Copilot P, ChatGPT-3.5, ChatGPT-4). In this study, ChatGPT-4o showed a mean accuracy of 86.40%. These discrepancies may also be explained by differences in the types of questions posed, as well as by continuous learning and training of the underlying models, which complicate direct comparisons between studies conducted at different time points.

Role of Prompt Design

It has been demonstrated that he accuracy of recommendations by LLMs is largely contingent upon the input's precision, correctness, and reasoning [24,34]. Various prompting strategies have been introduced and assessed to enhance the output response of LLMs [23,25,53,54]. These include prompting strategies like zero-shot, few-shot, or the thought-generation [23]. Further subtypes of prompting techniques have been described to enhance the precision and relevance of model responses. Role prompting, for example, instructs the model to adopt a specific perspective (such as responding to a clinical expert) in order to generate a domain-specific output. Chain-of-thought prompting encourages step-by-step reasoning to enhance the clarity of the response. Moreover, knowledge-guided prompting directs the model to rely on established guidelines or scientific sources, improving factual accuracy. Finally, the determination of the output format constrains the structure of the response, for example, by instructing the model to answer only with correct or false, or to respond in bullet points or tables [23,53]. Although prompt engineering is an emerging area of research, many users remain unaware of how the precision of a prompt can influence the model's output [34]. A recent review on the innovation and application of LLMs in dentistry noted that even in LLM-related research, only a few studies have examined the impact of the input prompt design on the output quality [38,55,56]. In this study, the quality of the input prompt and the output response was assessed using Likert scales based on predefined criteria derived from the prompting strategies described above. Our results indicated that most students were not aware of the relevance of prompt formulation, resulting in a significant influence of the prompt quality on the output response. Even though the integration of AI-assisted tools in educational settings and, therefore, students' familiarity with LLMs, may differ between countries, the importance of the input prompt can be considered universal. However, prompts should be locally adapted, since treatment guidelines or disease prevalence may vary across regions, which may otherwise lead to inappropriate treatment suggestions or implausible differential diagnoses.

Role of Digital Tools in Learning

Previous research has demonstrated that a substantial proportion of medical and dental students rely on digital learning tools, frequently favoring them over conventional textbooks [57]. This tendency is especially pronounced in the context of short-term exam preparation, where efficiency and accessibility are key considerations [58,59]. Consequently, it is highly likely that students prefer to use apps or other digital tools to address knowledge gaps in clinical situations rather than relying on traditional textbooks, particularly when immediate support is required.

Although the groups using ChatGPT-4o and the AcciDent app performed equally in terms of accuracy, it is worth noting that the content provided by a mobile app can be controlled by its developers, for example, by aligning it with international guidelines, which increases its reliability and safety. In contrast to mobile apps, which often require regular updates and may involve purchase costs, one advantage of the use of LLM-based chatbots is the continuous access to a broad and dynamically evolving source of information. Nevertheless, educators and students should be encouraged to critically evaluate the AI-generated feedback in order to develop their clinical reasoning and problem-solving skills, rather than relying unreflectively on the model's output. Excessive dependence on AI may otherwise impair the development of independent clinical judgment and practical skills [60]. Therefore, conventional textbooks remain essential, as they provide reliable fundamental knowledge to understand and internalize clinical concepts over the long term, and help to mitigate the risks and limitations associated with LLMs.

Moreover, adequate application of LLMs includes a precise prompt design, as this directly influences the clarity and accuracy of AI-generated responses. In medical and dental education, this ability can be regarded as a core component of LLM literacy, which is teachable and measurable [61,62]. Aligning this competency with established frameworks, such as digital health literacy or AI-related competencies in health professions education, reinforces its curricular and theoretical relevance [61-63]. Ultimately, an acquired, ideally curriculum-integrated, competence in using LLMs enables students and professionals to engage with these tools in a safe, informed, and reflective manner.

Strengths and Limitations

In general, the format of the question has a significant impact on chatbot performance [51]. In this study, the dichotomous format was chosen for its simplicity, ease of automated scoring, and efficiency in covering a broad content range within a limited timeframe. It also minimized the influence of distractor quality, which can significantly affect the validity of multiple-choice items. Poorly constructed distractors—such as implausible or irrelevant answer choices—can reduce item discrimination and compromise test reliability, particularly in AI-assisted educational settings [64,65]. However, the use of dichotomous questions is not without limitations. Prior research has shown that the performance of LLMs can vary significantly depending on the question type, with multiple-choice formats potentially offering a more nuanced reflection of clinical reasoning processes [66,67]. Moreover, true/false formats have a higher chance of guessing (50%), with limited possibility to reflect complex clinical scenarios, and a reduced ability to discriminate between different levels of understanding [68]. Future studies may benefit from incorporating multiple-choice or open-ended formats as well as clinical vignettes to better evaluate critical

thinking and complex decision-making skills, especially in the context of AI-assisted learning [69,70].

Regarding more complex question formats, different approaches have been explored. For instance, ChatGPT-3.5 was shown to respond adequately to patient-related advice-seeking questions across medical scenarios, although without providing appropriate or personalized advice [71]. In internal medicine, another study assessed the diagnostic accuracy and the ability of stating differential diagnoses of ChatGPT-3.5 and ChatGPT-4 using case vignettes. The authors highlighted the potential utility of LLMs as a supplementary tool [72]. This finding was supported by a similar study on orofacial pain [73]. However, although GPT-4 can augment diagnostic workflows, particularly in primary care or educational settings, it does not yet outperform clinical experts [73]. With regard to the impact of LLM use on physicians' diagnostic reasoning when working with clinical vignettes in internal, family, or emergency medicine, it was demonstrated that providing physicians with an LLM as a diagnostic aid did not significantly improve clinical reasoning compared with conventional resources [74]. Interestingly, however, the LLM alone performed significantly better when given standardized zero-shot prompts than when used as a supportive tool by physicians, highlighting the importance of input prompt quality [74]. As mentioned before, the results of this study are limited to a question format with a relatively high likelihood of guessing. Even within this "easier-to-answer" format, however, we were able to demonstrate the impact of prompt formulation. It is reasonable to assume that in more complex clinical case scenarios, the quality of the input prompt will become even more critical.

This study involved a relatively small sample of 59 final-year dental students, a limitation primarily dictated by the cohort size of the final academic year. While the sample size constrains generalizability to some extent, the decision to restrict participation to senior students was intentional. This group was presumed to represent students with adequate clinical knowledge to comprehend the clinical implications of traumatic dental injuries, despite not having formal education on the topic. Including only students at the end of their undergraduate education ensured a more uniform baseline of dental knowledge and minimized potential bias due to major curricular differences across earlier academic years. Although our results are limited to the included cohort, it can be assumed that all evaluated support tools are helpful in trauma-related questions or clinical situations. However, users with less clinical experience and prior knowledge may face a greater risk of relying on incorrect chatbot responses. For these groups in particular, precise formulation of input prompts and critical appraisal of AI-generated output will be especially important. Our results demonstrated that any of the support tools increased the students' performance; however, there were differences regarding the total time required. It can be assumed that users who were more familiar with a specific tool required less time, as its handling was easier and more intuitive for them. Students' familiarity with the tools was not assessed prior to the study, which should be considered a limitation. However, participants were randomly allocated to the groups to minimize this potential influence.

One of the strengths of the study is that the students' input entries to the chatbot were considered and evaluated. Using clearly defined criteria, we achieved a high interrater agreement (Cohen κ) for both the input and the output quality, demonstrating the straightforward and reproducible application of the predefined Likert scale. Unlike previous studies that assessed chatbot accuracy and consistency using identical prompts, this study accounted for both the interindividual variability in question formulation and decision-making based on chatbot recommendations, a factor often disregarded in earlier evaluations [26,51,52].

Conclusions

The present findings indicate that all evaluated support tools improved the students' performance when answering dental trauma questions. Both ChatGPT-4o and the AcciDent app demonstrated high accuracy while requiring less time than the digital textbook group. However, the performance of ChatGPT-4o depends on the precision and specificity of the input prompt, an aspect students should be made aware of when using it as an information source. In general, AI-based apps have the potential to transform dental education by enhancing learning experiences and supporting instructional practices. At the same time, educators and students should be encouraged to critically evaluate the AI-generated feedback in order to address the current risks and limitations associated with the use of LLMs.

Acknowledgments

A total of 20 textbooks were kindly provided by Quintessence Publishing to support the implementation of the study. The authors would like to thank Dr Fabian Kück, Department of Medical Statistics, University Medical Center Göttingen, Göttingen, for the valuable support with the statistical analysis. We acknowledge support by the Open Access Publication Funds of the Göttingen University.

Data Availability

The datasets generated or analyzed during this study are available from the corresponding author on reasonable request.

Authors' Contributions

FH contributed to the conceptualization and formal analysis of the study and, together with TR and PL, participated in the investigation, methodology, and resource provision. FH and PL were responsible for project administration. FH led the writing

of the original draft, with TR and PL providing supporting contributions. All 3 authors—FH, TR, and PL—contributed equally to the review and editing of the manuscript.

Abstract

Background: The use of artificial intelligence (AI)–based large language model chatbots such as ChatGPT has become increasingly popular in many disciplines. However, concerns exist regarding ethics, legal considerations, accuracy, and reproducibility with its use in health care practice, education, and research.

Objective: This study aimed to assess current perceptions and use of AI chatbots in pharmacy practice from the perspective of pharmacist preceptors and determine factors that may influence the use of AI chatbots in practice.

Methods: A cross-sectional survey of pharmacy practice preceptors from Indiana, Illinois, and Michigan was conducted using the validated Technology Acceptance Model Edited to Assess ChatGPT Adoption (TAME-ChatGPT) survey tool to collect information regarding current use of AI chatbots and factors associated with use, including ease of use, perceived risk, technology or social influences, anxiety, and perceived usefulness.

Results: A total of 194 responses (194/1877, 10.34% response rate) were received. Approximately one-third (n=59, 30.4%) of respondents reported having used an AI chatbot, with 51.5% (n=100) indicating that they planned to start or would continue using chatbots in the future. In practice, common uses for AI chatbots included summarizing information (n=90, 46.4%), letter of recommendation writing (n=64, 32.9%), and obtaining disease state information (n=63, 32.5%). The 2 main constructs associated with the use of chatbots identified from the TAME-ChatGPT tool included perceived risk of using AI and attitude toward AI. Factors that predicted pharmacists' current use of AI chatbots included positive attitude toward technology (odds ratio [OR] 3.64, 95% CI 2.08-6.36), coworker use of AI (OR 7.41, 95% CI 2.64-20.8), and working in academia (OR 5.62, 95% CI 1.30-24.23).

Conclusions: Most pharmacist respondents had not used an AI chatbot and were unlikely to make patient care decisions based on information from a chatbot. The TAME-ChatGPT survey is validated for assessing chatbot use and attitudes among pharmacists, and future studies using this survey tool can guide the implementation of chatbots into pharmacy practice.

chatbot; artificial intelligence; pharmacy; health care practice; survey; technology

Introduction

Artificial Intelligence Chatbots

In November 2022, the artificial intelligence (AI)–based large language model chatbot ChatGPT was launched [1]. It quickly gained popularity, amassing over 100 million monthly users in just 2 months [2]. Since the release of ChatGPT, several other AI chatbots have debuted, including Gemini, Microsoft Bing AI, and Copilot. This expansion in AI chatbots has led to the diversification of their use in fields outside of the technology industry. ChatGPT has been explored for use in health care practice, education, and research, and specialized chatbots such as OpenEvidence and Dougall GPT have emerged, catering specifically to clinicians and health care workers [3-6].

Use of Artificial Intelligence in Healthcare

A survey evaluating the use and perceptions of ChatGPT in health care professionals was conducted at Northwestern University [7]. In addition to gathering information regarding applications of ChatGPT in health care, the survey focused on perceptions related to use in health care research, education, and practice. Participants reported uncertainty about the use of ChatGPT due to its recent release, although many respondents indicated an interest in future use. Similarly, in a survey of health care workers in Saudi Arabia, participants expressed concerns about ChatGPT use in health care, including lack of credibility and concerns about inaccurate medical information [8]. Despite these concerns, most respondents still anticipated a positive impact of ChatGPT on the future of health care practice, including medical decision-making, patient and family support, and medical research appraisal. Studies conducted in Jordan, Saudi Arabia, and the United Arab Emirates have reported similar findings among pharmacists [9-11].

These findings were reinforced in a 2023 systematic review that examined 60 studies focusing on the applications of and concerns about ChatGPT in health care practice, education, and research [6]. Potential uses for ChatGPT in practice included clinical documentation, creation of personalized care plans, improved health literacy, and provision of patient education. In education, ChatGPT was used in the creation of personalized learning tools and writing clinical cases. In research, ChatGPT was found to be beneficial in improving writing efficiency. However, in nearly all the studies, there were reported concerns with ChatGPT, including ethical, legal, and copyright issues; inaccuracy; and limited reproducibility. Specific to pharmacy, the use of ChatGPT has been explored with respect to drug information, medication therapy management, patient education, and adverse drug reaction assessment, with the general consensus that it has potential as a supplementary tool but is not yet able to handle complex problems [12-15].

On the basis of the findings from previously conducted surveys and research studies, it is evident that there is current and future potential for the use of AI technology in health care. However, information about the opinions and perceptions of pharmacists regarding the utility of AI chatbots in practice is limited. Pharmacists have been poorly represented in most surveys of health professionals conducted to date, and most studies regarding pharmacist perceptions have been conducted outside of the United States. Understanding the current perceptions, use, and barriers to use of chatbots will help inform and identify future roles for chatbots in pharmacy practice. Pharmacy preceptors are at the forefront of practice and education in the United States; therefore, this study aimed to assess current perceptions and use of AI chatbots in pharmacy practice from the perspective of pharmacist preceptors and determine factors that may influence the use of AI chatbots according to the Technology Acceptance Model Edited to Assess ChatGPT Adoption (TAME-ChatGPT) tool [16].

Methods

Overview

A cross-sectional survey was conducted using a convenience sample of pharmacy practice preceptors from Purdue University College of Pharmacy, University of Michigan College of Pharmacy, Wayne State University Eugene Applebaum College of Pharmacy and Health Sciences, University of Illinois Chicago Retzky College of Pharmacy, and Butler University College of Pharmacy and Health Sciences. Current pharmacist preceptors were recruited through their respective offices of experiential education. Pharmacists were excluded from the study if they had not precepted students in the previous year given the recent introduction of AI chatbots or if they did not practice in one of the affiliated states of Illinois, Indiana, or Michigan. Participants were instructed to only take the survey once.

Questionnaire Design and Administration

The survey instrument was built in Qualtrics XM (Qualtrics International Inc) and was primarily based on the TAME-ChatGPT survey tool, a validated tool adapted from the technology acceptance model (TAM) for assessing health care students' attitudes toward ChatGPT [16]. Before the first survey item, respondents were asked a screening question to ensure that they met the study inclusion criteria. The first section gathered information regarding pharmacists' practice setting and current use of AI chatbots. The second section contained questions from the TAME-ChatGPT that were adapted to detect an association with different factors of the TAM (perceived ease of use, perceived risk, technology or social influence, anxiety, perceived usefulness, and behavior) and the use of AI chatbots. The survey concluded with questions regarding demographic information and tasks in which preceptors would recommend the use of AI. The instrument was pilot-tested by 3 faculty members to ensure adequate formatting, comprehension, clarity, and completeness of the survey. The final survey instrument is available in Multimedia Appendix 1.

An email invitation to complete the survey instrument was sent to 1877 pharmacy preceptors on February 12, 2024. The survey link was accessible until April 22, 2024, and 3 reminder emails were sent out before the survey closed. Only fully completed surveys were included in the final analysis.

Data Analysis

Data were described using means and SDs for continuous variables and medians and frequencies for nominal variables. Univariable analysis was conducted using the student 2-tailed *t* test for continuous variables and chi-square test for nominal

variables. Normality was assessed using visual inspection of *Q*-*Q* plots.

An exploratory factor analysis was conducted to assess construct validity of the TAME-ChatGPT instrument. First, correlation matrices, the Bartlett test, and the Kaiser-Meyer-Olkin measure of sampling adequacy were assessed to ensure that proceeding with factor analysis was appropriate. Multicollinearity was assessed by examining the determinant of the correlation in the correlation matrix with a <0.00001 cutoff. If multicollinearity was present, items with *r* values greater than 0.8 were considered for removal. The number of factors included was based on performing parallel analysis in which an eigenvalue cutoff was determined from randomly generated correlation matrices and then compared with eigenvalues from the data. Factors were retained if the dataset eigenvalue was greater than the corresponding random eigenvalue. Promax rotation was used to allow for correlation of factors. The Cronbach α was calculated to assess internal consistency.

Multivariable analysis was conducted using logistic regression to assess the association between preceptor characteristics and the components of the TAME-ChatGPT with the outcome of use of AI or future use of AI. Variables included the TAME-ChatGPT constructs and factors that significantly predicted current or future AI use. The number of variables included in the model was limited based on the number of participants who responded that they used AI. Goodness of fit was evaluated using the Hosmer-Lemeshow test (*P*>.05 indicating model fit) along with −2 log likelihood ratio, with smaller values indicating improved fit. As a secondary analysis, the model's ability to discriminate between those who reported AI use and those who did not was evaluated using a receiver operating characteristic curve. The area under the curve was used as a summary measure of the model's discrimination. SPSS (version 29; IBM Corp) was used to conduct the data analysis. A *P* value of <.05 was considered statistically significant.

Ethical Considerations

This study was determined to be exempt research by the institutional review boards at all participating institutions—Butler University, Purdue University, University of Illinois Chicago, University of Michigan, and Wayne State University. The survey responses were anonymous and confidential, and all responses were stored without any identifiers. After survey completion, respondents were directed to an optional link to receive a US $10 Amazon gift card as compensation for participation.

Results

Overview

A total of 235 responses were received. Responses were excluded from the analysis if they were incomplete (n=10, 4.3%); if the respondent practiced outside of Indiana, Illinois, or Michigan (n=4, 1.7%); or if the respondent had not been a preceptor in the previous year (n=27, 11.5%). The final response number was 194, which represented an overall response rate of 10.3% (194/1877). Respondent demographics can be found in Table 1, and they were generally representative of pharmacy preceptors with the exception of years and area of practice based on data from the American Association of Colleges of Pharmacy 2024 preceptor survey [17]. Of the 194 responses that met the inclusion criteria, 59 (30.4%) indicated that the respondents had used an AI chatbot before. A total of 51.5% (100/194) of the respondents indicated that they would continue or plan to start using chatbots in the future.

Among those who had used AI chatbots before and those who had not, demographics were similar with respect to age, gender, and years of practice (Table 2). Most respondents (146/194, 75.3%) indicated that they were unlikely to make a patient care decision based on information from a chatbot. Of the respondents who had used AI chatbots (59/194, 30.4%), there was a substantially higher percentage who practiced in academia and a lower percentage who practiced in the community setting than among those who had not used AI chatbots. Additionally, respondents who had coworkers who used AI chatbots or an institutional AI policy were more likely to have used an AI chatbot themselves.

ChatGPT was the most frequently reported chatbot used (55/59, 93%), followed by Bing Chat (10/59, 17%) and Google Bard, now Gemini (7/59, 12%). The most common uses for AI chatbots in practice included summarizing information (31/59, 53%), letter of recommendation writing (20/59, 34%), and obtaining disease state information (14/59, 24%). Among respondents who had not used AI chatbots in practice before (135/194, 69.6%), 63% (85/135) selected not knowing how to use them effectively as the reason for disuse. Other common reasons for disuse included preference for other resources (80/135, 59.3%), lack of credibility or trust (63/135, 46.7%), and concerns of plagiarism (43/135, 31.9%).

All 194 respondents received the survey including questions about the respondents' recommendations for use of AI chatbots by pharmacists and pharmacy students in practice. The top recommendations for use for pharmacists included administrative purposes (92/194, 47.4%), summarizing information (90/194, 46.4%), creating meeting agendas (74/194, 38.1%), letter of recommendation writing (64/194, 33%), and obtaining disease state information (63/194, 32.5%); 15.5% (30/194) of respondents indicated that they would not recommend that pharmacists use AI chatbots in practice. In comparison, the top uses recommended for students were summarizing information (61/194, 31.4%), creating meeting agendas (45/194, 23.2%), obtaining disease state information (42/194, 21.6%), administrative purposes (42/194, 21.6%), and conducting literature searches (38/194, 19.6%). In total, 40.2% (78/194) of the respondents indicated that they would not recommend that students use AI chatbots in practice.

Factors Associated With AI Use

The first 13 items of the TAME-ChatGPT were included in the primary exploratory factor analysis. These items included all survey respondents, with an overall rate of AI use of 30.4% (59/194). The overall data were appropriate for conducting factor analysis (Bartlett test χ^2_{78}=1288.7; *P*<.001), and the Kaiser-Meyer-Olkin value (0.82) indicated that sampling was

adequate. There was no concern for multicollinearity, and parallel analysis identified 2 factors as the optimal number, with an eigenvalue cutoff of 1.31. The eigenvalues for the 2 factors were 4.49 and 1.97, which explained 49.7% of the cumulative variance. These 2 factors were classified as attitude toward the technology and perceived risk. Descriptive statistics for these constructs are provided in Table 3, and the pattern matrix is shown in Table 4. Including a third factor (eigenvalue=1.155), similar to the original TAME-ChatGPT validation study, resulted in an explanation of 57.1% of the cumulative variance. However, factors 2 and 3 were largely correlated (r=0.57), and many of the items were correlated with both factors 2 and 3. Cronbach α values for the 2 constructs were good at 0.86 for both comfort with technology and perceived risk.

In the secondary exploratory analysis, all items were included for the 30.4% (59/194) of respondents who had previously used AI. The overall data were appropriate for conducting factor analysis (Bartlett test χ^2_{528}=1301.5; P<.001), and the Kaiser-Meyer-Olkin value (0.70) indicated that sampling was adequate. There was concern for multicollinearity, and therefore, items 4, 14, and 31 were removed. Parallel analysis identified 4 factors as the optimal number, with an eigenvalue cutoff of 2.08. The eigenvalues for the 4 factors were 9.33, 4.36, 2.96, and 2.26, which explained 57.3% of the cumulative variance. The 4 factors identified included attitude toward the technology, perceived usefulness, perceived risk, and ease of use. Descriptive statistics for these constructs are provided in Table 3, and the pattern matrix is shown in Table 5. Cronbach α values for the 4 constructs were very reliable for attitude toward the technology (0.92), perceived usefulness (0.92), perceived risk (0.84), and ease of use (0.83).

Table 3. Technology Acceptance Model Edited to Assess ChatGPT Adoption constructs.

	Score, mean (SD)	*P* value

Had used AI chatbots before	19.19 (3.63)	
Had not used AI chatbots before	15.07 (4.06)	
Attitude toward technology among users[d]	44.53 (10.02)	—[e]
Perceived usefulness among users[f]	14.08 (5.80)	—
Perceived ease of use among users[g]	11.29 (2.54)	—
Perceived risk of use among users[h]	33.75 (7.98)	—

[a]Possible range from 8 to 40, with higher scores indicating lower perceived risk and a score of 24 indicating a neutral attitude.

[b]AI: artificial intelligence.

[c]Possible range from 5 to 25, with higher scores indicating positive attitude and a score of 15 indicating a neutral attitude.

[d]Possible range from 13 to 65, with higher scores indicating positive attitude and a score of 39 indicating a neutral attitude.

[e]Not applicable.

[f]Possible range from 6 to 30, with higher scores indicating higher perceived usefulness and a score of 18 indicating a neutral attitude.

[g]Possible range from 3 to 15, with higher scores indicating perceived ease of use and a score of 9 indicating a neutral attitude.

[h]Possible range from 5 to 50, with higher scores indicating lower perceived risk and a score of 27.5 indicating a neutral attitude.

Table 4. Pattern matrix of the 2 inferred factors for all respondents irrespective of previous artificial intelligence (AI) chatbot use.

Item	Perceived risk	Attitude toward technology
"I am concerned about the reliability of the information provided by AI chatbots."	0.435	<0.400
"I am concerned that using AI chatbots is considered plagiarism."	0.617	<0.400
"I fear relying too much on AI chatbots may decrease my critical thinking skills."	0.585	<0.400
"I am concerned about the potential security risks of using AI chatbots."	0.798	<0.400
"I am afraid of becoming too dependent on technology like AI chatbots."	0.618	<0.400
"I am afraid that using AI chatbots would result in a lack of originality in my work."	0.688	<0.400
"I am afraid that the use of the AI chatbots would be a violation of workplace policies."	0.655	<0.400
"I am concerned about the potential privacy risks that might be associated with using AI chatbots."	0.786	<0.400
"I am enthusiastic about using technology, such as AI chatbots for learning, practice, and research."	<0.400	0.887
"I believe technology, such as AI chatbots is an important tool for workplace success."	<0.400	0.844
"I think that technology like AI chatbots is attractive and fun to use."	<0.400	0.871
"I am always open to learning about new technologies like AI chatbots."	<0.400	0.672
"I trust the opinions of my friends or colleagues about using AI chatbots."	<0.400	0.444

Logistic regression was conducted to predict current and future use of AI (Table 6). Factors that remained significant in the model that predicted current AI use included positive attitude toward technology, coworker use of AI, and the respondent practicing in academia. Factors that predicted future use of AI included perceived risk, positive attitude toward technology, and coworker use.

Table 5. Pattern of the 4 inferred factors for only those who had used artificial intelligence (AI) chatbots before.

Item	Attitude toward technology	Perceived usefulness	Ease of use	Perceived risk
"I am concerned about the reliability of the information provided by AI chatbots."	<0.400	<0.400	<0.400	0.530
"I am concerned that using AI chatbots is considered plagiarism."	<0.400	<0.400	<0.400	0.652
"I fear relying too much on AI chatbots may decrease my critical thinking skills."	<0.400	<0.400	<0.400	0.457
"I am afraid of becoming too dependent on technology like AI chatbots."	<0.400	<0.400	<0.400	0.746
"I am afraid that using AI chatbots would result in a lack of originality in my work."	<0.400	<0.400	<0.400	0.762
"I am afraid that the use of the AI chatbots would be a violation of workplace policies."	<0.400	<0.400	<0.400	0.582

Discussion

Approximately one-third of pharmacy preceptors (59/194, 30.4%) reported use of an AI chatbot, with approximately half (100/194, 51.5%) indicating that they planned to start or would continue using chatbots in the future. Consistent with findings from other studies, we found that most respondents were unlikely to make patient care decisions based on information provided by an AI chatbot. However, they did report use for administrative tasks such as summarizing information and writing letters of recommendation. To our knowledge, this is the first study using the TAME-ChatGPT assessment tool among pharmacists. The findings show that this tool is valid and reliable for assessing pharmacists' attitudes toward chatbots and their use in pharmacy practice. Pharmacists' attitudes toward chatbots were largely influenced by their attitude toward the technology and their perceived risk related to use of the technology. Furthermore, among pharmacists who had used chatbots, attitudes toward use of chatbots were affected by the same 2 factors plus their perceived usefulness and ease of use. Positive attitudes toward technology, having coworkers who use AI, and working in academia predicted current use of AI chatbots, whereas factors predicting future use of the technology included perceived risk, positive attitudes toward technology, and coworker use of AI chatbots. Our results affirm that, when adopting ChatGPT and other AI chatbots, it is important to consider perceptions of risk, usefulness, and ease of use, as well as the users' attitudes toward technology.

Significantly more pharmacists practicing in academia have used chatbots than pharmacists in other practice settings, perhaps because these pharmacists are often at the forefront of exploring new technologies and their applications in pharmacy practice and may be more comfortable with adopting new technologies. While academic pharmacists may be at the forefront of chatbot adoption, the use of AI chatbots is expected to increase across all pharmacy practice settings as the technology becomes more

refined and its benefits become more apparent. Since the time of our data collection, more advanced AI chatbots have become available, such as OpenEvidence, which may provide more targeted information for pharmacists to use in practice.

However, most pharmacists surveyed (135/194, 69.6%) had not used an AI chatbot, with nearly two-thirds of them (85/135, 63%) stating that their reason for not using chatbots was that they did not know how to use them effectively; 46.7% (63/135) cited lack of credibility or trust in chatbots as the reason for lack of use. AI chatbots are relatively new technologies in health care, and many pharmacists may not have had sufficient exposure or training to use them effectively. Furthermore, there is currently no standardized approach to training pharmacists or other health care providers on the use of AI chatbots; thus, knowledge and skills across the profession may be inconsistent. Knowledge on how to use AI chatbots will likely improve as they become more prevalent in health care settings. Pharmacists will gain hands-on experience with these tools, become more comfortable using them, and learn to integrate them into their daily workflows. Preceptors are in an ideal position to help guide students who are just learning about AI capabilities and limitations on the optimal use of this new technology. Health care organizations, educational institutions, and postgraduate training programs should consider including training on the appropriate use of AI and risks of inappropriate use.

Our findings differ somewhat from those of the work by Sallam et al [16], who validated the TAME-ChatGPT in a sample of Jordanian health care students and identified factors affecting their attitudes toward ChatGPT and use of ChatGPT. Attitudes of Jordanian students toward ChatGPT were influenced by an additional third factor, anxiety related to fear of ChatGPT; attitudes toward use of ChatGPT were affected by behavior as a fourth factor instead of attitudes toward technology [16]. The differences are likely due to differences in the populations studied; US pharmacists and Jordanian students represent very different populations based on culture, age, practice experience, and other characteristics. Different approaches to factor analysis may also contribute to differences.

Risk perception is known to be a key factor affecting decision-making, and perception of risks associated with chatbots significantly influenced pharmacists' attitudes toward chatbots and their use [18]. The credibility of AI chatbots in health care is a complex and evolving issue. Reliability and accuracy can vary significantly between chatbots, and not all AI chatbots are reliable sources of information. Inaccuracies, hallucinations, potential for biased responses, and the inability of chatbots to provide nuanced or context-specific information have been documented [12,19-21]. These potential barriers highlight the need for health care professional scrutiny and oversight of chatbot responses. As the technologies continue to develop, ongoing research and validation will be crucial to establish and maintain the credibility of AI chatbots in health care applications and minimize their potential for harm.

Some of the limitations of this study include the sample size as only pharmacist preceptors in the Midwest who were affiliated with the participating colleges were surveyed, so the results may not be representative of pharmacy preceptors across the United States. However, based on comparison with the 2024 American Association of Colleges of Pharmacy preceptor survey, outside of years and area of practice, the surveyed sample seems to be fairly representative of preceptors in the United States [17]. Our response rate was low, which may be due to technology-related factors (ie, the email going to the spam folder) and may have resulted in selection bias in the sense that preceptors with experience using AI may have been more likely to respond. As the survey was anonymous, we could not explore differences between respondents and nonrespondents. It is possible that the use of AI at the time of our survey overestimated use in the target population. Additionally, the AI and chatbot space is constantly evolving, and although the survey was conducted recently, perceptions can change rapidly as more people are exposed to chatbots and start using them in their daily work. Future studies could expand the surveyed population to include pharmacist preceptors nationwide or include all pharmacists, along with following up on respondents over time to evaluate changes in responses. Additionally, the validated survey can be readministered following training and education on AI chatbots to determine how perceptions of AI technology have changed.

At the time of our study, it had been almost 2 years since AI chatbots were introduced, and pharmacist preceptors were still hesitant to use the new technology, with only approximately one-third of respondents (59/194, 30.4%) indicating that they had used a chatbot in practice. Pharmacist preceptors were hesitant to use the technology for clinical decisions and were uncertain about their place in practice. This study also demonstrated that the TAME-ChatGPT survey is a reliable and validated tool that can be used to assess pharmacists' attitude toward and use of chatbots. Constructs from the TAM, including attitude toward technology, perceived usefulness, ease of use, and perceived risk of use, as well as practice setting and coworker use, can determine and predict pharmacist use of AI chatbots. Future studies with this validated tool can be used to guide the implementation of chatbots into pharmacy practice and help inform policymakers and organization leaders on the education and training needed to promote the safe and effective use of AI chatbots in pharmacy practice.

Abstract

Background: Large language models (LLMs) offer the potential to improve virtual patient-physician communication and reduce health care professionals' workload. However, limitations in accuracy, outdated knowledge, and safety issues restrict their effective use in real clinical settings. Addressing these challenges is crucial for making LLMs a reliable health care tool.

Objective: This study aimed to evaluate the efficacy of Med-RISE, an information retrieval and augmentation tool, in comparison with baseline LLMs, focusing on enhancing accuracy and safety in medical question answering across diverse clinical domains.

Methods: This comparative study introduces Med-RISE, an enhanced version of a retrieval-augmented generation framework specifically designed to improve question-answering performance across wide-ranging medical domains and diverse disciplines. Med-RISE consists of 4 key steps: query rewriting, information retrieval (providing local and real-time retrieval), summarization, and execution (a fact and safety filter before output). This study integrated Med-RISE with 4 LLMs (GPT-3.5, GPT-4, Vicuna-13B, and ChatGLM-6B) and assessed their performance on 4 multiple-choice medical question datasets: MedQA (US Medical Licensing Examination), PubMedQA (original and revised versions), MedMCQA, and EYE500. Primary outcome measures included answer accuracy and hallucination rates, with hallucinations categorized into factuality (inaccurate information) or faithfulness (inconsistency with instructions) types. This study was conducted between March 2024 and August 2024.

Results: The integration of Med-RISE with each LLM led to a substantial increase in accuracy, with improvements ranging from 9.8% to 16.3% (mean 13%, SD 2.3%) across the 4 datasets. The enhanced accuracy rates were 16.3%, 12.9%, 13%, and 9.8% for GPT-3.5, GPT-4, Vicuna-13B, and ChatGLM-6B, respectively. In addition, Med-RISE effectively reduced hallucinations, with reductions ranging from 11.8% to 18% (mean 15.1%, SD 2.8%), factuality hallucinations decreasing by 13.5%, and faithfulness hallucinations decreasing by 5.8%. The hallucination rate reductions were 17.7%, 12.8%, 18%, and 11.8% for GPT-3.5, GPT-4, Vicuna-13B, and ChatGLM-6B, respectively.

Conclusions: The Med-RISE framework significantly improves the accuracy and reduces the hallucinations of LLMs in medical question answering across benchmark datasets. By providing local and real-time information retrieval and fact and safety filtering, Med-RISE enhances the reliability and interpretability of LLMs in the medical domain, offering a promising tool for clinical practice and decision support.

KEYWORDS

large language models; ChatGPT; medical question answering; health care communication; retrieval-augmented generation

Introduction

Large language models (LLMs), such as ChatGPT, have emerged as a powerful paradigm in natural language processing [1]. With its humanlike conversational capabilities, ChatGPT has become a potent tool for medical question answering (QA), improving virtual patient-physician communication and reducing health care professionals' workload [2-7].

Previous studies have focused on assessing the performance of LLMs in medical QA on standard datasets, such as MedMCQA, MedQA, and PubMedQA, and in specific specialties such as surgery, oncology, ophthalmology, and radiology [8,9]. The accuracy of models such as GPT-3.5 (50%-60%) and GPT-4 (70%-80%) is insufficient for clinical application, underscoring the need for further enhancements of LLMs regarding domain-specific medical knowledge [10-18]. Furthermore, the "hallucination" phenomenon in LLMs, which leads to factually inaccurate or irrelevant content, presents serious risks to patient care [19-23]. In medical practice, these hallucinations can lead to erroneous information, unsupported diagnoses, or inappropriate treatments. Consequently, many studies that have assessed LLM performance in medical applications highlight that major challenges in applying LLMs to clinical settings are insufficient accuracy; outdated knowledge; and potential safety issues, including hallucinations and bias [18,24,25]. Enhancing accuracy, timeliness, and safety is essential to make LLMs reliable for health care, ultimately improving patient outcomes.

Retrieval-augmented generation (RAG) is a promising strategy to enhance the accuracy of medical QA tasks and reduce hallucinations [26-29]. RAG improves LLMs' responses by retrieving relevant documents from external knowledge, grounding the responses in factual information and increasing their reliability [30]. Previous studies have investigated the use of external knowledge to augment LLMs in medical domains, such as Almanac [31] and RECTIFIER [32]. However, most of these studies that have used retrieval techniques are based on small, predownloaded datasets, leading RAG models to be applied mostly in specific disciplines rather than broadly across medical fields [33-36]. In our previous study, we developed an RAG framework called RISE to improve LLMs' performance in diabetes-related QA, achieving significant enhancements compared to the base LLMs [37]. Building on this framework, further exploration and refinement of knowledge augmentation techniques are warranted to expand its application across broader medical domains.

In this study, we introduced Med-RISE, an enhanced version of the RAG framework specifically designed to improve performance in medical QA tasks across broader medical domains. We assessed the impact of integrating the Med-RISE framework with the GPT-3.5, GPT-4, Vicuna-13B, and ChatGLM-6B LLMs and quantitatively evaluated its improvements in accuracy and reductions in hallucinations in the reasoning process using standard medical datasets, including MedQA (US Medical Licensing Examination [USMLE]), PubMedQA, and MedMCQA.

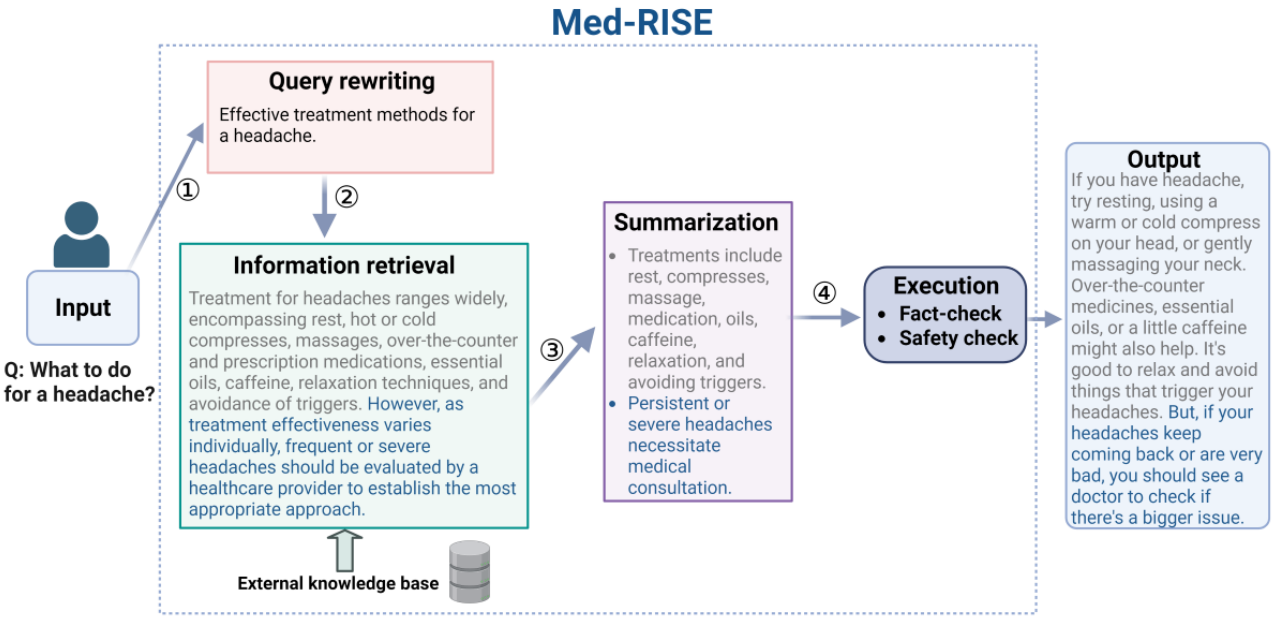
Methods

The Framework of Med-RISE

Overview

In this study, we developed an advanced framework called Med-RISE to enhance the performance of LLMs in medical QA tasks. Building on our previous work on the RISE framework [37], which focused on diabetes-related QA in a single specialty domain, Med-RISE expands the retrieval database and incorporates more authoritative medical sources, making it suitable for diverse medical domains. The Med-RISE implementation requires 8 V100 graphics processing units (GPUs; 32 GB each) and 4 TB of storage for the medical database and achieves response times of 5 to 20 seconds using parallel retrieval strategies. The Med-RISE framework involves 4 key steps: query rewriting, information retrieval, summarization, and execution (Figure 1). The framework is implemented using the Python programming language (Python Software Foundation) on the Ubuntu operating system (Canonical Ltd). We provide open-source code (Multimedia Appendix 1) that supports both web deployment and mobile app integration.

Figure 1. The Med-RISE framework: (1) the query rewriting step refines user queries using advanced large language models for better retrieval; (2) the information retrieval step searches for relevant context from an expanded medical local database and external real-time academic sources; (3) the summarization step summarizes the retrieved information into concise key points; and (4) the execution step generates the final answer, with fact-checking and safety validation to filter out incorrect, biased, or unsafe information before output, ensuring accuracy and safety.



Query Rewriting

In this step, Med-RISE first identifies the intent of the user or the patient's query through the following prompt: "Please identify the intent of the patient's query and select the most appropriate category from a list of predefined intents." The 50 intent categories were developed by our team through analysis of clinical practice patterns and validated by clinical physicians (YZ). The LLM selects the single most appropriate intent category using natural language processing. The complete list of the 50 intent categories is provided in Multimedia Appendix 1.

Med-RISE uses LLMs such as GPT-3.5, GPT-4, Vicuna-13B, and ChatGLM-6B to refine the initial query. The refinement process involves addressing typographical errors, introducing related terms, expanding the range of possible matches, and enhancing overall retrieval precision. This step ensures that the rewritten query accurately captures the user's intent and is well suited for subsequent information retrieval.

Information Retrieval

Med-RISE uses a dual retrieval approach combining local database and real-time academic sources to ensure comprehensive and current medical information. The system first converts the rewritten query into vector representation using the OpenAI Text-Embedding-ADA-002 model and then applies the Faiss similarity search algorithm to identify the 5 most relevant documents from the local database. Simultaneously, the framework performs automatic online retrieval through the Google search engine, filtering results using a predefined white list of 200 authoritative medical websites and academic institutions. This white list encompasses major medical journals (*The New England Journal of Medicine*, *Lancet*, and *The Journal of the American Medical Association*), medical databases (PubMed and Cochrane Library), professional medical organizations (the World Health Organization, Centers for Disease Control and Prevention, and National Institutes of Health), specialized medical societies, and official websites of medical schools and teaching hospitals. When local and real-time retrieval results are consistent, the information is integrated and synthesized. When discrepancies arise, priority is given to real-time retrieved information to ensure up-to-date medical knowledge. The filtered documents are then analyzed and integrated by the LLMs before proceeding to the summarization and execution steps.

To optimize retrieval latency, Med-RISE implements several strategies. For local database retrieval, the system uses 8 V100 GPUs (32 GB each) with parallel processing capabilities and optimized indexing methods such as IndexIVFFlat. For real-time retrieval, asynchronous parallel processing across multiple GPUs and network stability enhancements are used to minimize response delays, achieving response times of 5 to 20 seconds.

Summarization

In this step, Med-RISE summarizes the retrieved content into a clear and concise format, focusing on key points and eliminating redundancy. The model is prompted with the following: "You are an assistant skilled in organizing text. Summarize the following content clearly and briefly, keeping the important points and removing repeated information." This step ensures that the content is well suited for generating an effective response.

Execution

The final step involves generating the final answer from the summarized information using the LLMs. Before sharing with the user, the answer undergoes fact-checking and safety validation to filter out any biased, unsafe, or incorrect information, ensuring that the response is accurate, neutral, and safe.

For fact-checking, the retrieved information is broken down into individual claims, which are then verified against external knowledge sources to confirm their accuracy using the following prompt: "As an AI medical assistant, your current task is to break down your last response in the conversation into independent claims. Do not include claims about opinions, or subjective personal experiences." These claims are then verified against external knowledge sources to confirm their accuracy using the following prompt: "As an AI medical assistant, your current task is to fact-check the claims based on the external knowledge provided. You should label each claim as true or false. After that, output all the true claims without saying anything else. Now it is your turn to fact-check the claims based on the external knowledge."

For safety validation, 24 predefined rules were developed based on medical ethics principles, patient safety requirements, and responsible artificial intelligence guidelines. The rules were tested in pilot experiments and then reviewed and refined by 2 clinical experts (MG and FL) before finalization. The model is given the following prompt: "The final response should comply with the following 24 guidelines." These rules prevent specific medical diagnoses, treatment advice, and harmful generalizations and ensure that the responses recommend professional consultation when appropriate.

This 2-step process ensures that the final summarized content is filtered for safety and correctness before being presented to the user.

Local Database

The local database for Med-RISE was constructed using 5 main sources: PubMed, StatPearls, 15 widely used medical textbooks, clinical practice guidelines, and Wikipedia. Specifically, PubMed provides 60,000 carefully selected high-quality biomedical articles (2015-2024; impact factor of ≥5; *Journal Citation Reports* quartiles 1-2; ≥50 citations) covering a wide range of biomedical research [37,38]. StatPearls serves as a clinical decision support tool, and we included more than 3000 publicly available StatPearls articles. The 15 medical textbooks are widely used in medical education and are the main references for USMLE preparation. Clinical practice guidelines from major medical societies, including the American College of Physicians and Chinese Medical Association, were included as main references for clinical decision support. Wikipedia, an open-source encyclopedia, provides general medical knowledge to support broader medical topics. These sources cover various medical disciplines, including anatomy, pharmacology, pathology, pediatrics, psychiatry, internal medicine, and gynecology (Multimedia Appendix 2).

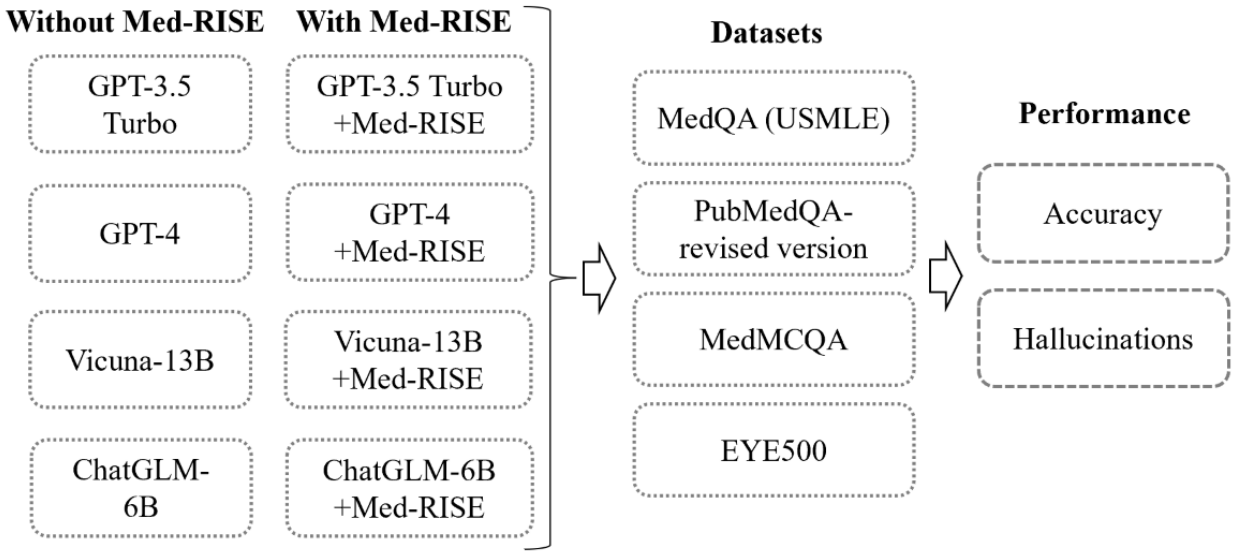
The collected documents (from the 5 main sources) underwent preprocessing to eliminate unstructured or extraneous information before being segmented into smaller units. Embeddings for these segments were generated using the OpenAI Text-Embedding-ADA-002 model and then indexed using the Faiss similarity search algorithm for efficient retrieval. The process for generating embeddings and retrieving data follows a methodology similar to that of our previous RISE framework [37]. Due to the stable nature of foundational medical knowledge, the local database is updated annually through manual curation by our team according to our local database inclusion criteria.

After receiving a user's query, the system transforms the rewritten query into an embedding vector. This vector is then matched against the database using cosine similarity to identify the 5 most relevant segments, which form the knowledge context for the query.

Study Design

As shown in Figure 2, our study focused on assessing how the Med-RISE framework influences the effectiveness of LLMs in answering medical questions. We selected 4 representative LLMs: proprietary models GPT-3.5 and GPT-4 and open-source LLMs Vicuna-13B and ChatGLM-6B. These models were accessed and used between March 2024 and August 2024. These models have distinct characteristics in terms of performance, organization, source of training data, and parameter size (Table S1 in Multimedia Appendix 3). By testing Med-RISE on these diverse LLMs, we aimed to demonstrate the effectiveness and versatility of the Med-RISE framework.

Figure 2. Flowchart of the overall study design. This study examined the accuracy and hallucination rates of large language models across 4 medical datasets with and without the Med-RISE framework. USMLE: US Medical Licensing Examination.



Ethical Considerations

The Zhongshan Ophthalmic Centre ethics committee (Guangzhou, China) approved this study (2024KYPJ124). As this research did not involve the collection of patient information or data, the ethics approval document includes an exemption from informed consent.

Validation Assessment

In the accuracy evaluation, we compared the performance of various LLMs with and without the application of the Med-RISE framework. This comparison was conducted on multiple-choice questions derived from several datasets: MedQA (USMLE), PubMedQA, MedMCQA, and EYE500. Accuracy was defined as the proportion of questions answered correctly out of the total number of questions compared to the standard answers provided in each dataset.

We assessed the presence of hallucinations in the reasoning process of the LLMs using the chain-of-thought (CoT) approach. Hallucinations are defined as content that is either factually incorrect or unrelated to the given information and are categorized into 2 main types: factuality hallucinations and faithfulness hallucinations [39]. Factuality hallucinations occur when the generated content conflicts with real-world information, which includes factual inconsistency (contradicting real-world information) and factual fabrication (generating content that cannot be verified using real-world information). Faithfulness hallucinations involve the inconsistency between the generated content and user instructions, input context, or internal logical coherence, which includes instruction inconsistency (output deviating from user instructions), context inconsistency (output contradicting contextual information), and logical inconsistency (inconsistency between reasoning steps and the final answer). The hallucination rate refers to the percentage of generated responses that included any form of hallucination. Two clinical physicians (DW and WS) independently evaluated the presence of each specific hallucination type, with disagreements resolved through consensus by a senior physician (YZ). Furthermore, we evaluated the proportion of each specific hallucination type.

Medical Datasets Used

In this study, we evaluated the performance of the Med-RISE framework using 4 medical datasets: MedQA (USMLE) [40], MedMCQA [41], PubMedQA [42], and EYE500 (Table S2 in Multimedia Appendix 3). MedQA (USMLE), MedMCQA, and EYE500 are multiple-choice medical board exam question datasets, whereas PubMedQA is a medical reading comprehension dataset [21,43]. For each dataset, we randomly selected 200 questions to reduce computational costs while maintaining evaluation comprehensiveness as preliminary testing showed comparable accuracy rates between the full datasets and subsampled questions.

The MedQA (USMLE) dataset, sourced from the USMLE, consists of challenging multiple-choice questions designed to assess medical knowledge. The MedMCQA dataset consists of diverse multiple-choice questions from the All India Institute of Medical Science and National Eligibility cum Entrance Test (Postgraduate) exam, encompassing various health care topics and medical subjects. These datasets cover diverse medical disciplines, including clinical medicine (internal medicine, surgery, pediatrics, and psychiatry), basic medical sciences (anatomy, physiology, and pathology), and specialized fields. We also introduce the EYE500 dataset, explicitly developed for this study in collaboration with ophthalmologists from Zhongshan Ophthalmic Center, Sun Yat-sen University (Multimedia Appendix 4).

The PubMedQA dataset, a medical reading comprehension dataset, contains questions based on biomedical article abstracts from the PubMed database, requiring models to answer questions with “yes,” “no,” or “maybe” based on the provided abstract information. However, the accuracy of the answers may be affected by the quality and interpretation of the original

studies. To ensure the reliability of the 200 questions and answers used in this study, we had 2 medical experts (DW and WS) independently reverify them. In cases of disagreement, a senior physician (YZ) made the final decision, creating the PubMedQA—revised version (Multimedia Appendix 5).

Prompts

We used 2 prompting strategies: zero-shot prompting for accuracy assessment (eg, "Please provide the answer to this question") and CoT prompting for hallucination evaluation to obtain step-by-step reasoning processes (eg, "Please use step-by-step reasoning to analyze this medical question systematically") [43].

Statistical Analysis

The data analysis was conducted using the SPSS software (version 25.0; IBM Corp). Chi-square tests were used to compare accuracy and hallucination rates. Two clinicians assessed hallucinations (>5 years of experience each), with disagreements resolved by a senior physician. Statistical analysis was conducted in consultation with Jin Ling, a professional biostatistician from Zhongshan Ophthalmic Center. Statistical significance was set at a *P* value of <.05.

Results

Enhanced Accuracy of LLMs Across All Datasets With Med-RISE Integration

Overview

This section presents a comparative analysis of the performance of the 4 LLMs—GPT-3.5, GPT-4, Vicuna-13B, and ChatGLM-6B—on the MedQA (USMLE), PubMedQA, PubMedQA—revised version, MedMCQA, and EYE500 medical datasets. The integration of Med-RISE with each of these LLMs significantly improved accuracy (Table 1 and Figure 3).

The incorporation of Med-RISE into each LLM led to a substantial increase in accuracy across the 4 datasets. Med-RISE enhanced overall accuracy rates, with improvements ranging from 9.8% to 16.3% (mean 13%, SD 2.3%) across the 4 models. Specifically, GPT-3.5 accuracy improved from 47.6% to 63.9% (improvement of 16.3%), GPT-4 accuracy improved from 67.9% to 80.8% (improvement of 12.9%), Vicuna-13B accuracy improved from 28% to 41% (improvement of 13%), and ChatGLM-6B accuracy improved from 37.8% to 47.6% (improvement of 9.8%).

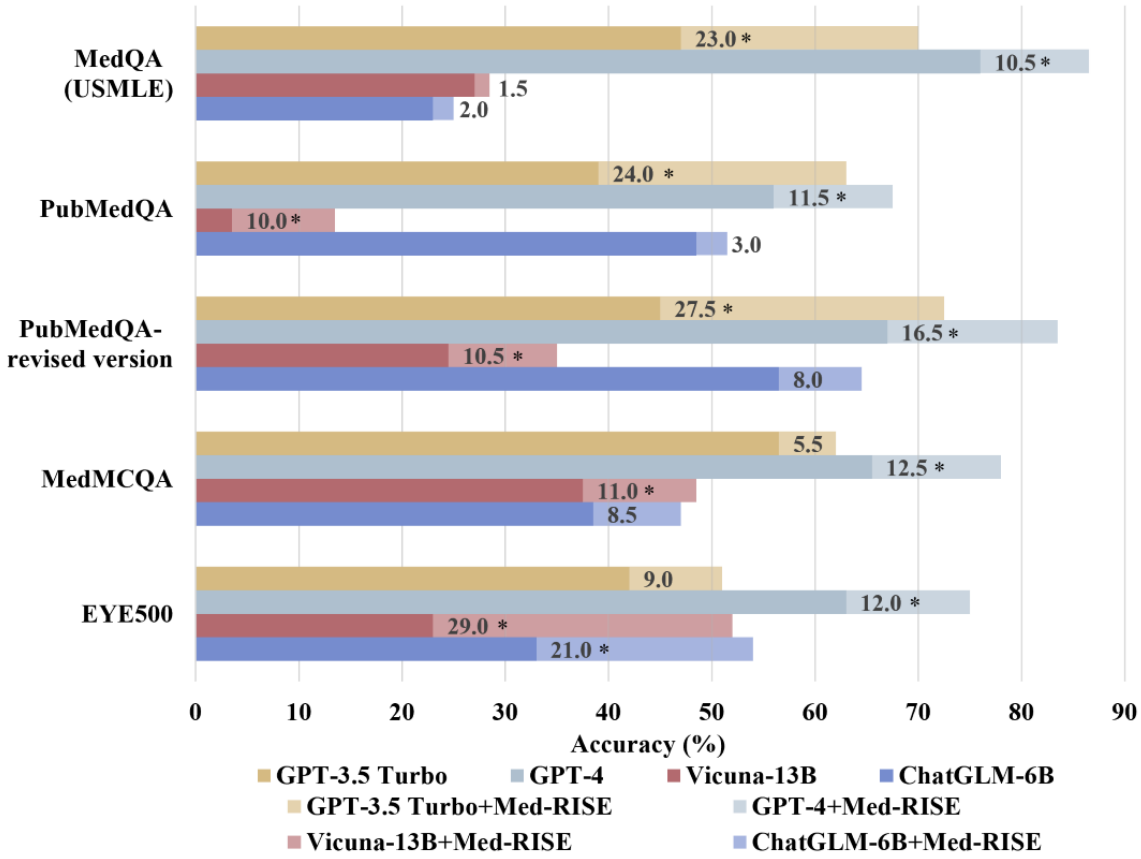
[b]USMLE: US Medical Licensing Examination.

[c]Represents the combined results from 4 datasets (MedQA, PubMedQA—revised version, MedMCQA, and EYE500) with 200 questions each (n=800).

Figure 3. Bar plot of enhanced accuracy in the large language models with Med-RISE. Each bar shows the accuracy of each model on a specific dataset, with the numbers representing the difference in accuracy before and after Med-RISE integration. *P<.05. USMLE: US Medical Licensing Examination.



GPT-3.5

The integration of Med-RISE led to an accuracy increase from 47% to 70% (a 23% improvement; P<.001) in MedQA (USMLE), from 39% to 63% (a 24% improvement; P<.001) in PubMedQA, from 45% to 72.5% (a 27.5% improvement; P<.001) in PubMedQA—revised version, from 56.5% to 62% (a 5.5% improvement; P=.26) in MedMCQA, and from 42% to 51% (a 9% improvement; P=.07) in EYE500.

GPT-4

After incorporating Med-RISE, GPT-4 significantly improved in accuracy across all datasets. The accuracy on the MedQA (USMLE) dataset increased from 76% to 86.5% (a 10.5% improvement; P=.02). For PubMedQA, accuracy increased from 56% to 67.5% (an 11.5% improvement; P=.02). For PubMedQA—revised version, accuracy increased from 67% to 83.5% (a 16.5% improvement; P<.001). For MedMCQA, accuracy increased from 65.5% to 78% (a 12.5% improvement; P=.01). For EYE500, there was a substantial increase in accuracy from 63% to 75% (a 12% improvement; P=.009).

Vicuna-13B

With the application of Med-RISE, Vicuna-13B improved in accuracy from 27% to 28.5% (a 1.5% improvement; P=.74) in MedQA (USMLE), from 3.5% to 13.5% (a 10% improvement; P=.001) in PubMedQA, from 24.5% to 35% (a 10.5% improvement; P=.02) in PubMedQA—revised version, from 37.5% to 48.5% (an 11% improvement; P=.03) in MedMCQA, and from 23% to 52% (a 29% improvement; P<.001) in EYE500.

ChatGLM-6B

The implementation of Med-RISE with ChatGLM-6B resulted in an increase in accuracy from 23% to 25% (a 2% improvement; P=.64) in MedQA (USMLE), from 48.5% to 51.5% (a 3% improvement; P=.55) in PubMedQA, from 56.5% to 64.5% (an 8% improvement; P=.10) in PubMedQA—revised version, from 38.5% to 47% (an 8.5% improvement; P=.09) in MedMCQA, and from 33% to 54% (a 21% improvement; P<.001) in EYE500.

Assessing Hallucinations in the Reasoning Process of LLMs via CoT

The reasoning process of the LLMs was evaluated using the CoT method, specifically focusing on the tendency of these models to generate hallucinations. It was observed that all LLMs were prone to this issue, albeit to varying extents. The average hallucination rates were 78.6% for Vicuna-13B, 67.3% for ChatGLM-6B, and 56.3% for GPT-3.5, with the lowest being that for GPT-4 at 35.3% (Table 2).

Integrating Med-RISE into these LLMs substantially reduced hallucination occurrences, with reductions ranging from 11.8% to 18% (mean 15.1%, SD 2.8%) across 4 datasets: MedQA (USMLE), PubMedQA—revised version, MedMCQA, and

EYE500 (Figure 4). Specifically, GPT-3.5 hallucination rates decreased from 56.3% to 38.6% (reduction of 17.7%), GPT-4 hallucination rates decreased from 35.3% to 22.5% (reduction of 12.8%), Vicuna-13B hallucination rates decreased from 78.6% to 60.6% (reduction of 18%), and ChatGLM-6B hallucination rates decreased from 67.3% to 55.5% (reduction of 11.8%). Furthermore, the application of Med-RISE to the LLMs even led to a reduction in hallucinations exceeding 20% in certain cases. In the MedQA (USMLE) dataset, GPT-3.5 exhibited a significant reduction in hallucinations of 23.5% (P<.001) after Med-RISE integration. In the EYE500 dataset, Vicuna-13B and ChatGLM-6B exhibited significant reductions in hallucinations of 32.5% (P<.001) and 20.5% (P<.001), respectively, after Med-RISE integration. Similarly, the PubMedQA—revised version revealed a substantial decrease in hallucinations of 31% (P<.001) for GPT-3.5 and 22% (P<.001) for GPT-4 when applying Med-RISE.

Table 2. Incidence of hallucinations in chain of thought among the large language models.[a]

Reduction in Different Hallucination Types Through Med-RISE

Table 3 presents the proportion of different types of hallucinations observed in CoT from the 4 different LLMs with and without Med-RISE integration. For this analysis, 50 questions were randomly selected from the 4 datasets, and these questions were answered by the 4 models with and without Med-RISE, resulting in 200 question-answer pairs for each set. The hallucinations were categorized into 2 main types: factuality hallucinations and faithfulness hallucinations, with further subtypes for each.

The results showed that the application of Med-RISE led to reductions in both main categories of hallucinations, with factuality hallucinations decreasing by 13.5% and faithfulness hallucinations decreasing by 5.8%. When examining specific subtypes, factuality hallucinations showed reductions in both factual inconsistency (42/200, 21%) and factual fabrication (12/200, 6%). Similarly, faithfulness hallucinations demonstrated reductions across instruction inconsistency (8/200, 4%), context inconsistency (15/200, 7.5%), and logical inconsistency (12/200, 6%). Representative examples of these different hallucination types are shown in Textboxes S1 and S2 in Multimedia Appendix 3.

Table 3. Proportion of different types of hallucinations of the large language models in chain of thought (N=200)[a].

Type of hallucination and pattern	Without Med-RISE, n (%)	With Med-RISE, n (%)	Change, n (%)
Factuality hallucination			
Factual inconsistency	85 (42.5)	43 (21.5)	42 (21.0)
Factual fabrication	38 (19.0)	26 (13.0)	12 (6.0)
Faithfulness hallucination			
Instruction inconsistency	23 (11.5)	15 (7.5)	8 (4.0)
Context inconsistency	29 (14.5)	14 (7.0)	15 (7.5)
Logical inconsistency	47 (23.5)	35 (17.5)	12 (6.0)

[a]A total of 50 questions were randomly chosen from the 4 datasets. Each group had 200 question-answer pairs.

Discussion

Principal Findings

This study demonstrates the effectiveness of Med-RISE across multiple medical disciplines in enhancing the medical QA capabilities of LLMs. Our evaluation shows that Med-RISE achieved accuracy improvements ranging from 9.8% to 16.3% (mean 13%, SD 2.3%) across all tested LLMs and datasets while significantly reducing hallucinations, with reductions ranging from 11.8% to 18% (mean 15.1%, SD 2.8%), factuality hallucinations decreasing by 13.5%, and faithfulness hallucinations decreasing by 5.8%. These comprehensive improvements in both accuracy and hallucination mitigation demonstrate Med-RISE's capability in addressing 2 fundamental challenges of medical LLMs: knowledge and response reliability.

Comparison With Prior Work

Compared to previous RAG frameworks [44,45], which often depend on static and more limited knowledge bases [46,47], Med-RISE represents a significant advancement through its dynamic, real-time knowledge retrieval across multiple medical disciplines. Building on RISE [37], which we previously implemented for diabetes-specific QA, Med-RISE extends these capabilities across broader medical domains with enhanced safety verification. Previous approaches—such as the focus on diffuse large B-cell lymphoma by Soong et al [35] using 500 PubMed articles, the liver disease–specific LiVersa by Ge et al [34], the Almanac framework by Zakka et al [31] for treatment guidelines, and the medical textbook augmentation by Wang et al [26]—have demonstrated limited application as they were constrained by their fixed knowledge bases. More importantly, even with RAG implementation, LLMs still face inherent challenges regarding errors and hallucinations. Med-RISE uniquely addresses this through its additional layer of accuracy and safety verification before output generation, significantly reducing error rates in medical responses. This dual-stage approach—combining dynamic knowledge retrieval with accuracy and safety verification—makes Med-RISE a more reliable and generalizable tool for medical QA than conventional RAG frameworks.

Research Implications

The integration of Med-RISE with LLMs achieved 2 critical improvements in medical QA performance: average accuracy increases of 13% across 4 general medical datasets and a 15% reduction in hallucinations, with the most substantial improvement in factual inconsistency (42/200, 21% reduction). These significant improvements stem from Med-RISE's novel mechanism that combines real-time medical knowledge retrieval with accuracy and safety verification filters, effectively reducing both outdated information and factual errors. Med-RISE functions as an external augmentation framework that enhances domain-specific performance without modifying underlying model parameters, offering cost-effective adaptation compared to expensive model retraining while enabling broader institutional adoption. In medical applications, even small improvements in accuracy can have profound implications given the field's sensitivity to precision. Each percentage point of enhanced accuracy directly impacts the quality of diagnoses, treatment strategies, and patient education. Medical misinformation can lead to severe consequences, from compromised clinical decision-making to patient safety risks [48]. Therefore, Med-RISE's substantial improvements in both accuracy and reliability represent crucial advancements for deploying LLMs in health care settings.

Future Directions

Med-RISE demonstrates significant potential for advancing clinical practice through its robust framework for medical applications. Its effectiveness stems from 2 key components: real-time knowledge retrieval across medical disciplines enabling transparent responses and verification of accuracy and safety. This proven performance allows for Med-RISE's integration across various health care processes—from preconsultation screening and surgical consent to patient decision support, postoperative follow-up, disease consultation, and public health education. Our study also revealed that, while Med-RISE achieved improvements across all tested models, smaller-parameter models exhibited greater performance variability across different datasets, whereas larger models demonstrated more consistent gains. Future work may consider using larger models as the foundational framework to achieve more stable performance. Currently, Med-RISE achieves response times of 5 to 20 seconds through parallel retrieval processing (using 8 V100 GPUs of 32 GB each). For faster responses, performance can be enhanced through higher-performance GPUs, increased parallel processing, and improved network speeds.

Limitations

This study has several limitations. It adopted random subsets from each dataset, which may lead to performance variations and might not fully reflect the outcomes of a comprehensive analysis of the entire dataset. Furthermore, Med-RISE's impact on response time, computational requirements, and user experience remains to be explored. Future work should focus on expanding knowledge diversity and incorporating reinforcement learning methods such as proximal policy optimization [49] and direct preference optimization [50] to enhance Med-RISE's alignment with human values and preferences, further improving response quality. Comprehensive evaluations that include feedback from clinical users and health care professionals in real clinical settings will also be essential to validate the framework's effectiveness and refine its practical implementation.

Conclusions

In conclusion, Med-RISE enhances the clinical application of LLMs through its unique integration of real-time knowledge retrieval and safety verification mechanisms. By significantly improving accuracy, reducing hallucinations, and enabling transparent responses through knowledge-grounded generation, the framework ensures safer and more reliable medical information delivery across diverse medical scenarios. Med-RISE demonstrates strong potential for advancing health care applications from patient consultation to public health education while maintaining essential safety standards.

Acknowledgments

This study was supported by the National Natural Science Foundation of China (grants 82171034 and 81721003).

Data Availability

The code for the retrieval component of the Med-RISE framework is publicly available (Multimedia Appendix 1). A sample of the Med-RISE local database (n=500) is included in Multimedia Appendix 2. A subset of the EYE500 dataset (n=50) is provided in Multimedia Appendix 4. The revised PubMedQA dataset (PubMedQA—revised version; n=200) used in this study is available with open access in Multimedia Appendix 5. The full code and local database of Med-RISE in this study are available from the corresponding author on reasonable request.

Authors' Contributions

Dingqiao W, JY, and J Li contributed equally as the first authors. MG, FL, WD, and Y-FZ contributed equally as co-corresponding authors. MG, FL, WD, and Y-FZ contributed to conceptualization. Dingqiao W, JY, and J Li performed the methodology. The investigation was done by J Liang, QZ, QH, CP, Dongliang W, ZL, and WS. Dingqiao W, JY, and J Li wrote the original draft. MG, FL, WD, and Y-FZ handled the writing—review and editing. MG, FL, WD, and Y-FZ performed supervision. Final approval of the version to be published was done by all authors.

Abstract

Background: Case-based learning using standardized patients is a key method for teaching communication skills in medicine. Besides logistical and financial hurdles, standardized patients portrayed by actors cannot cover the complete diversity of sociodemographic factors of patients. Large language models (LLMs) show promise for creating scalable patient simulations and could probably cover a broader diversity of factors. They could also be integrated into the continuous training of future health care professionals' communication and interaction skills.

Objective: This study aimed to introduce the system architecture of a digital tool that leverages LLMs to simulate patient conversations for medical education, focusing specifically on medical history taking. Through an explorative analysis, we aimed to assess the tool's usability and examine differences between LLMs in simulating patient encounters.

Methods: We followed a user-centered design process, gathering initial requirements from 2 medical students. We then developed a fully functional web prototype using a Python Flask backend and a PostgreSQL database, integrating 5 LLMs from OpenAI, Anthropic, and xAI. The system includes an artificial intelligence–assisted case vignette generator and a dynamic patient simulator. For the explorative analysis of the prototype, we conducted a task-based usability test with 5 medical students, measuring their experience using the System Usability Scale (SUS) questionnaire and qualitative questions. We then conducted an explorative analysis in which 4 practicing physicians evaluated the simulation quality of 3 models (Grok 3, GPT-4, and Claude 3 Opus) across 7 criteria on a 5-point Likert scale.

Results: Usability testing yielded a mean SUS score of 91.5 (SD 8.40), indicating high perceived usability in a small formative sample. Students praised the system's simplicity and intuitive design but noted the absence of a formal conclusion and performance feedback, expressing a desire for a "didactic loop" to maximize learning. The models showed limitations in simulating uncertainties and memory lapses, responding to follow-up questions, and producing natural conversational flow. They perform well in simulating a coherent symptom profile, in using patient-like language, and in describing a realistic timeline and symptom progression. The differences among the models were not statistically significant. Ratings showed limited discriminative reliability (Kendall W=0-0.19, ie, very low) and a ceiling effect, with most scores clustered at 4-5, constraining interpretation; all group differences should therefore be viewed as exploratory.

Conclusions: We successfully developed a highly usable patient simulation tool that serves as a foundation for further development. Our results show that while the tool could be effective for communication training, its full potential will only be realized by integrating an automated feedback mechanism to create a complete didactic loop, as requested by the test users. Future work should assess in more depth the differences among the models in simulating psychosocial patient characteristics.

Introduction

Background

Effective communication between physicians and patients is an established core competency in medical education and practice. The demand for more patient-centered medical decision-making requires that the various needs of patients must be identified in conversations [1]. Nevertheless, current guidelines for doctor-patient communication show deficits in communication skills, especially in dealing with psychosocial factors and cultural diversity, which are increasingly shaping everyday clinical practice [2].

Case-based learning is a well-established pedagogical strategy in medical education, designed to foster students' clinical reasoning by engaging them with authentic patient scenarios [3]. Unlike didactic teaching methods, case-based learning promotes active, contextualized learning, encouraging students to analyze complex clinical situations and develop vital decision-making skills [4]. A cornerstone of case-based learning—particularly for practicing communication competencies—is the use of standardized patients. Traditionally, these standardized patients are represented by trained actors who take the role of patients with specific medical histories and personalities [5]. The simulated interactions offer students a safe, low-risk environment in which they can practice conducting patient interviews, make mistakes, and receive direct feedback—all of which have been shown to significantly enhance clinical communication skills [6].

A fundamental element in constructing realistic patient simulations is the clinical vignette—a concise, precise description of a hypothetical scenario [7]. In medical education, vignettes are commonly used to represent complex clinical situations, assess diagnostic reasoning, and evaluate students' decision-making [8]. For a vignette to serve as a solid foundation for patient simulation, it must encompass not only primary medical information, such as current symptoms and medical history, but also secondary factors that influence communication, including demographic details, health literacy, socioeconomic status, and personality traits [9].

Standardized patients have proven effective in teaching basic conversation techniques, but they have significant limitations. The availability and scalability of standardized patient programs are limited by high logistical and financial costs, standardization between different actors is difficult to ensure, and the authentic simulation of complex psychosocial contexts is only possible to a limited extent for logistical reasons (eg, foreign languages, involvement of children, or emotionally extremely stressful topics such as domestic violence). Technical simulation dolls are primarily suitable for training procedural skills but offer only limited possibilities for training complex communicative interactions that require emotional sensitivity and adaptive responses [10]. Digital technologies now offer promising alternatives. Recent advances in large language models (LLMs) have enabled the dynamic generation of text based on patterns learned from vast corpora, making it possible to simulate dialog-based patient interactions. Interaction with LLMs is facilitated through user and system prompts—carefully engineered instructions that ensure the model has all relevant information to perform the desired task accurately.

Related Work and Contribution

The importance of psychosocial factors influencing doctor-patient communication has increased significantly in recent years. Factors such as migration background, language barriers, socioeconomic status, and cultural differences can hinder communication, promote misunderstandings, and impair therapy adherence and equal health opportunities [11,12]. Research on institutional mistrust, which can arise from historical discrimination and negative experiences and has a lasting impact on the quality of treatment, is particularly relevant [13]. Experienced discrimination in a medical context is directly linked to increased skepticism toward health care institutions and reduced use of care [14,15]. Dealing with these psychosocial factors during patient-doctor interactions becomes more important in medical education. This work aims to create an interactive tool that can be used to train communication and interaction skills in this context.

The potential of LLMs for the simulation of standardized patients has recently been demonstrated by multiple studies. In medical training, Cook et al [16] demonstrated the viability of using GPT-4 (OpenAI) for simulating standardized patients, evaluated based on anthropomorphism, clinical accuracy, and adaptability. The researchers also showed that the LLM can score the quality of the medical assessment. Similarly, Cook et al [16] compared 2 models (GPT-4.0-Turbo and GPT-3.5-Turbo [OpenAI]) for patient simulation and demonstrated their capability of simulating dialogues, representing patient preferences, and providing personalized feedback. In a second, preliminary study, Cook [17] also performed patient simulation and limited testing using Claude (Anthropic), performing "exceptionally well." Öncü et al [18] applied GPT-4o (OpenAI) to create an environment for intern physicians to practice case-management skills. Borg et al [19] combined the LLM-based simulation (GPT-3.5-Turbo [OpenAI]) with social robotics, comparing this setup with a conventional, computer-based simulation for fostering clinical reasoning skills in medical students. The mixed methods study showed that 15 students perceived the LLM-enhanced variant as more authentic and providing a beneficial overall learning effect. Targeting nursing education, Benfatah et al [20] showed that a small sample of 12 nursing students embraced the LLM-based interaction and recognized its value in training.

LLMs have not only demonstrated their potential to simulate virtual patients but also seem capable of generating the underlying clinical vignettes efficiently. For example, Coskun et al [21] conducted a randomized, controlled experiment for vignette generation using ChatGPT-3.5 (OpenAI) and showed that the quality of vignettes is comparable to those created by human authors. Another 2 studies demonstrate the vignette generation capability of LLMs for Japanese specifically [22,23].

We can recognize that LLM-based vignette generation and virtual patient simulation have recently received increased attention in medical informatics research. However, previous research seems to focus on each task separately (ie, vignette generation, patient simulation). Furthermore, none of the studies

mentioned above applied a user-centered development approach but rather performed experiments measuring the capability of the LLM-based simulation. Therefore, none of the studies focused on the integration of a simulation tool into existing learning processes of medical students. For example, Cook [17] used a simple, text-only Python interface.

We furthermore note that most of the studies were conducted using commercial models provided by OpenAI and do not include a comparison to other providers or models except Cook [17], who conducted limited testing with Claude (Anthropic).

Goals of the Study

Existing LLM applications in the medical education context focus primarily on medical content or general communication scenarios and neglect the systematic integration of psychosocial contexts. With this paper, we want to introduce a digital tool that leverages LLMs to simulate patient conversations based on clinical case vignettes that can be used for medical education purposes. In contrast to other patient simulators, we want to integrate the psychosocial context and offer the opportunity to train communication with patients with varying psychosocial contexts. To support the generation of case vignettes, we propose a human-in-the-loop approach consisting of a comprehensive case template and a vignette generator. In this paper, we describe the user-centered design process, the technical implementation of the tool, and the first results from usability testing. Furthermore, our goal is to study differences of LLMs in simulating patients based on case vignettes in an exploratory study. The simulation tool focuses specifically on the process of collecting the medical history.

Methods

Requirement Collection

The system development followed principles of user-centered design. Medical students, who are the targeted user group, were involved in the requirement collection process and in the usability testing. Explorative model evaluation involved medical doctors.

The initial system requirements were identified through a literature analysis and qualitative interviews with medical students as prospective end users. A total of 2 third-year medical students participated in the interviews (2/9 contacted), recruited from the social network of the authors. Both were in the 6th semester of their studies of medicine. To accelerate data collection and focus on the discussion, early functional prototypes were presented to the participants as a basis for discussion. The requirements were qualitatively analyzed and prioritized based on their perceived relevance as indicated by the students, with specific focus on the usefulness for learning clinical communication skills. This process yielded the following key functional requirements:

1. Vignette management: the system must provide a wide range of patient cases, ideally sortable by medical specialty and year of study.
2. Organization: case vignettes should be organized using a folder system inspired by familiar learning platforms.
3. Artificial intelligence (AI)–based simulation: patient simulations should be powered by generative AI to enable unpredictable and realistic dialogues.
4. Interaction design: the simulated patient should not reveal information directly but instead respond only to targeted inquiries, encouraging natural conversation flow.

Template for Case Vignettes

Building on the work of Reichenpfader and Denecke [9], a highly structured vignette template was developed to ensure realistic and diverse patient representations. Each vignette is technically stored as a JSON object within a JSONB field in the PostgreSQL (version 17; PostgreSQL Global Development Group) database. The structure is defined in the Python (version 3.11.9; Python Software Foundation) backend, which dynamically generates the user interface for vignette creation. The template comprises four main categories: (1) demographics, includes name, age, gender, occupation, and educational background; (2) medical history covers current symptoms, preexisting conditions, medications, allergies, and family history; (3) personality and communication describes health literacy, communication style, personality traits, and emotional state; and (4) social factors capture social support systems, socioeconomic status, cultural background, and language proficiency.

To facilitate thematic organization of the generated vignettes, the classification system of the Canadian Emergency Department Information System (CEDIS) Working Group [24] was implemented. Its suitability for use in medical education was confirmed by the participating students during the requirement analysis phase. Example vignettes can be found in Multimedia Appendix 1.

System Architecture

Overview

Our fully functional, web-based prototype for LLM-supported patient simulation includes the following core components: (1) AI-assisted case vignette generator—users can create vignettes manually by specifying values in a structured vignette form or have a complete vignette generated by interacting with an LLM using a “meta-prompt.” All vignettes can be organized in a folder structure (Figure 1). (2) Dynamic patient simulator—users can select a vignette and conduct a medical history gathering with a simulated patient (Figure 2).

Figure 1. Library of case vignettes. Each vignette is represented by a rectangle. Filtering along Canadian Emergency Department Information System categories is possible.

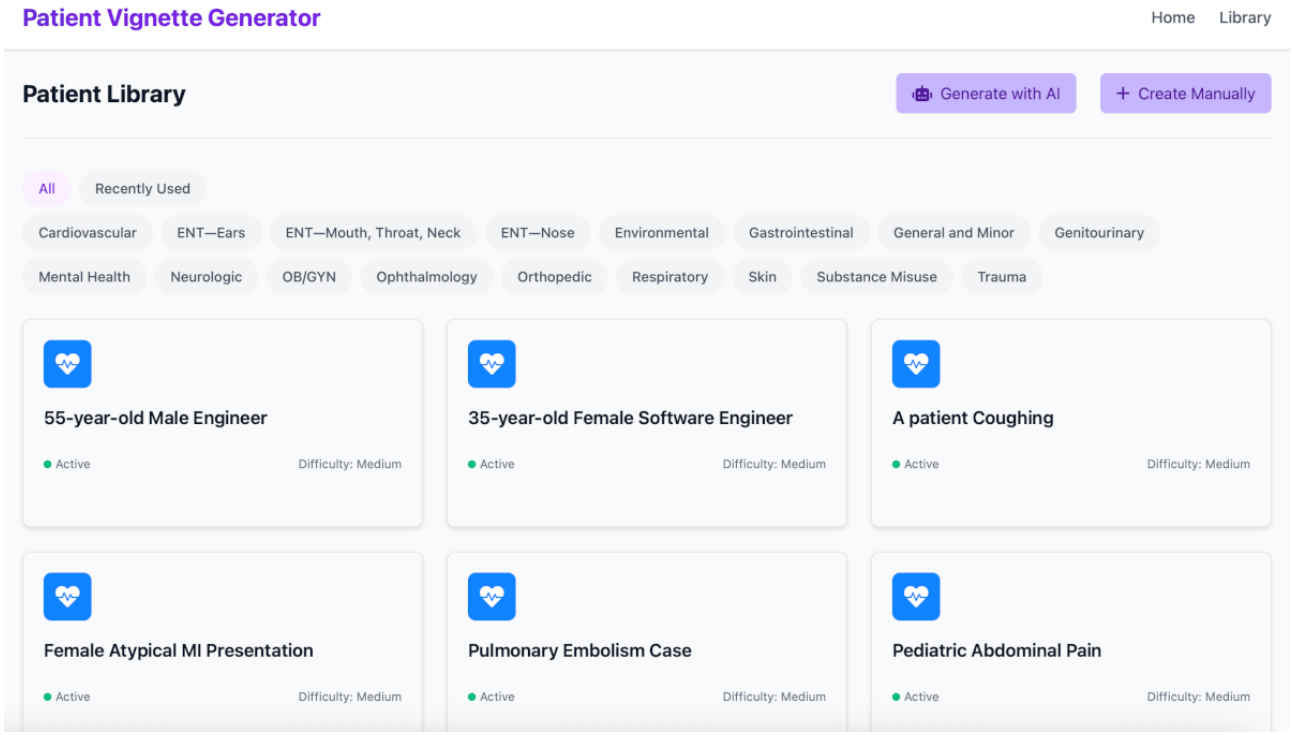

Figure 2. User interface for the interactive simulation tool. On the left, patient information is shown, together with the selected model and suggested questions as guidance for the interaction. On the right, the simulation chat is shown.

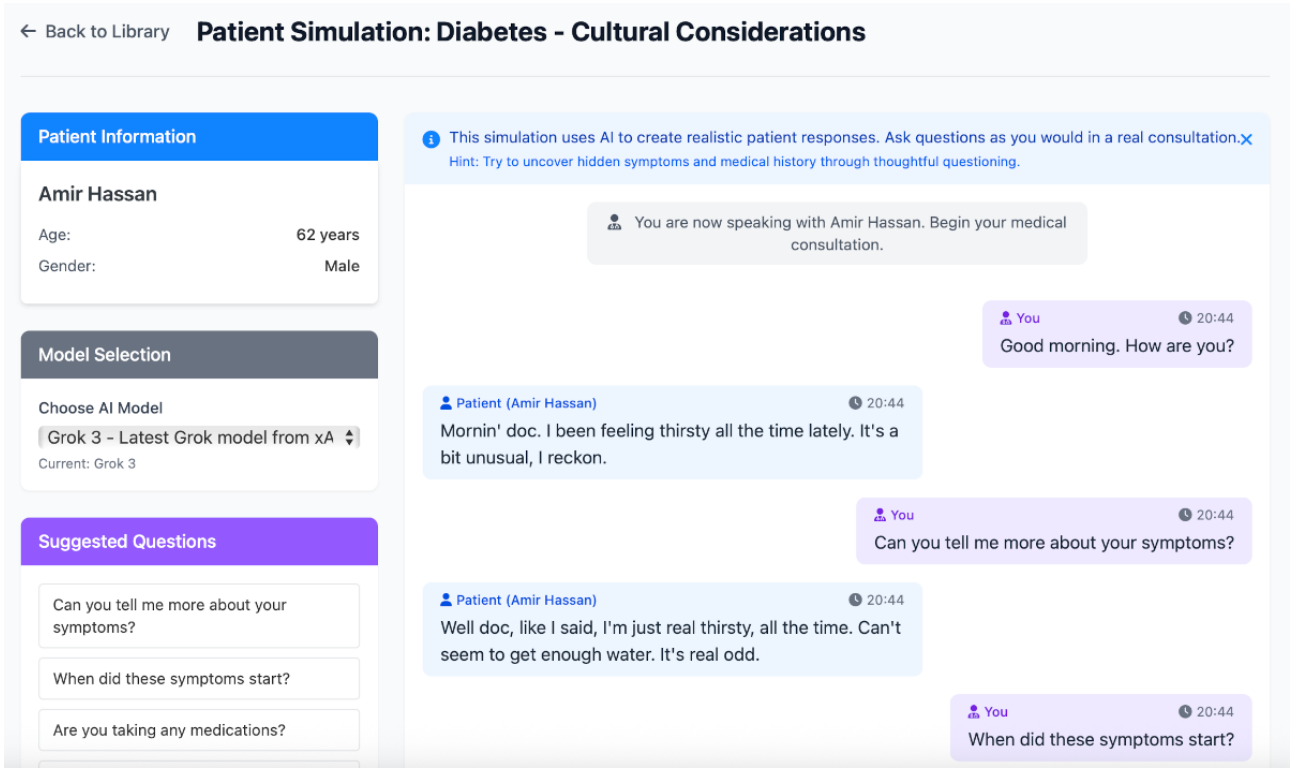
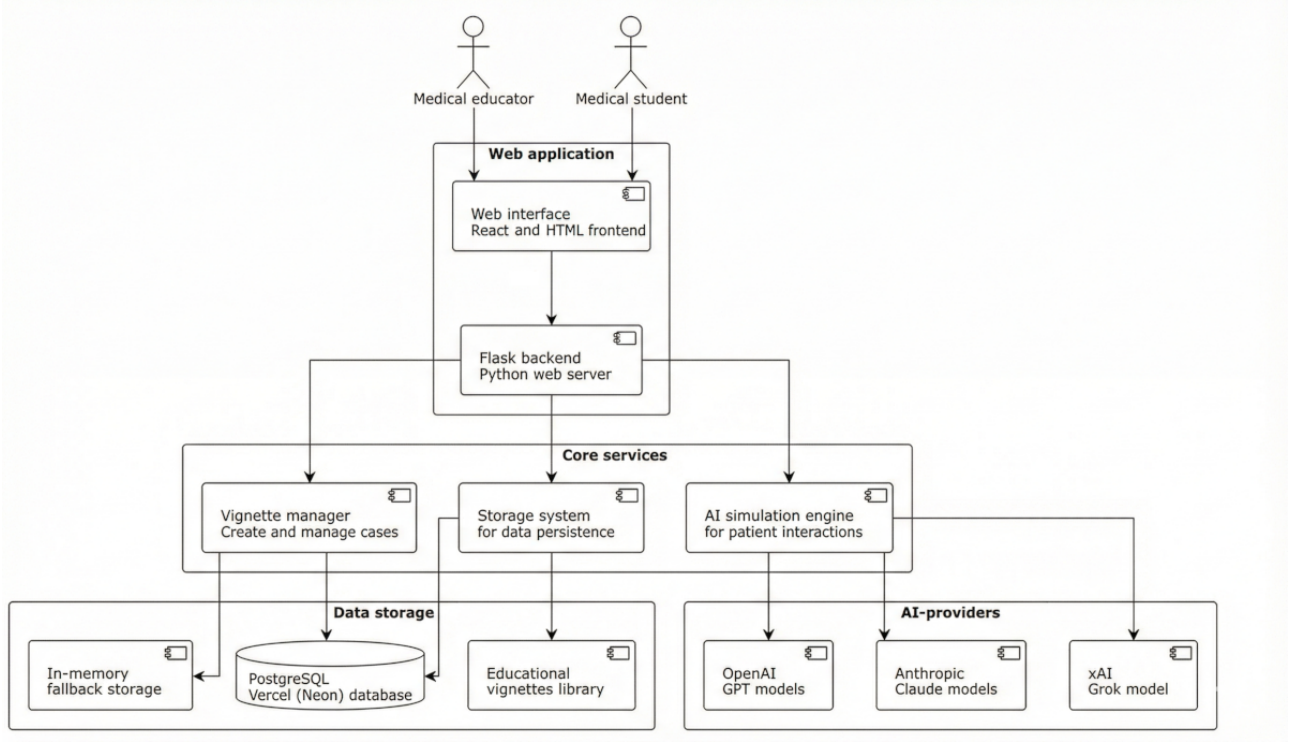


Access to the current version of the prototype will be provided upon request.

The system is implemented using a multilevel client-server architecture (Figure 3). Users interact with a web application consisting of a reactive frontend and a backend built with Flask in Python. The backend orchestrates several core services—a vignette management system for handling case definitions, a storage layer for data persistence, and an AI simulation engine that encapsulates communication with external AI services (OpenAI, Anthropic, xAI). The following technologies were used for implementing the prototype:

Figure 3. System architecture showing the users, the web application, the core components, data storage, and external artificial intelligence (AI) services.



1. Backend: Python (version 3.11.9) with the lightweight web framework Flask (version 3.0.2). Database access is abstracted via SQLAlchemy (version 2.0.41).
2. Database: PostgreSQL (version 17) was chosen for reliable and scalable data management.
3. Frontend: the user interface is implemented using standard web technologies (HTML5, CSS3).
4. Deployment: the application is deployed via the Vercel platform [25].

To ensure technological breadth and flexibility, the prototype developed in this work integrates 5 LLMs from 3 leading AI providers. These include GPT-4 and GPT-3.5-Turbo by OpenAI, Claude 3 Opus and Claude 3 Sonnet by Anthropic, and Grok 3 by xAI.

In the following, we provide more details on the two components.

AI-Assisted Case Vignette Generator

This component enables the generation of case vignettes using an LLM. It constructs a prompt that instructs an LLM to assume the role of a medical education expert and to output a case vignette in a predefined JSON format. The implementation incorporates multiple technical elements:

1. Strict output format: the prompt enforces a rigid JSON schema, including a naming convention of the form "[age]-year-old [gender] [occupation]," explicitly excluding any medical diagnoses.
2. Medical categorization: the LLM is provided with 17 predefined categories from the CEDIS. Internally, these are enriched with priority levels (CEDIS_PRIORITY) and icon mappings (CEDIS_ICONS) used for the visual representation of vignettes.
3. Clinical accuracy: the prompt includes explicit instructions to ensure realistic clinical content, such as appropriate medications, relevant comorbidities, and age-appropriate conditions.

The response from the LLM is processed by a parsing function, which uses boundary detection to extract the JSON object and validate the required fields. The generated tags are cross-checked against existing categories in the database. In case of generation failure, a fallback mechanism uses regex-based extraction to create a minimal vignette. An example LLM prompt with a generated case vignette is provided in Multimedia Appendix 2.

Dynamic Patient Simulator

The dynamic patient simulator produces highly personalized prompts for simulating realistic patient dialogues. At the core of the prompts is a strict role instruction, reinforced multiple times, ensuring that the LLM remains consistently in character as the patient: "You must stay in the character of the patient at all times. Never break character."

A key mechanism for realistic medical history taking is gradual symptom disclosure. The prompt explicitly instructs the LLM to reveal information incrementally. This is technically implemented through the hierarchical structuring of symptoms into primary and secondary groups, where secondary information may only be disclosed upon several conversation turns.

Patient behavior is dynamically modeled based on case vignette data through the following mechanisms:

1. Language modeling: the language complexity is adapted to the patient's health literacy and educational background. Patient simulations with lower literacy levels are instructed to use everyday language, analogies, and occasional

grammatical errors, while those with higher competence may use appropriate medical terminology.

2. Personality modeling: 12 predefined personality traits (eg, anxious, stoic) are mapped to specific behavioral instructions. For example, an anxious patient is guided to frequently seek reassurance, while a stoic one is prompted to minimize or downplay symptoms. These traits may interact to produce nuanced behaviors.
3. Anxiety-level integration: a numeric anxiety score (1-5) is translated into detailed behavioral descriptions ranging from "very calm and composed" to "extremely anxious and distressed."

To implement this behavioral control, advanced prompt engineering techniques are used, including negative instructions (eg, "NEVER reveal all symptoms at once") and few-shot learning. The latter is realized through the inclusion of concrete dialogue examples within the prompt to guide the model toward the desired conversational style [26-28]. An example prompt generated from a case vignette is provided in Multimedia Appendix 1.

System Evaluation

Formative Usability Test

To get feedback on the prototype and to identify aspects for improvement, we conducted a formative task-based usability test. It was conducted with 5 medical students; 1 student was in the 12th semester, 2 were in the 10th semester, and 2 were in the 6th semester. Participants were asked to complete 4 standardized tasks that cover the core functionalities of the application: manual vignette creation, AI-assisted vignette generation, organizing vignettes using folders, and conducting a patient simulation.

To quantitatively assess usability, the standardized System Usability Scale (SUS) was used [29]. Following the usability test, the participants were asked to answer a questionnaire with open questions about their user experience, specific strengths, weaknesses, and suggestions for improvement. These qualitative data were analyzed using a thematic analysis conducted by 1 coauthor.

Exploratory Language Model Comparison

Following the usability evaluation, a comparative analysis was conducted to assess the performance and differences of different LLMs in simulating patients based on case vignettes. The aim of this evaluation was to determine which model produces the most realistic and coherent patient simulations for medical history taking. A quantitative approach was applied. The participants consisted of 4 practicing physicians from the Department of Infectious Diseases at the University Hospital Basel, who served as domain experts. The group consists of 2 senior physicians and 2 assistant doctors, all aged 30 years or older, with an equal gender distribution (2 men and 2 women). Each expert conducted 3 simulated history-taking interviews using the same set of case vignettes, with each simulation powered by a different LLM. The evaluation was carried out using the developed web application. The evaluation cases were selected considering their clinical relevance to the participating physicians:

- Case 1: community-acquired pneumonia
- Case 2: complicated urinary tract infection
- Case 3: cellulitis in a diabetic patient

For the comparative evaluation of simulation quality, a targeted selection of models was made (GPT-4, Claude 3 Opus, and Grok 3). This selection represents a cross-section of state-of-the-art generative language models (in May 2025) and was intended to capture a range of capabilities in natural language understanding and dialogue generation relevant to realistic patient simulations.

A custom questionnaire was developed to rate the simulation quality across 7 criteria, using a 5-point Likert scale (ranging from "Strongly disagree" to "Strongly agree"). The evaluated criteria were (1) coherence of the symptom profile, (2) natural conversational flow, (3) patient-like language, (4) responsiveness to follow-up questions, (5) realistic emotional expression, (6) realistic uncertainty and conversational lapses, and (7) plausible time and symptom progression.

Participants received detailed written instructions. For each of the 3 cases, they were asked to launch the corresponding simulation, select the assigned LLM, and conduct a 2-5-minute history-taking interview in their preferred language. Immediately after each simulation, they completed the corresponding evaluation form. It is important to notice that each LLM was tested with a single case vignette, chosen to minimize expert workload. Neither the selected model nor the case was blinded to the participants.

Data were analyzed using Python 3 with SciPy and scikit-posthocs libraries. Normality was assessed using Shapiro-Wilk tests; given violations of normality assumptions (all $P<.001$), nonparametric procedures were used. The primary analysis used the Friedman test to compare ratings across the 3 models, accounting for the repeated-measures design. Post hoc pairwise comparisons used Wilcoxon signed-rank tests with Holm-Bonferroni sequential correction ($k=3$ comparisons, family-wise $\alpha=.05$) and Cliff δ for pairwise comparisons. Interrater reliability was assessed using the Kendall coefficient of concordance (W).

Ethical Considerations

All participants provided informed consent to take part in the study, agreeing to the anonymized analysis and publication of their responses. The study focused on quality assurance and usability evaluation of a patient simulator prototype and did not involve patient data or interventions. Accordingly, formal ethics committee approval was not required in accordance with institutional and national guidelines [30]. None of the participants received any compensation for their participation in the study.

Results

Results From Usability Testing

The analysis of the SUS assessment was performed using an online calculator. The individual SUS scores from the 5 participants were 82.5, 82.5, 95.0, 97.5, and 100. Based on these values, the mean SUS score was calculated as 91.5 (SD 8.4).

According to established benchmarks, a SUS score above 90 is generally considered "excellent" usability, in our case, high perceived usability in a small formative sample [31]. A post hoc analysis of the sample size was conducted based on the observed variability in SUS scores. With 5 participants (mean SUS score 91.5, SD 8.40), the 95% CI for the mean SUS score was 81.1-101.9, corresponding to a margin of error of ±10.4 points. While the sample size offers limited precision, this degree of uncertainty is acceptable for a formative usability evaluation, the objective of which is to identify significant usability issues rather than to achieve high statistical accuracy.

The thematic analysis of the open questions revealed consistent subject areas. The simplicity and intuitive usability of the system were unanimously cited as key strengths. The participants described the navigation as clear and well-organized and positively emphasized the appealing, simple visual design. There was a consensus that interaction with the system could be learned very quickly and without significant training.

At the same time, clear potential for improvement was identified. The most frequently mentioned point of criticism was the lack of a formal conclusion after the simulation. The students wanted feedback on their interaction, which is currently not provided, and a summary of the case in order to maximize the learning effect. One tester, who is about to graduate, noted that "only the case history is not enough" for them to use the tool regularly and therefore rated the application as "rather not" helpful for their studies. Furthermore, ideas for future extensions were mentioned, such as a note field or the integration of laboratory values.

Statistical Analysis of Model Comparison

Experimental Design

A within-participants experimental design was used to evaluate the performance of 3 LLMs (Grok 3, GPT-4, and Claude 3 Opus). Four independent raters (R1-R4, health professionals) assessed each model across 3 distinct use cases, answering 7 evaluation questions (Q1-Q7) for each case. Each rater evaluated all 3 models, with one model assigned to each case. This resulted in a balanced design with 84 total observations (N=84). Responses were recorded on a 5-point Likert scale (1=lowest; 5=highest), though the observed range was restricted to 2-5, with no ratings of 1 recorded.

Descriptive Statistics

The quantitative evaluation by 4 health professionals provided the differences in the LLM results as shown in Table 1 and Figure 4. Ratings showed limited discriminative reliability with an intraclass correlation coefficient (2, 1) of 0.165, and a pronounced ceiling effect, with most scores clustered between 4 and 5, constraining interpretation. Accordingly, all group differences should therefore be viewed as exploratory. For the 3 criteria, bigger differences in ratings can be recognized. We can see that Grok 3 and Claude 3 Opus performed better regarding realistic uncertainties and memory lapses than GPT-4. Regarding responsiveness to follow-up questions and natural conversation flow, Grok 3 was less good than the other two LLMs.

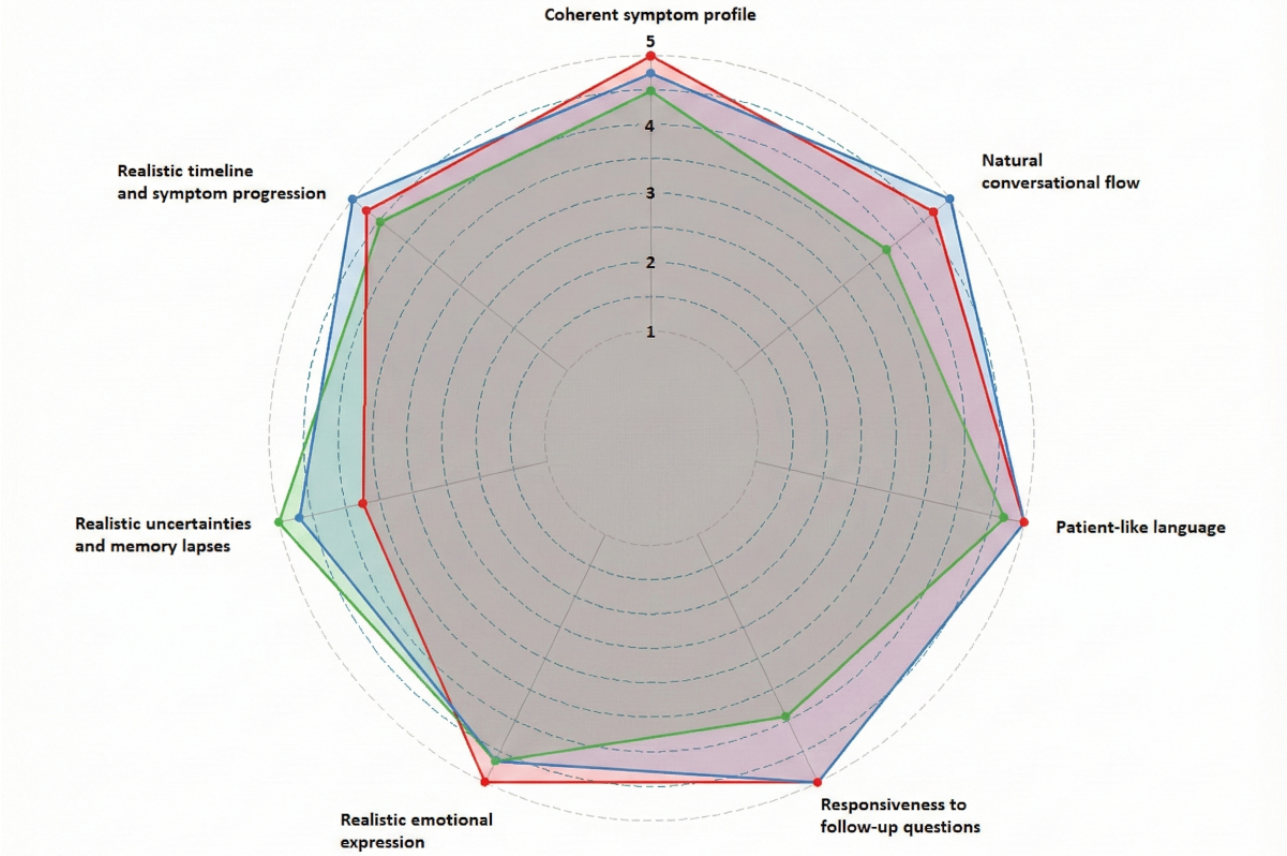
Table 1. Comparison of language models' quality assessed by clinical experts (n=4; scale 1 "totally disagree" to 5 "totally agree").

Evaluation criterion	Grok 3, mean (minimum-maximum)	GPT-4, mean (minimum-maximum)	Claude 3 Opus, mean (minimum-maximum)
The symptom profile described by the simulated patient is coherent.	4.5 (4-5)	4.75 (4-5)	4.25 (3-5)
The simulated patient describes the symptom presentation in language typical of real patients.	4.25 (4-5)	4.25 (4-5)	4.0 (2-5)
The simulated patient can describe realistic timelines and symptom progression.	4.75 (4-5)	4.5 (4-5)	4.25 (4-5)
The simulated patient displays realistic uncertainties and memory lapses.	3.75 (3-5)	3.0 (2-4)	4.0 (3-5)
The emotions portrayed appear realistic in the context of the simulated situation (medical history taking).	3.5 (3-4)	3.75 (3-4)	3.5 (2-5)
The flow and pace of the conversation appear natural.	4.25 (3-5)	4.0 (3-5)	3.25 (2-4)
The simulated patient responds appropriately to targeted follow-up questions.	4.75 (4-5)	4.75 (4-5)	3.75 (2-5)

Grok 3 demonstrated strengths in depicting realistic timelines and symptom progression, as well as in providing appropriate responses to follow-up questions (both mean scores 4.75, SD 0.5). Its lowest score was observed in the portrayal of realistic emotions (mean 3.5, SD 0.58).

GPT-4's primary strength was the coherence of the symptom presentation (mean 4.75, SD 0.5), outperforming the other 2 models in this category. It also matched Grok 3 in its ability to respond appropriately to follow-up questions (mean 4.75, SD 0.5). However, GPT-4 showed the weakest performance in conveying realistic uncertainties and memory lapses (mean 3.0, SD 0.82).

Figure 4. Strengths and weaknesses of 3 large language models (LLMs) for simulating patients. Colors refer to the different LLMs: green=Grok 3, red=GPT-4, and blue=Claude 3 Opus.



Claude 3 Opus exhibited the greatest variance in its ratings. The lowest scores of this model were found in the categories of natural conversation flow (mean 3.25, SD 0.96) and the portrayal of realistic emotions (mean 3.5, SD 1.0). Notably, the use of language typical of real patients (mean 4, SD 1.41) and the ability to respond appropriately to follow-up questions (mean 3.75, SD 1.26) showed the highest variability in responses. Figure 4 shows the comparison of the 7 evaluation criteria and the 3 language models in a spider chart.

A Friedman test was conducted to evaluate differences in ratings across repeated measures (raters and questions) among the 3 models (Table 2). None achieved statistical significance at the α=.05 level (all *P* values of >.14). The analysis revealed no statistically significant differences in performance between the models (χ^2_2=2.086; *P*=.45). Kendall coefficients of concordance (W values) are small (≈0-0.19), and the CIs are wide, so the degree of agreement on model rankings is very uncertain, suggesting that there are minimal practical differences in the performance of the models.

Table 2. Model comparison using Friedman tests per question: chi-square value, *P* value, and Kendall coefficient of concordance (W) with a bootstrap 95% CI to indicate agreement on model ranking.

Question	Chi-square (*df*)	*P* value	Kendall W (95% CI)
Q1	3.00 (2)	.22	0.14 (0.00-0.61)
Q2	0.00 (2)	>.99	0.00 (0.00-0.42)
Q3	3.00 (2)	.22	0.14 (0.00-0.61)
Q4	3.00 (2)	.22	0.14 (0.00-0.61)
Q5	0.67 (2)	.72	0.05 (0.00-0.61)
Q6	0.93 (2)	.63	0.11 (0.00-0.81)
Q7	4.00 (2)	.14	0.19 (0.00-0.75)

Interrater Comparison

Examination of rater-specific statistics revealed considerable heterogeneity in rating patterns. R1 exhibited the most lenient rating tendency (mean 4.524, SD 0.794), while R2 demonstrated the strictest ratings (mean 3.762, SD 1.064), exhibiting the greatest variability. Notably, R2's mean rating for Claude 3 Opus (mean 2.714, SD 0.881) was substantially lower than the ratings given by the other evaluators, which suggests either rater bias or a divergent interpretation of the evaluation criteria. R4

displayed the most consistent rating pattern, only rating with 3 or 4; however, this consistency may reflect restricted range use rather than genuine reliability.

Interrater reliability was assessed using the Kendall coefficient of concordance (W) across raters. Specifically, we thereby assessed how consistently they rank the 3 models. We used a bootstrap over raters (resampling columns with replacement) for percentile 95% CIs. Results are shown in Table 3. Values for Kendall W are all very low (0-0.19), showing at best a weak agreement. CIs start at 0 and extend up to 0.6, reflecting extreme imprecision.

Table 3. Interrater agreement per question, reported as the Kendall coefficient of concordance (W) across raters.

Question	Kendall W (95% CI)
Q1	0.141 (0-0.609)
Q2	0.000 (0-0.422)
Q3	0.141 (0-0.609)
Q4	0.141 (0-0.609)
Q5	0.047 (0-0.609)
Q6	0.109 (0-0.812)
Q7	0.188 (0-0.750)

Effect Size Analysis

Table 4 presents the results of the post hoc pairwise comparisons. We treated the data as within-rater and used a cluster bootstrap over raters to get a 95% CI percentile for Cliff δ. We calculated Cliff δ pooled across all 7 questions. None of the 3 pairwise comparisons achieved statistical significance after Holm-Bonferroni correction. The comparison between Claude 3 Opus and Grok 3 approached but did not reach significance (W=30.00; *P*=.07; Holm α=0.017), with a medium effect size (*r*=0.322). The comparison between Claude 3 Opus and GPT-4 showed a small effect (W=31.50; *P*=.18; *r*=0.249), while the comparison between GPT-4 and Grok 3 demonstrated a negligible effect (W=22.50; *P*=.59; *r*=0.096). In practice, the signed-rank statistics are very small because there are only 4 paired observations per contrast. With 4 raters, there is no robust evidence that any model consistently outperforms another on any single criterion. The data are descriptive rather than confirmatory.

Table 4. Results for post hoc Wilcoxon signed-rank tests, Holm-corrected for multiple comparisons.

Comparison	n	W statistic	*P* value	*z* score	Effect size (*r*)	Mean difference	Holm α	Cliff's δ (95% CI)
Claude 3 Opus vs Grok 3	28	30	.07	–1.704	0.322	–0.393	0.017	–0.21 (–0.591 to 0.059)
Claude 3 Opus vs GPT-4	28	31.5	.18	–1.318	0.249	–0.286	0.025	–0.15 (–0.128 to 0.556)
GPT-4 vs Grok 3	28	22.5	.59	–0.509	0.096	–0.108	0.05	–0.07 (–0.184 to 0.128)

Discussion

Principal Findings

This paper presents a training system for medical students to train interaction with diverse patient populations using LLMs and generating vignettes for case-based learning. The evaluation shows good usability and provides first insights into the differences of LLMs when simulating patients and their characteristics.

Usability and User Experience

The SUS results from 5 participants provide an initial indication that the tool may fulfill its core requirements for simplicity, efficiency, and appeal. The technical implementation can thus be deemed a success and forms a robust foundation for further development. However, good usability alone does not suffice to create an effective medical learning instrument. Qualitative responses highlighted a crucial shortcoming, that is, the repeated wish for a "didactic loop"—a cycle of history taking, diagnostic feedback, and case summary—was identified as an important finding in the qualitative evaluation. Without this step, the application remains primarily a tool for communication training, leaving its full potential for fostering clinical reasoning and diagnostic skills untapped. Such a feedback mechanism is considered critical for sustainable learning and repeated use. Traditionally, simulated patients are not only tasked with portraying a case but also with providing structured feedback to learners. This complex requirement—involving both role-play and performance evaluation—necessitates extensions to our simulator. An additional extension would be to consider the guidelines and communication strategies taught in medical education and to assess whether the students apply them in their interactions.

The feasibility and validity of an AI-based feedback system were demonstrated by Holderried et al [32], who showed that a GPT-4–powered chatbot could generate patient simulations and provide automated feedback, which closely matched expert human evaluations (Cohen κ=0.832). Their approach—using a dedicated "feedback prompt" to analyze the dialogue—directly aligns with the development pathway proposed in this work. This feedback capability of LLMs was also demonstrated by Cook et al [16] using GPT-3.5-Turbo.

Quality of AI-Generated Simulations and LLM Comparison

This analysis provides no evidence for statistically significant differences in performance among the 3 evaluated LLMs. Our findings should be interpreted in light of the limited discriminative signal in the rating data, reflected by very low interrater reliability and a strong ceiling effect (67/84, 81% of all ratings at 4-5). This reflects clearly the small rater panel. Accordingly, the comparative results are exploratory and underpowered and are offered as preliminary indications rather than definitive effects.

Overall, results show the general suitability of the tool, as all tested models were able to generate plausible, realistic patient roles useful for practicing history taking, with each statement rated between "Neutral" (3 points) and "Strongly agree" (5 points), and no ratings of "Strongly disagree" (1 point). These findings echo previous studies, which have also found that current LLMs can create clinical vignettes with high linguistic and medical accuracy, though expert revision is often required. For instance, Yanagita et al [23] found 97% of LLM-generated vignettes usable with minor modifications, while Takahashi et al [22] noted considerable potential for ChatGPT-4–generated cases in medical education, but with room for improvement in realism. Our system differs from such approaches, as we are suggesting a human-in-the-loop approach for vignette generation, providing 2 options—specifying all characteristics manually using the vignette template or using AI-support.

All models scored highest for symptom coherence and realistic timelines. Statements assessing the realism of the dialogue itself, however, received lower scores. This suggests that the models were better at maintaining factual accuracy than at simulating natural role play. The most significant difference between Grok 3 and GPT-4 was in their portrayal of realistic uncertainty (Figure 4). Although GPT-4 performed strongly overall and achieved the highest scores for symptom coherence and emotional realism, it struggled to depict realistic uncertainty—a key component of authentic medical interviews. By contrast, Claude 3 Opus received the lowest scores in most categories but performed best in conveying uncertainty. Grok 3 performed particularly well in core medical content, coherent symptom simulation, and realistic timeline generation. GPT-4 and Grok 3 demonstrated similar abilities when addressing follow-up questions, whereas Claude 3 Opus fell behind, particularly in terms of maintaining conversational flow and using language typical of patients. Claude 3 Opus also exhibited the greatest variability in expert ratings, particularly with regard to patient language, follow-up responses, and emotional realism. Furthermore, it was the only model to insert stage directions into the dialogue, which some users found distracting while others valued the added nonverbal context. These differences have to be considered with care, as each model was tested with a different case example, and the differences may also be due to the different sociodemographic characteristics of the simulated patients. Because of the small expert panel to judge the models, we cannot recommend any model as the primary model for medical patient simulations. Evaluations involving a larger number of raters are required to confirm these initial findings. Future improvements should also focus on prompting the models to simulate authentic human emotional expression and memory lapses, as these aspects are essential for the realism of clinical interviews.

In this study, we did not assess whether the answers from the simulated patient are realistic. A previous study showed that the answers of the simulated patient are correct, but the study was limited in size [9]. In principle, having an incomplete or even wrong answer from a simulated patient could be considered a realistic case, as in the real world, patients will not disclose everything and can share wrong information as well. This adds an additional dimension to the training scenario. In future work, we will study whether the correctness can be ensured and whether specific learning cases can be developed that allow training skills of diagnosing and medical history taking when patients are not honest or are incomplete in their answers.

Educational Use Cases and Implications

As exemplified, we describe 2 educational use cases of the patient simulator. The first use case concerns the dynamic and authentic patient simulation integrating psychosocial complexity. In this use case, the simulator supports learning the patient-doctor interaction, given the psychosocial complexity of patients. Besides medical symptoms, the simulator uses a variety of contextual factors in the simulated interaction, including language barriers, family-related stressors, cultural sensitivities, and varying levels of trust or mistrust in the health care system. By integrating these dimensions, learners can experience and learn to overcome communication difficulties that often arise when treating diverse patient populations. For example, a patient with limited health literacy may misinterpret medical terminology, while a patient from a different cultural background may express distress indirectly or be reluctant to share personal information due to systemic mistrust.

A second use case focuses on training young surgeons to hold informed consent discussions with patients before surgical procedures. Such discussions are crucial for ensuring ethical and legally sound medical practice, as well as fostering patient trust and facilitating shared decision-making. However, novice clinicians often feel uncertain about communicating complex medical information, addressing patient fears, or managing emotional reactions under time pressure. For this use case, the simulator provides an authentic, dialogic environment in which students or young surgeons can practice and refine their communication strategies during simulated preoperative consultations. The AI-driven patient responds dynamically based on the learner's explanations, empathy, and ability to balance technical accuracy with clarity and reassurance. This approach aligns with the principles of deliberate practice and experiential learning, emphasizing repeated, feedback-oriented engagement with realistic scenarios to achieve competence.

By interacting with the AI-based patient simulator, students will acquire domain-specific communication skills and develop a deeper understanding of the opportunities and limitations of AI in professional contexts. The simulated encounters provide an environment in which learners must navigate complex psychosocial dynamics, such as language barriers, family stressors, and mistrust of the health care system, requiring a high degree of empathy, cultural sensitivity, and adaptive

communication strategies. Although promising, the use of a simulator within student education raises some ethical challenges. Among them is a risk for overreliance on scripted behavior, as LLM behavior might be predictable, and students miss learning to deal with unpredictable behavior. Biases can be amplified when the personality modeling is not diverse. Further, students need to understand that the simulator is a training aid, not a real patient interaction.

For educators, the system opens up new possibilities for integrating innovative AI tools into medical education in a meaningful way from a pedagogical perspective. It supports the expansion of teaching practice through technology-enhanced learning approaches, enabling instructors to design more personalized, reflective, and data-driven learning experiences.

At a broader societal level, the use of such a simulator addresses the urgent need to improve health care by facilitating more effective communication between physicians and patients from diverse backgrounds. By explicitly incorporating psychosocial factors such as language barriers, cultural differences, and institutional mistrust, the system helps to foster equity and inclusion in medical education, and ultimately in patient care.

Limitations

Several methodological limitations must be considered when interpreting the results. The LLM evaluation was conducted with only 4 infectious disease experts, with low interrater reliability, limiting the statistical generalizability of the findings. In addition to these constraints, the study is statistically underpowered for detecting small or moderate differences between models. We used a frequentist analytic framework to generate CIs for the expert ratings; however, given the limited sample size, these intervals should be understood as descriptive indicators of uncertainty rather than tools for confirmatory inference. In other words, the frequentist estimates do not support strong population-level claims but instead provide a bounded range of plausible effect sizes based on the observed data. This aligns with the formative nature of the study. The statistical outputs offer preliminary signals to guide future, adequately powered evaluations rather than serving as evidence of definitive model differences. Because each model was tested on a single vignette and models were not counterbalanced across cases, the observed differences may also be due to the cases rather than model performance.

Only 2 students in their 6th semester contributed to the requirement collection process. Although attempted, it was not possible to gain the interest of additional students for this phase. The requirements were extended by information from scientific literature. It would be beneficial to get additional input from medical educators. Similarly, usability testing involved only 5 medical students, excluding the perspective of teachers in medical education who would use the tool for creating vignettes for teaching purposes. The raters were not specifically trained, which could have led to varying interpretations of the items of the Likert scale.

Each LLM was tested with a single case vignette, chosen to minimize expert workload but potentially limiting the assessment's breadth. The analysis was also confined to 3 proprietary, closed-source models, without including open-source alternatives—reflecting a gap that future research should address. Further, the case and LLM were not blinded to the expert raters. This may have introduced bias, as they were able to see the name of the model they were interacting with.

The survey instrument used for expert evaluation was newly developed for this study and had not been previously validated or piloted, representing a challenge common to this research field, as described by Yanagita et al [23]. They therefore analyzed subjective expert opinions descriptively without mean comparisons. The usability test focused on learners' perspectives without structured instructional units.

Subsequent studies should include a comprehensive evaluation with medical educators to validate the system's suitability as a patient simulation tool. Larger numbers of raters and randomized model assignments to different vignettes would address current methodological limitations. A longitudinal study measuring actual learning outcomes in students who regularly train with the system, compared to a control group, would be necessary to empirically demonstrate didactic effectiveness.

Future Work

In summary, this work successfully addresses the challenge of developing a highly usable simulation frontend and demonstrates the potential of LLMs as patient simulation tools. At the same time, it clearly outlines the necessary steps required to transform the tool into a comprehensive educational instrument. The most urgent improvement is the integration of an automated feedback mechanism that analyzes the conducted conversation and provides feedback to the student on what to improve. Building on validated approaches, another AI agent could analyze the dialogue and provide structured feedback on history-taking categories. This would address students' expressed need for a formal case closure and clearer learning outcomes. The addition of digital note-taking tools and integration of structured data (eg, laboratory values, vital signs) would increase both complexity and realism, better meeting the needs of advanced learners. To have a more realistic training situation, the simulation tool should be extended by a voice user interface that allows a speech-based interaction.

Emerging LLMs such as GPT-4o, Gemini, Grok 3, and Claude 3.5 Sonnet now offer advanced multimodal capabilities. Future iterations could leverage these features to enrich vignettes with relevant visual findings, further enhancing didactic value.

Acknowledgments

GPT-4.1 was used for translating the text written in German into English and for improving the writing style. The authors acknowledge the use of Genspark AI [33] for assistance with statistical data analysis, code generation, and visualization. All analytical approaches were independently validated, and all interpretations and conclusions are solely those of the authors.

Funding

This research received no specific grant from any funding agency in the public, commercial, or not-for-profit sectors.

Data Availability

Access to the system can be provided upon request. Example prompts are available as multimedia appendices. Additional data sharing is not applicable to this article as no data sets were generated or analyzed during this study.

Abstract

The Dellavalle/Dunnick Dermato-Epidemiology Lab transitioned from a single campus to a dual-campus collaboration between the University of Colorado and the University of Minnesota in 2024. Since the 2020 COVID-19 pandemic, the laboratory has been operating on Zoom and allows medical students from any institution to join. This innovative laboratory structure offers students and other researchers unique opportunities to engage in dermatological research and develop professional networks across two large academic institutions. The laboratory's model embraces a virtual collaborative approach, promotes inclusivity, encourages student-led inquiry, and provides a structured environment for professional development and academic output. Through its commitment to diverse student perspectives and interdisciplinary cooperation, the Dellavalle/Dunnick Dermato-Epidemiology Lab creates a new, equitable, nationwide model for research and mentorship in dermatology, supporting medical students, residents, and fellows to navigate future careers in dermatology.

(JMIR Med Educ 2025;11:e65697) doi:10.2196/65697

KEYWORDS

medical students; collaborative research; virtual collaboration; dermatology research; tutorial; editorial

Introduction

The Dellavalle/Dunnick Dermato-Epidemiology Lab represents an innovative collaboration between the University of Colorado (CU) and the University of Minnesota (UMN). This dual-campus model offers a unique platform for medical students, residents, and fellows, particularly those from institutions without dedicated dermatology programs, to engage in high-impact dermatological research. The laboratory's goals are multifaceted: to foster professional networks, promote a culture of scientific curiosity and inquiry within the dermatology field, and enhance students' research credentials. This editorial will summarize the key components and operational structure contributing to the laboratory's sustained engagement and productivity across institutions, providing a practical framework for medical educators, researchers, or administrators looking to replicate this scalable model in other medical specialties. By focusing on strategies for creating an inclusive, collaborative research environment, we will explore how mentorship strategies, logistical planning, digital tools, and virtual collaboration can bridge gaps in medical education and support the next generation of physician-scientists, particularly in settings where formal dermatology programs or research infrastructure may be limited.

Laboratory Background

The Dellavalle/Dunnick Dermato-Epidemiology Lab was founded as an in-person research group at CU. It operated under a traditional model of weekly on-site meetings, primarily with CU medical students. This structure had been in place since the laboratory's creation in the early 2000s.

During the COVID-19 pandemic, the laboratory transitioned to a fully virtual format using platforms such as Zoom (Zoom Communications) and Google Workspace. This transition significantly expanded the laboratory's geographic reach and accessibility, allowing medical students from over 30 institutions nationwide to participate. Participation is open and nonselective; students are not required to apply but are vetted and invited to join meetings and become involved as their interest develops.

While the laboratory has an accessible website, its growth has largely been driven by its strong reputation, word-of-mouth referrals, and visibility at academic conferences. The research

credentials of the laboratory's principal investigators, authors RPD and CAD, further enhance its appeal, attracting motivated trainees eager to contribute to impactful dermatological projects. RPD has an h-index of 70 and more than 145,000 citations, and CAD has an h-index of 36 and more than 5,000 citations [1,2].

When RPD transitioned to UMN, the lab's commitment to virtual collaboration ensured continuity. Weekly Zoom meetings provide a platform for updates, allowing for the seamless integration of students and residents from multiple locations. This virtual approach supported the laboratory's ongoing success, allowing it to thrive as a dual-campus operation.

The laboratory's focus on collaboration has led to contributions from students at a range of institutions, including Rocky Vista University College of Osteopathic Medicine, Case Western Reserve University, Kansas City University, Texas Tech El Paso, A.T. Still University, SUNY Upstate University, Texas A&M, The Ohio State University, and many others. These efforts have resulted in numerous publications and sustained high-impact research projects, further cementing the laboratory's role in advancing dermatological science through interdisciplinary collaboration.

Laboratory Operations

Joining the Laboratory

The Dellavalle/Dunnick Dermato-Epidemiology Lab uses an open-access, inclusive model for student participation. When students learn about the laboratory through the website, a conference presentation, or word of mouth, they email CAD and/or RPD. One of the unique aspects of our laboratory is that students are not required to apply or be selected to join. Instead, interested students are provided the Zoom link and the shared laboratory Google Doc (Textbox 1 and Multimedia Appendix 1). They are invited to attend weekly meetings without expectations of prior research experience.

New participants are encouraged to observe their first few meetings to gain familiarity with the laboratory's structure and active projects. As they become more comfortable, they are encouraged to contact established laboratory members to join projects that interest them. This approach reduces barriers to participation and allows self-directed engagement based on availability, interest, and experience.

Weekly Operations

Consistent, weekly Zoom meetings serve as the backbone of laboratory operations. The meetings follow a structured format, including a "popcorn-style" check-in, where each member introduces themselves, their role, medical school, and current location. After the check-in, we engage in personal development activities, such as discussing key insights from recent conferences or watching brief faculty development videos from the Association of Professors of Dermatology [3].

Following the professional development segment, we review the current list of ongoing projects. This includes updates on submitted projects awaiting decisions, projects needing revisions, and new ideas. Laboratory members provide updates on their respective projects, and if papers or posters need review, the members will share their screen to go through the material with the group. We then go over any upcoming deadlines for conferences or grant applications. The meeting ends with a final "popcorn-style" check-out with the opportunity to provide any last-minute updates.

Shared Laboratory Document

The shared laboratory document is key to our operations and is essentially the "holy grail" of the laboratory. This Google Doc is a centralized hub for all essential information related to laboratory activities. It includes a comprehensive list of laboratory members' contact details, ensuring easy communication across our collaborative network.

Key sections of the document include the following:

- Lab member information
- Projects submitted awaiting decision (this section tracks all projects that have been submitted for review and are waiting for feedback or approval)
- Projects with revisions (this lists projects that have received reviewer comments and are currently undergoing revisions)
- Active projects (this section highlights ongoing research projects)
- Institutional review board (IRB) protocols (a list of all active IRB protocols currently in effect for our research projects)
- Active grants (this section includes information on approved grants and details on who is leading or contributing to each)
- Open conferences with submission deadlines (this section provides an updated list of conferences open for submissions, along with their deadlines)
- Grant submission deadlines (a list of upcoming grant applications with specific submission dates)
- Upcoming dermatology events (a calendar of dermatology-related events that may interest lab members for networking or continuing education)

The shared laboratory document lists the names of the members currently working on each active project, IRB protocol, and grant. This ensures that all laboratory members can stay updated on who is involved in each initiative and fosters a collaborative, transparent research environment. The document is updated weekly to ensure all members can access current information and deadlines.

Project Development

Participation in the laboratory is self-motivated, and each member is encouraged to develop their own unique research ideas. Once an idea is proposed, our principal investigators, along with other laboratory members, offer suggestions and support to help get the project started. In addition to individual project ideas, our principal investigators often provide project concepts and assemble teams to work on them. After a project is initiated and a team is formed, smaller, more focused meetings take place outside of the weekly laboratory meetings to continue project work.

Funding

The laboratory operates without dedicated, laboratory-specific funding. Instead, students are encouraged to seek financial support for their research projects through grants available at their home institutions or from national sources. While many projects do not require funding beyond literature access and student time, grant opportunities are essential for supporting conference travel, publication fees, and community outreach efforts. Students who secure funding are encouraged to share their grant proposals with other laboratory members as templates, creating a cycle of shared learning and resource building. The shared Google Doc also lists all active grants that laboratory members have received, as well as open grant applications, providing students with up-to-date opportunities to apply for funding. By using this collaborative approach to funding, the laboratory fosters a culture of self-sufficiency and resourcefulness, allowing students to secure financial support for their community-based research endeavors.

Steps for Creating a Successful Collaborative Laboratory

Step 1: Setting Clear Goals and Objectives for Research Programs

Every successful research program begins with a clear set of objectives that guide its mission and outcomes. The Dellavalle/Dunnick Dermato-Epidemiology Lab operates with well-defined goals rooted in the desire to offer students

substantial research opportunities and mentorship while promoting the exploration of novel scientific questions. Key goals include providing professional mentorship, fostering a collaborative research environment that encourages scientific curiosity, and enhancing student research opportunities. These objectives are not only important for the success of the laboratory but are also critical for helping medical students navigate the competitive landscape of dermatology residency applications, which became more difficult with the transition of the United States Medical Licensing Examination Step I exam to pass/fail grading in 2022 [4,5].

To replicate this model, laboratory groups must first identify their core objectives. These could include goals such as improving students' exposure to field-specific research, encouraging scientific curiosity, providing mentorship opportunities, and offering access to high-impact, publishable projects. Once these objectives are established, they will serve as a framework for the program's success and provide clarity on how to best serve the students involved.

Step 2: Structuring the Program for Success

The success of the Dellavalle/Dunnick Dermato-Epidemiology Lab is heavily dependent on its strong organizational structure and clear communication channels. To maintain the flow of projects and ensure consistent progress, the laboratory holds weekly meetings where students and faculty members provide updates on ongoing research, discuss any challenges, and plan the next steps. These regular check-ins foster a sense of continuity and accountability, which is especially important when managing research teams spread across multiple campuses. One of the key benefits of this structure is that it allows students from various institutions to remain engaged, regardless of their geographic location.

Weekly meetings and centralized documentation keep research organized and moving forward. Using tools like Google Docs supports team transparency and accountability. Replicating this model involves consistent communication, flexibility, and logistical coordination across institutions. In addition, it's important to maintain a flexible, adaptable approach to account for the varying schedules and needs of participants from different institutions.

Step 3: Creating an Inclusive and Collaborative Research Environment

The laboratory's success can be attributed to its focus on creating a collaborative environment where students feel valued and empowered to contribute to meaningful research, regardless of their academic background. This ethos is reflected in the laboratory's recruitment policy, which invites students from institutions with and without established dermatology programs to participate in research. This inclusive approach fosters camaraderie between MD and DO students, enhancing professional networks and building connections early in their careers.

Replicating such an inclusive environment requires institutions to recruit and include participants consciously and to create a culture that values all contributions, regardless of a student's institutional affiliation. Offering mentorship and guidance from experienced researchers and ensuring that students from various backgrounds have equal access to resources and support are essential steps in creating a thriving research community.

Step 4: Ensuring Program Sustainability and Resources

Long-term sustainability of a virtual collaborative research program requires strategic planning, flexible leadership, and efficient resource management. Many collaborative research programs rely on extramural grants and institutional support to finance operations. Program leaders should prioritize securing long-term funding sources, including government grants, philanthropic support, or institutional backing, to ensure the sustainability of the research program. Since most academic institutions already provide access to platforms like Zoom and Microsoft 365, investing in a solid technology infrastructure can significantly streamline communication and enhance collaboration.

Step 5: Replicating the Model: Key Insights

To replicate the success of the Dellavalle/Dunnick Dermato-Epidemiology Lab, it's important to focus on several core principles, outlined in Textbox 2.

Textbox 2. Core principles.

Defining clear objectives

Establish clear and measurable goals for the program, ensuring they align with students' goals and the broader goals of your institution or research community.

Structuring for organization

Implement a consistent structure for regular meetings, project tracking, and task management.

Promoting inclusivity

Create an inclusive research environment that invites participation from students across multiple institutions and backgrounds and encourages collaboration.

Securing resources

Plan for the sustainability of the program by securing funding and investing in technology platforms that facilitate virtual collaboration.

Performing ongoing evaluation

Continuously assess the program's impact and refine based on participant feedback.

Conclusion

The Dellavalle/Dunnick Dermato-Epidemiology Lab offers a practical model for building scalable, inclusive, and collaborative multicampus research programs. Its structured virtual environment lowers access barriers, supports consistent mentorship, and engages students from schools without dermatology departments, addressing common gaps in academic medical training.

As medical education adapts to more decentralized and technology-driven formats, this model illustrates how virtual infrastructure and intentional design can sustain student scholarship and faculty engagement. By applying the principles outlined in this editorial—clear objectives, open access, consistent workflows, and distributed leadership—other institutions can replicate the success of the Dellavalle/Dunnick Dermato-Epidemiology Lab and contribute to the next generation of physician-scientists who are prepared to excel in an increasingly competitive medical landscape.

Abstract

Background: As artificial intelligence and machine learning become increasingly influential in clinical practice, it is critical for future physicians to understand how such novel technologies will impact the delivery of patient care.

Objective: We describe 2 trainee-led, multi-institutional datathons as an effective means of teaching key data science and machine learning skills to medical trainees. We offer key insights on the practical implementation of such datathons and analyze experiences gained and lessons learned for future datathon initiatives.

Methods: We detail 2 recent datathons organized by MDplus, a national trainee-led nonprofit organization. To assess the efficacy of the datathon as an educational experience, an opt-in postdatathon survey was sent to all registered participants. Survey responses were deidentified and anonymized before downstream analysis to assess the quality of datathon experiences and areas for future work.

Results: Our digital datathons between 2023 and 2024 were attended by approximately 200 medical trainees across the United States. A diverse array of medical specialty interests was represented among participants, with 43% (21/49) of survey participants expressing an interest in internal medicine, 35% (17/49) in surgery, and 22% (11/49) in radiology. Participant skills in leveraging Python for analyzing medical datasets improved after the datathon, and survey respondents enjoyed participating in the datathon.

Conclusions: The datathon proved to be an effective and cost-effective means of providing medical trainees the opportunity to collaborate on data-driven projects in health care. Participants agreed that datathons improved their ability to generate clinically meaningful insights from data. Our results suggest that datathons can serve as valuable and effective educational experiences for medical trainees to become better skilled in leveraging data science and artificial intelligence for patient care.

KEYWORDS

data science education; datathon; machine learning; artificial intelligence; undergraduate medical education

Introduction

The exploration of machine learning (ML), artificial intelligence (AI), and other data science-driven technologies is becoming increasingly popular within clinical medicine [1-5]. Given the rapidly growing presence of ML in health care innovation, it is important for both current and future physicians to understand the fundamentals of ML technology and how they may help inform clinical decision-making.

However, data science and AI education in current medical school curricula are lacking. Despite recent efforts to integrate AI learning objectives into medical education [6-10], few US medical schools have formally integrated AI-based topics into their curricula. Pupic et al [11] and Civaner et al [12] report studies of small self-selected groups of medical students and

residents participating in both student- and faculty-led electives covering the fundamental theory behind AI applications for medicine. However, opportunities facilitating real-world experience remain limited [13,14].

One potential method for hands-on AI education popular across many fields of science and engineering is the "datathon," which is a short competition where teams of students work together to create new solutions to domain-specific challenges through leveraging real-world data and algorithms. Following Daneshvar et al [15], we also make the important distinction between datathons and hackathons. Traditionally, hackathons are product-orientated initiatives where team projects are primarily focused on programming novel products and applications. By contrast, the primary learning objectives for our datathons were to (1) teach student participants how to analyze complex datasets to support clinical insights, and (2) leverage ML models to derive these clinical insights from data. Oyetade et al [16] offer a scoping review of datathons and found that such events help students learn both technical and soft skills and argue that datathon-based pedagogies be incorporated in classroom environments. Silver et al [17] describe a hackathon event for current attendings in clinical practice and found that study participants were better equipped to accelerate specialty-focused innovation after the hackathon. However, similar events specifically designed for medical students and other undergraduate trainees are not well described in the literature.

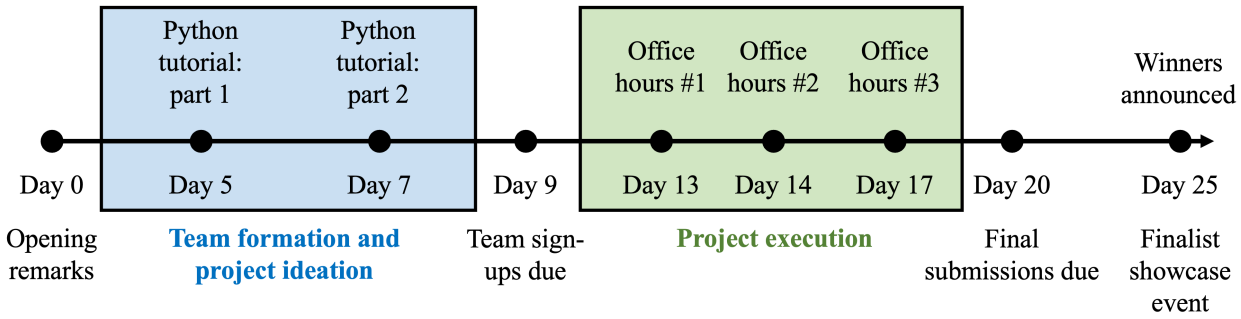
In this work, we hypothesize that datathons can be an effective training initiative to teach skills in AI to medical trainee participants. To evaluate this hypothesis, we describe 2 datathons hosted by MDplus, a 501(c)3 national student-run nonprofit whose mission is to support and empower future physician-innovators. We describe the structure of the events, present data on educational outcomes, and offer resources and recommendations for putting together similar events in the future. Our results suggest that datathons and similar events may be an effective means for AI education for medical students.

Methods

Overview

In this section, we detail the logistics of organizing and executing 2 trainee-led datathon events. A number of features distinguish our events from prior work. First, the datathons are trainee-led; all members of the organizing committee were undergraduate medical trainees at the time of the event. Second, the datathons were held digitally over the course of approximately 3 weeks (Figure 1). Finally, the target participant audience of our datathons included current undergraduate medical trainees at institutions granting doctoral degrees. These features of our datathons substantially differentiate them from prior work [15-17], and also affected our design and organization of the events that we detail below.

Figure 1. Overview of the datathon event. The MDplus datathon ran for approximately 4 weeks and was loosely divided into two parts: (1) Team formation and project ideation and (2) project execution.



Timeline and Participant Recruitment

We, the datathon organizing team, detail 2 datathon events organized by MDplus between 2023 and 2024, herein referred to as "the datathons." Each datathon ran for approximately 3 weeks (Figure 1), and was organized by the medical trainee-led executive team of MDplus, consisting of a core datathon planning team of 8 medical trainees. To accommodate the participation of medical trainees from across the United States, the entirety of both datathons was held digitally. The MDplus' Slack community, monthly newsletter, and social media pages (LinkedIn, Instagram, and Twitter) were used to advertise the datathon. Over the span of 3 months prior to the start of the datathon, 2 organizing team members were tasked with recruiting sponsors, mentors, knowledge experts, and judges through the MDplus and personal networks, while 3 organizing team members—all with prior experience working as software engineers prior to medical school—crafted and iterated the educational material and dataset curation for the event. One team member helped publicize the event on social media. Registration for the event was limited to current trainees (ie, medical students, residents, and graduate students) in the United States. To provide a fair learning environment for trainees, our organizing team opted to exclude attending physicians, industry professionals, and individuals with extensive technical backgrounds in software engineering from participation. Participants were asked to form their own teams of 3-5 individuals.

Datathon Theme and Dataset

Each of the datathons focused on a specific theme to help participants contextualize their projects within a specific application relevant to health care. The theme of the 2024 datathon was responsible generative AI and that of the 2023 datathon was value-based care (VBC). Generative AI is an area of ML that uses technologies such as large language models (LLMs) to create new content by learning patterns from existing human-generated examples [18-20]. While such technologies

have the potential to improve health care delivery, recent work has highlighted a growing need to better evaluate how clinicians can use these tools responsibly before real-world integration is possible [21-23]. Separately, VBC refers to a health care delivery model in which providers are held accountable for improving patient outcomes. In a VBC system, providers are often rewarded with incentivized payments based on quality of care, provider performance, and the patient experience [24].

To enable participants to explore projects related to each of these themes, a medical dataset was made available for participants to use in each of our datathons. All datasets were made available via Hugging Face (Hugging Face, Inc), a public repository to facilitate the sharing of ML data and models. In our 2023 VBC datathon, participants were required to use the Medical Information Mart for Intensive Care (MIMIC)-IV dataset [25], a single-site dataset of patient records and admission details. Briefly, the MIMIC-IV dataset contains anonymized patient data aggregated from over 500,000 patients at the Beth Israel Deaconess Medical Center between 2008 and 2019. Variables from this rich dataset include electrocardiograms, medical imaging studies, health records, and patient laboratory values and outcomes, among others. We chose to use this dataset specifically for the datathon because of the following factors:

Public Availability

In similar prior events organized by the authors, we found that procuring a real-world dataset of health care data can often be prohibitively expensive or constraining, especially for trainee-led initiatives with limited budgets. To circumvent this problem, we used the MIMIC-IV dataset, which is made publicly available by Johnson et al [25].

Real Patient Data and Outcomes

The primary learning objective of our datathons is to teach participants how to derive data-driven insights to affect and ultimately improve patient care. We therefore sought to provide real patient data for participants to explore and use for their projects in alignment with this goal.

Prevalence of Prior Work

The vast majority of our participants have minimal (if any) prior experience with programming and data analysis techniques. For this reason, the abundance of prior literature and publicly available coding resources for interacting with the MIMIC-IV dataset helped lower the barrier to participating in the datathon.

Multiple Modalities of Data

Many participants have individual academic and personal interests in medicine, and we sought to encourage participants to craft and work on projects that were interesting to them. The abundance of textual, image, biomedical signal, and laboratory data available in the MIMIC-IV dataset was important to make this possible.

All participants in the datathon were required to sign a data use agreement and complete responsible data handling training in order to gain access to the MIMIC-IV dataset. Participating teams were tasked with thinking critically about quantitative methods, conducting appropriate analyses (eg visualization, statistics, and other computational tools), and contextualizing clinical insights into actionable proposals that solve a problem related to VBC for relevant stakeholders.

While organizing for the 2024 generative AI datathon, we found that one limitation of the MIMIC-IV dataset was its size and complexity, making it unwieldy for some participants to work with for their projects. To overcome this challenge while simultaneously retaining the desirable features listed above, our 2024 datathon introduced the concept of datathon “tracks”: teams were able to choose to participate in 1 of 3 tracks within the broader theme of responsible generative AI. Each track was associated with its own dataset: (1) Clinical Documentation track participants used the MTS-Dialog dataset of patient-physician conversation transcripts from Abacha et al [26]; (2) Medical Education track participants used the MedQA dataset of practice medical board examination questions from Jin et al [27]; and (3) Mental Health track participants used the SuicideWatch and Mental Health Collection dataset of tagged social media posts from Ji et al [28]. Participants were allowed to participate in at most 1 of the 3 tracks.

Resources and Support

An official datathon page [29] was created for participants as a central hub with instructions, registration, and materials for the event. Links to the datathon’s Github Repository were provided with written tutorials and example code, including (1) downloading and overview of the datasets; (2) introduction to Python (Python Software Foundation; offered in both the 2023 and 2024 datathons; see Multimedia Appendix 1); and (3) an introduction to R (R Foundation; offered only in the 2023 datathon). Optional workshops and private Zoom (Zoom Communications, Inc) events with experienced data scientists were offered to participating trainees, including Python and R bootcamps, oral presentation workshops, and a prerecorded Zoom talk with physician experts. The scope of the projects was largely left up to the discretion of individual team members; participant teams were encouraged to leverage the optional workshop sessions and public discussion channels on Slack if they would benefit from discussing potential project ideas with others, although no explicit guidance on project ideation or constraints was given other than all teams had to (1) use the official datathon dataset and (2) work on a project under the broad datathon theme (ie, VBC in 2023 and responsible generative AI in 2024) and track. No tutorials or structured datathon programming were provided for teaching participants how to use GitHub, GitLab, Microsoft Excel, or other computing tools. Communication and announcements throughout the datathon were conducted through Slack.

Submission Requirements and Judging Criteria

In the 2023 VBC datathon, teams were asked to submit a written technical report of their work without restrictions on the word count and were asked to record a 5-minute-long oral presentation highlighting key contributions and findings. Participants were free to use any programming language or software to perform their analysis. In the 2024 generative AI datathon, teams were asked to submit a 1-page extended abstract with at most 1 figure and unlimited references and a written technical report without word count restrictions. Judging criteria in both datathons

included statistical rigor, relevance to the datathon theme (VBC), creativity of visualization and analysis, and team diversity (Multimedia Appendix 2).

Final Showcase Event

In the 2023 VBC datathon, an internal set of 4 blinded judges composed of members of the MDplus datathon organizing committee evaluated the initial anonymized submissions and selected 7 finalist teams to present at the finalist datathon showcase event. Each team played their recorded 5-minute oral presentations and were allotted 2 minutes immediately after for responding to judge questions. A panel of 5 judges—recruited for their diverse range of expertise in the VBC space—evaluated the finalists' submissions. In total, 3 of the judges are health care executives, 4 are practicing clinicians, and 1 is a product manager.

In the 2024 generative AI datathon, an internal set of 3 blinded judges composed of members of the organizing committee evaluated the 14 initial anonymized team submissions and selected 8 finalist teams to present at the final datathon showcase. Finalist teams were invited to a 2-hour finalist showcase event where they were each allotted 8 minutes for a live oral presentation followed by 2 minutes of question answering with the judges. We recruited a panel of 4 judges to evaluate the finalist submissions: 1 judge is a software engineer at a health care company, 1 judge is a postdoctoral fellow in a health care AI lab, and 2 judges are practicing physicians in the United States. In general, we found the live oral presentations to be better received by the judges and audience members than playing prerecorded presentations.

Postdatathon Survey

Upon the conclusion of each datathon, an anonymous 16-question open survey (Multimedia Appendix 3) was electronically sent to all registered participants that submitted a final project via both Slack and email; this survey study was exempted by the University of Pennsylvania Institutional Review Board (protocol #856530). The survey was created in close collaboration with an attending physician at a US academic medical institution with expertise in medical education and assessing educational outcomes and was piloted within the datathon organizing team prior to the public release of the survey. Participants were requested to complete the survey within the 2 weeks immediately following the conclusion of the respective datathon, and the survey remained open for 3 weeks. Participant emails were collected to ensure that no individual filled out the survey multiple times but were removed prior to analysis. The optional, opt-in survey asked respondents questions pertaining to team demographics, medical education status, medical specialty interest, familiarity with technical and computational tools, and subjective datathon quality. The questions were divided between 4 survey pages, each taking approximately 1 minute to complete; no partial survey responses were submitted. Participants were asked to rate their familiarity with quantitative tools before and after the datathon on a 4-point scale (1=no familiarity, 4=a lot of familiarity) and were also informed that the study results would be anonymized and deidentified prior to analysis. To assess the efficacy of the aforementioned technical Python and R tutorials for datathon participants, we compared them against participant subjective familiarity with quantitative tools—namely, GitHub and Microsoft Excel—that were not taught explicitly as a part of the datathon. Data were analyzed using the Fisher exact test in Python 3. To better characterize participant experiences during the datathon, survey respondents also rated their agreement with a set of 5 standardized statements regarding (1) overall enjoyment of the datathon, (2) VBC topic understanding, (3) ability to identify problems in health care, (4) ability to generate insights from data, and (5) likelihood of future datathon participation. Participant sentiment was quantified using a 5-point Likert scale (1=strongly disagree, 5=strongly agree) [30].

Ethical Considerations

This study was exempted by the University of Pennsylvania Institutional Review Board (protocol #856530). All opt-in participants provided informed consent prior to data collection and were not compensated for participating in our optional, opt-in survey as a part of our study. Confidentiality and privacy were maintained during data acquisition and analysis, and participants had the right to withdraw their data from the study at any time without any consequences.

Results

Datathon Logistics

In the 2023 datathon, 28 teams consisting of a total of 109 participants registered for the datathon, of which 13 of the initial registered teams submitted a final project, while in the 2024 datathon, 25 teams consisting of 110 participants registered for the datathon, of which 14 of the initial registered teams submitted a final project. Among the submitted projects, 7 and 8 were chosen as finalists to present at the synchronous digital showcase in 2023 and 2024, respectively. In the 2023 VBC datathon, the 7 projects addressed a variety of topics related to VBC, including chronic kidney disease underdiagnosis, the efficacy of social work referrals, and readmission rates for alcohol-related conditions, among others. Similarly, the 2024 responsible generative AI datathon featured 2 clinical documentation track teams, 3 medical education track teams, and 3 mental health track teams. We include brief descriptions of each of the finalist projects in Table 1. The final showcase was followed by the announcement of the 3 winning projects; we announced the winning teams at the end of the showcase in the 2023 datathon and 48 hours after the end of the showcase in the 2024 datathon.

Table . Sample datathon project descriptions. Descriptions of finalist datathon projects for the 2023 and 2024 MDplus datathons are shown to illustrate the diversity of project submissions from participating teams.

Theme or track	Project description
Value-based care	• Minimizing chronic kidney disease (CKD) underdiagnosis using machine learning • Significant association of social work referral and 30-day unplanned hospital readmission for patients with alcohol-related disorders using MIMIC[a]-IV data • Can we curb frequent emergency department (ED) visits due to alcohol-related conditions? • Automatic knowledge graph extraction from medical discharge notes for clinical decision support • Contrast overuse in patients with renal disease: a targeted analysis • Analyzing acuity as a tool for value-based care • Machine learning-driven forecasting and characterization of the intensive care unit (ICU)-admitted heart failure patient population in the MIMIC-IV (version 04) database
Responsible generative AI: clinical documentation	• Cost-benefit analysis of non-artificial intelligence (AI) and AI models implemented for predicting chief complaints • Bridging speech documentation and clinical support through LLM[b] automation • Automating trust in AI-generated clinical notes: developing a look-up tool for real-time verification
Responsible generative AI: medical education	• Using a LLM for USMLE[c] preparation via generative AI • Use of LLMs in assessing how age and gender affect model accuracy in clinical reasoning
Responsible generative AI: mental health	• Reassessing specialist models: risks in fine-tuning LLMs for mental health tasks • Robust text classification and grounded LLM integration for personalized mental health support • Characterizing suicidal ideation subtypes in social media posts via unsupervised contrastive feature identification

[a]MIMIC: Medical Information Mart for Intensive Care.

[b]LLM: large language model.

[c]USMLE: United States Medical Licensing Examination

The organization-accrued cost of organizing and running the datathons was US $28 per participant, averaged over the number of participants who individually registered for the datathon regardless of whether they ultimately submitted a final project. The majority of expenses supported prize money, computing resources for participants, technical skill-based workshops, and other resources that were provided during the datathon. In our experience, most of the costs accrued were for (1) the prize money of the datathon winners and (2) honorariums for the guest judges in the finalist showcase events. We primarily relied on sponsorships from industry partners to provide computing resources for participants, and MDplus community members readily volunteered to help lead technical skill-based workshops and offer pro-bono mentorship to participating teams.

Survey Results

Out of the 219 registered participants (summed over both datathons), 61 (28%) completed the postdatathon survey (Table 2). A majority who completed the survey identified as male (71%, 43/61) and were under the age of 25 years (61%, 37/61). Survey respondents self-reported as Asian (69%, 42/61), White (20%, 12/61), Middle Eastern or North African (3.3%, 2/61), Hispanic or Latinx (3.3%, 2/61), or Black or African American (1.6%, 1/61); and 3.3% (2/61) preferred not to say. In total, 49/61 (80%) of survey respondents were medical students (Table 3); there was a wide range of medical specialty interests amongst the medical trainee survey respondents, with internal medicine (21/49), surgery (17/49), and radiology (11/49) being the most popular specialties.

Table . Demographic information of participants who completed the postdatathon survey (N=61).

Characteristics	Value, n (%)
Age, years	
<25	37 (61)
25–30	22 (36)
30–35	1 (1.6)
≥35	1 (1.6)
Self-reported race and ethnicity	
Asian	42 (69)
Hispanic or Latinx	2 (3.3)
Middle Eastern or North African	2 (3.3)
White	12 (20)
Black or African American	1 (1.6)
Prefer not to say	2 (3.3)
Gender	
Male	43 (71)
Female	18 (29)
Sexual orientation	
Heterosexual or straight	57 (93)
Bisexual, gay, lesbian, or other	4 (6.6)
Disability status	
Does not identify as a person with a disability	54 (89)
Does identify as a person with a disability	5 (8.2)
Prefer not to answer	2 (3.3)
Current education status	
Medical student or resident physician	49 (80)
Other	12 (20)

Table . Datathon participant analysis. Current medical education status and medical specialty interest information for participants who completed the postdatathon survey (N=49) filtered by medical student and resident physician status. Note that respondents were allowed to select multiple medical specialties.

Characteristics	Value
Current medical education status, n (%)	
First-year medical student	14 (29)
Second-year medical student	19 (39)
Third-year medical student	6 (12)
Year-out medical student	4 (8.2)
Fourth-year medical student	5 (10)
Resident physician	1 (2.0)
Medical specialty interests, n (%)	
Anesthesia or critical care	9 (18)
Cardiology	1 (2.0)
Dermatology	5 (10)
Emergency medicine (EM)	4 (8.2)
Family medicine (FM)	1 (2.0)
Internal medicine	21 (43)
Mental health counseling and therapy	2 (4.1)
Neurology	9 (18)
Obstetrics and gynecology (OB/GYN)	3 (6.1)
Ophthalmology	5 (10)
Pediatrics	5 (10)
Physical medicine and rehabilitation (PM&R)	1 (2.0)
Plastic surgery	1 (2.0)
Psychiatry	8 (16)
Radiology	11 (22)
Surgery (general or unspecified)	17 (35)
Orthopedic surgery	2 (4.1)
Not currently exploring a medical specialty	1 (2.0)

Familiarity with quantitative tools, Python, R, Github/Gitlab, and Microsoft Excel before and after participating in the datathon was assessed (Figure 2). As a reminder, a core component of the programming of both our VBC and generative AI datathons was the educational workshops and tutorials on data analysis and ML skills using Python. Workshops on the programming language R were only offered in the 2023 VBC datathon. As our negative controls, we also asked participants to rate their skills with Github/Gitlab and Microsoft Excel; neither of these software were primary educational components of the datathons. As expected, participant familiarity with GitHub/Gitlab and Microsoft Excel did not significantly change before and after the datathon (GitHub/Gitlab: P=.92; Microsoft Excel: P=1.00; pairwise Fisher exact test). In contrast, subjective participant familiarity with Python significantly improved through participation in the datathons (P=.04; pairwise Fisher exact test); familiarity with R showed some evidence of improvement (P=.83; pairwise Fisher exact test), although it did not reach the traditional threshold for statistical significance likely due to the limited sample size of the study. Our reports support that targeted educational tutorials during the datathon event can empower participants with improved technical skills relevant to data science applications in medicine.

Figure 2. Bar plot visualizing participant self-assessment of technical skills before and after participating in the datathon for all 61 survey responses. Python was the only skill out of the 4 above that was an educational component in both the 2023 VBC and 2024 generative AI datathons. Participant scores correspond to the following: (1) no familiarity; (2) a little familiarity; (3) some familiarity; (4) a lot of familiarity. * Indicates a statistically significant difference in the distribution of scores before and after participating in the datathon (Python: *P*=.041; pairwise Fisher exact test). n.s. indicates no statistically significant difference in the distribution of scores. (R: *P*=.83; GitHub/Gitlab: *P*=.92; Microsoft Excel: *P*=1.00; pairwise Fisher exact test).

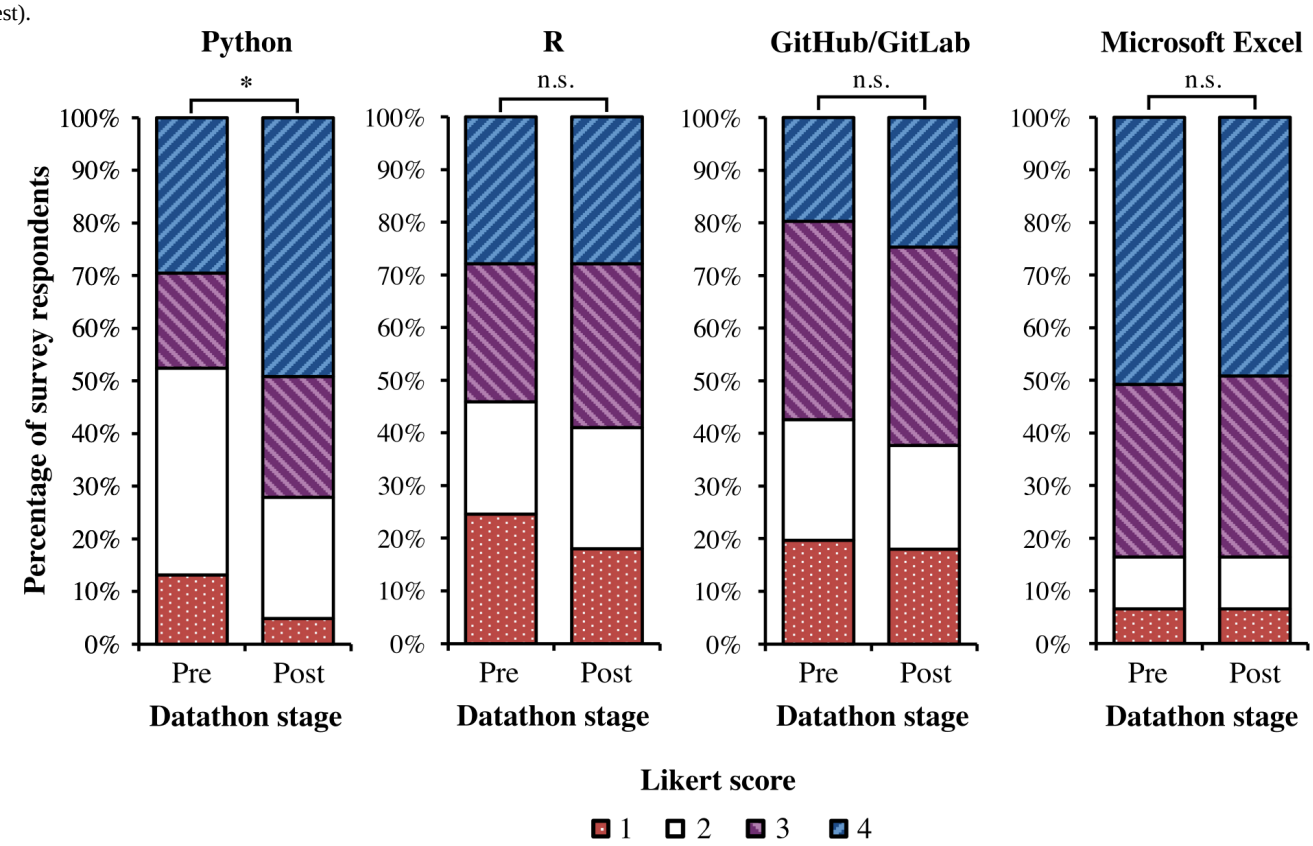


Figure 3 examines the participant experience quantified by participant agreement with a set of standardized statements. Overall, 57/61 (93%) survey respondents enjoyed participating in the datathon, and 38/61 (62%) respondents affirmed that the datathon improved their understanding of the VBC or responsible generative AI theme (ie, Likert score of 4 or 5). We also found that 47/61 (77%) respondents stated that their ability to identify problems in health care improved, and 50/61 (82%) respondents agreed that they were better equipped to generate meaningful insights from data. Of the 61 participants, 50 participants (82%) also expressed interest in participating in similar datathon events in the future. For each of these statements, an “agreeable sentiment” was determined by indicating a Likert scale value of either 4 (“I somewhat agree with the statement”) or 5 (“I strongly agree with the statement”) on a 5-point scale in the participant survey response.

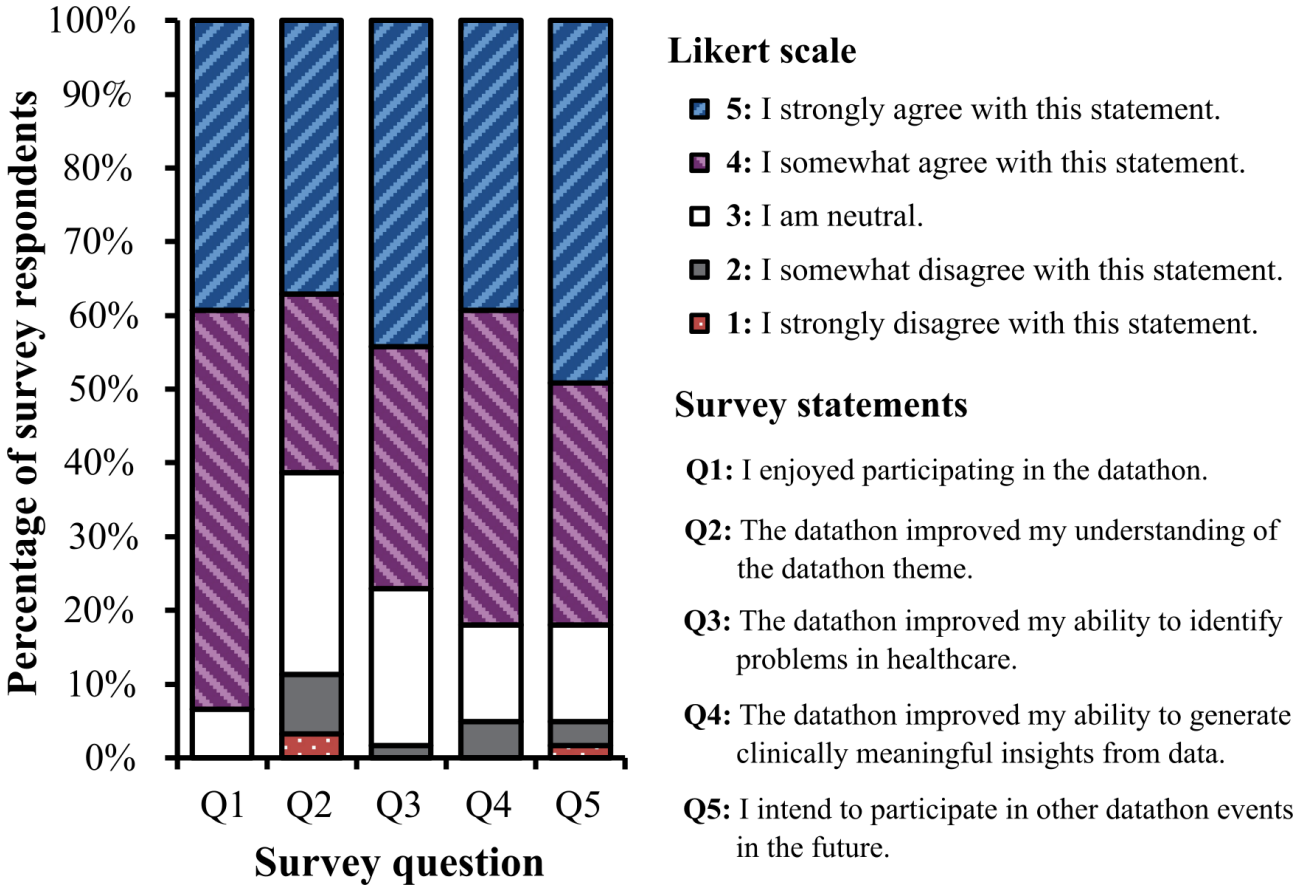
Figure 3. Bar plot visualizing survey results assessing for subjective datathon quality. Participant scores correspond to the following: (1) Strongly disagree; (2) Disagree; (3) Neither agree nor disagree; (4) Agree; and (5) Strongly agree.



Qualitative Survey Results

The survey also included an open-ended response option for participants to provide any additional comments. There was a mix of short, positive comments and comments that offered suggestions for future events. Based on our qualitative analysis, key areas for improvement to consider for future datathon iterations include (1) ensuring a balanced distribution of technical skills between participating teams; (2) expediting the team creation process; and (3) offering additional technical workshops and tutorials to participants. Representative example unedited participant comments are shown below:

> *I think in the future, it'd be more effective to make sure each team at least has a "senior" tech lead (someone with 3-5+ years of tech experience) and a "junior" tech lead (1-2 years) to ensure there is great education for all parties involved, as well as greater quality of work. This is of course for folks seeking out teams and not those who already have a team formed that they are comfortable with.*

> *…I feel like the team creation process could've been a little faster and I was only able to join a team around halfway into the datathon which didn't give us enough time to work on our idea. But overall, I really appreciate the effort and time put in by everyone involved and I definitely hope to be involved in this again!*

Discussion

Principal Findings

In this work, we describe an instance of a trainee-led datathon to teach medical trainees how to effectively leverage modern computational tools to solve real-world problems in medicine. We show preliminary evidence that trainees become more familiar with foundational skills such as reading and writing computer programs in Python and R, are satisfied with their participation, and are eager to participate in similar initiatives in the future. To our knowledge, our national, trainee-led datathons were the first to bring together teams of medical students, residents, and graduate students to propose data-driven solutions within VBC. Our study ultimately supports that datathons can be effective platforms to teach medical trainees how to leverage AI to advance clinical medicine.

Logistical Insights and Best Practice Recommendations

In this section, we offer additional discussion on subjective design choices and lessons learned from the MDplus datathon organizing team. We hope that our experiences and takeaways can serve as a foundation for which future datathon educational initiatives can build upon.

Perhaps one of the most notable logistical details that distinguish our datathons from related hackathons that are traditionally organized by computer science students outside of medicine is that our datathons each spanned the course of multiple weeks asynchronously, whereas hackathons are often held over the

course of a few days in a single physical location. While we recognize that there are likely untapped benefits with this alternative strategy, we chose to run an extended digital datathon due to two primary reasons: (1) to support participation from MDplus members spanning multiple countries and timezones; and (2) to minimize potential time conflicts with concurrent medical school curricula for participants. In our work, these 2 constraints together necessarily precluded an in-person datathon; in situations where either one or both constraints are not limiting, future work may warrant exploring similar datathon initiatives spanning a few days hosted in a single physical location.

Separately, we also emphasize the importance of carefully choosing the datasets used in the datathon. In our 2023 VBC datathon using the MIMIC-IV dataset, we retrospectively observed that some participants initially struggled with the technical implementation details of working with the MIMIC-IV dataset due to the sheer volume of data available and the preprocessing steps before any ML modeling could be done. This consideration was especially important as the majority of participants registered in the datathon with little or no prior experience with computer programming (Figure 2). At the same time, participants also voiced enthusiasm for the diversity of data available in the MIMIC-IV dataset—making multiple modalities of data available, such as medical imaging, textual clinical documentation, biometric signals, and tabular data, allowed for participating teams to design and execute projects tailored to their specific interests. In our 2024 generative AI datathon, we found that the introduction of datathon "tracks" enabled us to offer 3 diverse dataset options while simultaneously removing the extra data processing steps outside the scope of the datathon learning objectives.

We also evaluated the utility of unstructured "office-hour" sessions where participating teams could ask experienced members of the community for assistance with their projects. Despite holding multiple office-hour sessions at different times of the day throughout the datathon, we found that only 1 team attended any of the office-hour sessions in the 2023 VBC datathon. Because of this low attendance, we opted to remove synchronous office hours from the 2024 datathon programming and instead implemented a custom anonymous discussion forum via the datathon Slack communication channel where participants could ask questions anonymously that could be viewed and answered by anyone. Subjectively, we found that this asynchronous mode of communication made it easier for participants to seek help with their projects and observed greater engagement in public discussions after this feature was implemented. Future work is warranted to more rigorously evaluate the utility of such interventions.

Finally, we acknowledge that disciplines such as medicine and computer science have historically seen disproportionate participation from trainees of certain racial, socioeconomic, and gender backgrounds. These systemic trends well described in prior work [31,32] are reproduced in our datathons as well (Table 2); as topics such as data science, VBC, and generative AI become increasingly important components of modern health care, it is crucial that all future clinicians from all backgrounds can interact meaningfully with these concepts and their applications. We hope that future work will explore how to reduce barriers to participation for historically marginalized groups of trainees.

Related Work

The majority of prior work published in related literature details short datathons lasting a few days at a single physical location with a different target participant group. Hochheiser et al [33] describe a 2-day datathon consisting of 5 participating teams of clinicians and informaticians working on elucidating potential sources of bias within health care ML models. While their synchronous datathon model may be suitable for participants at a single physical site, such a model was intractable for our purposes as participating trainees were distributed across multiple institutions and time zones. Sobel et al [15] detail a similar datathon at a single physical location, but their study was primarily conducted with undergraduate and graduate students with pre-existing computational backgrounds, as opposed to undergraduate medical trainees from institutions granting postdoctoral fellowships as in our case. Anecdotally, we found evidence of similar initiatives held at the institutional level, such as the Digital Critical Care Datathon [34], the New York University Health Tech Datathon [35], and the Society of Critical Care Medicine Datathon [36]; each of these were single-institution initiatives with different datathon design constraints. To our knowledge, we are the first to describe a trainee-led, multi-institutional, asynchronous datathon effort and demonstrate preliminary evidence of its efficacy and potential role in the future of medical education.

Limitations

There are also limitations associated of our study. Firstly, our datathon was coordinated digitally with participants joining from across the United States. While we acknowledge there are both benefits and drawbacks to a datathon (as opposed to their in-person counterparts), we leave a rigorous comparison between their utilities in modern medical education paradigms for future work. Furthermore, both participating in the datathon and completing the postparticipation survey were opt-in processes, and so it is unclear how our findings would translate to undergraduate medical trainees who might have systematically chosen to not participate in the datathons—for example, potential participants who were more hesitant in learning about AI and data science practices in medicine and those whose medical school coursework made concurrent participation in the datathon unfeasible. Our survey results also exclude individuals who initially signed up to express interest in participating in the datathon but ultimately decided not to submit a final project. Given the opt-in design of our survey study, we were unable to assess the efficacy of our datathons for these individuals. Future work might evaluate how similar initiatives could scale across more diverse participant profiles and foster participation from student trainees of all backgrounds and perspectives. Finally, our postparticipation survey makes use of retrospective questions that ask participants to subjectively reflect on their skill development, rather than an objective evaluation of participant skills through a standardized programming examination. We chose this study design for two primary reasons: (1) because of the diverse array of participant projects, the skill sets that they developed through their

participation in the datathon are likely equally diverse, making a single standardized examination challenging to construct; and (2) in our initial efforts in organizing the datathon, we hypothesized that the survey response rate would be too low to adequately power our study if we asked participants to complete opt-in programming examinations. We leave the exploration of using more standardized assessments of programming skill competencies attained through datathon initiatives as future work.

Conclusions

Ultimately, the goal of this datathon was to provide opportunities for trainees—especially medical students—to improve their data skills and to identify data-driven solutions to problems in health care. Participants practiced using hands-on data science and artificial intelligence to explore meaningful clinical problems and voiced a collective interest in continuing to participate in similar initiatives in the future. Overall, our results and collective experiences suggest that datathons can be valuable within undergraduate medical education.

Acknowledgments

The authors thank the teams at Hugging Face, Doximity, Merck, Conduce Health, and AvoMD for their generous support and sponsorship of the 2023 and 2024 MDplus datathon events, and the datathon judges (listed in no particular order) Reza Alavi, MD, MHS, MBA; Caroline Berchuck, MD, MPH; Amit Phull, MD; Sid Salvi; Kathryn Teng, MD, MBA, FACP; Andrea Green; David Dupee, MD; Marc Triola, MD; and Jannes Jegminat, PhD for lending their time and expertise in helping run a successful datathon event. The authors also thank Eric Shan, Katie Link, Julia Bondar, Vamsi Chodisetty, and other members of the MDplus community and executive team for their help in organizing and running the datathon event. MSY was supported by NIH F30 MD020264, and ELL was supported by NIH T32 training grant GM146636; the content in this manuscript is solely the responsibility of the authors and does not necessarily represent the official view of the NIH.

Abstract

Background: Approximately 4000 preventable surgical errors occur per year in the US operating rooms, many due to suboptimal teamwork and safety behaviors. Such errors can result in temporary or permanent harm to patients, including physical injury, emotional distress, or even death, and can also adversely affect care providers, often referred to as the "second victim."

Objective: Given the persistence of adverse events in the operating rooms, the objective of this study was to quantify the effect of an innovative and immersive virtual reality (VR)–based educational intervention on (1) safety behaviors of surgeons in the operating rooms and (2) sense-making regarding the overall training experience.

Methods: This mixed methods pre- versus postintervention pilot study was conducted in a large academic medical center with 55 operating rooms. Safety behaviors were observed and quantified using validated Teamwork Evaluation of Non-Technical Skills instrument during surgical cases at baseline (101 observations; 83 surgeons) and postimmersive VR based intervention (postintervention: 24 observations within each group; intervention group [with VR training; 10 surgeons] and control [no VR training; 10 surgeons]). VR intervention included a 45-minute immersive VR-based training incorporating a pre- and postdebriefing based on Team Strategies and Tools to Enhance Performance and Patient Safety (TeamSTEPPS) principles to improve safety behaviors. A 2-tailed, 2-sample *t*-test with adjustments for multiplicity of the tests was used to test for significance in observable safety behaviors between the groupings. The debriefing data underwent analysis through the phenomenological analysis method to gain insights into how participants interpreted the training.

Results: Preintervention, all safety behaviors averaged slightly above "acceptable" scores, with an overall average of 2.2 (range 2 - 2.3; 0 - 3 scale). The 10 surgeons that underwent our intervention showed statistically significant (P<.05) improvements in 90% (18/20) of safety behaviors when compared to the 10 surgeons that did not receive the intervention (overall average 2.5, range 2.3 - 2.7 vs overall average 2.1, range 1.9 - 2.2). Our qualitative analysis based on 492 quotes from participants suggests that the observed behavioral changes are a result of an immersive experience and sense-making of key TeamSTEPPS training concepts.

Conclusions: VR-based immersive training intervention focused on TeamSTEPPS principles seems effective in improving safety behaviors in the operating rooms as quantified via observations using the Teamwork Evaluation of Non-Technical Skills instrument. Further research with larger, more diverse sample sizes is needed to confirm the generalizability of these findings.

Introduction

High-quality health care necessitates ongoing efforts to reduce the occurrence of medical errors [1]. Surgical patients face heightened risks of adverse outcomes related to errors due to the invasive nature of surgical procedures [2]. It is estimated that more than 4000 preventable surgical errors occur annually on a national scale [1,2]. Such errors can result in temporary or permanent harm to patients, including physical injury, emotional distress, or even death, and can also adversely affect care providers, often referred to as the "second victim." A notable example is the unintended retention of foreign objects, which is believed to happen at least once in every 5500 surgeries [3]. This can lead to the need for reoperation, extended hospital stays, and complications such as sepsis. Furthermore, the average additional cost associated with each incident of unintended retention is estimated to exceed US $200,000 [4]. Common underlying causes of surgical errors identified by the Joint Commission include the lack of established policies and procedures, issues related to hierarchy and intimidation, ineffective communication among care team, and the failure of staff to relay pertinent patient information [5]. Additionally, factors such as excessive workload, time constraints, and burnout are linked to increased error rates [5]. Addressing these root causes has proven challenging, as complex health care delivery systems tend to evolve over time, leading to the emergence of new failure sources and pathways. Teamwork skills are often essential for preventing such errors that could lead to patient harm [6]. [7], To address these issues, the Team Strategies and Tools to Enhance Performance and Patient Safety (TeamSTEPPS) framework was specifically designed as a resource to help health care providers improve patient safety behaviors through effective communication, leadership, situation monitoring, and mutual support [8]. [9,10] By using the TeamSTEPPS framework, it is possible to assess the use and quality of patient safety education and behaviors among operating room staff and establish a baseline for improvement.

Virtual reality (VR) is a digital technology that enables a virtual manifestation of the real world [11]. VR provides a more captivating experience compared to viewing a conventional video, as it fully envelopes the viewer within the narrative [12]. In VR, the audience becomes an integral part of the story rather than merely an onlooker. The advantages of immersive VR primarily include: (1) viewers are placed within a 360-degree environment, where each movement of the head unveils new dimensions of the scene. Conversely, traditional video confines viewers to a fixed perspective on a flat screen. (2) Participants in VR actively engage with the narrative, rather than remaining passive spectators. (3) A profound experiential learning opportunity, allowing participants to engage with the contextual realities of a surgical error in the surgical environment.

While live mock simulations with standardized patients are used for certain health care scenarios, the logistical demands of accurately recreating a surgical environment are substantial. These include the coordination of a full surgical team, time spent in an operating room, and the creation of a realistic setting, along with patient representation and various special effects that must align with the error, necessitating cleanup and reset after each simulation. The extensive resources required make this approach neither cost-effective nor scalable for providing multiple realistic experiences for individual learners. Furthermore, a live mock simulation often fails to address the comprehensive needs of learners, as it does not provide insights into the broader contributing factors and repercussions that extend beyond the confines of the operating room. While this disconnect may not significantly affect certain types of learning, such as factual recall, the deeper cognitive processing of theoretical scenarios, particularly in the context of complex situations, could be enhanced through more experiential learning methods such as VR [13]. Experiential learning fosters a personalized and cognitive interaction with educational content, highlighting the relationship between learning and its practical application in the real world. If health care workers are to engage in sense-making regarding the intricate realities associated with adverse events, VR may provide distinct advantages over 2D content and live mock simulations by offering an immersive perspective of events as they would unfold in real life.

In recent years, VR has seen increasing use for safety training across industries [14-17]. VR safety training has great potential, as it allows trainees to experience complex, challenging situations that are difficult to replicate in the real world due to ethical, cost, and time constraints. However, there is a lack of research examining the efficacy of immersive VR-based interventions focused on safety education and behaviors as proposed by the TeamSTEPPS framework. Thus, given the persistence of adverse events in the operating rooms, the objective of this pilot study was to quantify the effect of an innovative and immersive VR-based educational intervention focused on TeamSTEPPS on (1) safety behaviors of surgeons in the operating rooms and (2) sense-making regarding the overall training experience and contributing factors associated with the surgical error.

Methods

Ethical Considerations

This study obtained ethics approval via the Institutional Review Board of the University of North Carolina at Chapel Hill (22 - 1150). Participants were provided with and signed an informed consent form before engaging with activities related to this study. Participants in the intervention group were provided with a small token of appreciation ($25) for compleating the VR intervention process. Patients or the public were not involved in the design, conduct, reporting, or dissemination plans of our research. All results are reported in an aggregate manner to ensure the privacy and confidentiality of participants. The protocol for the full mixed methods pre-versus postintervention study design was published in *JMIR Research Protocols* [18].

Recruitment

A scripted email with a flyer was sent through a listserv to inform prospective participants about this study. Our research team was on standby to answer any questions from prospective participants, and the principal investigators' contact information was available on the flyer. First, for the baseline measurement, a volunteer sample of 83 surgeons (35 attendings, 41 residents,

and 7 fellows; 36 female and 47 male) was enrolled and participated. Surgeons volunteered by providing verbal consent to be observed and scored for safety behaviors before each surgical case. One surgeon refused to participate (no reasons stated). For the pilot study, 10 out of 83 (12%) surgeons (7 attendings and 3 residents; 5 female and 5 male) volunteered to undergo the immersive VR-based educational intervention and to undergo the follow-up observations and scoring. An additional 10 of 83 (12%) surgeons (10 attendings and 0 residents; 3 female and 7 male) volunteered to undergo follow-up observation and scoring without being exposed to the intervention.

Study Design

This mixed methods pre- versus postintervention study with a baseline and intervention or control groups was conducted at a large academic medical center with 55 operating rooms. For the baseline measurement, safety behaviors were quantified while observing 101 surgical cases from October 31, 2022, to February 21, 2023, with 83 surgeons. For the pilot study, 24 observations within each group were conducted from April 17, 2023, to November 2, 2023, with 10 surgeons in the intervention and control group, respectively. Data was collected using the Teamwork Evaluation of Non-Technical Skills (TENTS) instrument. We opted for the TENTS instrument instead of alternatives such as the TeamSTEPPS Team Performance Observation Tool due to our requirement for a more focused evaluation of nontechnical teamwork aspects. TENTS is specifically designed to assess nontechnical dimensions of teamwork, encompassing team member interactions, task delegation, and information management, which makes it particularly relevant in situations where technical skills are not the primary concern. Additionally, TENTS provides a more detailed observational framework, allowing for a comprehensive evaluation of specific teamwork behaviors, in contrast to the broader categories covered by the TeamSTEPPS Team Performance Observation Tool. In our study, we used TENTS items 1A to 4D to assess individual behaviors of surgeons in independent settings (except for the 3 residents who were part of the intervention group), while items 5 and 6 were used to evaluate the overall team functioning and leadership. To train the observers for scoring items 5 and 6, we assembled a team of 17 medical student volunteers who were tasked with conducting observations using the TENTS instrument. They used a simplified scoring scale ranging from 0 to 3, where 0 indicates expected behavior not observed, 1 signifies observed behavior that was poorly executed or counterproductive, 2 denotes acceptable performance, and 3 represents excellent performance. The students received 1.5 hours of instruction on TeamSTEPPS patient safety behaviors and were trained to apply the validated TENTS instrument consistently. Following this, they participated in facility tours and were guided through the observation protocol, which included a practical demonstration of the TENTS scoring process. The students were assigned to surgical cases by aligning their weekly schedules with the relevant cases, while being blinded to the treatment status of the surgeons during postintervention observations. TENTS scores were recorded during real-time observations of surgical procedures using paper forms, and students were required to provide written justifications for behaviors rated as 1 (poor) or 3 (excellent) to offer context for their evaluations.

Interventions or Exposures

We used state-of-the-art filming equipment to capture a 360° view of the event and the perspective of those involved in the error event and contributing events. We built the scripts for the scenes, recruited actors (attendings, residents, students, and administrators) with lived experiences in health care to help with the filming, identified filming locations, rehearsed all the scenes, and filmed our scenes. This training was delivered to the participants using a VR head-mounted display to ensure an immersive environment (see Multimedia Appendix 1 for a 1-minute summary clip of the training). Specifically, we used the Pico Neo 3 Pro Eye headset (PICO Technology Co Ltd) with 6DoF VR hardware or software to administer the training.

Participants were exposed to a 45-minute immersive VR-based training based on TeamSTEPPS principles to improve safety behaviors. Overall, our overarching training story is focused on a human error that occurs at the operating table but is caused by many factors, as explained by the James Reason Swiss Cheese Model [19] and Human Factors Analysis and Classification System (HFACS) [20]. Training involved a standardized pre- and postbriefing aimed at comprehending and identifying potential behavioral enhancements within the training narrative, grounded in TeamSTEPPS principles. Specifically, we sought to collect participants' perspectives on the overall training experience and their interpretation of the TENTS and HFACS-related factors that contributed to the patient safety incident illustrated in the VR training. The debriefing data underwent analysis through the phenomenological analysis method [21] to gain insights into how participants interpreted the training and the patient safety incidents they encountered, thereby refining their understanding, behavior, and commitment to TeamSTEPPS practices. This qualitative analysis was performed by 2 researchers, a senior surgical attending and a fourth-year surgical resident, using the data frame theory of sense-making [22]. The primary objective of this qualitative effort was to enhance our understanding of the main outcomes and measures outlined below.

Main Outcomes and Measures

The primary outcome measures were the pooled average and 95% CI of observed TeamSTEPPS related behaviors quantified using the validated TENTS instrument (including 20 types of safety behaviors across 4 domains [communication, leadership, situation monitoring, and mutual support] scored from 0=expected but not observed, 1=observed but poorly performed or counterproductive, 2=observed and acceptable, and 3=observed and excellent).

Statistical Analysis

A 2-tailed, ANOVA was used to test for significance between the groupings. For given comparators (eg, [1] vs [2] or [2] vs [3]), we used a false discovery rate (FDR) control (the Benjamini-Hochberg procedure) to adjust the resulting *P* values (from the 2-sample *t*-tests) to account for the multiplicity of the tests. We claimed a result to be statistically significant if the adjusted *P* value is less than .05. All analyses were performed

with R statistical software. Data analysis was conducted from August 10 to December 1, 2023.

Results

Preintervention, all safety behaviors averaged slightly above 2 (“acceptable”), with an overall average of 2.2 (range 2 - 2.3). There was no significant difference between the intervention and the control group at the preintervention stage. The results indicated that the 10 surgeons that underwent our intervention showed statistically significant (P<.05) improvements in 90% (18/20) of safety behaviors when compared to the 10 surgeons that did not receive the intervention (overall average 2.5, range 2.3 - 2.7 vs overall average 2.1, range 1.9 - 2.2; Table 1). Our qualitative analysis revealed 492 individual quotes. The results suggest that the observed behavioral changes are a result of a sense-making emerging from 5 specific themes as discussed below.

Table . Summary of results (baseline vs intervention).

	TENTS[a] behavior	Baseline, mean (SD)	Intervention, mean (SD)	*P* value
1a	Communicates and receives information appropriately	2.227 (0.53)	2.708 (0.455)	.001
1b	Comfortable speaking up and asking questions	2.237 (0.452)	2.625 (0.484)	.001
1c	Responses to feedback between team members	2.135 (0.504)	2.458 (0.498)	.02
1d	Communicates and receives information to or from patient	2.097 (0.433)	2.261 (0.439)	.14
1e	Uses language in urgent situations appropriately	2.133 (0.505)	2.444 (0.497)	.04
1f	Uses teamwork tools	2.26 (0.464)	2.542 (0.498)	.03
1g	Learns together, focuses on improvement following a problem	2.222 (0.451)	2.55 (0.497)	.02
2a	Leaders effectively manage team during their roles	2.274 (0.493)	2.708 (0.455)	.001
2b	Verbalizes plan: intentions, recommendations, or timeframes	2.247 (0.501)	2.583 (0.571)	.02
2c	Delegates tasks appropriately	2.104 (0.369)	2.458 (0.498)	.007
2d	Instructs as appropriate to the situation	2.281 (0.475)	2.542 (0.498)	.03
3a	Pays attention to surroundings or environment	2.11 (0.526)	2.5 (0.5)	.005
3b	Aware of each other, contributions, strengths, and weaknesses	2.208 (0.433)	2.5 (0.5)	.02
3c	Verbalizes adjustments in plan as changes occur	2.236 (0.428)	2.524 (0.499)	.03
4a	Willingness to ask for help or additional resources	2.26 (0.464)	2.708 (0.455)	.001
4b	Willingness to support others across different roles	2.253 (0.437)	2.417 (0.493)	.15
4c	Accomplishes and prioritizes tasks appropriately	2.103 (0.338)	2.333 (0.471)	.04
4d	Employs conflict resolution	2.038 (0.341)	2.316 (0.465)	0.03
5	Rating of how well the team functioned as a whole	2.258 (0.44)	2.708 (0.455)	0.001
6	Rate how well leaders functioned and how the team responded	2.247 (0.434)	2.708 (0.455)	0.001

[a]TENTS: Teamwork Evaluation of Non-Technical Skills.

Discussion

Principal Results

Overview

The results show that participants exposed to our intervention displayed improved levels of safety behaviors, as quantified by the TENTS instrument, in 90% (18/20) of the safety behaviors measured. Specifically, quantitative data suggests that surgical teams were more effective in developing and maintaining a dynamic awareness of the situation in the operating room. This was achieved by assembling and understanding data from various sources (eg, patient, team, time, displays, and equipment), and using strong communication and leadership skills to think ahead and provide clear direction while being

considerate of individual team members' needs. Importantly, these improvements were observed not only at the individual level, as shown by the TENTS instrument, but also in the overall team functioning and leadership, as indicated by aggregate measures of "how well the team functioned as a whole," "how well the leaders functioned," and "how the team responded."

The 2 behaviors that did not reach statistical significance, despite trending positively, were 1d (communicating and receiving information with patients), and 4b (willingness to support others across different roles) (Table 1). For the communication behavior, very few such interactions were observed during the surgical cases, limiting our assessment of this behavior. Regarding the willingness to support others across roles, this was the highest-scoring behavior at baseline, suggesting it may have been challenging to improve further. This implies that in the dynamic and complex surgical environment, team members may struggle to step outside their designated roles to provide support to one another, as they focus intently on delivering excellent patient care and ensuring safety within their specific responsibilities.

Our qualitative analysis suggests that these behavioral improvements materialized from the enhanced understanding of skills needed in the operating room by reinforcing critical behaviors related to the sense-making of themes presented below.

Need for Effective Teamwork and Communication

The VR training modeled effective versus ineffective team communication, demonstrating how dismissing or ignoring concerns can lead to errors and decrease team trust. Participants may have practiced assertive communication, such as how a resident can escalate a concern when an anesthesiologist is distracted or how surgical technology can improve instrument handling. VR also emphasized calling out errors in a constructive way, rather than scolding or ignoring them.

The most consistent topics addressed by the subjects during the poststudy interview were teamwork and communication, and how these traits are essential for a well-functioning operating room. Participants noted how the VR training vividly illustrated both the consequences of poor communication and the benefits of a cohesive team. The training emphasized that errors often arise not solely from technical mistakes but from an inability to effectively relay and escalate concerns. The lack of teamwork and communication in the ineffective VR scenario was particularly alarming to participants. One individual highlighted the disconnect among team members: "There was clearly not a deep relationship between the surgeon, the resident, the scrub, the circulator, and the anesthesiologist; they just seemed completely disconnected [and] in their own worlds." Another key issue was the absence of assertive communication when concerns arose. One participant recalled: "The resident did pick up on the change in the heart rate tone, questioned the anesthesiologist about it, who blew her off." The absence of closed-loop communication was another prevalent theme. Participants remarked on how essential feedback loops were often missing in the ineffective scenarios, which contributed to preventable errors: "No closed-loop communication. Just a lot of people suggesting things but the other person either wasn't listening or just kind of ignored it and moved along. Even when it was something that could have prevented safety issues." Overall, the poststudy interviews reinforced that teamwork and communication are foundational to operating room effectiveness. The VR training provided a powerful demonstration of how dismissing concerns, failing to engage in open dialogue, and neglecting structured communication can significantly hinder patient safety. By recognizing these pitfalls and emphasizing assertive, closed-loop communication, participants reported a newfound appreciation for fostering a more cohesive and communicative operating room team.

Emphasis on Empathetic Workplace Culture and Psychological Safety

VR heightened participants' awareness of how fatigue, dismissive communication, and team dynamics impact psychological safety in the operating room. By simulating real-world scenarios, it demonstrated how exhaustion and distractions compromise decision-making, how seemingly minor quips or sarcasm can erode team cohesion, and how validating trainee concerns fosters a culture of safety and respect. This reinforced the importance of clear, professional communication and proactive leadership in creating a supportive and effective surgical intervention.

The VR training underscored how the psychological safe environment of the operating room directly impacts team effectiveness, patient safety, and overall workplace culture. Participants became more empathetic and attuned to how fatigue, dismissive behavior, and team dynamics can create a toxic versus supportive surgical setting. By immersing participants in scenarios where exhaustion led to oversight, sarcasm eroded trust, and concerns were either validated or dismissed, the training highlighted the importance of maintaining a psychologically safe and healthy work environment. One of the most striking realizations was how fatigue and distraction—often seen as inevitable in surgical practice—could significantly impair decision-making and communication. As one participant noted, "Exhaustion, lack of sleep, and lack of focus on the attending's part... distraction from the anesthesiologist... these are indicators that their wellness score is probably not stellar." Additionally, the training revealed how subtle, seemingly harmless behaviors can undermine psychological safety. Participants observed how sarcastic remarks or casual quips, even when meant humorously, created an environment where individuals felt less comfortable speaking up. "There were a lot of quips...I don't think they contributed too much. And they can be detrimental." Another crucial takeaway was the need to legitimize concerns when raised, rather than allowing the pressures of a high caseload to override safety. One participant reflected, "I think we can always do better legitimizing people raising concerns...the pressure to feel rushed and move quickly ... can obviously be counterproductive." Perhaps most telling was the recognition that team dynamics set the tone for the entire operating room. When interpersonal relationships are strained, it affects everyone, from the attending surgeon to the anesthesia technician. One participant encapsulated this sentiment: "Because I think we've all been in rooms where [if] the staff doesn't get along …it makes it miserable for everyone." The VR training effectively demonstrated how the psychological

environment of the operating room shapes both patient safety and team dynamics, making participants more aware of the subtle but powerful ways fatigue, communication styles, and validation of concerns impact surgical outcomes. By immersing participants in realistic scenarios, the training seemed to inspire an appreciation for operating rooms, where they do have a psychologically healthy environment.

Need for Leadership With Personal Responsibility and Accountability

VR simulation highlighted the ripple effect of individual actions—how fatigue, inattention, or lack of engagement from a team member impacts the whole operating room. It also reinforced that leaders (attendings, residents, or nurses) set the tone for safety culture, whether by ensuring protocols are followed or by fostering an environment where concerns can be raised. The VR training may have helped participants recognize their personal accountability in maintaining operating room safety and identifying behaviors that contribute to or undermine team effectiveness.

The training reinforced the critical role that leadership plays in shaping operating room culture, particularly in fostering accountability and ensuring adherence to safety protocols. Participants observed how leadership—or the lack thereof—had a cascading effect on communication, decision-making, and overall team cohesion. By placing participants in scenarios where leadership failures led to errors or unsafe practices, the training emphasized the responsibility of every operating room member to contribute to a culture of accountability. A key takeaway was the attending surgeon's responsibility in setting the tone for the operating room environment. As 1 participant remarked, "The attending surgeon sort of sets the tone in many ways, and by not looking into concerns...[and] cutting corners in order to be able to increase throughput...—that's just not good leadership." Beyond the attending, participants recognized how personal accountability extends to every team member. The training exposed moments where concerns were voiced quietly but never formally escalated, leading to missed opportunities to address potential safety issues. One participant reflected, "...everyone was making little comments, but no one was, again, like really saying them. They were all kind of talking to themselves...." The VR also made participants more aware of how the pressure to move quickly can lead to cutting corners, potentially compromising patient outcomes. One participant acknowledged, "We all get caught up in rush, rush, rush…and I've done that before, where you look through the labs, like, it's probably fine. It usually is. But what if it's not?" Ultimately, the training reinforced the idea that each case demands responsibility and accountability. The VR experience demonstrated how a disengaged or inattentive leader could undermine these traits by dismissing concerns or prioritizing efficiency over protocol.

Need for Stability

The VR training elicited participants' desires and personal experiences to have surgical teams that are consistent and connected. Understandably, those who are working in a high-stakes, high-stress environment would want to mitigate other factors that could lead to negative patient outcomes or contribute to workplace burnout and distress. The VR training showed participants what can happen with a more discordant or unstable working environment, which can mimic reality, and many participants were quick to point out how deleterious that can be to the dynamics of an operating room.

The training highlighted the critical role that stability plays in fostering an effective and supportive surgical environment. Participants emphasized the need for consistency in team composition, resource availability, and leadership presence—elements that are often taken for granted but can significantly impact patient safety and staff well-being. In the high-stakes, high-stress environment of the operating room, an unstable or discordant team structure can lead to inefficiencies, miscommunication, and increased burnout, all of which were vividly demonstrated in the VR scenarios. Many participants noted how instability, whether due to staffing shortages, systemic pressures, or administrative constraints, can disrupt operating room dynamics. One participant reflected on the broader hospital structure, stating, "It didn't seem like there was support from a majority of people...No one person can do it all." A major recurring theme was the strain placed on attendings who were expected to be in multiple places at once, highlighting the impact of systemic pressures on operating room stability. As 1 participant observed, "I mean, there were clearly systemic pressures for the attending to be in multiple places at one time, I would say primarily pressure for throughput, short staffing." This speaks to the broader challenges of balancing efficiency with quality care. This particularly resonated with our interviewees as it is something that a vast majority of health care workers can relate to. By experiencing the challenges of an unstable operating room environment with the constant, relatable pressure to do more, participants gained a deeper appreciation for the structures and policies needed to foster a more reliable and effective surgical setting.

Emphasis on Outcome and Attention to Detail

This VR module showed participants what can happen when means do not at all justify ends. In a system where outcomes, whether it be several cases completed or the speed of the operation, are prioritized over how those end points are achieved, it can lead to consequential errors. While operating rooms need to maintain a high level of efficiency, the consequences of doing so can come at the expense of the patient. It can be challenging for surgeons to balance their commitment to good patient care with intense pressures for increased efficiency and decreased case turnaround time.

The VR training underscored the risks of prioritizing efficiency and case volume over patient safety and procedural integrity. Participants recognized how a results-driven culture, where speed and throughput are emphasized over safe surgical practice, can lead to critical errors and compromise team effectiveness. While efficiency is a necessary component of modern surgical workflows, the VR scenarios illustrated the consequences of allowing productivity pressures to override fundamental principles of patient care. One participant stated, "many other factors—fatigue [and]the pressure from hospital administration for revenue and productivity," when reflecting on the systemic pressures driving an outcome-based mindset. The VR module

demonstrated how this tunnel vision manifests at different levels of the operating room team. One participant observed, "The resident's main mission was 'I gotta close so I can go to the other room.' The surgeon was like 'I gotta get these 12 cases done because that's what administration says.' The circulator was like 'We gotta get these cases done so we can all go home.'" Participants also reflected on the human cost of this approach, not just for the patients but for the surgical teams themselves. One particularly striking insight was, " ...it's fine to be efficient. It's not fine to be in a hurry. And I think that it's really, really important for all of us to think about...." The training allowed participants to experience the tension between efficiency and quality care, a concept that is ubiquitous among health care settings. By highlighting the potential dangers of an outcome-driven approach, the VR module reinforced the need for deliberate, methodical teamwork, where safety is never sacrificed in the name of speed or the bottom line.

The VR training also reinforced the critical importance of attention to detail in the operating room, highlighting how even small lapses in accuracy can lead to significant consequences. By immersing participants in real-world scenarios, the module demonstrated how factors such as fatigue, communication breakdowns, and time pressures can contribute to oversights. It emphasized that attention to detail is not just an individual responsibility but a collective effort, where every team member plays a role in maintaining surgical precision.

The training reinforced the critical role of accuracy in the operating room, emphasizing how seemingly minor lapses in attention to detail can have significant consequences for patient outcomes. Participants recognized that surgical safety is not solely dependent on technical skill but also on the thoroughness of preoperative preparation, intraoperative vigilance, and collective situational awareness. Several interviewees pointed out the dangers of neglecting critical details in the operating room. For example, many participants highlighted that the failure to properly assess a patient's anticoagulation status before surgery leads to cancellation of cases and delays in care. Another key theme was the lack of a shared mental model among the surgical team, leading to fragmented awareness of the patient's condition. As one participant described, "I'm not sure that there was a complete understanding of the entire situation... that global shared mental model of where everybody was, the implications of the decisions, and how things were happening was kind of missing." The scenarios also illustrated that once the ball was set in motion, no one had the care or will to change it. One participant noted, "It seemed like both the surgeon and the resident didn't have a good sense of who the patient was, what the case was, if they were on anticoagulation. And then even when the resident realized and brought it up to the attending, the attending was like, 'It's fine, it's too late, moving on.'" Ultimately, the VR experience reinforced the necessity of meticulous preparation, comprehensive team awareness, and an environment where concerns are acknowledged rather than dismissed. It demonstrated that attention to detail is not merely an individual responsibility but a collective effort, where every member of the surgical team plays a vital role in ensuring safe and effective patient care.

Comparison With Prior Work

This pilot study is the first to quantify the effects of an immersive VR-based educational intervention focused on improving TeamSTEPPS-related behaviors among surgeons in the operating room. Overall, the findings align with previous non–VR-based research highlighting the importance of teamwork training for enhancing soft skills critical to patient safety [23-27]. Our findings also align with the conclusions of the work by Abelson et al [11] that supports the motion that VR is a feasible solution for team-based training, and Gasteiger et al [12] that postulate that technical and nontechnical skills training programs using VR for health care staff may trigger perceptions of realism and deep immersion and enable easier visualization, interactivity, enhanced skills, and repeated practice in a safe environment, which in turn may improve skills and increase learning, knowledge, and learner satisfaction. Notably, prior work using VR to teach TeamSTEPPS for cesarean section surgery showed that the VR-based content improved teamwork competencies in interprofessional surgical teams [28]. By addressing the need for teamwork training, while using the TeamSTEPPS framework, and incorporating innovative educational technologies such as VR, this study demonstrated how collaboration among surgical team members can be enhanced [28]. Finally, in a randomized trial, Liaw et al [13] showed that learning outcomes did not show an inferiority of team training using VR when compared with live simulations, which supports the potential use of VR to substitute conventional simulations for communication team training.

However, many of these initiatives concentrate on skills pertinent to the immediate context of errors, such as communication and teamwork in the operating room, as well as technical competencies, while often neglecting training related to systemic flaws, the culture of patient safety, and the unreliable thought processes and behaviors that can lead to mistakes or hinder their prevention. We propose that trainees' comprehension of the factors leading to patient safety incidents as highlighted by the HFACS framework, their sense-making of safety behaviors as outlined by the TENTS tool, and their understanding of TeamSTEPPS principles in the context of the surgical error can lead to improvements in patient safety.

Limitations

While the findings of this study offer valuable insights, there are several important limitations to consider. First, the results are based on a single experiment with a relatively small sample size from 1 academic medical center. To address the small sample size, we used a 2-tailed, ANOVA for significance between the groupings using the FDR to adjust the resulting *P* values (from the 2-sample *t*-tests) to account for the multiplicity of the tests. For a 2-tailed, ANOVA for significance between the groupings, without the FDR control, the analysis would require approximately 68 participants to obtain a medium and to large effect size, the power level of 0.8, and an α of .05. Larger-scale studies could also take into account various confounding factors, such as training levels, gender, and race. Additionally, the possibility that more motivated individuals enrolled in the intervention group may have skewed the results. Second, the participants' awareness of being observed may have

influenced their performance, potentially biasing the results toward better patient safety practices. To mitigate this effect, all participants were allowed to withdraw from the study at any time and were assured that their individual results would remain confidential. Third, the TENTS instrument and scoring could be imperfect. We address this by conducting robust training and practice with the TENTS tool and by blinding students to the treatment status of the surgeons during postintervention observations. Despite the limitations associated with this approach, the involvement of medical student volunteers was essential for executing this extensive observational study without incurring financial costs. Future iterations of this research could leverage such a program, benefiting both the institution through enhanced understanding of behaviors in operating rooms and the students through valuable operating room exposure and hospital experience. In summary, while the findings offer valuable insights, the limitations of this single-site study with a small sample size and potential participant bias must be considered. Larger, more robust studies will be needed to validate and expand upon these preliminary results. There is also a need for longitudinal studies to assess effects over time.

Conclusions

A VR-based immersive training program focused on TeamSTEPPS principles appears effective at improving safety behaviors, as measured by the TENTS tool. Our qualitative analysis based on 492 quotes from participants, suggest that the observed behavioral changes are a result of an immersive experience and sense-making of key training concepts where participants could see the consequences of suboptimal teamwork (eg, poor leadership and communication, lack of attention to detail, failure to take responsibility, low psychological safety to speak up, etc). Given the persistent patient safety issues in operating rooms nationwide, such innovative and immersive patient safety education programs could provide a scalable intervention to help reduce patient harm in the long run. However, further research with larger, more diverse sample sizes is needed to confirm the generalizability of these findings.

Acknowledgments

The authors want to acknowledge the contribution of the following medical student volunteers in collecting the data used for this study: Kwadwo Ansah, Cameron Kurz, Julian Mobley, SL, Ricardo Crespo, Mary Kaufman, Kainat Aslam, Dakota Perez, Grace Fuller, Grace Tabor, Lily Bender, Alexander Requarth, Hannah Black, Brenderia Cameron, Annie Bright, Zhanè Washington, Sierra Parkinson, Collin Shick, and Mandi. We also want to send special thanks to the following medical students for their contribution to the qualitative data analysis: Anu Chaparala, Nathan Adams, and SL.

Abstract

Bing Chat (subsequently renamed Microsoft Copilot)—a ChatGPT 4.0–based large language model—demonstrated comparable performance to medical students in answering essay-style concept appraisals, while assessors struggled to differentiate artificial intelligence (AI) responses from human responses. These results highlight the need to prepare students and educators for a future world of AI by fostering reflective learning practices and critical thinking.

(JMIR Med Educ 2025;11:e72034) doi:10.2196/72034

KEYWORDS

essay-type questions; large language models; generative AI; Microsoft Copilot; artificial intelligence

Introduction

Large language models (LLMs) are of growing interest in medical education. LLMs have demonstrated passing scores on the United States Medical Licensing Examination (USMLE), raising questions about their impact on assessment frameworks [1], including whether artificial intelligence (AI) can successfully answer essay-style, reasoning-based questions and whether assessors can distinguish AI-generated and student-written responses. Our medical school's preclinical students complete application-level, essay-type questions—concept appraisals (CAPPs)—every week (Multimedia Appendix 1) [2]. We evaluated LLMs' performance on CAPPs and examined assessors' ability to distinguish AI-generated and human responses.

Methods

Study Design

Ten retired CAPP questions were selected, ensuring representation from multiple preclinical organ-system blocks, including gastroenterology, endocrinology, musculoskeletal science, cardiorespiratory medicine, hematology, renal biology, and immunology. Retired CAPPs were used, so that currently used ones were not exposed to students. Answering these required literature review and application of knowledge to clinical scenarios.

Five student responses from previous classes (before availability of LLMs) were randomly selected and deidentified. Individuals at various medical training levels generated AI responses via Bing Chat (subsequently renamed Microsoft Copilot; Multimedia Appendix 1), which used GPT-4 algorithms and had similar performance on medical tasks as ChatGPT 4.0—the most advanced LLM at the time of study [3,4]. Users first prompted Bing Chat by using the original CAPP text and then iteratively refined prompts to generate more comprehensive answers and match institutional standards without manual editing (Multimedia Appendix 1).

Ten expert assessors graded responses to 1 CAPP question each. While unaware that any responses had been AI-generated, they graded 5 deidentified student responses and 2 AI-generated responses (presented in random order) for their CAPP question, using a standard rubric (Multimedia Appendix 1). For 2 CAPPs, 4 student responses were used instead of 5 due to lack of consent for inclusion in the registry. Grading each CAPP took approximately 30 minutes; thus, a larger sample size was infeasible for this exploratory study. Afterward, assessors

identified whether responses were AI- or student-generated and provided their rationales.

Scoring differences between human- and AI-generated responses and identification accuracy were evaluated, using descriptive statistics. Thematic analysis was conducted on assessors' classification rationales; 2 team members independently analyzed reasons to identify themes, compared findings, and reconciled differences (Multimedia Appendix 1).

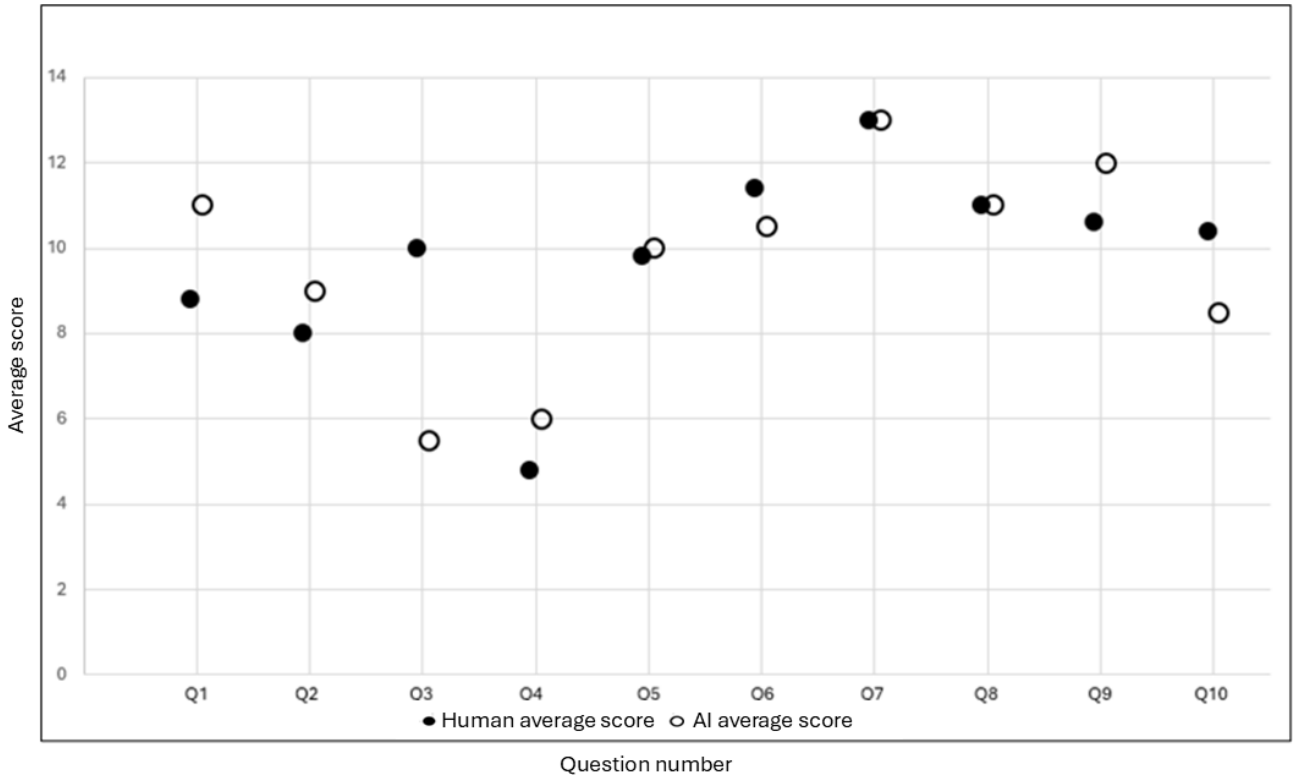
Ethical Considerations

This study used deidentified data from the Cleveland Clinic Institutional Review Board–approved registry #6600. Since this was a registry for which students had already provided informed consent, separate informed consent was not required. Each CAPP reviewer was paid US $100.

Results

AI responses received scores higher than or equal to those for human responses for most questions, with substantial performance variability; AI scored better than, equivalent to, or worse than humans, depending on the CAPP question (Figure 1).

Figure 1. Average of human vs AI scores for each question. CAPP questions were answered either by students (human) or by prompting Microsoft Copilot (AI). Expert graders scored the CAPP questions based on a rubric. The average scores received by humans and AI are shown by question (colored vs open circles, respectively). AI responses received scores higher than or equal to those for human responses for most questions. Each question had a unique maximum score. This figure illustrates the relative scores of humans vs AI. AI: artificial intelligence; CAPP: concept appraisal.



Assessors correctly identified response sources 53% (36/68) of the time (student responses: 27/48, 56%; AI-generated responses: 9/20, 45%). Only 1 assessor correctly classified all responses. Consistent with other studies, 1 assessor who used AI detection tools did not have much success [5] (Table 1).

Table . Percentage of responses correctly identified as human or artificial intelligence (AI) responses for each critical appraisal (CAPP) question.[a]

Question number	Correctly identified responses, n/N (%)
Q1	3/6 (50)
Q2	3/7 (43)
Q3	3/7 (43)
Q4	6/7 (86)
Q5	3/6 (50)
Q6	2/7 (29)
Q7[b]	0/7 (0)
Q8	5/7 (71)
Q9	4/7 (58)
Q10[c]	7/7 (100)

[a]Responses for each question were graded by 1 expert. Expert graders were blinded and were not told which responses were generated by humans vs AI.

[b]Despite utilization of AI detection tools, 1 assessor did not correctly classify any of the responses (Q7).

[c]Only 1 assessor correctly classified all responses for their CAPP question (Q10).

Thematic analysis showed that the most cited reason for identification was the perceived "writing style," though many assessors noted an inability to distinguish categories (Multimedia Appendix 1).

Discussion

We demonstrate that AI can provide high-quality answers to essay-style medical education questions requiring detailed research and knowledge application. Content experts struggled to distinguish AI-generated and human-written responses, underscoring the challenges of identifying academic misuse of generative AI.

Iterative prompting of Microsoft Copilot was essential for generating acceptable responses. This process mirrors students' typical workflow for refining drafts through edits; thus, iterative prompting does not necessarily disadvantage AI. Our findings highlight concerns about potential overreliance on AI and its implications for assessment validity, especially as recent survey data suggest that 89% of students use ChatGPT during self-study [6,7].

Given AI responses' similarity to human responses, institutions must consider frameworks for integrating AI into assessments without compromising academic integrity [8]. Potential strategies include structured classroom use of AI during collaborative group work (eg, requiring students to assess AI responses and cite primary evidence to support or refute them) [7,9].

Study limitations include a small sample of AI-generated responses and the research's exploratory nature. Expanding the sample size and including additional questions could provide insights on AI's performance (relative to humans) for specific question types (Multimedia Appendix 1). Additionally, the findings prompt further discussions on ethically integrating generative AI into medical curricula while ensuring students develop critical appraisal and independent reasoning skills [7,10].

AI's performance suggests its potential as a learning enhancement tool. However, medical educators must implement strategies for preventing overreliance on AI, fostering reflective learning practices and critical thinking, and maintaining assessment integrity.

Acknowledgments

The authors would like to thank the following individuals for serving as concept appraisal (CAPP) graders: William Albabish, William Cantrell, Thomas Crilley, Ryan Ellis, Andrew Ford, Emily Frisch, Jeffrey Schwartz, Michael Smith, Mohammad Sohail, and Anirudh Yalamanchali. Financial support was received from The Jones Day Endowment Fund.

Authors' Contributions

IBB and NM contributed to the literature review. NM, AKM, and CCL contributed to the conceptual design. SM, NM, ASN, and AD contributed to data analysis and visualization. IBB and SMB contributed to thematic analysis. SM, ENH, and NM contributed to manuscript writing. All authors contributed to the critical revision of the manuscript.

Conflicts of Interest

None declared.

Abstract

An April 2025 survey of 118 first-year Japanese medical students found high use of generative artificial intelligence (84.7%) but limited formal learning (49.2%), with strong learning interest yet neutral assignment use, indicating a need for structured literacy in generative artificial intelligence.

(JMIR Med Educ 2025;11:e77552) doi:10.2196/77552

KEYWORDS

generative artificial intelligence; medical students; digital literacy; perceptions; learning behavior; Japan

Introduction

Generative artificial intelligence (GenAI), particularly large language models like ChatGPT (OpenAI), has emerged as a tool for brainstorming, information gathering, proofreading, translating, and other academic tasks [1]. The rapid evolution of ChatGPT has made it essential for medical students to understand and use these tools [2]. As digital technologies become more embedded in health care education, understanding how future physicians will engage GenAI is vital. Many students demonstrate familiarity with digital tools and are exposed to them during childhood. One study showed that medical students had positive attitudes toward GenAI, albeit with low use rates [3]. In Japan, although some educators have adopted GenAI, information on how incoming medical students educated during the GenAI boom perceive these tools remains limited [4]. Thus, we explored GenAI use, learning behaviors, and perceptions of first-year medical students in Japan.

Methods

Overview

An anonymous online survey targeting first-year students immediately after high school graduation was conducted at the Chiba University School of Medicine in April 2025; 120 students were invited to participate and 118 valid responses were received (response rate 98.3%).

The questionnaire comprised four sections: (1) demographics; (2) prior GenAI exposure; (3) willingness to learn and perceptions (16 items rated on a 5-point Likert scale [1=strongly disagree to 5=strongly agree], based on prior studies [5,6]); and (4) an open-ended item on academic use. The items were pilot-tested for clarity and reliability.

Group differences were examined using independent 2-tailed *t* tests and chi-square tests. Spearman correlations were used to identify factors associated with learning motivation. Internal consistency (Cronbach α) was 0.81 for risk awareness (6 items), 0.81 for benefit recognition (6 items), and 0.53 for concern items (4 items; reverse-coded). Statistical significance was set at $P<.05$. Two independent coders performed content analysis of open-ended responses, with substantial agreement (κ=0.67). Analyses were conducted using JMP Pro (version 18; JMP Statistical Discovery LLC).

Ethical Considerations

This study was approved by the ethics committee of Chiba University Graduate School of Medicine (approval 3425). Electronic informed consent was obtained prior to participation. The study database was anonymized. Study data are stored on an offline, password-protected computer with full-disk encryption. Participants received no compensation for this study. All methods were in accordance with the relevant guidelines and regulations.

Results

Among 118 responses (n=79, 66.9% male; mean age 18.5, SD 0.7 years), 84.7% (n=100) reported GenAI use, mainly for language learning (n=53, 44.9%) and information searches (n=46, 39.0%). Only 49.2% (n=58) of the participants had

learned about GenAI, primarily through browsing (n=34, 28.8%) or through peers (n=24, 20.3%).

Students demonstrated high willingness to learn (mean score 4.3, SD 0.9), with good understanding (mean scores 3.9 - 4.6) and positive attitudes, especially regarding the relevance of GenAI (mean score 4.3, SD 0.8) (Table 1). Perceived individualization was lower (mean score 3.5, SD 1.0), with concerns over educational impact (mean score 3.6, SD 0.9).

Willingness to learn correlated positively with expectations of GenAI's benefits, such as enhancing digital literacy and career preparedness (both $P<.001$).

Students with learning experience were slightly younger (mean age 18.4, SD 0.7 vs 18.7, SD 0.8 years; $P=.02$) and demonstrated greater awareness of potential bias in GenAI outputs ($P=.045$).

Table . Medical students' responses regarding demographics, knowledge, willingness to use, and concerns about generative artificial intelligence (GenAI) technologies.

Item		All (n=118)	Experienced[a] group (n=58)	Inexperienced group (n=60)	*P* value
Sex, n (%)					.13
	Male	79	35	44	
	Female	39	23	16	
Age (years), mean (SD)		18.5 (0.7)	18.4 (0.7)	18.7 (0.8)	.02
Willingness to learn about GenAI (1=strongly negative to 5=strongly positive), mean score (SD)		4.3 (0.9)	4.3 (0.8)	4.2 (0.9)	.32
Attitude toward using GenAI for assignments (1=strongly negative to 5=strongly positive), mean score (SD)		3.0 (1.0)	2.9 (1.0)	3.0 (1.0)	.65
Knowledge of GenAI technologies, mean score (SD)					
	I understand that GenAI has limitations in handling complex tasks.	3.9 (0.9)	4.1 (0.9)	3.9 (0.9)	.21
	I understand that GenAI may produce outputs that are factually incorrect.	4.6 (0.7)	4.6 (0.6)	4.6 (0.7)	.67
	I understand that GenAI may generate outputs that are contextually inappropriate.	4.4 (0.7)	4.4 (0.7)	4.4 (0.6)	.9
	I understand that GenAI outputs may sometimes reflect bias or discrimination.	4.0 (0.9)	4.2 (0.9)	3.9 (0.9)	.04
	I understand that GenAI is pattern-based and may have limited applicability in specific contexts.	4.0 (1.0)	4.1 (1.0)	3.8 (0.9)	.11
	I understand that that GenAI lacks emotional intelligence and may produce insensitive content.	4.1 (1.0)	4.2 (0.9)	3.9 (1.0)	.11
Willingness to use GenAI technologies, mean score (SD)					
	I am considering incorporating GenAI into my learning and practice in the future.	3.9 (0.8)	3.9 (0.8)	3.8 (0.9)	.53
	Students need to learn how to effectively leverage GenAI for their career paths.	4.3 (0.8)	4.3 (0.7)	4.3 (0.9)	.59
	I believe that GenAI can enhance my digital literacy skills.	3.7 (1.0)	3.8 (0.9)	3.6 (1.1)	.33
	I believe GenAI can offer novel insights beyond my own thinking.	3.8 (0.9)	3.8 (0.8)	3.9 (0.9)	.73

Item		All (n=118)	Experienced[a] group (n=58)	Inexperienced group (n=60)	*P* value
	I believe that GenAI can instantly offer personalized suggestions for my assignments.	3.5 (1.0)	3.5 (1.0)	3.5 (1.0)	.99
	I think GenAI is a great tool because it is available 24-7.	4.0 (0.9)	4.0 (0.8)	3.9 (1.0)	.36
Concerns about GenAI technologies, mean score (SD)					
	Completing assignments using GenAI undermines the value of a university education.	3.6 (0.9)	3.6 (0.9)	3.5 (0.9)	.53
	GenAI limits opportunities for students to interact during face-to-face lectures and group work.	3.2 (1.0)	3.3 (0.9)	3.1 (1.0)	.25
	GenAI hinders the development of portable skills, such as teamwork, problem-solving, and leadership.	3.5 (0.9)	3.6 (0.8)	3.4 (1.0)	.12
	I feel that I am becoming overly dependent on GenAI.	2.1 (1.1)	2.2 (1.2)	2.0 (1.1)	.25

[a]"Experienced" refers to students who reported any learning about GenAI, including formal instruction and learning from informal sources, such as web browsing or peers.

The attitude toward using GenAI for assignments was neutral (mean score 3.0, SD 1.0). Open-ended responses were categorized into 3 attitudinal groups, "positive," "cautious," and "negative," reflecting enthusiasm, balanced concerns, or skepticism (Table 2).

Table . Keyword categories extracted from free-text responses regarding the academic use of generative artificial intelligence (GenAI).

Category		Keywords	Responses, n	Quotes
Positive				
	Convenience and efficiency	Efficient, convenient, easy	25	GenAI improves work efficiency because it can quickly search for information.
	Information handling and use	Information gathering, use, referencing, critical thinking	23	Using GenAI as a mock interviewer to question my responses was helpful.
	Quality and outcomes	Quality improvement, attractive, useful	9	High-quality information can be obtained.
	Necessity and attitude	Necessary, available resources	6	We should develop the ability to use GenAI effectively.
	Creativity	Original, idea	4	By integrating it with my own ideas, I can come up with more original concepts.
Cautious				
	Quantity and scope	Excessive, limited range, moderate, balance	27	I believe using GenAI within a limited range, such as proofreading my own writing, is acceptable.
	Use and operation	Assistance, proper use, permission	11	I think using GenAI as a learning assistant is good, but relying on it entirely is not advisable.
	Perception and emotion	Unclear, anxiety	5	I still don't fully understand GenAI, so I have some anxiety, but I also have a desire to master its use.
Negative				
	Thinking and creativity	Think independently, cessation of thinking, boring	40	Our ability to think independently will be lost.
	Ethics and norms	Dishonesty, fairness, rules	9	Presenting GenAI-generated work as one's own is, in my view, equivalent to plagiarism.
	Uncertainty and constraints	Ambiguity, limitations	3	Accuracy of GenAI is not guaranteed.

Discussion

Most medical students had used GenAI before university; however, structured learning was limited. Minor differences in perceptions between those with and without learning experience suggest that casual exposure alone may be insufficient to develop a critical understanding of GenAI, highlighting the need for foundational GenAI education in universities [7].

Although the students were interested in learning about GenAI, they remained cautious about using it for assignments, reflecting varied levels of familiarity and trust. While most viewed GenAI positively, some expressed concern that overreliance could hinder creativity and critical thinking.

GenAI dependence may hinder originality and decision-making [8], whereas trust in GenAI may foster motivation and proactive learning [9]. Students' neutral views suggest uncertainty or low confidence regarding appropriate use, underscoring the need for a balanced education that addresses concerns and fosters critical evaluation skills. This aligns with previous studies highlighting the importance of reforming curricula to integrate GenAI-related competencies, including ethical reasoning, clinical relevance, and communication skills [10].

A limitation of this study was that only first-year students at a single institution were included. Further, the "concern" subscale had relatively low internal consistency, and qualitative analysis relied on a single open-ended item. Finally, multiple comparisons were performed without correction, increasing the risk of type I errors. Nevertheless, this exploratory study aimed to identify trends rather than test specific hypotheses.

In conclusion, our findings support the inclusion of structured GenAI curricula in higher education, suggesting that such programs go beyond technical training to address students' expectations, values, and concerns.

Abstract

Background: Health care practitioners use clinical decision support systems (CDSS) as an aid in the crucial task of clinical reasoning and decision-making. Traditional CDSS are online repositories (ORs) and clinical practice guidelines (CPG). Recently, large language models (LLMs) such as ChatGPT have emerged as potential alternatives. They have proven to be powerful, innovative tools, yet they are not devoid of worrisome risks.

Objective: This study aims to explore how medical students perform in an evaluated clinical case through the use of different CDSS tools.

Methods: The authors randomly divided medical students into 3 groups, CPG, n=6 (38%); OR, n=5 (31%); and ChatGPT, n=5 (31%); and assigned each group a different type of CDSS for guidance in answering prespecified questions, assessing how students' speed and ability at resolving the same clinical case varied accordingly. External reviewers evaluated all answers based on accuracy and completeness metrics (score: 1 - 5). The authors analyzed and categorized group scores according to the skill investigated: differential diagnosis, diagnostic workup, and clinical decision-making.

Results: Answering time showed a trend for the ChatGPT group to be the fastest. The mean scores for completeness were as follows: CPG 4.0, OR 3.7, and ChatGPT 3.8 (P=.49). The mean scores for accuracy were as follows: CPG 4.0, OR 3.3, and ChatGPT 3.7 (P=.02). Aggregating scores according to the 3 students' skill domains, trends in differences among the groups emerge more clearly, with the CPG group that performed best in nearly all domains and maintained almost perfect alignment between its completeness and accuracy.

Conclusions: This hands-on session provided valuable insights into the potential perks and associated pitfalls of LLMs in medical education and practice. It suggested the critical need to include teachings in medical degree courses on how to properly take advantage of LLMs, as the potential for misuse is evident and real.

Introduction

Clinical reasoning and decision-making are at the core of the medical workflow. If they are accurate and grounded on solid and updated evidence, they help ensure the best health outcomes for patients. Clinical decision support systems (CDSS) have been implemented to aid practitioners in this duty [1-3]. Clinical practice guidelines (CPG) serve as the prototype for CDSS. They are published and updated at varying frequencies by scientific societies and policy makers, covering virtually every medical field or disorder. Over time, the number and complexity of CPG have increased, resulting in more detailed and robust recommendations. However, this has also led to reduced immediacy and ease of access and comprehension for medical professionals. Additionally, there may be multiple CPG for a single pathological condition, sometimes with conflicting recommendations. As a potential solution, emerging technologies on the internet have given rise to new CDSS options known as online repositories (ORs). These repositories, like encyclopedias, consolidate and synthesize knowledge

related to various medical disorders. They draw from current practices, available CPG, and the latest published evidence, making this information easily accessible to physicians. Typically provided by publishing groups, ORs often require subscription-based access. Two of the most popular options are "UpToDate" (by Wolters Kluwer [4]) and "BMJ Best Practice" (by BMJ Publishing Group [5]), both available as websites and mobile apps. The recent introduction of large language models (LLMs) for public use has generated both excitement and debate. Their adoption has rapidly grown across various human activities [6]. Many foresee the immense potential benefits of applying such technology to medical practice, while others harbor concerns about the dangers it might pose if left unregulated and misaligned [7-12].

Without a doubt, LLMs like ChatGPT represent a new generation of CDSS with unparalleled assistance capabilities. They can engage in active interactions with users and directly interpret medical information, extending far beyond simple guideline consultation. They can suggest possible diagnostic workups (DWs) or treatment algorithms [6]. In such cases, physicians would no longer need to navigate extensive datasets of clinical information, distill practical advice from lengthy text pages, or grapple with uncertainty about consulting the correct or sufficient sources. On the flip side, it is evident that LLMs also carry the potential for misuse, which could lead to significant harm to patients [7-9,11,13]. There's a risk of guiding clinicians down erroneous thought processes, potentially resulting in wasted time and the unintentional complication of cases. When the alternatives being evaluated are either incorrect or become excessively numerous, the complexity of a case may inevitably worsen. As a result, there is legitimate concern regarding how the indiscriminate use of LLMs might inadvertently drive-up health care costs. This underscores the importance of integrating LLMs into clinical decision-making (CDM) processes with caution and judiciousness.

However, although the adoption of innovative CDSS tools is steadily rising, the lack of dedicated training in their proper utilization undermines their full potential as valuable aids [9,10].

The aim of the present study was to investigate how senior medical students employ CDSS in the resolution of a clinical case with the ultimate intention of designing specific educational programs. Specifically, we conducted a hands-on session to compare CPG, ORs, and an LLM (ChatGPT) in terms of speed and accuracy of the clinical decisions proposed after consultancy with the CDSS.

Methods

Study Design

The present is a report of a hands-on practical session taking place during the Course of Internal Medicine at our university. The subject of the analysis was the quality of students' answers to a number of open-ended questions related to clinical reasoning and problem-solving, as a proxy for their capacity to employ different CDSS. A fictional clinical case was designed by the authors to control for complexity. Additionally, ChatGPT (version 3.5) generative capabilities were used to fabricate vital parameters, physical examination, and laboratory results for the fictional patient. ChatGPT was asked to include confounding factors in the answers provided. The authors revised generated elements to make sure they met the study requirements. The complete clinical case, open-ended questions and conversation with ChatGPT are available in Multimedia Appendix 1 and Multimedia Appendix 2.

Participants, Recruitment Strategies, and Sampling Method

Students attending the last lesson in the academic year 2022/23 Course of Internal Medicine of the International MD Program degree at Vita-Salute San Raffaele University, Milan (IT), were all included in the study, with convenience sampling. No exclusion criteria were applied.

Experimental Groups, Randomization, and Blinding

In total, 3 groups with comparable numbers of students were defined at the beginning of the lesson (Multimedia Appendix 3). Starting from the first seating rows, students were randomly assigned a number from 1 to 3 and consequently formed the 3 groups. Each group nominated a delegate who randomly picked an envelope containing the indication of the type of CDSS to be used by his or her group, either (i) CPG, (ii) OR, or (iii) ChatGPT. For each group, only the delegate was allowed web-based access to the CDSS. Group assignments were open label. The group assigned to CPG was allowed to use the internet to search for and consult CPG deemed useful to solve the case. The group assigned to OR was allowed to use the internet to access UpToDate and look for articles and algorithms or tables deemed useful to solve the case. The group assigned to ChatGPT was allowed to log into the LLM and use it to ask and gather information deemed useful to solve the case.

The delegate was also in charge of sending his or her group's clinical decision to the researchers via a mobile phone SMS text message. An inspector of the research staff was assigned to each group to guarantee that only the assigned CDSS was used. The questions were shown along with the presentation of the clinical case in a Microsoft PowerPoint (Microsoft Corporation) slideshow. For each question, a countdown timer was shown on the projector screen, and the start time was recorded by the researchers. Time required by each group for each answer was calculated by subtracting the start time from the mobile message arrival time.

Outcomes/Assessment

In total, 1 junior resident in internal medicine, 1 senior resident in internal medicine, and 2 internal medicine junior consultants were asked to perform blind external assessment of the answers. They were provided with a form containing the same clinical case and questions shown to the students together with the answers given by each group, with no details on CDSS used. Answers were graded from 1 to 5 in terms, respectively, of completeness and accuracy. Completeness was described as: "Is the answer complete or does it miss anything?". Accuracy was described as: "Is the answer precise and adherent to clinical practice, or too vague, too wide, too superficial?"

Sample Size

Sample size was not defined a priori. Sample size was determined by the number of students that attended the lesson on that day.

Statistical Analysis

Scores are reported as mean. For further analysis, the 8 questions were grouped into 3 domains according to the students' skill investigated: (1) differential diagnosis (DD, Q 1-5-6), (2) DW (Q 2 - 7), and (3) CDM (Q 3-4-8). The Kruskal-Wallis test was performed to establish whether there was a significant difference among the 3 groups in the times and scores overall and in each student skill domain. Microsoft Excel (Microsoft Corporation) and GraphPad Prism (version 9.0; GraphPad Software) were used as software tools for the analysis.

Ethical Considerations

This study does not require ethical approval as this is a report of data collected for monitoring and reporting purposes of innovative teaching activities taking place at Vita-Salute San Raffaele University, according to the Self-assessment-Evaluation-Accreditation system (AVA) of ANVUR, to which our institution is subject [14]. The data were generated during a hands-on session taking place during a usual lesson and in a teaching, non-experimental environment, with no risks for the participants. Data represent the output of each student group; they therefore collect aggregated information, with no individual identity linked to them. No confidential data were collected. No compensation was provided to participants, and they were able to opt out at any time during the lesson. AVA aims to improve the quality of teaching and research carried out in the Italian universities through the application of a quality assurance model based on internal procedures for planning, management, self-assessment, and improvement of training and scientific activities and on an external verification carried out in a clear and transparent manner. The requirements of the new AVA3 model underline the importance for the universities to promote, support, and monitor the participation of teachers in training and teaching refresher initiatives in the various disciplines, including those relating to the use of innovative teaching methodologies, also through the use of online tools and the provision of multimedia teaching materials [14]. The presented data were collected in this context, and, accordingly, no ethics approval was applied for (Page 3, Art.5, Clause 2 of [15]).

Results

A total of 16 students were included: 6 allocated to the CPG group (*F*=5, 83%), 5 to the OR group (*F*=2, 40%), and 5 to the ChatGPT group (*F*=3, 60%).

During the presentation of the clinical case, all 3 groups were presented with questions, and students were required to provide their responses as quickly as possible, within predefined time limits. The time taken to answer each question was recorded for all groups. Except for one response, all answers were given within the allocated time (see Table 1). Of the 49 total allocated minutes, the CPG group took 41 minutes to complete the clinical case, the OR group 45 minutes, and the ChatGPT group 38 minutes. The total time taken to answer, expressed as a percentage of the allocated time, was not significantly different among groups (*P*=.69).

Table . Time (min) required for answers and mean score received at the external assessment in terms of completeness and accuracy for each answer given by each group. Overall time for completion and median score across all answers for each group are also reported. Allotted time was exceeded only in Q4 by OR group.

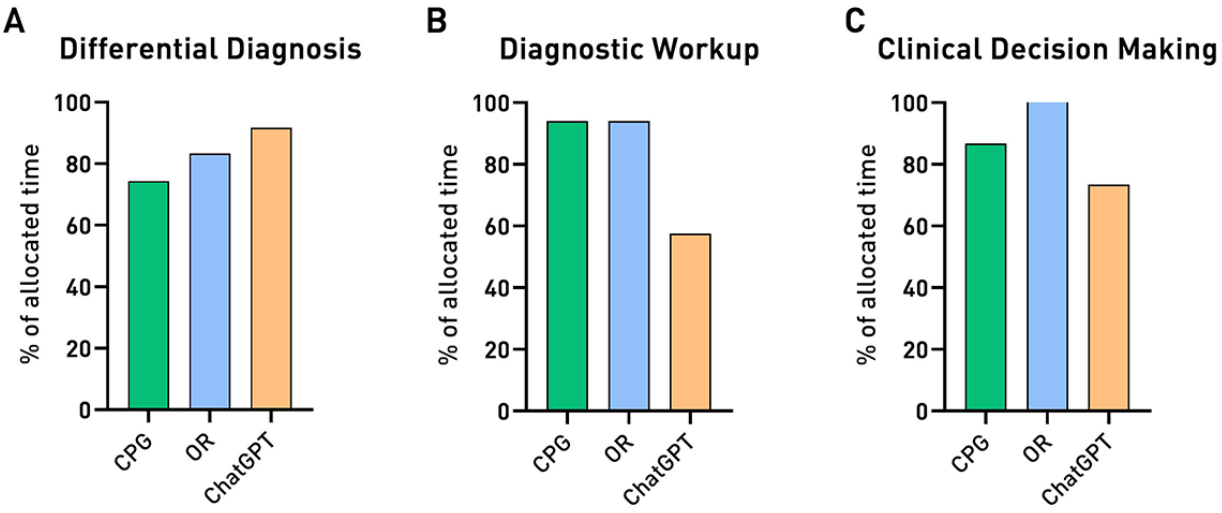
[d]*P*=.02.

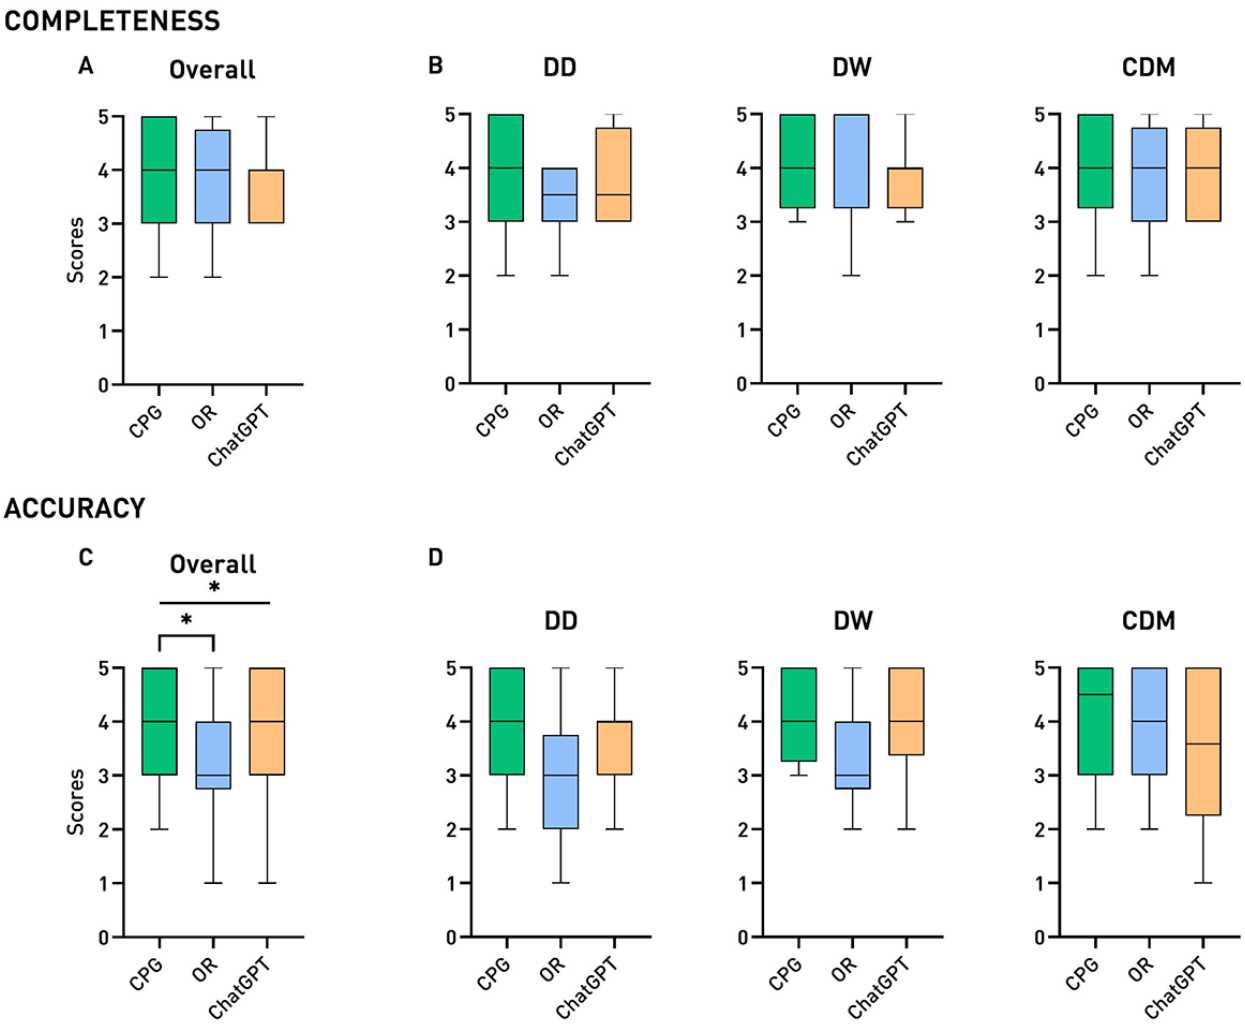
The questions were then categorized into 3 major domains: DD (Q 1-5-6), DW (Q 2 - 7), and CDM (Q 3-4-8). The time taken to answer, as a percentage of the allocated time, by each group of students according to the provided domains is shown in Figure 1(A, B and C). While no statistically significant differences were observed, it is worth noting that the ChatGPT group tended to respond more quickly to questions related to DW and CDM.

Figure 1. Sum of the time taken by the 3 groups of students to answer questions in the 3 domains. Results are shown as the percentage of the total allocated time for that domain. CPG: clinical practice guidelines; OR: online repositories.



Answers were assessed for completeness, which considered the depth of information provided, and for accuracy, which assessed adherence to clinical practice versus an excess or superficiality of information. These evaluations were conducted by 4 external reviewers who were blinded to the group assignment. Scores are reported in Table 1 and Figure 2.

Figure 2. Box plots of scores obtained by the 3 groups of students for (A)overall completeness, (C)overall accuracy, (B)completeness in the 3 domains, (D)accuracy in the 3 domains. DD: differential diagnosis; DW: diagnostic workup; CDM: clinical decision-making (*P<.05).



Overall, the CPG group performed best, reaching the highest mean scores for completeness (4.0) and accuracy (4.0) (Figure 2A and C). The ChatGPT group comes in second place, with equal completeness (3.8 vs 3.8) compared to the OR group but higher accuracy (3.7 vs 3.3). The Kruskal-Wallis test showed non-significant difference among groups for overall completeness (P=.49), and a significant difference in overall accuracy between the 3 groups (P=.02), particularly—at post hoc analysis—between the CPG and the OR group (P=.02).

Aggregating scores according to the 3 students' skill domains, trends in differences among the groups emerge more clearly (Figure 2B and C). When it comes to generating differential diagnoses, the CPG group was the most complete (3.9) and accurate (3.9) among the 3, whereas the OR group has the worst scores for both completeness and accuracy categories, with mean scores of 3.4 and 2.9, respectively, among the lowest registered. On the contrary, whenever students were asked to provide a DW for the patient, the OR group appeared as the most complete (4.3), although the least accurate (3.0), considering the source of the competition. In this domain, the other 2 groups come quite close (4.1 and 4.1 for CPG; 3.9 and 4.0 for ChatGPT) and maintain coherent scores in between their own completeness and accuracy. Lastly, when knowledge had to be applied to drive clinical decisions, as tested in CDM questions, the 3 groups obtained similar scores in terms of completeness, while the CPG group succeeded as the most accurate (4.1), followed by the OR group (3.9) and the ChatGPT group (3.5).

Of note, it appears evident how the CPG group performed the best in nearly all domains and maintained almost perfect alignment between its completeness and accuracy. The ChatGPT group maintained an overall mediocre yet stable performance, without ever achieving the best scores. On the other hand, the OR group showed mixed features, with notable peaks of performance–with scores equal to or higher than the ChatGPT contender–but some other dramatic drops in answer quality in terms of accuracy in more than one skill domain.

Discussion

In recent years, the availability of tools to support clinicians in the diagnostic and therapeutic processes has grown considerably. Although the use of CDSS is widespread, individuals often use them without specific education and pay little attention to their

inherent limitations, especially in the case of their newest potential counterparts, such as ChatGPT [1].

To assess how final-year medical school students make use of the available CDSS and to begin considering an instructional approach for the use of such tools, we designed the experiment outlined in this study. Observing the students' interaction with the assigned CDSS during the resolution of a clinical case and analyzing their answers, we recorded specific criticalities regarding the use of each CDSS.

In terms of rapidity of use, ChatGPT seems to represent a significant breakthrough in the world of CDSS. If traditional encyclopedic or textbook-like written resources call the reader to go through the entire material to properly understand a topic and retrieve correct clinical answers or guidance, an instantaneous chat environment allows for both a quick overview of disciplines and—at the same time—deep vertical dives into specific details. Students using ChatGPT arrived at the required answer almost always faster than their colleagues aided by CPG or OR, especially in questions regarding DW and CDM. It seems that the role of ChatGPT in the chat dialogue more closely resembles the attitude of a human counterpart (for example, a senior teaching physician asked for guidance), whose responses are fast, direct, and usually finely targeted. Such answers follow the students' line of reasoning and indirectly encourage them to choose a unique path of solution out of many possible scenarios. This dynamic emerges as brilliantly effective whenever the students embark on the correct clinical thought process but can lead to disastrous consequences whenever students feed cognitive biases or overt errors into their chat conversation. On the contrary, CPG and OR offer vast amounts of information, such as long lists of items and in-depth descriptions, whose digestion is neither easy nor fast. Therefore, whenever consulted correctly and for enough time, CPG and OR—especially the former, our results seem to suggest—generally help students give answers of higher quality, both in terms of completeness and accuracy. No real-time interaction is present; therefore, they appear almost immune to reader-introduced bias and misinterpretation.

In the modern era, velocity is a precious commodity, especially in the fast-paced clinical context, where less and less time is available for extensive reference consultation. This might influence current and future generations of medical school students to prefer chatbot-based guidance over preformed texts as routine help throughout their study [1,8].

As said, in terms of highest answer quality, there seems to be no rival to CPG. Old-fashioned guidelines might be slower to consult but grant far greater quality information to students, helping them to be complete and accurate in key tasks, such as generating differentials and deploying clinical decisions. Possibly, CPG might also enhance the student's comprehension of the analyzed topic, given the broader context and deeper description always provided. Nonetheless, in a continuously evolving context of increasing number and complexity of CPG, it would be presumptuous to expect students to rely on their use only [4,5,9].

ORs offered unexpected and ambiguous results, as the performance of these students was not stable across questions, and their answers could reach both extremes of the score spectrum. ORs are intrinsically designed and thought of as an evolution of CPG, more accessible and applicable to practice. This aspect may emerge in the excellent quality of answers given by this group in the DW domain, where students were able to follow the detailed workup algorithms offered by OR, which can graphically synthesize even complex clinical scenarios. An interesting experience across teaching hospitals in Japan evidenced a somewhat significant positive correlation between the use of OR and score performance in a national general medicine test, in a numerous population of over 3000 residents. According to the authors, frequent logging into and consultation of UpToDate might have contributed to improved clinical reasoning skills, specifically in the tested domains of DD generation, and clinical decision deployment [16].

Specific Observations Around the Students' Use of Each Type of CDSS

CPG Group

For this group's ability to reach a correct solution, the crucial step seemed to be selecting the proper guideline to consult. Once correctly identified, suitable CPG contain virtually everything a physician should know about a disease. During the initial process of elaboration of a clinical scenario, though, it is not immediately clear which disease entity, often more than one, is going to be selected as a candidate diagnosis for the patient. Choosing the right CPG can therefore be quite challenging. Additionally, CPG deliver their content in the form of plain text and interspersed summary tables and charts. The students had some difficulty in focusing on the right chart.

OR Group

Likely due to their lack of experience with the tool, the students failed to search for symptoms within the query. One hypothesis could be that they relied on their prior knowledge to make decisions rather than on the results obtained from each query, preventing them from breaking free from their preconceptions.

ChatGPT Group

Our results revealed students to lack substantial background on how to properly approach an LLM chatbot. *Masterprompting*, referred to as the assignment of the role and behavior expected from the chatbot, was not provided by the students.

Using an LLM as a CDSS inevitably introduces a "prompt bias," for which the human subjective way of reasoning and choice of questions to be asked directly influence how the chatbot perceives the information and how it transforms its responses accordingly. Along such a general trend, the students' prompts were not properly designed and translated into confused and misleading answers by ChatGPT. For example, clinical details were provided without any structure or further clinical context, triggering diverging suggestions by the chatbot. Accordingly, hints were given by the instructor on asking the LLM directly how to convey information for it to understand and elaborate on such information at its best, but consistent results did not follow.

On other instances, it was ChatGPT itself that derailed students' reasoning. For example, a chatbot answer about laboratory

values, lacking a relative unit of measurement and normal reference ranges, leads to misinterpretation of hypercalcemia as hypocalcemia, a critical mistake.

ChatGPT does not provide any literature citation and guideline reference to support its own line of reasoning, as other CDSS do in the form of easily accessible links to further explanations and deeper dives (eg differential diagnoses, varying DWs, tables of available first-line therapies, etc) [6]. Such an absence seemed to be associated with a significantly lower propensity of students to question either their own knowledge or the answers formulated by ChatGPT, blindly accepting the information provided. Whenever such indulgence was noted and pointed out by the instructors, students confessed how certain answers provided by ChatGPT were not completely clear and understandable; nonetheless, they willingly accepted them as valid.

Limitations

Some limitations of this report must be underlined. First, the restricted number of students who took part in the experiment. This may have led to uneven distribution of differently ranked students in the groups, despite the random strategy used for group definition. Second, our methodological constraints lead to insufficient statistical power to draw sound conclusions. Lastly, the experiment has not yet been repeated, and the results have been further confirmed or discarded with other clinical cases.

Conclusions

As in many other disciplines, the adoption of LLMs in medical practice and in the medical school curriculum is inevitable [10]. Our hands-on session suggests the critical need to include in medical degree courses teachings on how to properly take advantage of LLMs such as ChatGPT, as we verified that the potential for misuse is evident and real.

Our experience suggests the need for medical students to be acquainted with LLMs in their learning process and future profession. ChatGPT does not provide nor teach a reasoning method to approach a medical case resolution, a relevant issue for it to be recognized as part of the armamentarium in formal medical education. CPG and OR, on the contrary, most often provide step-by-step guidance on how to behave in each clinical scenario, how to approach diagnosis, and how to address treatment of diseases. References and recommendation strength form the cornerstone of these tools and help the student get progressively acquainted with ever-updating medical knowledge [4,5].

In conclusion, regarding the upcoming future, we suggest medical educators to:

- start to increasingly incorporate and refer to LLMs in their teachings, also by building tailored case studies [17-20];
- favor practice-based learning by using LLMs as a help to navigate guidelines and repositories with more ease and speed;
- exploit the very limitations of LLMs—such as the lack of an explicit reasoning method or unsure reliance on the latest published literature—to prompt students to consciously provide them themselves to the chatbot, turning the CDSS consultation process into a bidirectional teaching environment, possibly uncovering biases and misconceptions on both sides;
- help students in focusing on their accountability: they should be pushed to continuously look for evidence and validation of their own clinical reasoning, avoiding relying completely on that of LLMs.

Abstract

Background: Burnout among emergency room health care workers (HCWs) has reached critical levels, affecting up to 43% of HCWs and 35% of emergency medicine personnel during the COVID-19 pandemic. Nurses were most affected, followed by physicians, leading to absenteeism, reduced care quality, and turnover rates as high as 78% in some settings such as Thailand. Beyond workforce instability, burnout compromises patient safety. Each 1-unit increase in emotional exhaustion has been linked to a 2.63-fold rise in reports of poor care quality, 30% increase in patient falls, 47% increase in medication errors, and 32% increase in health care–associated infections. Burnout is also associated with lower job satisfaction, worsening mental health, and increased intent to leave the profession. These findings underscore the urgent need for effective strategies to reduce stress and burnout in emergency care.

Objective: This study aimed to evaluate the effectiveness and effect size of a multimodal learning approach—Emergency Room Virtual Simulation Interprofessional Education (ER-VIPE)—that integrates medical movies, massive online open courses (MOOCs), and computer- or virtual reality (VR)–based simulations with co-debriefing for reducing burnout and stress among future health care professionals compared with approaches lacking co-debriefing or using only movies and MOOCs.

Methods: A single-blind, quasi-experimental study was conducted at a university hospital from August 2022 to September 2023 using a 3-group treatment design. Group A (control) participated in a 3D computer-based, simulation-based interprofessional education (SIMBIE) without debriefing. Group B received the ER-VIPE intervention. Group C received the same as Group B, but the computer-based SIMBIE was replaced with 3D VR-SIMBIE. SIMBIE activities simulated a COVID-19 pneumonia crisis. Outcomes included the Dundee Stress State Questionnaire (DSSQ) and the Copenhagen Burnout Inventory, with trait anxiety as a behavioral control. Stress and burnout were measured at baseline, pre-intervention, postintervention, and 1-month follow-up. Generalized estimating equations were used to analyze group differences, with statistical significance set at $P<.05$.

Results: We randomized 87 undergraduate students from various health programs into the 3 groups (n=29 each). Participants' mean age was 22 years, with 71% (62/87) as women. After the 1-month post-SIMBIE follow-up, adjusted analyses revealed positive trends in DSSQ-engagement across all groups, with Group B showing a significant increase compared with Group A (mean difference=3.93; *P*=.001). DSSQ-worry and DSSQ-distress scores decreased nonsignificantly across all groups. Burnout scores also improved across groups, with Group B having a significantly lower score than Group A (mean difference=–2.02; *P*=.02). No significant burnout differences were found between Group C and Groups A or B.

Conclusions: A multimodal learning approach combining medical movies, MOOCs, and 3D computer-based SIMBIE with co-debriefing effectively improved engagement, reduced stress, and lowered burnout among future health care professionals. This scalable educational framework may help enhance well-being and resilience in high-pressure clinical environments.

Introduction

Background

Prior to the onset of the COVID-19 pandemic, burnout was already a significant concern among emergency health care professionals. For example, 60% of emergency medicine (EM) physicians [1] and 26% of emergency nurses [2] reported experiencing burnout on a regular basis. Although no quantitative, emergency department–specific studies from Thailand exist for the pre-COVID-19 period, broader national surveys have documented substantial levels of burnout among Thai nurses. In a study of more than 2000 nurses working in community hospitals, 32% reported high emotional exhaustion, 18% reported high depersonalization, and 35% experienced low personal accomplishment [3]. Notably, Nantsupawat et al [3] found that each 1-unit increase in emotional exhaustion score was associated with a 2.63-fold increase in the likelihood of reporting fair or poor quality of care, 30% increase in patient falls, 47% increase in medication errors, and 32% increase in infections. Supplementing this quantitative evidence, a qualitative study by Yuwanich et al [4] identified unique emergency department–specific stressors, such as patients' and their relatives' behaviors as well as power imbalances, affecting nurses in Thailand. Together, these baseline findings underscore that emergency health care workers (HCWs) were already highly vulnerable to burnout prior to the COVID-19 pandemic.

Working in an emergency room during crises or pandemics under tight time constraints, limited experience, and with newly formed teams is highly stressful. HCWs face heavy workloads, interpersonal conflicts, limited social support, and high-acuity patients [5]. The need for rapid, complex decision-making in this unpredictable environment intensifies stress, contributing to high burnout rates, especially during COVID-19 [6-8]. A systematic review reported that the prevalence of overall burnout among HCWs during the COVID-19 pandemic was high, reaching 43%, with 35% of EM HCWs identified as being at high risk for burnout [9]. The profession type—such as nurse, physician, or resident—was a significant factor influencing the rate of burnout and its domains, whereas gender did not show a consistent association. Among EM professionals, nurses were the most affected, followed by physicians [9]. The psychological impact of the COVID-19 pandemic extended beyond burnout, encompassing a wide range of adverse mental health outcomes, including stress, anxiety, depression, inadequate sleep, posttraumatic stress disorder symptoms, and secondary trauma [10]. Anxiety, depression, stress, and burnout levels were notably higher among physicians and nurses than in other health care roles, consistent with findings from other systematic reviews [9,11]. Gualano et al [11] further identified several pandemic-related factors associated with increased burnout risk, such as resource shortages, fear of COVID-19 infection, and social stigma. Consequently, the prevalence of turnover intention among emergency nurses has been reported at 45% globally [12], with a notably higher rate of 78% observed in Thailand [13]. Thailand is currently facing a critical nursing workforce shortage, reflected in a nurse-to-population ratio of approximately 1:400. Projections estimate an annual attrition of around 7000 nurses [13].

The COVID-19 health care crisis has profoundly impacted frontline health care professionals, exposing them to cumulative traumatic experiences that elevate stress and burnout levels. Frontline workers consistently report higher emotional exhaustion and depersonalization compared with those in non-COVID-19 units. Resilience and adaptive defense mechanisms are crucial for mitigating these effects, while younger age, female gender, increased COVID-19 exposure, and less resilient coping strategies predict greater vulnerability to stress and burnout. These findings highlight the urgent need for support programs focused on resilience-building and stress management for HCWs directly involved in COVID-19 patient care [14].

Health care workforce retention is a growing global concern, particularly in the postpandemic context. Depression and anxiety also positively correlate with higher absenteeism rates [15], reduced job commitment [16], lower job satisfaction [17], more medical leave [18], and poorer quality of life [19]. A 2023 study in Thailand reported that the revised model fit the data and accounted for 45% of the variance in nurses' intention to leave [20]. Burnout was the strongest factor, affecting intention both directly and indirectly via job satisfaction and professional commitment. Work-family conflict and the nursing practice environment influenced intention indirectly through these pathways. Thailand also faces a physician shortage, with only 0.5 to 0.8 doctors per 1000 people—below the World Health

Organization (WHO) standard of 1:1000. The pandemic exacerbated these challenges, leaving many frontline providers with burnout and limited mental health support [21]. These findings highlight the urgent need for targeted retention strategies. Thailand's experience offers insights for global health systems aiming to reduce burnout and strengthen workforce resilience.

Prolonged stress and burnout among HCWs have serious consequences for both individual well-being and the health care system. These conditions contribute to a range of physical and mental health issues, including fatigue, anxiety, social isolation, depression, and an elevated risk of suicide [22,23]. They also adversely affect patient care, leading to decreased quality, increased medical errors, patient dissatisfaction, and reduced job satisfaction [22,24-26]. Furthermore, stress and burnout are linked to higher turnover intentions and career disengagement [22,27]. Consistent with these findings, a study in Thailand reported that job stress significantly influences physicians' intentions to resign from their roles in health care [28]. These findings underscore the critical need for effective strategies to protect HCWs' well-being and maintain high-quality patient care. The COVID-19 pandemic underscored the critical importance of strengthening preparedness for future pandemics and health crises. A key lesson involves the need to enhance the effectiveness and efficiency of HCWs, which aligns with the first objective of the *Global Strategy on Human Resources for Health: Workforce 2030*, issued by WHO in 2016 [29].

Prior Work

Overview

A comprehensive literature review identified and analyzed existing studies on burnout and its prevention strategies, characterizing burnout as a chronic response to prolonged stress in work or academic settings. The review emphasized online learning as a key approach to mitigating burnout, highlighting the importance of providing emotional support; enhancing educator training; and using diverse, interactive tools to foster student engagement and motivation [30]. In addition, several strategies aimed at enhancing collaboration to combat stress and burnout in health care, including interprofessional education (IPE), medical movies, massive open online courses (MOOCs), and simulation-based interprofessional education (SIMBIE) incorporating co-debriefing and psychosocial support, will be discussed in detail in the following sections.

IPE to Enhance Collaboration as a Strategy to Combat Stress and Burnout in Health Care

Among various methodologies, such as mentorship and supervision [31,32], improving collaborative practice has demonstrated success for boosting HCW effectiveness and efficiency. Collaborative practice is when "multiple health workers from different professional backgrounds provide comprehensive services by working with patients, their families, careers and communities to deliver the highest quality of care across settings" [33]. It enhances effectiveness and efficiency by focusing on 4 key competencies: values and ethics, roles and responsibilities, communication, and teams and teamwork [34]. These competencies foster effective communication, satisfaction with high-quality teamwork, interprofessionalism, and a positive attitude with mutual respect for diverse health care disciplines [35,36]. Therefore, collaborative practice is crucial for enhancing patient safety in emergency departments [37-40]. Studies suggest that collaborative practice skills should be developed early in professional education [41-44].

IPE, where "two or more professions learn about, from and with each other to enable effective collaboration and improve health outcomes" [33], is more effective for teaching collaborative practices than other methods, such as traditional lectures [45], meeting discussions [42], video-based education [46], or simulation-based education involving only one profession [46]. IPE fosters positive perceptions of interprofessionalism through experiential learning, helping HCWs develop the 4 key competencies essential for collaborative practices. For over a decade, IPE has been integrated into university studies to promote teamwork [47,48], enhance understanding of professional roles and responsibilities [49], strengthen communication skills [50,51], and expand interprofessional knowledge [52,53].

A meta-analysis review study by Sezgin and Bektas [54] found IPE significantly improves communication competency (n=7; 95% CI 0.26 to 0.82; $P<.001$) and teams-and-teamwork competency (n=4; 95% CI 0.25 to 0.56; $P<.001$) among HCWs. However, the analysis included only 8 randomized controlled trials (RCTs)—too few for subgroup analysis of key intervention characteristics. Similarly, the meta-analysis by Marion-Martins and Pinho [55] showed IPE enhances values-and-ethics competency by fostering cross-professional mutual respect ($P=.007$; n=1) and improves roles-and-responsibilities competency (n=2; $P=.004$), yet the limited number of studies in each analysis restricts the generalizability of these findings. Overall, meta-analyses have shown that IPE interventions significantly improve health care systems (12 studies: standardized mean difference [SMD]=1.37, 95% CI 0.92 to 1.82 [56]; 6 studies: mean difference 7.19, 95% CI 2.61 to 11.77 [55]). A recent scoping review also highlighted IPE's positive impact on organizational culture, climate, and staff attachment [57]. Additionally, IPE initiatives improve health care professionals' work environments and strengthen multidisciplinary team effectiveness [58].

Based on previous evidence-based studies, we can conclude that IPE is an effective methodology for fostering collaborative practices, indirectly alleviating workplace stress, reducing burnout, and decreasing turnover intentions while enhancing HCWs' well-being, career satisfaction, and perceived service quality. Despite these benefits, Frenk et al, for The Lancet Commissions [59], criticized health education curricula for being fragmented and focused on a single profession, failing to prepare students for team-based clinical practice [59]. Traditional siloed education persists, hindering collaboration and patient safety [60].

Medical Movies to Enhance Collaboration as a Strategy to Combat Stress and Burnout in Health Care

The integration of films and television series into medical education, a practice known as cinemeducation [61], has been demonstrated to effectively enhance learning outcomes [62,63].

Cinemeducation has been widely implemented across various disciplines, including medical diagnostics [64], nursing [65], pharmacology [66,67], psychiatry [68-70], and psychology [71,72]. Importantly, cinemeducation extends beyond the mere screening of films in classrooms; it is grounded in a structured pedagogical framework that involves a sequence of carefully designed steps before, during, and after the educational activity [73,74]. Surprisingly, to the best of our knowledge, no study has examined the direct relationship between cinemeducation and stress or burnout among HCWs. Most studies investigated the effectiveness of cinemeducation for alleviating stigma, one of the greatest barriers to mental health treatment [75-79] that indirectly contribute to levels of stress [80,81] and burnout [82,83].

The study by Zeppegno et al [84] indicated that cinemeducation has the potential to reduce stigma, foster positive attitudes toward psychiatry, and enhance students' ability to manage anxiety when confronted with others' distress, with effects lasting up to 6 months. The pilot study by Rehl et al [85] demonstrated the effectiveness of cinematic virtual reality (cine-VR) training—a combination of cinemeducation and VR—for reducing stigmatizing attitudes among osteopathic medical students toward patients with opioid use disorder. The study also reported increased empathy, aligning with Vygotsky's theory of learning, which emphasizes learning through collaboration with others using reflection and authentic activities in real-life situations [86]. Similarly, the study by Kontos et al [87] used a filmed version of a research-based theatrical production to reduce caregivers' stigmatizing toward dementia. The study by Hawke et al [88] demonstrated that film-based interventions could reduce stigma among health care service providers toward individuals with bipolar disorder, with effects persisting for 1 month. Additionally, the pilot study by Linton et al [89] found that the film "Wounded Healer" significantly reduced stigma toward mental illness among health care students. Based on the reviewed studies, there is no doubt that cinemeducation is an effective approach for reducing stigma among HCWs and students.

MOOCs to Enhance Collaboration as a Strategy to Combat Stress and Burnout in Health Care

MOOCs are characterized as (1) "massive," enabling access to thousands of learners; (2) "open," with no enrollment fees; (3) "online," delivered via the web; and (4) "courses," offering structured content aligned with specific learning objectives [90]. They were first introduced in 2008 by Stephen Downes and George Siemens [91]. MOOCs have since revolutionized distance learning, driven by growing demand for flexible, accessible education [92,93]. The COVID-19 pandemic further accelerated their adoption, making MOOCs a central focus in education, with over 16,300 courses offered by 950 universities and more than 180 million enrollments globally [94] on platforms such as Coursera, edX, FutureLearn, Thai MOOCs, and Udacity [95,96].

Pedagogically, MOOCs fall into 3 categories: cMOOCs (connectivist), xMOOCs (extension of something else), and iMOOCs (integrated) [97,98]. cMOOCs, based on Downes' connectivist principles, emphasize networked learning; peer interaction; and evolving, learner-driven content [99-101]. In contrast, xMOOCs prioritize instructor-led, content-centered learning with limited interaction [102]. iMOOCs, developed by Universidade Aberta, blend the collaborative, flexible features of cMOOCs with the structured, assessed nature of xMOOCs, encouraging self-directed learning, peer engagement, and artifact-based assessment (eg, presentations, videos, mind maps) [98]. Due to their scalability and accessibility, MOOCs are highly effective for educational interventions across diverse global audiences [103]. In health care education, MOOCs serve various roles—from promoting health literacy among the public (eg, dementia education [104]) to supporting just-in-time training during health crises [105] and enhancing HCWs' well-being and resilience against stress and burnout [106].

MOOCs are an effective platform for delivering evidence-based interventions—such as stress and burnout education and mindfulness training—to HCWs, improving resilience while reducing stress and burnout. Recently, Ricker et al [107] conducted a single-group cohort study evaluating the Physician Well-being Course, a 4.5-hour online program covering well-being fundamentals (sleep, nutrition, exercise, resilience, and mindfulness), followed by a 2-week self-selected resiliency activity (10 minutes daily). The course was offered to postgraduate year-1 residents who could join voluntarily. Among 87 enrollees, 53 (61%) completed the course, with meditation being the most frequently selected resiliency activity (36/53, 68%) and sleep being the most frequently reported wellness behavior (22/36, 61%). Postintervention assessments showed statistically significant improvements in emotional exhaustion, depersonalization, and resilience (P<.05, paired t test). The authors suggested a key strategy to obtain a relatively high completion rate was attributed to offering the course during the preresidency timing, when residents had additional time and energy. Limitations of the study were the lack of follow-up assessing long-term effects and a control group.

Peterson et al [106] conducted a single-group cohort study to evaluate a pilot program supporting nursing students with coping with stress and burnout during the COVID-19 pandemic. The intervention consisted of an 8-hour self-paced online course and a 1-hour Zoom support group addressing 7 objectives including stress recognition, crisis response, self-care planning, and psychological safety. Psychoeducational resources such as mindfulness and breathing exercises were embedded, and participants were encouraged to choose a "battle buddy" for peer connection. Of 360 enrollees, 224 completed both pre- and postcourse surveys. Significant improvements were observed in calmness, connectedness, coping capacity, and hopefulness (P<.001, paired t test), reflecting gains in psychological flexibility [108], a protective factor against mental health deterioration [109-111]. The program also enhanced a sense of agency [65] through shared experiences and personalized resilience strategies, contributing to reduced acute stress [112]. Notably, burnout risk decreased significantly (OR 0.58, 95% CI 0.4-0.9; P<.006), which the authors linked to reduced isolation and increased social connectedness—consistent with theoretical models that identify social support and community belonging as key protective factors [113]. However, the study

lacked a control group and follow-up data to assess long-term effects.

The asynchronous nature of MOOCs enables participants to engage with content at their own convenience and pace, thereby accommodating demanding clinical schedules. Additionally, MOOCs can support virtual peer groups, which promote shared coping strategies, social connectedness, and a sense of community. These elements are critical mechanisms for fostering psychological resilience and enhancing HCWs' sense of agency, ultimately contributing to a reduction in acute stress—even under challenging circumstances [112].

SIMBIE With Co-Debriefing and Emotional Psychosocial Support to Enhance Collaboration as a Strategy to Combat Stress and Burnout in Health Care

As elaborated in the IPE section, IPE is an effective method for fostering the 4 competencies essential for collaborative practices, resulting in the mitigation of stress and burnout among health care professionals. Among other educational strategies [114-118], a recent scoping review and related studies indicate that SIMBIE, defined as "when participants and facilitators from two or more professions are engaged in a simulated health care experience to achieve shared or linked objectives and outcomes" [119], is an effective method for teaching the 4 interprofessional competencies in the emergency department [120-123]. In addition to improving technical skills [118,124,125], evidence-based studies have also demonstrated that SIMBIE enhances nontechnical skills such as communication and teamwork [54,118,124-130], with effects sustained for up to 6 months [124]. This is particularly significant given the increasing recognition that nontechnical skills are critical determinants of patient safety and quality of care [131-133].

Additionally, studies demonstrated unique advantages of SIMBIE over other educational strategies for learning IPE. First, SIMBIE offers a safe [134,135], controlled [127,136], and realistic [121,137] environment where learners from various health care professions can practice collaboration and teamwork without posing any risk to real patients [44,127]. Second, SIMBIE enables repetitive and deliberate practice, allowing learners to refine their skills by learning from mistakes in a risk-free setting—something not always feasible in real clinical environments [138-143]. Third, SIMBIE facilitates active authentic experiential learning by immersing learners in realistic clinical situations that prepare them for real-world practice [137,144,145]. Unlike passive formats, substantial research in adult education arguably emphasizes that active participation significantly enhances learning effectiveness [118,146-152]. Authentic experiential learning of SIMBIE benefits its uses in stress inoculation (SIT) training. Couarraze et al [153] reported positive effects on stress, anxiety, and burnout of anesthesia and critical care workers after attending simulation training based on critical situation exposure: The effects lasted for at least 1 week. Fourth, SIMBIE can expose learners to rare and complex medical conditions that they may not encounter during typical clinical rotations [145,154], thereby equipping them to manage a broader range of clinical scenarios more effectively. Studies have shown that using simulation as a teaching strategy significantly reduces State-Trait Anxiety Inventory (STAI) scores, with this reduction persisting at a 1-week posttraining follow-up. These findings underscore the benefits of simulation-based education, particularly for residents in anesthesia and intensive care [153]. Similarly, Shamputa et al [155] highlighted the effectiveness of virtual IPE initiatives for fostering interprofessional collaboration (IPC), particularly during the COVID-19 pandemic.

Beyond economical [156], logistical [157], scalability [158], and resilience-related [159] benefits, virtual SIMBIE has shown potential for enhancing educational outcomes. A recent meta-analysis reported that virtual SIMBIE significantly improves students' clinical reasoning and performance [39]. A systematic review and meta-analysis by Jiang et al [151] found no significant differences between virtual and real-world SIMBIE in terms of improving knowledge, procedural skills, clinical reasoning, or communication skills. Liaw et al [160] reported that desktop VR–induced stress levels of medical and nursing students, measured using blood pressure and heart rate, were comparable to the level induced by face-to-face simulation with during simulated rapidly deteriorating patient situations. Similarly, Shamputa et al [155] highlighted the effectiveness of virtual IPE initiatives at fostering IPC, particularly during the COVID-19 pandemic. Although virtual SIMBIE offers standardized and immersive practice scenarios, development of tacit knowledge for clinical practice is facilitated through debriefing [161-164]. Students consistently rated debriefing as essential to their learning experience, a finding supported by prior research [165-167]. Therefore, it is imperative that facilitators of virtual SIMBIE receive appropriate debriefing training to effectively guide these critical reflective processes [93].

Debriefing in the context of simulation-based health care education refers to "the facilitated discussion between two or more individuals in order to guide reflection and review performance, with the intent of gaining insight and understanding such that future performance is improved" [168]. Debriefing is regarded as an interactive, bidirectional, and reflective conversation that involves some degree of facilitation—whether by a facilitator, multiple facilitators (co-debriefing [169]), or the learners themselves (self-guided debriefing [170])—to support the reflective learning process [168,171,172]. When conducted effectively, debriefing thus serves as a critical component of learning in SIMBIE [163,173-175]. Its importance lies in its role as a process of reflection-on-action [176,177], which is a central element of Kolb's [178] experiential learning cycle. Experience alone during simulation is insufficient to produce learning; rather, it is the intentional reflection on that experience that facilitates deeper understanding [164,173,174,179-182].

Attending debriefing sessions has been studied as a potential strategy for reducing stress and preventing burnout. Although a small study reported no significant effect on burnout scores, most participants appreciated the emotional and social support offered through these sessions and recommended debriefing as a beneficial approach for junior medical residents [183]. Attending debriefing sessions has been shown to significantly reduce the risk of burnout and alleviate work-related

posttraumatic stress among intensive care staff, even after accounting for resilience and other contributing factors [184].

Several studies demonstrated that team debriefing after critical events provides various aspects of job and personal resources [185]: for example, (1) psychosocial support [186-193], (2) improvement in teamwork and interprofessional relationships [190,191,194-197], (3) learning and performance improvement [191,193,196-198], and (4) team-based cultural enhancement [189,190,199]. The Job Demands-Resources (JD-R) model [185] hypothesizes that the resources—both job-related (eg, knowledge, skills, abilities, social support) and personal (eg, self-efficacy)—function as a protective "buffer" that mitigates the adverse impact of job demands on individual strain, thereby reducing the risk of burnout [185,200,201].

This hypothesis is supported by both qualitative and quantitative evidence. Qualitative studies highlight the benefits of SIMBIE and debriefing interventions for enhancing emotional support and team reflection [140,186,187,190,191,193,195,202-206]. Quantitative studies further support these findings. For example, although Gunasingam et al [183] found no statistically significant reduction in burnout scores, participants valued the emotional and social support gained from debriefing sessions. Similarly, Colville et al [184] reported that debriefing was significantly associated with reduced burnout and work-related posttraumatic stress among intensive care staff, even after adjusting for resilience and other factors. These findings underscore debriefing as a time-efficient, evidence-based strategy for mitigating burnout in both simulation-based and real-world clinical environments.

Theoretical Frameworks

Stress and Burnout

Stress experienced within teams engaged in collaborative practice can be broadly categorized into 2 types, based on the differential impact of stressors: individual stress and team stress [207-209]. One of the most widely accepted definitions of stress is provided by Lazarus and Folkman [210], who conceptualize individual stress as "a particular relationship between the person and the environment that is appraised by the person as taxing or exceeding his or her resources and endangering his or her well-being" [211]. Weaver et al [208] extended the definition to the team context, defining team stress as "a particular relationship between the team and its environment, including other team members, that is appraised by the team members as taxing or exceeding their resources and/or endangering their well-being." Fundamentally, team stress represents a distinct collective psychological construct, whereas individual stress reflects a psychophysiological phenomenon experienced at the individual level [207].

Although individual stress and team stress occur at different levels, they can exert reciprocal and cross-level influences on performance at both levels [209]. Cross-level studies have revealed how specific team-level stressors—such as role ambiguity [212], team climate [213], and team conflict [214]—affect individual team members' attitudes, behaviors, and emotional states in ways that are relevant to their performance. Conversely, studies have also demonstrated that individual-level stressors, including workload [215] and time pressure [216], can significantly impact team performance. For instance, Savelsbergh et al [217] found that excessive team-level quantitative workload negatively affects both individual and team performance by inhibiting team learning behaviors and further impairs individual performance indirectly through elevated individual workload [217]. Additionally, Kamphuis et al [218] reported that team-level intervention strategies can modulate the effectiveness of individual-level interventions aimed at enhancing individual performance. Collectively, these findings underscore that both individual performance and team performance are shaped by complex interactions between team-level stressors—reflecting characteristics of the team environment—and individual-level stressors—reflecting the attributes and experiences of individual team members.

Several studies have reported that prolonged exposure to occupational distress can ultimately lead to burnout [187,219-229]. This burnout induction process can be explained by the JD-R model [185], which is 1 of the 2 leading theoretical frameworks on burnout [230]. According to the JD-R model, burnout occurs when the availability of resources—both job-related (eg, knowledge, skills, abilities, social support) and personal (eg, self-efficacy)—is insufficient over time to buffer the negative effects of job demands on individual strain [185,200,201]. The model hypothesizes that increasing access to resources—physical (eg, assistance with wearing personal protective equipment [PPE]), psychological (eg, positive feedback from peers or supervisors), social (eg, peer support), or organizational (eg, stress-coping programs)—can help mitigate the risk of burnout.

Cinemeducation

Our cinemeducation was created on the basis of vicarious learning, which is the modification of an observer's behavior that is similar to that of a model by watching the model's behavior be reinforced or punished [231]. The effectiveness of cinemeducation stems from its ability to simplify the comprehension of complex situations by presenting real-life role-playing scenarios that illustrate both effective and ineffective practices. This approach enhances the understanding of human behaviors and their impact on colleagues and patients. Movies in cinemeducation serve as a unique and engaging learning tool [232,233], capable of stimulating debate [234] and providing insights into students' perspectives on topics that might otherwise remain unexpressed [235-237] or be overshadowed by technical considerations [238]. Cinemeducation thus transforms implicit aspects of human behavior, teamwork, and professional interactions into explicit, tangible learning experiences, fostering deeper comprehension, critical reflection, and meaningful discussions.

Furthermore, movies effectively evoke emotions that foster active participation and deeper learning [239]. They leverage vicarious learning by allowing viewers to emotionally connect with characters [240]. Emotional experiences tend to be more vividly remembered [241-243], facilitating vicarious learning among students, a process supported by the Yerkes-Dodson law [244]. Our arguments on the effectiveness of cinemeducation have been further supported by empirical evidence suggesting

that movies are effective at reducing stigma by fostering active learning through emotional engagement [245-247] and by imparting values centered on lived experiences [88]. Moreover, movies could represent a highly complex form of symbolic content that conveys nuanced and richly layered audiovisual information to students through storytelling. Beyond merely delivering content, cinema functions as both a tool and a reflective space, akin to psychotherapeutic sessions, allowing viewers to project aspects of their own psyche onto movies [248]. This process enables viewers to immerse themselves in the narrative, fostering self-reflection and deeper engagement. Additionally, cinema is believed to provide a contemporary experiential medium that momentarily detaches viewers from their daily lives, engaging their unconscious mind in a manner comparable to hypnosis and dreaming [249]. These immersive experiences contribute to the formation of subjective world views, a concept theoretically grounded in Jungian [250] and Hillmanian [251] perspectives on the relationship between images and archetypes. According to this framework, archetypal experiences—facilitated through engagement with cinematic imagery—support learning from both cognitive and emotional perspectives [252]. Such experiences encourage students to engage in discovery and self-reflection, aligning with the principles of inductive learning [253].

Cinemeducation for teaching professionalism as well as stress and burnout education was delivered to HCWs using xMOOCs. xMOOCs represent a practical and scalable solution to deliver interventions that mitigate stress and prevent burnout to health care professionals. The asynchronous nature of xMOOCs enables participants to engage with content at their own convenience and pace, thereby accommodating demanding clinical schedules.

SIMBIE and Co-Debriefing

Experiential and Phase Learning

In this study, the learning facilitated by SIMBIE and co-debriefing is grounded in experiential learning theory [178]. The experiential learning theory conceptualizes learning as an ongoing, cyclical process comprising 4 stages "whereby knowledge is created through the transformation of experience" [178]. The cycle begins with a concrete experience, which, in this context, is generated through SIMBIE, which provides a safe and controlled environment for repetitive and deliberate practice. This is followed by reflective observation and abstract conceptualization, both of which primarily happen during co-debriefing sessions. In the reflective observation stage, facilitators guide learners to examine their experiences from multiple perspectives, fostering deeper insight into the significance of their actions and decisions. These insights then serve as the foundation for abstract conceptualization, where learners attempt to synthesize and generalize their experiences into broader theories or hypotheses. The final phase, active experimentation, occurs when learners are encouraged to test their emerging understandings by engaging in subsequent simulated scenarios in SIMBIE. At this stage, learners apply their knowledge of "good" and "bad" responses, decisions, and actions to analogous situations. These new experiences then initiate another cycle of learning. Experiential learning theory underscores that meaningful learning does not arise from experience alone but rather from deliberate reflection on those experiences.

Additionally, the intervention program was developed based on the 3 sequential stages of phase learning [254], which are rooted in experiential learning theory [178] and principles of instructional scaffolding [255]: (1) prebriefing, (2) participation, and (3) co-debriefing. The prebriefing phase is defined as "a time when the facilitator illustrates the purpose of the simulation, the learning objectives, the process of debriefing, and what it entails" [172]. This phase aims to enhance learners' engagement and involvement [256]. Effective prebriefing must communicate to learners that they are entering a controlled and purposeful environment for reflective practice, where making errors is not only accepted but expected as part of the learning process [256]. Critically, psychological safety should be established from the outset—ideally during the very first interaction between facilitators and learners [135,168,257]. In the participation phase, the virtual SIMBIE environment enables learners to acquire concrete experiences by enacting prior knowledge about social and medical skills, clinical roles, and IPC. This occurs within a setting that is safe [134,135], controlled [127,136], and realistic [121,137]. These conditions allow for repetitive and deliberate practice, which supports skill refinement through learning from mistakes in a low-risk environment—an opportunity often not feasible in actual clinical practice [138-143]. Following participation, the co-debriefing phase facilitates learners' reflective learning through a bidirectional, interactive dialogue, often cofacilitated by multiple instructors [168,171,172]. When implemented effectively, co-debriefing serves as a critical component of learning through SIMBIE [163,173-175]. The concrete experiences gained during simulation, while necessary, are not sufficient for learning; it is the intentional reflection on those experiences that enables learners to derive deeper understanding [173]. Through this reflective process, learners engage in observation and abstract conceptualization, promoting active experimentation and eventual behavioral change—core mechanisms described in experiential learning theory [164,174,179-182].

Theoretical Framework for SIMBIE

In addition to constructivism, experiential learning theory, situated learning theory, and andragogy, as outlined in [258], our SIMBIE approach is also grounded in resilience theory. The term "resilience" is derived from the Latin word resilire, meaning "to leap back" [259]. Resilience has been explored across a wide range of scientific disciplines—including engineering [260], ecology [261], psychology [262], and health care [263]—resulting in varied definitions and conceptualizations [259,262]. Even within the field of psychology, perspectives differ: Some researchers define resilience as the capacity for positive adaptation in the face of significant adversity [264], whereas others view it as the ability to maintain a stable equilibrium under stress [265]. Despite these variations, most definitions converge on 2 core elements: positive adaptation and the presence of adversity [266]. Given the conceptual ambiguity, our study does not aim to redefine resilience but instead focuses on evaluating whether proposed resilience factors (such as the 4 competencies of collaborative

practice) demonstrably confer resilience. To guide this inquiry, we adopted the bidimensional framework for resilience research [267], which categorizes influencing factors into 2 domains: intrinsic factors (resilience and risk factors internal to the individual or team) and external factors (protective and environmental risk factors).

One of the most compelling findings in resilience research, which informs our SIMBIE design, is the concept of the steeling effect—the idea that resilience can be cultivated through exposure to manageable risk rather than through avoidance of all adversity. There is increasing recognition that an appropriate level of exposure may be essential for organizing, calibrating, or "tuning" the adaptive systems of a unit, such as an individual [268,269] or a team [270], in preparation for future, more intense, unpredictable adversity. Crucially, the type, degree, and duration of the exposure must remain within a range that is manageable for the unit. If the exposure exceeds the unit's adaptive capacity, the resulting impact differs depending on the nature of the unit. In individuals, unmanageable exposure may lead to the sensitizing effect, increasing vulnerability to future stressors [271]. In contrast, teams subjected to overwhelming adversity may experience a breakdown in collective identity, with members becoming increasingly individualistic and self-protective, thereby eroding team cohesion and effectiveness [272]. The steeling effect is consistent with the broader understanding that coping with, engaging in, and confronting challenges—rather than avoiding them—are fundamental to adult growth, learning, and development [273]. Persistent avoidance of adversity in individuals can result in reduced self-efficacy, low adaptive flexibility, and the stagnation of higher-order cognitive and emotional development, ultimately limiting self-actualization [273]. At the team level, avoidance may lead to increased brittleness and decreased tolerance to disruption, which can compromise safety and elevate the risk of harm during future crises [274]. Furthermore, such avoidance can hinder a team's ability to identify and revise latent systemic threats, which, when accumulated, can significantly impair team performance [275].

Theoretical Framework for Co-Debriefing

Learners' engagement in co-debriefing within this study was grounded in 3 interrelated theoretical frameworks: (1) social constructivism [276], (2) zone of proximal development [277], and (3) transformative learning theory [278]. The theory of social constructivism emphasizes the centrality of social interaction in collaborative learning. It conceptualizes learning as an active, meaning-making process shaped by learners' engagement with lived experiences [276,279]. Meaning, in this view, is coconstructed through dialogue and shared reflection with peers. Learning is thereby characterized as active, constructive, self-controlled, social, and situational [280]. Complementing this perspective, Vygotsky's [277] zone of proximal development further explains that learning is optimized when learners are supported in tasks slightly beyond their independent abilities, guided by a more knowledgeable other such as a facilitator. In co-debriefing, facilitators assume this role by guiding reflective discussions that help learners bridge knowledge gaps and deepen clinical reasoning and team collaboration.

Transformative learning theory emphasizes the transformation of learners' "frames of reference"—the existing ready-made meanings for interpreting experiences [281]. These frames consist of deeply held assumptions that guide how learners perceive, understand, and respond to situations. Frenk et al [59] identified transformative learning as the most advanced of 3 successive learning levels—informative, formative, and transformative—with the latter aiming to fundamentally shift perspectives, rather than merely convey knowledge or instill professional behaviors [59]. According to Mezirow [278], transformation occurs when learners revise their frames of reference to become "more inclusive, discriminating, open, emotionally capable of change, and reflective so that they may generate beliefs and opinions that will prove more true or justified to guide action." This transformation unfolds through 3 key processes. First, disorienting dilemmas, such as challenging simulated scenarios in SIMBIE, disrupt learners' assumptions [278]. Second, critical reflection enables them to question and evaluate these assumptions [282], going beyond technical methods to examine underlying reasoning. Third, reflective discourse involves dialogic engagement, allowing learners to explore alternative perspectives and collaboratively seek mutual understanding in a psychologically safe environment [278]. In co-debriefing, facilitators foster this safety, encouraging open dialogue that supports both individual and collective transformation through shared reflection of their peers, making the transformation both individual and collective.

Psychological Safety

Co-debriefing in this study was guided by the principle of psychological safety to enhance its effectiveness and efficiency [283]. Psychological safety is recognized as a foundational—and even essential—condition for effective debriefing [120,171,284]. It fosters open dialogue by creating an environment where participants feel safe to share experiences and emotions without fear of judgment, embarrassment, or punishment [173,256,285,286]. This environment supports creativity, engagement, speaking up, and learning [283,287,288] while reducing face-saving behaviors such as withdrawal or avoidance of critique [164,284].

To foster psychological safety, facilitators use both explicit strategies, such as setting clear objectives, ensuring confidentiality, and choosing appropriate settings [289], and implicit cues, including respectful tone and open body language [284]. Quiet, private simulation spaces and thoughtful physical arrangements further support this environment [164,290]. However, co-debriefing interprofessional groups poses unique challenges due to differences in participants' backgrounds, experiences, professional identities, and learning goals [164,291,292]. These complexities extend to co-debriefers themselves, who may also differ in training, experience, and facilitation styles [163,169,293]. Maintaining emotional and psychological safety amid such diversity can be difficult, especially when power imbalances are present [284,286].

Power dynamics—how authority and influence affect interpersonal interactions [294-296]—exist in both clinical settings [297,298] and simulations like SIMBIE [120]. If unaddressed, power imbalances may suppress participation and

hinder the development of interprofessional competencies [292,299]. Despite their importance, power dynamics are often avoided in co-debriefings, possibly because the topic is perceived as taboo [164,289]. Given SIMBIE's goal of enhancing real-world collaborative practice [33], explicitly addressing power imbalances during debriefing may strengthen psychological safety and improve learning outcomes [299]. Power imbalances may also arise among co-debriefers. Poorly managed dynamics can lead to tension, miscommunication, and perceived hierarchies [169,299]. These issues may stem from positional power (based on role) or expert power (based on knowledge) [300,301]. In practice, one debriefer may dominate discussions, interrupt others, or address only one profession, undermining the value of co-debriefing and diminishing diverse perspectives [163,302]. To fulfill SIMBIE's interprofessional goals, co-debriefers must be mindful of these dynamics and intentionally foster equitable, respectful collaboration that models the competencies they aim to teach.

Goal of This Study

Although prior research supports the individual benefits of cinemeducation, SIMBIE with co-debriefing, and MOOCs for emergency health care professionals, these modalities have primarily been studied in isolation. A few studies have examined integrated approaches—such as combining simulation with cinemeducation—but focused on different contexts and outcomes [74,85,303]. To the best of our knowledge, no study has integrated medical movies, MOOCs, and virtual SIMBIE with co-debriefing as a combined strategy. This study aimed to explore their integration as an IPE approach to enhance collaborative practice, mitigate stress, and prevent burnout among health care professionals. This study was intended for medical educators and other health care education professionals—including nurses, pharmacies, and allied health educators—as well as policymakers involved in health professions education and curriculum development. However, a quasi-experimental design was adopted due to practical constraints in randomizing participants within a clinical setting during the COVID-19 pandemic.

Therefore, to address these gaps in the literature and build upon the promising effects of individual strategies, the goal of this study was to evaluate the effectiveness and effect size of a multimodal learning approach—grounded in the aforementioned theoretical frameworks—that integrates medical movies, MOOCs, and either computer-based or VR-based simulation with co-debriefing, collectively referred to as Emergency Room Virtual Simulation Interprofessional Education (ER-VIPE), at improving self-reported stress levels and reducing burnout among future health care professionals. Stress and burnout were measured using the Dundee Stress State Questionnaire (DSSQ) and the Copenhagen Burnout Inventory (CBI), respectively. This quasi-experimental study compared the outcomes of the ER-VIPE intervention with alternative approaches, including (1) computer-based simulation without co-debriefing, (2) VR-based simulation without co-debriefing, and (3) medical movies and MOOCs alone. We hypothesized that the ER-VIPE multimodal learning model would be more effective at reducing stress and preventing burnout than any single-component or nondebriefing method.

Methods

Research Design and Setting

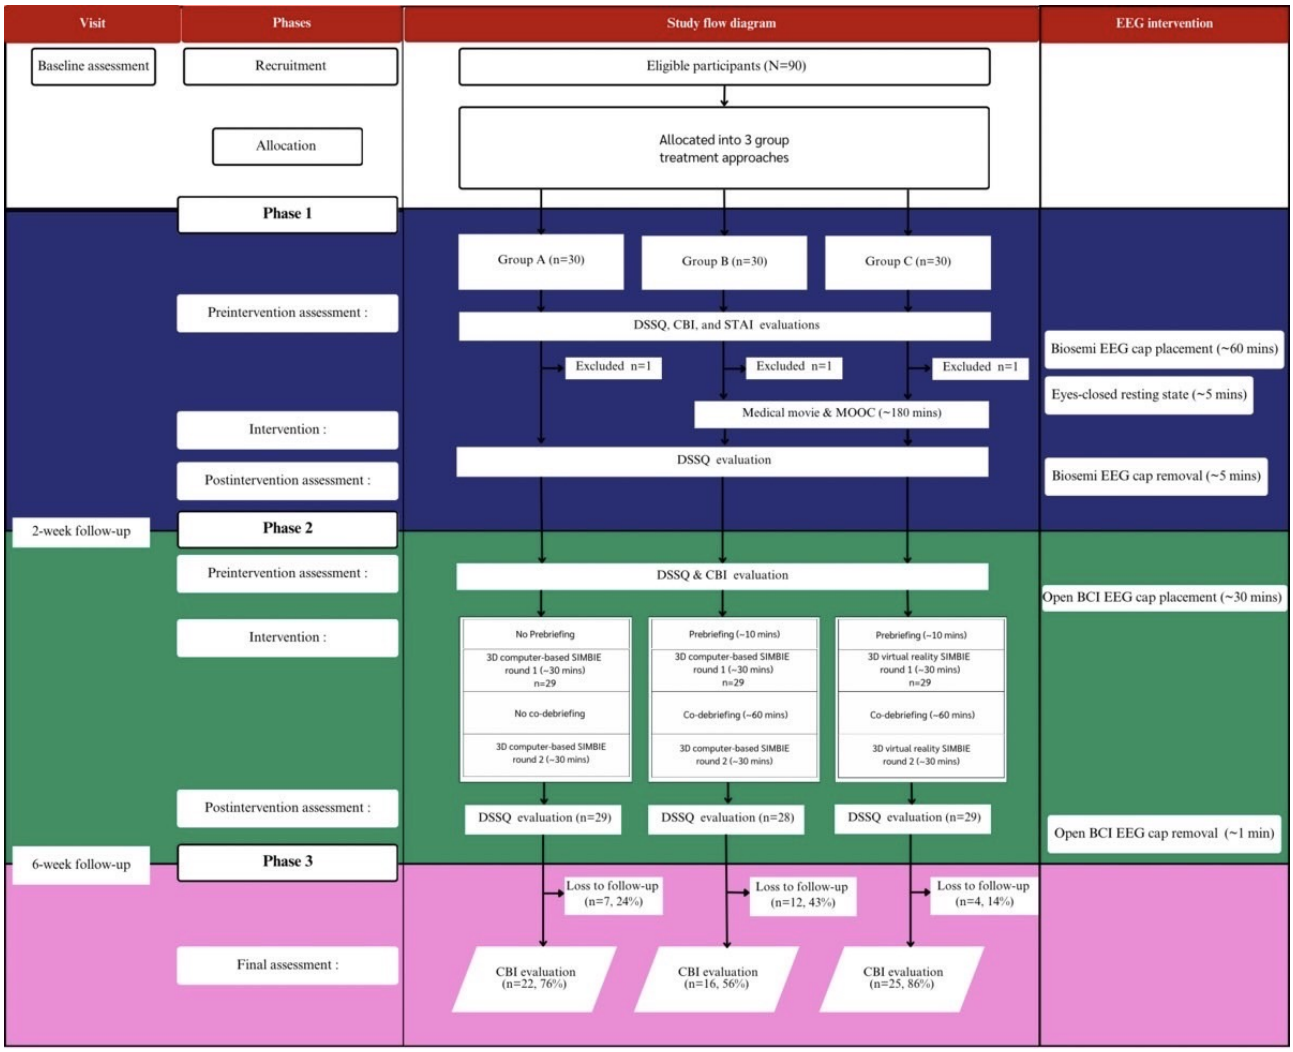
A quasi-experimental study with a single-blinded statistician was conducted to compare stress and burnout levels among health care professional students who were divided into 3 groups: 2 groups received novel educational interventions, and 1 group served as the control group with traditional learning methods. The study was conducted at a 1500-bed university-affiliated hospital in Bangkok, Thailand, which serves as a training site for multiple health care professional programs. A quasi-experimental design was used due to the practical challenges of randomization in a clinical setting during the COVID-19 pandemic.

Participants and Sampling

After institutional review board approval, undergraduate clinical students from 5 health care disciplines (medicine, nursing, pharmacy, radiologic technology, and medical technology) were recruited via announcements, Line, and posters and provided informed consent. Interested students enrolled through a QR-linked Google Form. The principal investigator's contact was provided for inquiries. Participation was voluntary and scheduled outside of regular academic activities to avoid disruption.

Eligibility criteria included healthy individuals aged 18 years to 25 years who were enrolled as 5th-year medical students, 5th- or 6th-year pharmacy students, 4th-year medical technologist students, or 3rd- or 4th-year nursing students or radiological technologist students. The population size included approximately 533 undergraduate clinical students across 5 health care professions: medicine, nursing, pharmacy, medical technology, and radiological technology. A total of 147 students expressed interest and registered to participate in the study. Exclusion criteria included substance use (eg, smoking), a history of neurological or psychiatric disorders, Patient Health Questionnaire-9 (PHQ-9) score ≥9 [304], regular use of antidepressants, and belonging to vulnerable groups, such as pregnant individuals or students with severe illnesses. Moreover, since the potential impact of SIMBIE-induced stress was uncertain during this initial phase of the study conducted amid the COVID-19 pandemic, we prioritized participant safety. There was a concern that SIMBIE could induce stress levels exceeding the optimal arousal threshold for learning, as described by the Yerkes-Dodson law [244]. Participants were also excluded if they missed 2 scheduled appointments or failed to comply with study preparation requirements on 2 occasions (see Figure 1).

Figure 1. CONSORT (Consolidated Standards of Reporting Trials) diagram [305] and participant flow throughout the study, which used a 3-group treatment design. BCI: brain-computer interface; CBI: Copenhagen Burnout Inventory; DSSQ: Dundee Stress State Questionnaire; EEG: electroencephalography; MOOC: massive open online course; PHQ-9: Patient Health Questionnaire-9; RT: radiological technology student SIMBIE: Simulation-Based Interprofessional Education; STAI: State-Trait Anxiety Inventory.



The study recruited undergraduate clinical-level students from the faculty of medicine, the institute of nursing, the faculty of pharmaceutical sciences, and the faculty of allied health sciences. Of the 90 students who initially met the inclusion criteria, 3 radiological technology students were excluded due to PHQ-9 scores exceeding the clinical threshold for depression, resulting in a final sample of 87 participants. The sample included 15 medical students, 30 nursing students, 15 pharmacy students, 15 medical technologist students, and 12 radiological technologist students. These exclusions were made to minimize potential confounding effects and ensure that observed outcomes could be more accurately attributed to the intervention.

Participants were allocated into 3 groups (A, B, and C) using a stratified convenience sampling method to ensure balance in baseline characteristics such as age, education level, and prior clinical experience. Each group was further divided into 5 interprofessional subgroups, with each subgroup consisting of 1 medical student, 2 nursing students, 1 pharmacy student, 1 medical technologist student, and 1 radiological technologist student.

Group A (control) participated in a 3D computer-based SIMBIE without oral debriefing. Group B received a medical movie, a MOOC, a 3D computer-based SIMBIE, and an oral co-debriefing session. Group C received a medical movie, a MOOC, a 3D VR SIMBIE, and an oral co-debriefing session. Stress levels were assessed using the DSSQ at 4 time points: before and after the medical movie and MOOC sessions (intervention phase 1) and before and after the SIMBIE sessions (intervention phase 2). Burnout levels were measured using the CBI at 3 time points: prior to the medical movie and MOOC sessions (intervention phase 1), prior to the SIMBIE sessions (intervention phase 2), and during the follow-up assessment conducted 4 weeks after completing intervention phase 2 (phase 3). The flow of electroencephalogram procedures is also shown in Figure 1 (also see Multimedia Appendix 1), explaining how this potential confounding factor varied across groups. All times reported were approximate.

Data Collection

Data were collected between August 2022 and September 2023. Baseline assessments included demographic information, the DSSQ to measure stress, and the CBI to evaluate burnout as the

primary outcomes. Trait anxiety was assessed once at baseline using the STAI. All questionnaires were administered online via Qualtrics. Data were collected in 3 phases. Phase 1 included DSSQ assessments before and after participants watched a medical movie and completed a MOOC, with only a pre-intervention CBI assessment conducted. Phase 2 involved DSSQ assessments before and after the SIMBIE activity, conducted 2 weeks later, along with a pre-activity CBI assessment. Phase 3 was a follow-up burnout assessment using the CBI, conducted 4 weeks after the completion of all activities. To minimize bias, data collection and analysis were performed by a single-blinded statistician. The timeline and details of the study are summarized in Figure 1.

In addition, the online survey has been reported in accordance with CHERRIES (Checklist for Reporting Results of Internet E-Surveys), which is provided as Multimedia Appendix 2. Although this study is not an RCT and thus does not require a trial registration number, we completed the CONSORT-EHEALTH (Consolidated Standards of Reporting Trials of Electronic and Mobile Health Applications and Online Telehealth; V1.6.1) submission/publication form to ensure transparency and completeness in reporting. This form is included as Multimedia Appendix 3.

Traditional Learning Approaches

The traditional learning approach involved online, lecture-based instruction provided to health care students during the COVID-19 pandemic within a uniprofessional educational framework. These methods did not include any curriculum nor intervention specifically designed to reduce stress, build resilience, or promote interprofessional team training. Group A, serving as the control group, received no IPE exposure nor preparatory learning activities beyond the traditional lecture format. Specifically, they did not participate in lectures or cinemeducation on interprofessional collaboration, role-play activities, or pair-and-share exercises. Additionally, Group A did not undergo any preparatory learning before the simulation. Instead, they virtually engaged in a 3D computer-based SIMBIE scenario with other participants in group A and without oral co-debriefing, which served as the traditional learning condition in this study.

Experimental Groups and Interventions

This study used a 2-arm design with Groups B and C as the experimental groups. Both groups underwent a series of interventions, including a combination of medical movie, MOOC, and 3D SIMBIE simulation, followed by a co-debriefing session, collectively referred to as ER-VIPE. Group B used a computer-based 3D SIMBIE for approximately 30 minutes, while Group C used a 3D VR SIMBIE for the same duration. Both groups participated in a 60-minute oral co-debriefing session (see Figure 1). The medical movies used in the simulations were standardized across all participants to ensure consistency in content. Similarly, the MOOC materials were delivered and maintained uniformly throughout the study to ensure consistent learning experiences. In addition, the simulation scenarios were standardized so that all participants were exposed to the same conditions and challenges, thereby minimizing potential variability.

Multimodal IPE Design Based on the SIT Framework

For the experimental groups, we implemented SIT [194] to induce the steeling effect through the integration of cinemeducation, coping-with-stress strategies via MOOC, SIMBIE, and co-debriefing. SIT is a structured cognitive behavioral intervention aimed at fostering resilience by equipping individuals with the tools needed to effectively manage stress. The approach consists of 3 interrelated and overlapping phases: conceptualization, skills acquisition and consolidation, and application and follow-through.

In the conceptualization phase, participants were introduced to the cognitive, emotional, and behavioral manifestations of stress using cinemeducation through medical movies and coping-with-stress strategies. A flipped classroom approach via cinemeducation and MOOC were used to optimize preparedness for the coming SIMBIE sessions [306]. Presession engagement with medical content via xMOOC platforms supported the development of interprofessional knowledge and encouraged positive attitudes IPE, Team Strategies and Tools to Enhance Performance and Patient Safety (TeamSTEPPS), and stress coping strategies [307]. This model enhanced learner engagement and emotional investment, thereby maximizing the effectiveness of in-session SIMBIE activities [308]. The integration of stress management into clinical education has been widely recognized as essential to the development of professional competencies [309].

In the skills acquisition and consolidation phase, learners developed a repertoire of coping mechanisms—including relaxation techniques; cognitive restructuring; Identify, Situation, Background, Assessment, and Recommendation (ISBAR) [49]; closed-loop communication; and collaborative communication strategies—within SIMBIE sessions that approximate real-world clinical stressors, such as time constraints and multisensory demands (visual and auditory stimuli). Skills consolidation was reinforced through co-debriefing, which provided structured opportunities for critical reflection and feedback.

In the final application and follow-through phase, learners applied these skills during a second round of SIMBIE and were progressively intensified to balance cognitive load and emotional challenge while maintaining learners within their zone of proximal development. SIT not only supports the development of self-regulation and problem-solving capabilities but also enhances self-efficacy by helping participants reframe stressors as challenges rather than threats. Moreover, it fosters a psychologically safe learning environment in which learners can engage with high-stakes situations without fear of failure—ultimately promoting more adaptive coping strategies, reduced anxiety, and improved performance under pressure.

Medical Movie (Cinemeducation)

Participants viewed a 75-minute medical movie developed in-house that depicted an interprofessional emergency team managing high-stress scenarios. The film emphasized communication, shared mental models, team reasoning, team support, and collaborative problem-solving for stress mitigation. Viewing was conducted individually and asynchronously, with

no postfilm group discussion. Although cinemeducation is evidence-based for reducing stigma [84,85,88], its impact on stress or burnout has not been previously studied.

MOOCs

The MOOCs comprised 7 lessons covering essential topics, including Interprofessional Education Collaborative core competencies for IPC practice, TeamSTEPPS principles, team-based clinical reasoning for diagnosis, stress management and coping strategies, IPE for patient safety, and ethical principles for collaboration. A 15-minute segment focused specifically on stress management and coping strategies, addressing significant stressors faced by emergency department personnel, such as disease outbreaks, heavy workloads, and interpersonal challenges. These stressors were categorized as external (eg, workplace pressures and unexpected events) or internal (eg, personality traits like perfectionism and difficulties with work-life balance). The module emphasized problem-solving approaches over emotional reactions to challenges, aiming to mitigate the long-term effects of stress, including burnout symptoms like emotional exhaustion, depersonalization, and reduced personal accomplishment. All participants were required to complete both the medical movie and MOOCs as well as pass the pre- and posttest exams to receive a certificate and meet the eligibility criteria for the flipped classroom before attending the SIMBIE session.

Prebriefing Design

To promote psychological safety, we implemented structured prebriefing strategies based on best practices [135,168,257]. Facilitators and learners introduced themselves, shared prior experiences, and established ground rules emphasizing confidentiality, active participation, and a focus on performance improvement rather than individual critique [162,171,172,284]. Effective prebriefing must communicate to learners that they are entering a unique, controlled environment for reflective practice where making errors is acceptable and expected as part of the learning process [256].

A “fiction contract” was cocreated to encourage engagement and suspend disbelief despite simulation limitations [310-312]. Learners were oriented to the simulation space, equipment, and environment to reduce anxiety and enhance participation [182,313-315].

For co-debriefing, facilitators conducted prebriefing discussions to align objectives, align areas of expertise, clarify roles, agree on debriefing methods, clarify who will lead different elements, and address potential challenges [168,169]. This precoordination ensured a smooth, cohesive, and collaborative debriefing process and helped establish a shared mental model between co-debriefers [169]. Facilitators also attended to implicit cues—such as tone, expressions, and body language—to foster trust and a positive psychological climate [316-318].

3D SIMBIE Design

The 3D SIMBIE simulations, available in both computer-based and VR formats, were designed to progressively increase in complexity and stress, replicating high-acuity emergency scenarios reflective of real-world challenges during the COVID-19 pandemic. Each simulation integrated both technical and TeamSTEPPS-based nontechnical learning objectives in the context of a multidisciplinary emergency department encounter. Participants worked as a 6-member health care team to diagnose and manage a complex case involving a 70-year-old male patient with COVID-19, chronic obstructive pulmonary disease, hypertension, diabetes mellitus, and a documented allergy to ceftriaxone. The presence of a distressed spouse added an emotionally charged layer to the scenario, requiring participants to apply both clinical and interpersonal skills.

Technical training included time-sensitive interventions such as intubation, ventilator management, laryngeal mask airway insertion, cricothyroidotomy, hyperkalemic crisis, use of PPE, and coordination of portable chest imaging. Clinical reasoning was guided toward formulating an accurate diagnosis and implementing a safe treatment plan under pressure, closely mirroring the demands of real-world emergency care clinical environments and emphasizing decision-making under pressure, as illustrated by the multiple stressor events shown in Figures 2 and 3. Nontechnical training focused explicitly on the 5 TeamSTEPPS domains—team structure, communication, leadership, situation monitoring with the STEP framework, and mutual support—using strategies such as ISBAR, closed-loop communication, and real-time psychosocial support. Communication occurred via open microphones to simulate authentic interprofessional interaction, and learners engaged with the patient’s spouse through a branching dialogue system that enabled them to select empathetic responses in real time.

An interactive game-based interface further reinforced TeamSTEPPS competencies as our main learning objectives. Each participant was equipped with a HP bar, a symbolic “health point” indicator representing emotional resilience under pressure. The HP bar depletes over time, particularly during high-stakes decision points or delays in clinical action such as managing a “can’t intubate, can’t ventilate” situation, video laryngoscope battery failure, or sudden hypotension**.** Mutual support was emphasized as teammates could replenish each other’s HP by pressing a “plus” button—an interactive metaphor for peer support and collaborative coping. The HP bar thus served both as a visual representation of stress load and as a positive reinforcement mechanism for TeamSTEPPS-aligned behaviors. These features were designed to enhance psychological fidelity and simulate cognitive load realism by integrating both clinical complexity and emotional dynamics.

This study was conducted during the COVID-19 pandemic, during which all learners were limited to online lectures without clinical exposure. Given these constraints, along with the logistical challenges of assembling multiprofessional student teams and facilitators, we designed the study to ensure both research feasibility and standardization. To address safety concerns for both participants and researchers, a control group (Group A) was exposed to a 3D computer-based SIMBIE simulation without debriefing. All participants provided informed consent after being fully briefed on the study’s potential risks and benefits. Inclusion criteria required that participants have a PHQ-9 score within the normal range, to minimize psychological risk. Trained research assistants were present throughout the simulation to observe and provide support

as needed. Participants were also informed of their right to withdraw from the study at any time without penalty. These measures were implemented to uphold ethical standards and ensure fairness, psychological safety, and relevance to the context of the pandemic.

The 3D SIMBIE and 3D VR SIMBIE platforms were developed by our ER-VIPE team, which comprises professionals from various disciplines including emergency physicians, nurses, pharmacists, medical technologists, radiologic technologists, communication arts specialists, instructional designers, architects, psychologists, and experts in the humanities and education. This interdisciplinary team collaborated with a specialized group of engineers in immersive learning technologies for health care education. Both platforms use advanced simulation software to create realistic, interactive environments that enable participants to engage in high-stakes medical scenarios.

The key distinction lay in the level of immersion: The 3D version used standard computer input devices (eg, screen, keyboard, and mouse), while VR SIMBIE used headsets and controllers to deepen emotional engagement and presence. This allowed participants to physically move and interact within the environment in a fully immersive and realistic manner. The VR format enhances the sense of presence, making participants feel as though they are "inside" the clinical scenario, which may result in greater cognitive and emotional stress compared with the 3D desktop version. Figures 2 and 3 illustrate the user interface, visual comparisons, and experiential differences between both platforms. In addition, they show the health point (HP) bar, which can reach a maximum of 50 points, with the ability to restore a teammate's energy up to 5 times, adding 10 points each time. Each simulation concluded with a structured co-debriefing session, enabling participants to reflect on clinical decision-making and TeamSTEPPS performance, consolidating targeted nontechnical teamwork competencies.

Figure 2. Health point (HP) bar's features, functions, and examples of stressful situations encountered by health care professionals while practicing stress coping strategies in 3D computer-based simulation-based interprofessional education (SIMBIE): (A) triage nursing student entering for patient assessment, walking in, putting on a mask, assessing the patient, and measuring vital signs; (B) medical student struggling with unsuccessful endotracheal tube insertion due to a difficult airway; (C) nursing student connecting a patient to a ventilator; (D) a pharmacy student advising a patient's family against taking photos, emphasizing patient privacy and ethical confidentiality; (E) radiological technologist and nursing students collaborating to reposition the patient for a chest X-ray while monitoring for accidental dislodgment of the endotracheal tube; and (F) medical technologist student improperly removing PPE after working in a lab where COVID-19 was detected, triggering a system warning for the wrong sequence.

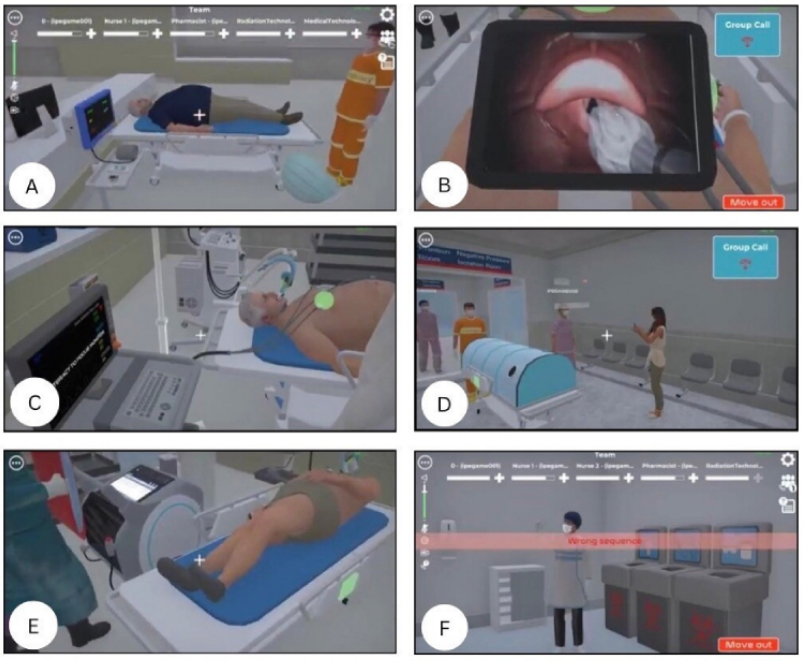


Figure 3. Health point (HP) bar's features and functions and examples of stressful situations and professional perspectives encountered by 6 health care professionals while practicing Team Strategies and Tools to Enhance Performance and Patient Safety (TeamSTEPPS) and stress-coping strategies in a 3D virtual reality (VR)–based simulation-based interprofessional education (SIMBIE) scenario: (A) nursing student perspective during initial triage, including vital sign measurements, such as temperature using a green laser pointing at the ear; (B) medical student perspective while performing endotracheal intubation using a video laryngoscope; (C) nursing student perspective while receiving a phone call from a pharmacy student alerting the team to a drug allergy and each profession's HP bar; (D) pharmacy student perspective while politely warning a patient's relative taking a photo of the patient and clinical staff; (E) radiologic technologist student view while assisting the nursing student with repositioning the patient to safely remove a lead X-ray plate, ensuring proper side rail placement to prevent accidental extubation or falls; and (F) medical technologist student perspective while urgently communicating a critical potassium level using the Identify, Situation, Background, Assessment, and Recommendation (ISBAR) communication framework to the team via phone.

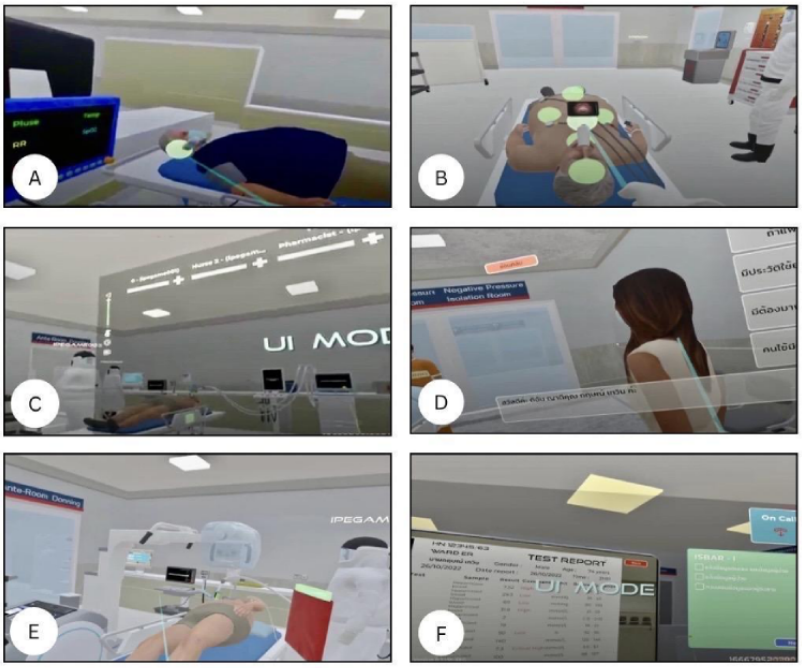

Co-Debriefing Design

Following the initial 30-minute SIMBIE session, participants engaged in a 60-minute oral co-debriefing session, guided by TeamSTEPPS as the primary learning framework. This session provided a safe, nonjudgmental environment for team-based problem-solving and crisis management. Facilitated by instructors, it aimed to enhance experiential learning, reinforce team dynamics, and foster a no-blame culture. After the co-debriefing, participants in Group B replayed the 3D computer-based SIMBIE for a final 30-minute session, while participants in Group C replayed the 3D VR SIMBIE for their concluding 30-minute session.

In this study, co-debriefing was conducted using two complementary conceptual frameworks designed to optimize critically reflective learning: (1) the PEARLS (Promoting Excellence and Reflective Learning in Simulation) framework [169] and (2) the "divide and conquer" approach [169]. The PEARLS framework offers a straightforward and structured method for facilitating consistent, reliable exchanges of information during co-debriefing. It involves 4 sequential phases: reactions, during which learners can voice emotionally salient concerns or choose discussion points; description, during which facilitators and learners establish a shared, factual account of what happened; analysis, which explores performance gaps and encourages critical discussion; and summary, which consolidates the discussion into key learning points.

The reaction phase helps to establish a shared and psychologically safe foundation for learning and reflection by allowing learners to express their immediate thoughts and emotional responses [315]. For instance, facilitators began with questions such as, "What emotions are you experiencing right now?" to validate participants' initial reactions and set a supportive tone for reflection. The inclusion of this phase not only supports psychosocial well-being but also may enhance learner engagement by increasing the relevance and resonance of subsequent discussions. In the description phase, debriefers introduce observations coupled with evaluative judgments and may shorten the phase if learners appear to have a shared understanding of the case. This is followed by the analysis phase, in which facilitators guide group reflection using structured prompts. Examples of such prompts included: "Can you describe what was on your mind during the most intense moments?" "In what ways did your team interact and support each other under pressure?" "What specific actions did you take to address the issue, and how successful were they?" and "Are there any other methods you think might have worked in that situation?" Facilitators also applied the plus/delta technique, asking questions such as "What aspects of the scenario went smoothly?" and "What elements could be improved next time?" In addition, the advocacy-inquiry model was used to promote deeper insight into decision-making. For example, a facilitator might say "I'd like to talk about mutual support in TeamSTEPPS. I observed three unsuccessful intubation attempts. I was concerned about the effect of prolonged hypoxia.

What was going through your mind as your team worked to establish the airway?"—encouraging participants to share their thought processes and mental models. Finally, the summary phase concluded the session with a review of critical insights. Facilitators asked learners to identify key lessons they planned to apply in future clinical practice, such as, "What are the main takeaways from this experience that you would carry into real-life situations?"

Additionally, we implemented the "divide and conquer" approach during co-debriefing, assigning a lead role—typically the medical debriefer—to guide the session [59,163,319]. Under this model, co-debriefers conveniently divide thematic responsibilities based on the TeamSTEPPS framework, thereby minimizing redundant cognitive processing. This division of labor helps reduce the intrinsic and extraneous cognitive load experienced by co-debriefers—a key consideration in accordance with cognitive load theory, which posits that reducing unnecessary mental burden enhances co-debriefers' performance and consequently learning outcomes of learners [311,320].

To prevent power imbalances among co-debriefers, we followed strategies suggested by Oriot et al [293] on agreeing in advance about the techniques, approaches, and educational strategies we will use—including our use of nonverbal communication. This is important because, as Holmes and Mellanby [164] noted, "debriefers debrief slightly differently, everybody has a slightly different focus, different speeds and different process for how you do it." Establishing nonverbal communication allows co-debriefers to "authorize" each other to speak using pre-agreed signals. This approach helps prevent interruptions or conflicts, ensuring that one debriefer does not undermine the other's process. Additionally, we also conducted a "post-debriefing huddle," which includes peer coaching and provides an opportunity for co-debriefers to review challenges, resolve misunderstandings, and collaboratively develop strategies for future sessions [168,290].

Outcome Assessments

To assess outcomes, DSSQ and CBI were administered. Additionally, Anxiety Trait scores from the STAI were measured as a control variable. Anxiety Trait scores were assessed prior to each intervention. Participants self-reported on the DSSQ before and after each intervention (4 total measurements per participant). Burnout assessments were conducted before each intervention and followed up 1 month later (3 measurements per participant). The e-survey was developed and administered using the Qualtrics platform (see Multimedia Appendix 4).

DSSQ and CBI were selected based on their strong psychometric properties and suitability for use with health care professionals in short-term interventions. The DSSQ provides a multidimensional assessment of psychological stress, capturing emotional, cognitive, and motivational states, and is particularly suited for evaluating acute stress responses. We selected the CBI because it is more applicable to the context of our study population—health care students undergoing both clinical and academic training. The CBI is particularly relevant for assessing 3 core dimensions of burnout: work-related, personal, and client-related. Unlike the Maslach Burnout Inventory, which was originally developed for use with long-term professionals in workplace settings, the CBI offers a broader conceptualization of burnout that includes personal exhaustion—an important consideration for student populations. Designed specifically for health care contexts, the CBI has demonstrated high reliability and validity across diverse clinical settings. Furthermore, it has shown greater sensitivity than the Maslach Burnout Inventory, with studies reporting higher burnout detection rates (53% vs 35%) [321]. This suggests that the CBI may be more effective at identifying early or less overt symptoms of burnout, aligning well with our goal of preventive intervention among students. It is considered a reliable tool across cultures and has been associated with future risks such as absenteeism, sleep issues, painkiller use, and intention to leave. Its subscales also reflect meaningful changes in burnout over time [322].

These instruments were chosen over other tools due to their brevity, sensitivity to short-term changes, and practical applicability within the study's timeframe. Both scales are concise, enabling efficient administration without overburdening participants—an important consideration during pandemic-related disruptions and online learning contexts. Although both tools are self-reported and may be subject to response bias, they offer a balanced trade-off between feasibility and diagnostic utility. The DSSQ may not fully capture stress under extreme crisis conditions, and the CBI may not reflect long-term burnout trajectories; however, their capacity to assess immediate changes in stress and burnout levels makes them appropriate for evaluating the short-term impact of the ER-VIPE intervention.

A Measure of Anxiety Trait

The subscale of trait anxiety from the short version of the Spielberger STAI [323] was ordered and paid for with the necessary permissions obtained. It is used to assess an individual propensity to anxiety. Trait anxiety data were collected and included as a control variable in the analysis. There are 5 items, and the items use a 4-point Likert scale (1=not at all to 4=very much so). An example is, "In general, I feel that difficulties are piling up so that I cannot overcome them." The Cronbach α of the original scale was found to be acceptable (α=0.91). This measure was translated into Thai using a back-translation method by J Chavanovanich, PhD (email, August 21, 2024; see Multimedia Appendix 4).

A Measure of State Stress

The short-version DSSQ [324] was used to assess the level of subjective stress state. Professor Helton granted us permission for its use. The DSSQ is a 24-item multidimensional measurement comprising task engagement, distress, and worry. The items use a 5-point Likert scale (1=not at all to 5=extremely). An example item is, "I was motivated to do the task." DSSQ is a well-established tool for assessing acute stress, recognized for its reliability and validity. It consistently achieves high internal consistency, with Cronbach α for the original scale found to be acceptable, exceeding 0.80 across all dimensions. This measure was translated into Thai using a back-translation method by J Chavanovanich, PhD (email, August 21, 2024). We chose psychological tools, such as the DSSQ, instead of physiological measures like heart rate and heart rate variability because they allow for more detailed differentiation between

engagement (items: 2, 5, 11, 12, 13, 17, 21, and 22), distress (items: 1, 3, 4, 6, 7, 8, 9, and 10), and worry (items: 14, 15, 16, 18, 19, 20, 23, and 24), offering a comprehensive understanding of stress states (see Multimedia Appendix 4).

A Measure of Burnout

A 6-item personal burnout subscale from the CBI [322] was used to assess the level of prolonged physical and psychological exhaustion. The items use a 5-point Likert scale (1=never/almost never to 5=always). An example item is, "How often are you physically exhausted?" The measure was translated into Thai using a back-translation method by J Chavanovanich, PhD (email, August 21, 2024). Permission to translate and use the CBI for this research was granted by the National Research Centre for the Working Environment by T Clausen, PhD (email, June 28, 2022). The CBI has demonstrated strong psychometric properties across various studies. It exhibits high internal consistency, with Cronbach α coefficients typically exceeding 0.90 for both the overall scale and its subscales (personal, work, and patient burnout). Construct validity was supported by confirmatory factor analysis, and convergent validity was demonstrated through strong correlations with a previously validated measurement [322,325-327]. We focused exclusively on personal burnout, as the participants were students who were neither working nor patients. Concentrating on personal burnout was expected to provide a more direct response to the research question and increase the likelihood of successful study completion, although this may reduce validity (see Multimedia Appendix 4).

Statistical Analysis

Differences and Changes Over Time

Descriptive statistics were summarized using means (SDs) and medians (IQRs). Frequencies and percentages were used for categorical data. Comparisons between groups in demographic characteristics at baseline were conducted using the Wilcoxon Mann-Whitney *U* test, Kruskal-Wallis *H* test with the Dunn post hoc test, chi-square test, or Fisher exact test, as appropriate. Generalized estimating equations (GEEs) were used to analyze changes over time and assess differences in improvement scores for burnout and DSSQ between groups, with adjustments for anxiety. DSSQ engagement, distress, and worry scores were measured using specific items from the DSSQ. Engagement scores among Groups A, B, and C were obtained from items 2, 5, 11, 12, 13, 17, 21, and 22. Distress scores were derived from items 1, 3, 4, 6, 7, 8, 9, and 10, while worry scores were obtained from items 14, 15, 16, 18, 19, 20, 23, and 24. To assess changes over time and compare improvements in burnout and DSSQ scores between groups, GEEs were used, with adjustments for anxiety as a covariate. Both an intention-to-treat (ITT) analysis and a per-protocol (PP) analysis were performed. Missing data were imputed using the last observation carried forward method. Statistical significance was set at a 2-tailed *P* value of <.05 for all analyses. Stata version 15 (Stata Corp) [328] was used for data analyses.

Effect Size Calculation for Burnout Reduction

To assess the magnitude of intervention effects on burnout reduction, Cohen *d* was calculated for each of the 5 intervention conditions using mean differences and pooled SDs. Five effect sizes were computed according to the structure of the study. A negative effect size indicated a reduction in burnout compared with baseline, while a positive effect size indicated an increase in burnout.

I. Effect Size of Medical Movies and MOOCs

To evaluate the effect of medical movies and MOOCs on burnout after 2 weeks, we calculated the mean difference in burnout scores between phase 2 (pre-SIMBIE) and phase 1 (before medical movies and MOOCs) within Group B and C, using pooled SDs. An alternative comparison using Group A as a control group was also considered to assess whether burnout reduction occurred over 2 weeks without movie and MOOC exposure, accounting for potential external factors.

II. Effect Size of Computer-Based SIMBIE

To evaluate the effect of the computer-based SIMBIE simulation after 4 weeks, we calculated the mean difference in burnout scores between phase 3 (4 weeks post-SIMBIE) and phase 2 (pre-SIMBIE) within Group A using pooled SDs.

III. Effect Size of VR-Based SIMBIE

To evaluate the effect of VR-based SIMBIE simulation after 4 weeks, we calculated the mean difference in burnout scores between phase 3 and phase 2 within Group C (after follow-up losses) using pooled SDs.

IV. Effect Size of ER-VIPE (Computer-Based Version)

To evaluate the full ER-VIPE program (medical movies + MOOCs + computer-based SIMBIE with co-debriefing) after 6 weeks, we calculated the mean difference in burnout scores between phase 3 (6 weeks post-SIMBIE) and phase 1 (before medical movies and MOOCs) within Group B using pooled SDs.

V. Effect Size of ER-VIPE (VR-Based Version)

To evaluate the VR-based version of ER-VIPE (medical movies + MOOCs + VR-based SIMBIE with co-debriefing), the same approach was used. Burnout scores at phase 3 and phase 1 were compared within Group C using pooled SDs.

Sample Size Calculation

A power analysis for a repeated measures multivariate analysis of variance (MANOVA) conducted in G*Power (version 3.1.9.4) with a within-between interaction indicated a required sample size of 82 participants to detect an effect size of 0.35, with an α level of .05 and a power of .80. To account for potential dropout, 10% was added, resulting in a total sample size of 87 participants.

Ethical Considerations

The study protocol was approved by the Ethics Committee for Research in Human Subjects of the Faculty of Medicine, Chulalongkorn University, Thailand (IRB number 0366/65). Participants were informed about the study's objectives, procedures, potential risks, and benefits. Each participant received US $30 in recognition of their time and contribution, in accordance with institutional review board approval. This information was provided both orally and in writing before obtaining informed consent. Participants were assured of their

right to make voluntary decisions and withdraw from the study at any time. Data were anonymized to maintain confidentiality.

Results

Demographics

A total of 87 undergraduate clinical students from various professional programs participated in the study, with 29 students in each group (A, B, and C). The sample was predominantly female (62/87, 71%) with a mean age of 21.87 (SD 1.13) years. No significant differences were found in demographic characteristics between the groups. However, analysis of the debriefing duration revealed significant differences between Group B (mean 50.93, SD 12.61) and Group C (mean 60.33, SD 9.75), as shown in Table 1.

Table 1. Demographics by treatment group.

Factor	Total sample	Group A[a]	Group B[b]	Group C[c]	*P* value
Gender, n (%)					.80[d]
Female	62 (71)	22 (76)	20 (69)	20 (69)	
Male	25 (29)	7 (24)	9 (31)	9 (31)	
Age (years), mean (SD)	21.87 (1.13)	21.83 (0.93)	21.86 (1.03)	21.93 (1.41)	—[e]
Age (years), median (IQR)	22 (21-22)	22 (21-22)	22 (21-22)	21 (21-22)	.90[f]
Academic year, n (%)					.63[g]
Third year	12 (14)	3 (10)	7 (24)	2 (7)	
Fourth year	47 (54)	17 (59)	13 (45)	17 (59)	
Fifth year	18 (21)	6 (21)	5 (17)	7 (24)	
Sixth year	10 (11)	3 (10)	4 (14)	3 (10)	
Academic grade, mean (SD)	3.23 (0.38)	3.24 (0.40)	3.23 (0.43)	3.22 (0.31)	—
Academic grade, median (IQR)	3.24 (3-3.50)	3.25 (3-3.53)	3.23 (3.03-3.50)	3.24 (3-3.48)	.92[f]
Debriefing duration (minutes), mean (SD)	54.96 (12.29)	—	50.93 (12.61)	60.33 (9.75)	—
Debriefing duration (minutes), median (IQR)	57 (45-63)	—	49 (45-58.50)	63 (60-69)	.01[h]
Debriefing staff, mean (SD)	5.33 (1.75)	—	5.69 (1.85)	4.97 (1.59)	—
Debriefing staff, median (IQR)	6 (4-6)	—	6 (4-7)	6 (5-6)	.06[h]

[a]Group A (control) participated in 3D computer-based simulation-based interprofessional education (SIMBIE) without oral debriefing.

[b]Group B received a medical movie, a massive open online course (MOOC), a 3D computer-based SIMBIE, and an oral co-debriefing session.

[c]Group C received a medical movie, a MOOC, a 3D virtual reality SIMBIE, and an oral co-debriefing session.

[d]Chi-square test.

[e]Not applicable.

[f]Kruskal-Wallis *H* test.

[g]Fisher exact test.

[h]Wilcoxon Mann-Whitney *U* test.

Baseline Outcomes and Time Interval Assessments Across Groups

Baseline assessments of burnout and DSSQ measures (engagement, distress, and worry) showed no significant differences among Groups A, B, and C (see Table S1 in Multimedia Appendix 5). Similarly, the mean interval between the postintervention DSSQ assessment in phase 1 and the pre-intervention DSSQ assessment in phase 2 did not differ significantly across groups. However, a significant difference emerged in the mean burnout assessment interval between the postintervention assessment in phase 2 and the final assessment in phase 3: Group A (mean 33.82, SD 12.90 days) differed significantly from Group B (mean 48.20, SD 23.48 days) and Group C (mean 37.20, SD 6.52 days). See Table S2 in Multimedia Appendix 6.

Overall Assessment Outcomes Among Groups

The study aimed to assess individual state stress, as measured using the mean DSSQ scores, and burnout outcomes, as measured using the CBI, across Groups A, B, and C. Group A (control) participated in a 3D computer-based SIMBIE without oral debriefing. Group B received a medical movie, MOOC, 3D computer-based SIMBIE, and oral co-debriefing session. Group C received a medical movie, MOOC, 3D VR SIMBIE, and oral co-debriefing session. Statistical analysis was conducted

using a GEE approach, with adjustments for confounding factors such as anxiety trait. Measurements were taken during 3 phases, as illustrated in Figure 1: phase 1 (movie and MOOC intervention), phase 2 (SIMBIE intervention), and phase 3 (6-week follow-up). These results were obtained through an ITT analysis (see Figure 4, Figure 5, and Table S3 in Multimedia Appendix 7). A PP analysis further corroborated the findings from the ITT analysis, demonstrating consistent results and interpretations for the mean change in DSSQ scores (see Table S4 in Multimedia Appendix 8, Figure S1 in Multimedia Appendix 9, and Figure S2 in Multimedia Appendix 10).

Figure 4. Based on intention-to-treat analysis, changes in (A) Dundee Stress State Questionnaire (DSSQ)-engagement scores, (B) DSSQ-distress scores, and (C) DSSQ-worry scores with the movie and massive open online course (MOOC) intervention as well as changes in (D) DSSQ-engagement scores, (E) DSSQ-distress scores, and (F) DSSQ-worry scores with the simulation-based interprofessional education (SIMBIE) intervention. VR: virtual reality.

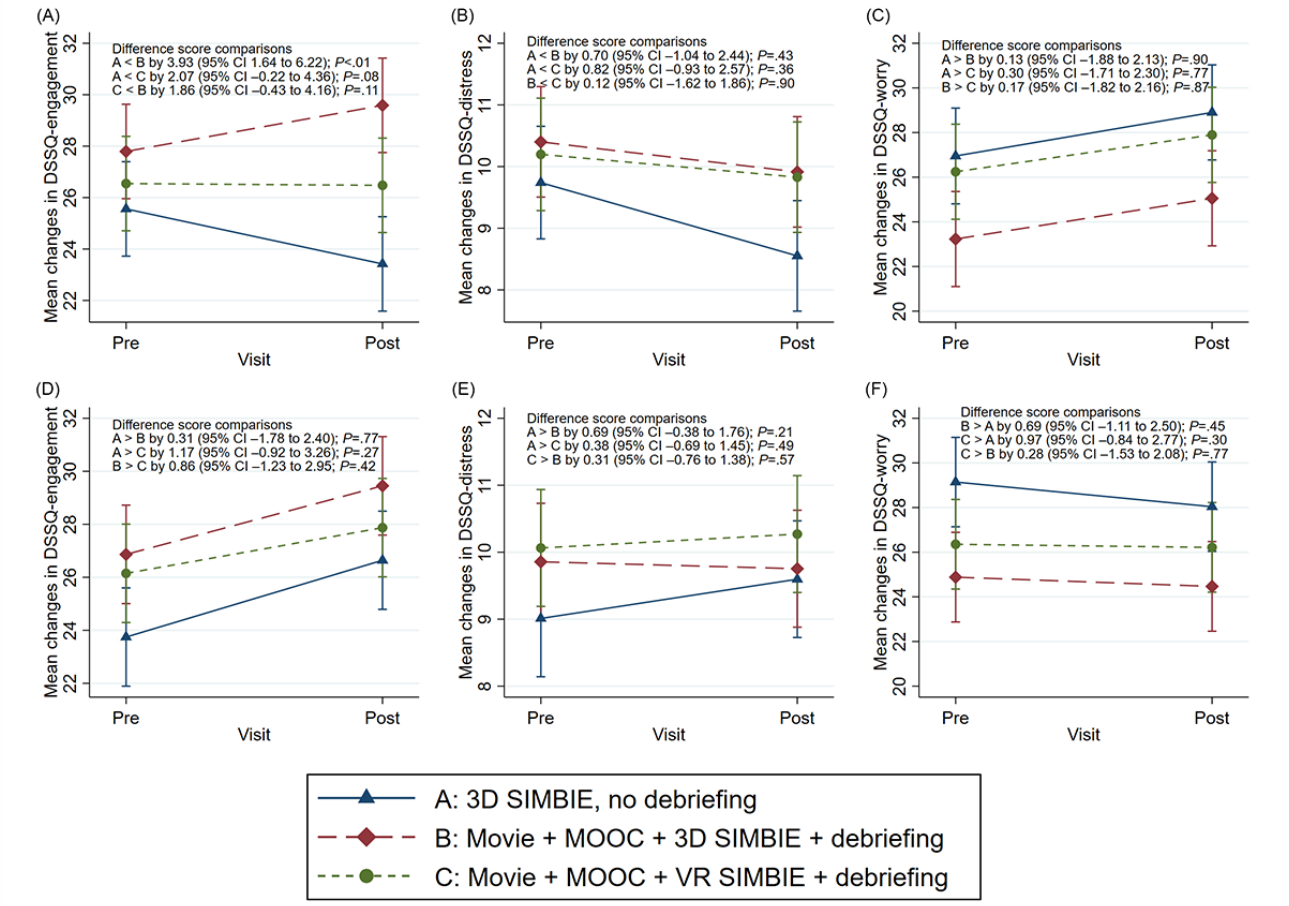

Figure 5. Changes in Copenhagen Burnout Inventory (CBI) scores based on intention-to-treat analysis using generalized estimating equations (GEEs), adjusted for anxiety traits as a control variable. MOOC: massive open online course; SIMBIE: simulation-based interprofessional education; VR: virtual reality.

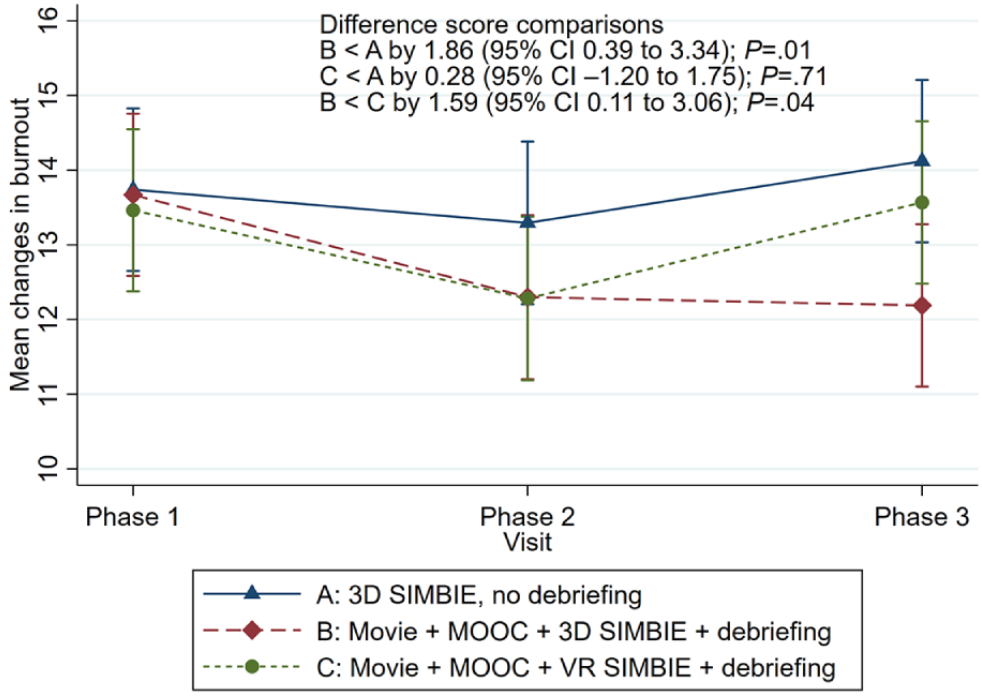

Measuring State Stress With the DSSQ

Overview

The DSSQ [329] was selected as the primary tool in this study due to its ability to assess momentary stress states across 3 dimensions: task engagement, distress, and worry. Designed for real-time application, the DSSQ is particularly well-suited for simulation-based educational research [330]. It enabled the detection of subtle, immediate changes in learners' stress responses before and after each ER-VIPE session. In contrast, the Perceived Stress Scale-10 [331] is a globally recognized instrument widely used in health care studies. It provides a reliable measure of general perceived stress over the past month and is appropriate for large-scale screening.

DSSQ-Engagement Scores Among Groups

Following exposure to a medical movie and MOOCs, Group B had significantly higher DSSQ engagement scores, adjusted for confounding factors, than Group A (mean difference 3.93; *P*<.001). Group C had nonsignificantly higher scores than Group A (mean difference 2.07; *P*=.08), and nonsignificantly lower scores than Group B (mean difference –1.86; *P*=.11). After participating in the SIMBIE process all 3 groups demonstrated positive trends in DSSQ engagement scores, adjusted for confounding factors. Group B scored higher than Group A, though the difference was not significant (mean difference –0.31; *P*=.77). Similarly, Group C had nonsignificantly higher scores than Group A (mean difference –1.17; *P*=.27) and nonsignificantly lower engagement scores than Group B (mean difference –0.86; *P*=.42). See Figure 4, Table S3 in Multimedia Appendix 7, Table S4 in Multimedia Appendix 8, and Figure S1 in Multimedia Appendix 9.

DSSQ-Distress Scores Among Groups

Focusing on DSSQ-distress following exposure to a medical movie and MOOCs, the results indicated negative trends across all 3 groups. Group B exhibited nonsignificantly higher distress scores than Group A, with a mean difference of 0.70 (*P*=.43). Similarly, Group C had nonsignificantly higher distress scores than Group A, with a mean difference of 0.82 (*P*=.36) and nonsignificantly lower distress scores than Group B, with a mean difference of 0.12 (*P*=.90). After participating in the SIMBIE process and adjusting for confounding factors, only Group B exhibited negative trends in DSSQ distress scores. However, the differences for all 3 groups were not significant. Group B scored higher than Group A, but the mean difference was not statistically significant (mean difference –0.69; *P*=.21). Similarly, Group C had nonsignificantly higher scores than Group A (mean difference –0.38; *P*=.49) and nonsignificantly lower scores than Group B (mean difference 0.31; *P*=.57). See Figure 4, Table S3 in Multimedia Appendix 7, Table S4 in Multimedia Appendix 8, and Figure S1 in Multimedia Appendix 9.

DSSQ-Worry Scores Among Groups

Regarding DSSQ-worry following exposure to a medical movie and MOOCs, all 3 groups exhibited positive trends. Group B had nonsignificantly lower worry scores than Group A, with a mean difference of –0.13 (*P*=.90). Group C also had nonsignificantly lower worry scores than Group A (mean difference –0.30; *P*=.77) and nonsignificantly higher scores than Group B (mean difference –0.17, *P*=.87). After participating in the SIMBIE process and adjusting for confounding factors, all 3 groups had negative trends in DSSQ-worry, though no significant differences were detected.

Group B had nonsignificantly lower worry scores than Group A (mean difference 0.69; *P*=.45). Similarly, Group C had nonsignificantly lower worry scores than Group A (mean difference 0.97; *P*=.30) and nonsignificantly higher scores than Group B (mean difference 0.28; *P*=.77). See Figure 4, Table S3 in Multimedia Appendix 7, Table S4 in Multimedia Appendix 8, and Figure S1 in Multimedia Appendix 9.

Measuring Burnout: Comparative Outcomes by Group

Our analysis of the CBI scores revealed discrepancies in results and interpretations between the ITT and PP analyses. In the ITT analysis comparing burnout outcomes between the pre-intervention assessment (phase 1) and the final assessment (phase 3), Group B had significantly lower burnout scores than Group A (mean difference –1.86, 95% CI 0.39 to 3.34; *P*=.01). Similarly, Group B had significantly lower burnout scores than Group C, with a mean difference of 1.59 (95% CI 0.11 to 3.06; *P*=.04). No statistically significant differences were observed between Group C and Group A, with a mean difference of –0.28 (95% CI –1.20 to 1.75; *P*=.07). See Figure 5, Table S3 in Multimedia Appendix 7, Table S4 in Multimedia Appendix 8, and Figure S2 in Multimedia Appendix 10.

In the PP analysis comparing burnout outcomes between the pre-intervention assessment (phase 1) and the final assessment (phase 3), Group B again had significantly lower burnout scores than Group A, with a mean difference of –2.02 (*P*=.02). However, the mean difference between Group B and Group C was not significant (mean difference 1.6; *P*=.07). Similarly, no statistically significant differences were observed between Group C and Group A, with a mean difference of –0.42 (*P*=.61). See Table S3 in Multimedia Appendix 7, Table S4 in Multimedia Appendix 8, and Figure S2 in Multimedia Appendix 10.

Effect Sizes for Burnout Change Across the Multimodal Interventions

The ER-VIPE computer-based intervention (Group B) at 8 weeks demonstrated the largest reduction, with a small-to-moderate effect size (*d* =–0.31, 95% CI –0.78 to 0.15). Similarly, the combined medical movie and MOOC intervention (Groups B and C, pre-SIMBIE) at 2 weeks yielded a small-to-moderate effect (*d*=–0.30, 95% CI –0.63 to 0.03). In contrast, the computer-based SIMBIE with co-debriefing intervention (Group B) at 4 weeks showed a slight increase in burnout, with a small effect size (*d*=0.09, 95% CI –0.50 to 0.67). The ER-VIPE VR-based intervention (Group C) at 8 weeks was associated with an increase in burnout, with a moderate-to-large effect size (*d*=0.45, 95% CI –0.25 to 1.15). Notably, the VR-based SIMBIE with co-debriefing (Group C) at 4 weeks resulted in a substantial increase in burnout, demonstrating a large effect size (*d*=0.83, 95% CI 0.22 to 1.44), as shown in Table 2.

Table 2. Effect sizes for changes in burnout across multimodal interventions.

Group(s)	Intervention				Phase comparison	Duration (weeks)	Effect size, Cohen *d* (95% CI)[a]
	Medical movie + MOOCs[b]	Computer-based SIMBIE[c]	VR[d]-based SIMBIE	Co-debriefing			
B[e]	Yes	Yes	No	Yes	1[f] vs 3[g]	8	–0.31 (–0.75 to 0.15)
B, C[h]	Yes	No	No	No	1 vs 2[i]	2	–0.30 (–0.63 to 0.03)
A[j]	No	Yes	No	No	2 vs 3	6	–0.19 (–0.75 to 0.36)
B	No	Yes	No	Yes	2 vs 3	6	0.09 (–0.50 to 0.67)
C	Yes	No	Yes	Yes	1 vs 3	8	0.45 (–0.25 to 1.15)
C	No	No	Yes	Yes	2 vs 3	6	0.83 (0.22 to 1.14)

[a]Negative values indicate reductions in burnout: positive values indicate increases in burnout.

[b]MOOCs: massive open online courses.

[c]SIMBIE: simulation-based interprofessional education.

[d]VR: virtual reality.

[e]Group B received the movie + MOOCs, 3D computer-based SIMBIE, and co-debriefing.

[f]Phase 1: baseline; before movie + MOOCs.

[g]Phase 3: 8-week follow-up from baseline.

[h]Group C received the movie + MOOCs, VR-based SIMBIE, and co-debriefing.

[i]Phase 2: before SIMBIE; 2-week follow-up.

[j]Group A (control) received only 3D computer-based SIMBIE without debriefing.

Discussion

ER-VIPE: An Innovative Approach to Reducing Stress and Burnout

This study evaluated the effectiveness and quantified the effect sizes of multimodal educational strategies—medical movies, MOOCs, and computer- or VR-based SIMBIE with co-debriefing (collectively termed ER-VIPE)—for reducing burnout among future health care professionals. The ER-VIPE computer-based intervention (Group B) demonstrated the most notable reduction in burnout, with a small-to-moderate effect size (d=–0.31), followed closely by the combined medical movie and MOOC intervention after 2 weeks (d=–0.30).

In contrast, the computer-based SIMBIE with co-debriefing intervention (Group B) was associated with a minimal increase in burnout, reflected by a small effect size (d=0.09). The ER-VIPE VR-based intervention (Group C) showed a moderate-to-large increase in burnout (d=0.45), while the VR-based SIMBIE after 4 weeks resulted in the largest increase (d=0.83).

These findings suggest that the ER-VIPE computer-based multimodal approach, particularly when combined with co-debriefing, is more effective at mitigating burnout than the VR-based ER-VIPE intervention or single-component SIMBIE interventions. Additionally, medical movies and MOOCs alone contributed to a modest reduction in burnout after 2 weeks.

Discussion: On the Meaningfulness of Effect Sizes in Burnout Prevention

The ER-VIPE computer-based intervention (Group B) demonstrated a small-to-moderate effect on burnout reduction, with an SMD of 0.31 (95% CI –0.15 to 0.78). Although the CI includes 0, the upper bound suggests a potentially meaningful impact, warranting further investigation in larger samples.

The ER-VIPE VR-based intervention (Group C) demonstrated a small-to-moderate effect for increasing burnout, with an SMD of 0.45 (95% CI –0.25 to 1.15). Although the CI includes 0, the upper bound suggests a potentially meaningful impact, warranting further investigation in larger samples.

Group B (ER-VIPE computer-based) demonstrated significantly lower burnout scores than Group A (computer-based SIMBIE without co-debriefing), with a mean difference of –1.86 (95% CI 0.39 to 3.34; P=.01). Although the beta coefficient (β=1.8, 95% CI 0.39 to 3.34) indicates a statistically significant effect, these findings should be interpreted with caution. Sole reliance on P values can be misleading, as statistical significance does not necessarily imply clinical or practical relevance. To address this, we calculated effect sizes (Cohen d) to better understand the magnitude of the observed effects. The ER-VIPE computer-based intervention yielded a small-to-medium effect size (d=–0.31), supporting its potential educational and clinical value.

From a practical standpoint, even small to modest effect sizes may have meaningful implications, especially in the context of early burnout prevention. The CBI (maximum 30 points), which was used in this study, is a culturally validated and widely adopted tool for assessing prolonged physical and psychological exhaustion. Previous studies have linked CBI scores to future risks such as absenteeism, sleep disturbances, increased use of painkillers, and intention to leave the profession [322]. In our study, a maximum reduction of approximately 3.34 points across 6 items (an average change of 0.56 per item on a 5-point Likert scale for 6 items) may reflect a meaningful shift in participants' experiences—for example, from reporting they "always" feel overwhelmed to "seldom" feeling that they "can't take it anymore." Such changes, particularly in at-risk populations, could represent significant psychological relief.

Nonetheless, these findings should be interpreted cautiously. Self-reported burnout scores may be influenced by short-term emotional states or response-shift bias. Although the observed trend in burnout reduction is promising, especially for the ER-VIPE computer-based group, we consider the results preliminary and recommend further exploration through longitudinal research and real-world implementation studies.

Effectiveness of Preparatory Tools and Instructional Design Considerations

Medical movies and MOOCs were used as preparatory tools prior to SIMBIE participation. Although these online modalities demonstrated some positive effects, their impact was variable and appeared to depend on factors such as learner readiness, the presence of an instructor [332], and the incorporation of structured guidance to direct learner attention toward key instructional scenes [333]. Consistent with our findings, the integration of cinemeducation and simulation has been demonstrated to be both feasible and effective, producing synergistic and convergent benefits from the perspectives of preclinical medical students. This combined approach also helps address some limitations of simulation alone in replicating complex professional scenarios, as supported by survey responses [334]. These findings underscore the critical role of intentional instructional design for optimizing the effectiveness of online educational interventions. Among all the interventions examined, the ER-VIPE computer-based model produced the most pronounced reduction in stress and burnout. This outcome may be attributed to its congruence with evidence-based learning principles; the integration of thoughtful SIMBIE design elements; and the use of accessible, user-friendly technology.

Applying Experiential, Flipped, and SIT Frameworks in Learning Design

The learning design in this study was grounded in 3 complementary educational frameworks: Kolb's experiential learning cycle, the flipped classroom model, and SIT. According to [335], learning is most effective when it progresses through 4 stages: concrete experience, reflective observation, abstract conceptualization, and active experimentation. To support this cycle, MOOCs were used to deliver theoretical foundations, while medical movies promoted critical thinking and contextual understanding by translating abstract concepts into realistic scenarios. Mayer's cognitive theory of multimedia learning suggests that such video-based materials enhance knowledge retention by presenting information in a more concrete and engaging format [336]. Furthermore, analyzing film content through the lens of learned theories supports both cognitive and

emotional development [337], while audiovisual elements foster realism and a more immersive learning experience [338-340].

Learners initially engaged in a SIMBIE session to establish a baseline experience, followed by co-debriefing guided by trained facilitators. This reflective process emphasized TeamSTEPPS concepts and aligned with Kolb's stages of reflective observation and abstract conceptualization. Learners then applied newly acquired insights in a subsequent SIMBIE session, fulfilling the active experimentation phase.

To enhance preparedness, a flipped classroom approach was used. Presession exposure to medical movies and MOOCs helped build interprofessional knowledge and promoted positive attitudes toward IPE, TeamSTEPPS, and stress coping strategies [307]. This model improved learner engagement and emotional investment while maximizing the effectiveness of in-session SIMBIE activities [308]. Importantly, integrating stress management into real-world clinical education has been recognized as essential to professional education [309].

SIT further supported the design by providing a structured approach to building stress resilience. SIT involves 3 phases: conceptualization (understanding stress and personal reactions) via cinemeducation and MOOCs, skill acquisition (developing coping strategies such as communication) via SIMBIE, and skills consolidation reinforced through co-debriefing and application (practicing these skills in simulated or realistic scenarios as second round). This approach enabled learners to build psychological readiness for high-stress clinical environments. Similarly, Liaw et al [160] demonstrated that computer-based virtual SIMBIE could positively influence stress responses, measured via blood pressure and heart rate, and enhance team rescue performance, showing no significant difference compared with physical simulations. These findings were particularly valuable during the COVID-19 pandemic, as desktop VR offered a safe and effective alternative. Building on this, our study contributes new evidence that desktop-based SIMBIE within the ER-VIPE framework not only supports immediate stress management but also leads to sustained reductions in burnout observed at the 8-week follow-up.

In contrast, an RCT by Blanchard et al [268] found that a tutorial module on stress and stress management, followed by repeated non-IPE VR simulations under moderate to high stress conditions, was a feasible instructional approach. Participants in the intervention group reported lower perceived stress; reduced electrodermal activity, a physiological marker of stress measured through changes in the electrical conductivity of sweat on the hands or feet; and greater perceived competence after completing the test module compared with the control group. The training also appeared to facilitate desensitization to stress in future simulated scenarios. The differing outcomes between our study and the RCT by Blanchard et al [268] may be attributed to key methodological and contextual differences. Although the study by Blanchard et al used a controlled design with repeated VR exposure under moderate stress, induced by ecologically salient auditory stimuli, our quasi-experimental study featured more complex IPE scenarios involving a greater number of multiprofessional participants and team-based stress dynamics. These high-stakes, emotionally charged simulations may have exceeded the optimal arousal level described by the Yerkes-Dodson law [244], potentially leading to heightened stress.

Interestingly, a multicenter prospective randomized trial involving EM residents examined the effects of brief mental skills training delivered 1 month prior to simulation. The study reported no significant differences in subjective or objective stress responses, measured using heart rate variability and the STAI, during a non-IPE, manikin-based resuscitation simulation. This lack of measurable impact may be attributed to the extended gap between the conceptual (didactic) phase and the skill acquisition (simulation) phase, potentially hindering effective learning transfer. Moreover, the high-stress experiences of real-life clinical pressure may have reduced the simulation's ability to elicit authentic stress responses. Notably, the study did not describe the debriefing process (consolidation phase) and did not include a second simulation for deliberate practice (application phase), which may have further limited the effectiveness of the SIT framework.

SIMBIE Design Elements Supporting Safe, Realistic, and Collaborative Learning

The SIMBIE platform in this study was intentionally designed to replicate realistic clinical scenarios involving diverse health care students, with a focus on psychological safety, structured learning, and interprofessional collaboration. The learning sequence began with a prebriefing to outline objectives, facilitate ice-breaking activities, foster familiarity among participants, and establish a safe learning climate. A unique HP bar feature was incorporated to provide peer support during gameplay, and the session concluded with structured debriefing led by trained facilitators using a no-blame, psychologically safe approach—all conducted within a clearly defined time frame.

These design features align with evidence emphasizing that high-quality simulation-based education should include structured scenario progression, adaptability to learner actions, and the identification of critical performance points. Time-conscious design and high-fidelity environments further enhance learner engagement and realism. Equally important is the role of facilitators, who not only guide learning but also ensure that cultural diversity, psychological safety, and shared understanding of team roles are respected. Their guidance reinforces learning outcomes, encourages reflection, and supports the development of interprofessional competencies [341,342].

Findings from this study align with those of previous literature suggesting that interprofessional simulation-based approaches, when combined with skilled debriefing, enhance active engagement, self-efficacy, realistic role enactment, and collaborative team-based learning [340]. These experiences help students build essential interprofessional skills prior to clinical practice [343], gain insight into other professional roles [344,345], and foster deeper participation, particularly when stress is acknowledged and validated by peers or facilitators [346].

Enhancing Accessibility and Reducing Stress Through User-Friendly Technology

The use of a computer-based platform in SIMBIE significantly enhanced accessibility and ease of use compared with VR headsets, which often require more complex operation. Consistent with previous studies, computer-based simulations have been shown to reduce negative emotional responses during learning [124,347]. Moreover, cine-VR training—delivered through head-mounted displays or 360-degree video—has been shown to enhance empathy among health care professional students, with no reported technological issues nor adverse effects [348]. In contrast, VR-based simulations have been associated with higher levels of distress due to technostress (eg, ergonomics, cybersickness, visual fatigue), or technological barriers, including user unfamiliarity, discomfort, and reluctance to adopt new tools [349-351]. Poorly designed VR experiences may further limit accessibility and user comfort [352,353]. In light of these challenges, computer-based simulation emerges as a more practical, scalable, and cost-effective educational approach [334], particularly in contexts aiming to reduce stress and promote learner engagement.

Limitations

This study has several limitations. Conducted in a single university-based setting, the findings may have limited generalizability to other settings that differ in context and available facilities. This study was conducted during the middle of the COVID-19 pandemic, limiting its comparability to conventional clinical teaching, which is primarily conducted in clinical settings. The exclusion of participants with pre-existing mental health conditions may limit the generalizability of findings to broader populations. Although anxiety traits were controlled as a confounding factor, other potential influences on stress and burnout, such as individual stressors, baseline coping mechanisms, and levels of social support, were not assessed in this study and may have influenced participants' responses. As a result, the findings should be interpreted with caution, as unmeasured psychosocial factors may have moderated participants' responses to the simulation-based intervention. Although the DSSQ specifically measures stress during assigned tasks and the CBI captures broader aspects of exhaustion, these tools may not fully reflect the complexity of stress experiences in all contexts.

Additionally, dropout rates of 24%, 44%, and 14% in Groups A, B, and C, respectively, during the transition from phase 2 to phase 3 were addressed. We did not know the exact reasons for participant dropout. However, potential contributing factors may include exam schedules, personal or academic stress, mental health concerns, and minor technical issues related to the online survey platform sent via email. Additionally, the delayed delivery of monetary incentives—provided only after the second simulation, several weeks before the final assessment—may have reduced participants' motivation to complete the study. We used GEEs to minimize sensitivity to missing data. An ITT analysis with imputed data was also performed to validate the PP findings. This indicates that, even though the dropout rate was low, the results were likely not significantly different from the original findings.

Future Study

Future research should investigate the effectiveness of movies, MOOCs and virtual SIMBIE for reducing stress and burnout among diverse groups, such as postgraduate professionals and those in intensive care or prehospital settings. Future studies should consider including participants with mild or well-managed mental health comorbidities to enhance the generalizability and applicability of the intervention to more diverse, real-world clinical settings. We also recommend conducting an RCT comparing the intervention with traditional educational approaches in a nonpandemic context, such as in-person clinical teaching. To strengthen the rigor of future research, objective measures of stress, such as heart rate variability, electrodermal activity, or electroencephalography, should be incorporated. Additionally, potential confounding factors, including individual stressors, baseline coping mechanisms, and levels of social support, should be carefully assessed and controlled. A mixed methods approach is suggested to explore the mechanisms of impact and identify areas for improvement. Furthermore, longitudinal studies using multiple stress and burnout assessment methods are necessary to comprehensively evaluate long-term outcomes.

Conclusion

This study highlights the effectiveness of a novel multimodal learning approach that integrates movie-based education, MOOCs, and a virtual 3D computer-based SIMBIE with co-debriefing for reducing burnout and improving self-reported stress levels by enhancing engagement and reducing worry and distress among undergraduate clinical students. These innovative IPE strategies are designed to help multiprofessional students manage stress, reduce burnout, and develop collaborative problem-solving skills within authentic simulation environments. By alleviating the pressures and risks typically associated with clinical practice, the interactive and scalable 3D computer-based ER-VIPE platform supports 21st-century health care learners, where patient safety is paramount. Integrating these tools and strategies into IPE programs offers significant potential to enhance well-being and resilience while preparing health care students and early-career professionals for a smooth transition into clinical practice.

Acknowledgments

This research was supported by the Second Century Fund, Chulalongkorn University. The authors thank the Chulalongkorn Healthcare Advanced Multi-Profession Simulation Center (CHAMPS) for their invaluable assistance. The authors are also grateful to Surachai Pianpetchlert, Thepwinphan Theppitak, and the research assistants—Kitnipat Boonydhammakul, Sutasinee Chaidej,

Chayanit Trakulpipat, Sirisopha Suwanchinda, Thanyared Sangsawad, Chaiwat Takkanat, Thanes Yunirundorn, and Nuttarin Panswad—for their contributions to data collection, graphic design, and IT support.

We gratefully acknowledge the *Emergency Room Virtual Simulation Interprofessional Education (ER-VIPE)* study group for their collaboration in developing the educational movies, massive open online courses (MOOCs), and the simulation-based interprofessional education (SIMBIE) platform. Abstract

Background: Team performance is crucial in crisis situations. Although the Thai version of Team Strategies and Tools to Enhance Performance and Patient Safety (TeamSTEPPS) has been validated, challenges remain due to its subjective evaluation. To date, no studies have examined the relationship between electroencephalogram (EEG) activity and team performance, as assessed by TeamSTEPPS, during virtual simulation-based interprofessional education (SIMBIE), where face-to-face communication is absent.

Objective: This study aims to investigate the correlation between EEG-based brain-to-brain synchronization and TeamSTEPPS scores in multiprofessional teams participating in virtual SIMBIE sessions.

Methods: This single-center study involved 90 participants (15 groups of 6 simulated professionals: 1 medical doctor, 2 nurses, 1 pharmacist, 1 medical technologist, and 1 radiological technologist). Each group completed two 30-minute virtual SIMBIE sessions focusing on team training in a crisis situation involving COVID-19 pneumonia with a difficult airway, resulting in 30 sessions in total. The TeamSTEPPS scores of each participant across 5 domains were independently assessed by 2 trained raters based on screen recording, and their average values were used. The scores of participants in the same session were aggregated to generate a group TeamSTEPPS score, representing group-level performance. EEG data were recorded using wireless EEG acquisition devices and computed for total interdependence (TI), which represents brain-to-brain synchronization. The TI values of participants in the same session were aggregated to produce a group TI, representing group-level brain-to-brain synchronization. We investigated the Pearson correlations between the TI and the scores at both the group and individual levels.

Results: Interrater reliability for the TeamSTEPPS scores among 12 raters indicated good agreement on average (mean 0.73, SD 0.18; range 0.32-0.999). At the individual level, the Pearson correlations between the TI and the scores were weak and not statistically significant across all TeamSTEPPS domains (all adjusted $P \geq .05$). However, strongly negative, statistically significant correlations between the group TI and the group TeamSTEPPS scores in the alpha frequency band (8-12 Hz) of the anterior brain area were found across all TeamSTEPPS domains after correcting for multiple comparisons (mean −0.87, SD 0.06; range −0.93 to −0.8).

Conclusions: Strong negative correlations between the group TI and the group TeamSTEPPS scores were observed in the anterior alpha activity during online hexad virtual SIMBIE. These findings suggest that anterior alpha TI may serve as an objective metric for assessing TeamSTEPPS-based team performance.

Introduction

The COVID-19 pandemic has highlighted the crucial importance of effective interprofessional collaboration in health care, especially in high-pressure environments such as emergency and critical care settings. Beyond individual cognitive abilities, medical professionals in these settings must work as a team, requiring shared goals, clear role understanding, and continuous communication [1]. Team Strategies and Tools to Enhance Performance and Patient Safety (TeamSTEPPS) has become a widely recognized framework for improving teamwork, communication, and overall clinical performance in such contexts. Supported by a robust body of evidence, TeamSTEPPS has been integrated into various simulation-based training programs, including online virtual simulations, which have become prominent during and after COVID-19 [2]. Although TeamSTEPPS includes 5 specific domains with validated psychometric evidence, the assessment process remains complex. Challenges include rater training, interrater reliability, and the subjective nature of evaluations. Additionally, the time and cost required for training raters add further complications [3]. Despite the availability of validated tools to measure teamwork (eg, a one-shot public goods game [4]), there are few objective measures—such as total interdependence (TI) (Multimedia Appendix 1) [5], debiased weighted phase lag index [6], and intersite phase clustering [7]—that directly link team dynamics with real-time electroencephalogram (EEG) neurological responses during collaborative tasks. An advantage of these objective measures is that they tend to predict team performance better than validated tools that are inherently subjective [8].

Hyperscanning—a method of simultaneously measuring brain activity in 2 or more individuals—has been used to explore the neural basis of social dynamics [9,10] using various neuroimaging techniques, including functional magnetic resonance imaging [11,12], functional near-infrared spectroscopy [13], EEG [14-17]. Different experimental paradigms have been used to investigate social dynamics, including movement synchronization [18], social decision-making [19], joint attention [20], team problem solving [8], team coordination [21], team communication [17], and classroom engagement [14]. Recent advancements in affordable wireless EEG technologies make EEG well suited for studying brain-to-brain synchronization, which refers to the coordinated brain activity between 2 or more individuals [22], during collaborative tasks in less controlled environments.

Reinero et al [8] demonstrated that brain-to-brain synchronization, measured by TI, predicts team performance on problem-solving tasks better than traditional self-report measures with real-time brain activity monitored using affordable wireless EEG devices. Dikker et al [14] further identified that TI-based brain-to-brain synchronization predicts class engagement and social dynamics, while Bevilacqua et al [23] extended Dikker's findings to show that social factors, such as perceived closeness, can predict cognitive outcomes, including academic performance. These studies highlight that EEG-based brain-to-brain synchronization reflects neural alignment and provides insights into the cognitive and emotional processes underlying teamwork. However, to our knowledge, previous studies focused on face-to-face interactions, and no study has explored the correlation between EEG-based brain-to-brain synchronization and TeamSTEPPS performance in virtual simulation–based interprofessional education (SIMBIE), where face-to-face communication is absent. In additional, Guttmann et al [24] introduced stricter sample size methodologies for EEG studies, whereas Asaad and Sheth [25] emphasized the need to balance rigor and practicality, ensuring ethical and scientific standards with meaningful interpretations using efficient sample sizes. We incorporated these considerations into this study's sample size justification to enhance research quality.

This study aims to address this gap by investigating the correlations between TI-based EEG brain-to-brain synchronization and TeamSTEPPS scores, from both individual and team perspectives, in 6 multiprofessional student groups during online virtual SIMBIE sessions. On the basis of previous studies, we hypothesized that these correlations would likely not be strongly positive owing to the absence of face-to-face communication in online virtual SIMBIE sessions. The findings may support the development of an objective, evidence-based approach to assessing team dynamics in the absence of face-to-face communication. This approach has the potential to enhance the validity and reliability of TeamSTEPPS evaluations and to facilitate automatic, real-time feedback.

Methods

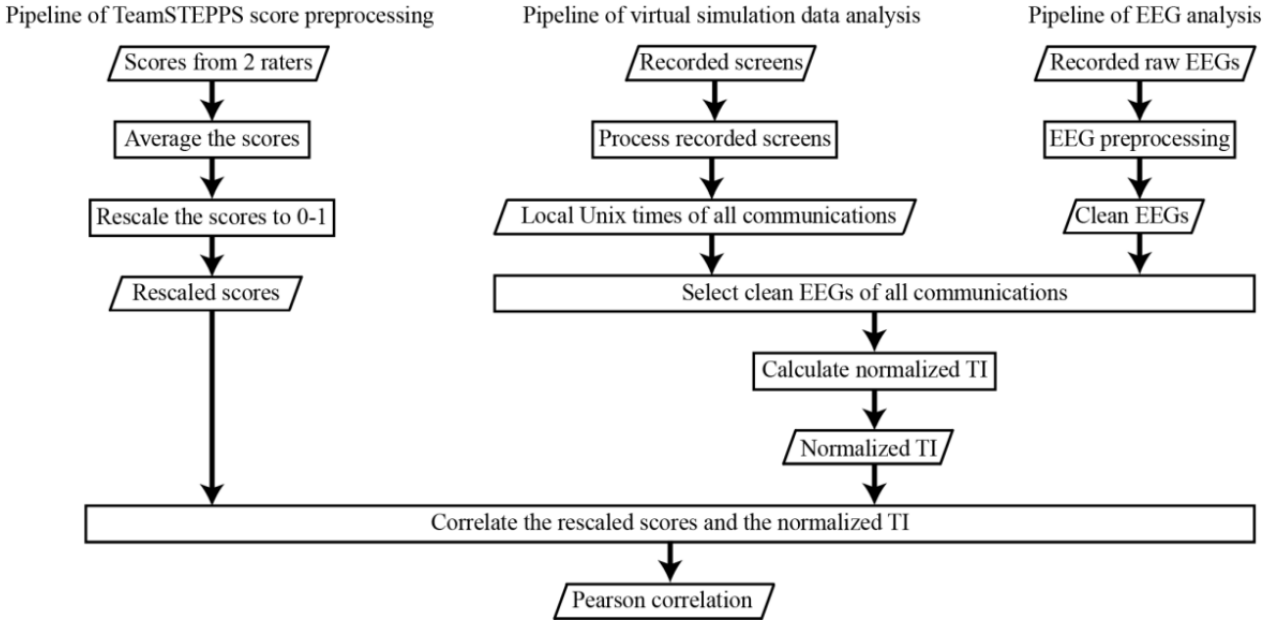
Study Design and Setting

This study was part of a larger study [26,27] conducted at the Chulalongkorn Healthcare Advanced Multi-Profession Simulation Center in a single university hospital from August 2022 to September 2023. It was designed as a cross-sectional correlational study using quantitative approaches. The variables of interest were TeamSTEPPS scores, which measure participants' teamwork and communication constructs of participants, and EEG features of brain activity capturing brain-to-brain synchronization; further details on TeamSTEPPS scoring are available elsewhere [28]. Although the scores and EEGs are applicable in free environments, we conducted the study during the typical hours of 6 PM to 9 PM in a controlled laboratory environment within the simulation center, where we controlled potential confounding variables (eg, temperature, visual and auditory noise, arousal confounds, motor confounds, and gameplay fluidity) [29].

This study included 30 sessions of gameplay in a virtual simulation, in which 6 participants each assumed one of 6 unique professions: (1) radiological technologist, (2) medical technologist, (3) medical doctor, (4) pharmacist, (5) circulation nurse, and (6) airway nurse. In the Emergency Room–Virtual Interprofessional Education platform—Thailand's pioneering virtual reality (VR) system for medical interprofessional training designed and developed by Dhanakoses et al [30]—participants were represented as avatars and interacted using microphones and speakers. Multimedia Appendix 2 provides detailed descriptions of the virtually simulated scenario. Each participant attended 2 sessions; the study thus required 90 participants to complete 30 gameplay sessions. Of the 30 sessions, 10 were conducted with participants wearing VR headsets (HTC VIVE Cosmos [31]; Figure S1D in Multimedia Appendix 3), and 20 without. Participants performed cooperative tasks on their personal computers (PCs) in the laboratory. In this scenario, a male patient (aged 70 years) with chronic obstructive pulmonary disease, a history of hypertension, diabetes mellitus, and ceftriaxone allergy arrived at an emergency department with his wife. Recently discharged from an intensive care unit, his vital parameters and laboratory tests suggested hyperkalemia and COVID-19 pneumonia with acute respiratory failure. Each of the 6 participants assumed a distinct role corresponding to a fully qualified, licensed profession within the simulation scenario. The 6 simulated professions were required to collaborate to diagnose the patient and implement a treatment plan. The virtually simulated scenario emphasized the development of interprofessional communication and clinical reasoning skills and provided an ideal controlled environment to study correlations between brain-to-brain synchronization within a team and TeamSTEPPS scores.

During the sessions, we recorded each participant's EEG signal and gameplay, while the corresponding TeamSTEPPS scores were obtained from the larger study [26]. Figure 1 provides an overview of the analysis pipelines for the 3 types of data. The EEG signal was preprocessed to mitigate artifacts, resulting in a clean EEG signal [32], while video recording of gameplay were preprocessed to extract Unix times [33] of verbal communications. The Unix times were used to segment the clean EEG signals corresponding to the communications. The segmented EEG signals were then used to compute normalized values of TI, an EEG feature measuring brain-to-brain synchronization [34]. The normalized TIs were correlated with the scaled TeamSTEPPS scores obtained by scaling the TeamSTEPPS scores to values between 0 and 1.

Figure 1. Flowchart of data analysis pipelines showing the Team Strategies and Tools to Enhance Performance and Patient Safety (TeamSTEPPS) score (left), virtual simulation data (middle), and electroencephalogram (EEG) data (right). Clean EEGs were partitioned by local Unix times of all communications, then used to calculate normalized total interdependence (TI), which was correlated with the rescaled scores.



Study Population

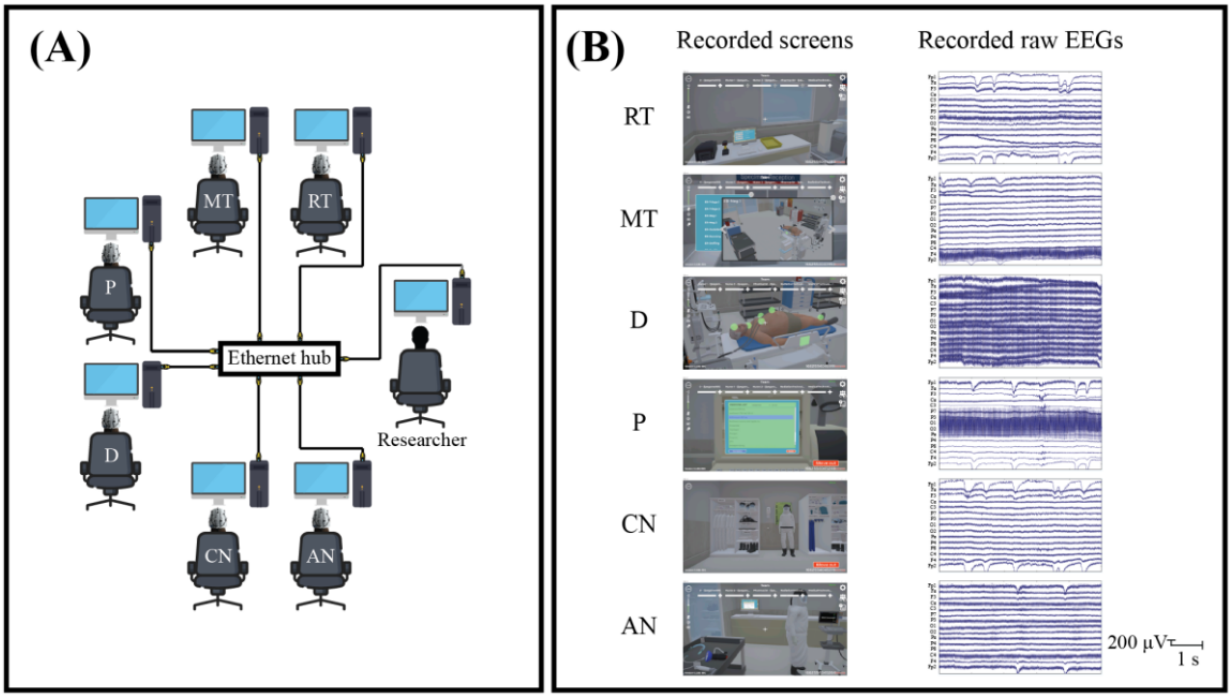
The target population comprised healthy adults aged 18-25 years who did not meet any of the following exclusion criteria: (1) predisposition to major depression, defined as a score ≥9 on the 9-item self-reported Patient Health Questionnaire-9 (PHQ-9) [35]; (2) history of substance use disorder, including cigarette smoking and alcohol addiction; (3) history of neurological or psychiatric disorders, including epilepsy; and (4) periodic use of antidepressants during the 2 weeks before the experiment. The study population, drawn from this target population, consisted of students in radiological technology, medical technology, medicine, pharmacy, and nursing from a university-affiliated hospital. We used convenience sampling by advertising the study through posters and social media on campuses, targeting 5th- or 6th-year medical students and pharmacy students, 4th-year medical technology students, as well as 3rd- or 4th-year radiological technology and nursing students. Students registered for the study through online forms without knowledge of the inclusion or exclusion criteria. Participants who were eligible and completed the experiment received monetary compensation, as indicated in the advertisement. Of 147 potential participants, 85 were eligible for the study, and 5 met the exclusion criteria but joined for practical reasons; we excluded these 5 participants from our

analysis. Note that they joined the sessions without knowing that their EEG activity would be excluded from analysis. Because virtual simulators can induce simulator sickness [36], participants experiencing symptoms were administered a 10 mg oral dose of dimenhydrinate.

Laboratory Setting

The experiments were conducted in a controlled 7×7 m room with 6 participants and a researcher, each using high-performance PCs connected through a low-latency network (Figure 2A). Non-VR sessions used monitors and audio equipment for communication, while VR sessions involved VR headsets and EEG caps, which were set up by research assistants to enhance immersion and reduce simulator sickness. The researcher's PC managed the simulation and EEG data to ensure smooth operation (Figure 2A). Multimedia Appendix 4 provides additional details.

Figure 2. Experiment setup and recorded data. (A) 6 participants' and the researcher's personal computers connected in a star network topology with the ethernet hub as the center node. Collected data include participants' video screens (B, left) and electroencephalogram (EEG) brain activity (B, right). AN: airway nurse; CN: circulation nurse; D: medical doctor; MT: medical technologist; P: pharmacist; RT: radiological technologist.



Data Sources

TeamSTEPPS Scores

The TeamSTEPPS framework was used to assess teamwork and communication skills on a 5-point Likert scale across five topics: (1) team structure, (2) communication, (3) leadership, (4) situation monitoring, and (5) mutual support (as verified and validated in a pervious study [28]). A participant's performance in each topic was quantitatively measured by a total score, calculated as the sum of scores ranging from 1 (worst) to 5 (best) across different aspects representing that topic. Each participant's TeamSTEPPS scores was determined by the 5 scores from the 5 topics. The TeamSTEPPS scores for this study were obtained from the larger study [26].

EEG Signals

EEG signals were recorded simultaneously from 6 participants during the virtual simulation using mobile EEG devices (OpenBCI; Figure S1A in Multimedia Appendix 3) with sintered-electrode caps (Figure S1 in Multimedia Appendix 4). We used 15 passive, gel-based electrodes placed according to the international 10-20 system [37] at the following locations: Fp1, Fp2, F3, Fz, F4, C3, Cz, C4, P7, P3, Pz, P4, P8, O1, and O2 (Figure S1B in Multimedia Appendix 3). The EEG signals were initially referenced to CPz and later rereferenced to an average reference [38] during offline analysis, effectively yielding a net zero potential across the scalp for components derived from independent component analysis, thereby facilitating manual inspection. To ensure signal quality, electrode impedances were maintained below 50 kΩ on average (mean 45.59, SD 116.41 kΩ) [39], validated using OpenBCI software (version 5.1.0) [40]. EEG data was digitized at 125 Hz with high precision, and participants adjusted the sound from the virtual simulation using in-ear speakers to a comfortable level.

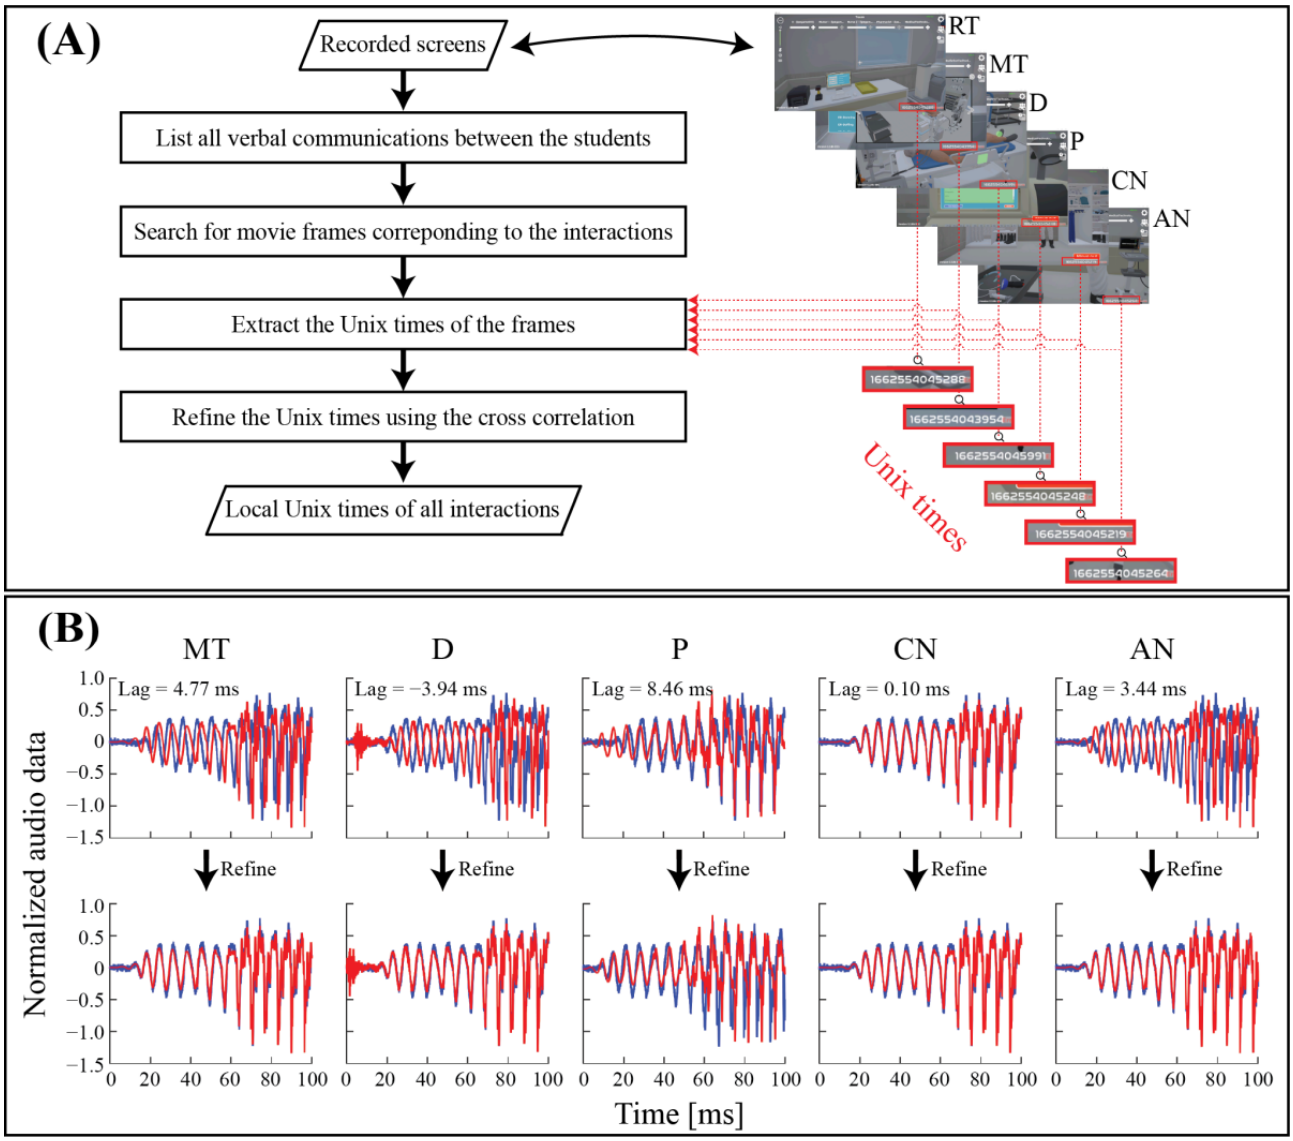
To monitor EEG signals in real time, we developed custom C# software that transmitted data from the participants' PCs to the researcher's PC (Figure S1 in Multimedia Appendix 4 provides a schematic). The process was as follows: first, EEG signals were transferred from the biosensing board of the mobile EEG device to the participant's PC using BrainFlow software (version 4.9.0 [41]). Next, every second (125 samples), a local Unix timestamp [33] was assigned to each sample on the participant's PC. The software then transmitted these 125-sample chunks through Ethernet using Lab Streaming Layer software (version 1.15.2 [42]) to the researcher's PC. EEG data from all 6 participants were received and stored in a proprietary file format for offline analysis (Figure 2B, right column, shows examples

of recorded EEG signals). Additionally, we performed multiple sanity checks to ensure that the data received by the researcher met strict quality standards (Multimedia Appendix 5).

Video Recordings of Virtually Simulated Scenarios

Participants' PC screens during the virtually simulated scenario were recorded at 60 frames per second with a resolution of 2560×1440 pixels, and audio was captured at 48,000 Hz using NVIDIA ShadowPlay software (version 3.25.1.27 [43]; Figure 2B, left column, shows examples of the 6 PC screens). In addition to capturing participants' actions, the screen recordings displayed local Unix timestamps [33], which were obtained using the DateTime function of C# to precisely time each action (Figure 3A, red boxes, shows examples). These video and audio recordings were saved locally on each participant's PC in MP4 format. The recorded screen footage was later used for offline synchronization between the simulated scenario actions and corresponding EEG signals.

Figure 3. Temporal alignment of verbal social interactions. (A) Extraction of temporal information from recorded screens, indicated by Unix times in red boxes. (B) Adjustment of time lags between participants' audio using cross-correlation, with RT as reference (blue) and other participants (red) before (top) and after (bottom) compensation. AN: airway nurse; CN: circulation nurse; D: medical doctor; MT: medical technologist; P: pharmacist; RT: radiological technologist.



Data Preparation

Preprocessing of the TeamSTEPPS Scores

Two trained raters independently rated the TeamSTEPPS scores for each profession (Table 1, "Rater 1" and "Rater 2" rows [26]). We averaged the scores from the 2 raters and scaled them using the minimum and maximum values (Table 1, "Range" rows), resulting in scaled TeamSTEPPS scores with values between 0 and 1 (Table 1, "Scaled AVG" rows). Additionally, we created an overall TeamSTEPPS score by summing all 5 topic scores to summarize each participant's teamwork and communication skills (Table 1, "Overall" column). Analogously, we defined a scaled overall TeamSTEPPS score (Table 1, "Scaled AVG" rows intersecting the "Overall" column). We evaluated the performance of a team using a group TeamSTEPPS score, calculated by averaging the scaled overall TeamSTEPPS scores of all 6 professions in the team.

Table 1. Descriptive statistics of the Team Strategies and Tools to Enhance Performance and Patient Safety (TeamSTEPPS) scores (N=30).

Professions	TeamSTEPPS scores					
	Team structure	Communication	Leadership	Situation monitoring	Mutual support	Overall
Radiological technologist (n=22)						
Range	2-10	4-20	5-25	5-25	4-20	20-100
Rater 1, mean (SD)	5.86 (2.88)	8.45 (2.65)	10.73 (2.35)	12.5 (2.52)	6.27 (1.55)	43.82 (9.73)
Rater 2, mean (SD)	5.64 (3.03)	9.27 (2.45)	10.95 (3.43)	12.59 (2.36)	5.77 (1.15)	44.23 (10.44)
ICC[a]	0.94	0.74	0.73	0.63	0.35	0.89

EEG Preprocessing

Overall, EEG preprocessing removed noise, corrected artifacts, rereferenced signals, and reduced dimensionality. Cleaned EEG data were filtered (1-40 Hz), grouped into 3 brain regions, and prepared for independent component analysis and TI analysis to ensure high-quality results (details provided in Multimedia Appendix 6).

Preprocessing of the Video Recordings: Aligning EEG Signals With the Recordings

To conduct our hyperscanning study in the virtual simulation, we focused on synchronizing verbal social interactions recorded from participants' screens. Figure 3A (left side) illustrates the flowchart for processing these recordings to obtain Unix times corresponding to the interactions. First, we imported the recordings of 6 participants from the same session into Adobe Premiere Pro (version 22.2.0) and marked the start and end frames of each verbal interaction by visually matching the auditory stimuli of both the sender and receiver (Figure 3B, top row). After identifying these frames, we extracted the corresponding Unix timestamps (Figure 3A, red boxes). To enhance the accuracy of the timestamps, we adjusted for any lag using cross-correlation analysis of the average auditory stimuli from both left and right channels (Figure 3B, bottom row). This refined timing was then aligned with the clean EEG signal timestamps, allowing us to isolate periods of EEG data associated with specific verbal interactions. These selected time periods were crucial for calculating brain-to-brain synchronization among participants.

Computation of Normalized TI

In this study, we used the TI method to assess brain-to-brain synchronization among participants during the virtual simulation. TI is a technique that analyzes the temporal relationships between two signals, extending beyond zero-lag [34]. For our analysis, we focused on 2 specific frequency ranges: (1) all frequencies between 1-20 Hz defined as all frequency bands; and (2) the alpha frequency band (8-12 Hz), given its putative role in attention regulation [44,45] and cognitive control [46,47]. Further mathematical details regarding the TI calculation can be found in Multimedia Appendix 1.

TI calculation involved aligning participants' recorded screens (Figure 4A) and segmenting EEG signals into 1-second epochs (Figure 4B). Epochs exceeding 6 times the golden SDs—nonbiased estimates of variability derived from clean EEG signals (Multimedia Appendix 6)—were rejected (Figure 4B, gray boxes). The remaining commonly clean epochs (Figure 4C, green boxes) were used to compute TIs for the anterior, central, and posterior brain regions (Figure 4D). Because TI depends on duration, normalization was necessary (Multimedia Appendix 1 provides details on normalizing TI). We applied this procedure to calculate the communication TI for all possible pairs of participants. We defined the communication TI of a student as the average of the communication TIs of all pairs including that participant, and the student TI as the average of the communication TI across all valid communications for that student. We then derived a group TI by averaging all student TIs in that group. TIs were computed separately for the anterior, central, and posterior brain regions (Figure 4D). To our knowledge, this is the first study to apply the TI normalization technique.

Figure 4. Steps for calculating total interdependence (TI). (A) Alignment of recorded screens from 6 participants during a simulated scenario. (B) Aligned clean electroencephalogram (EEG) signals epoched into 1-second periods (vertical bars), with rejected epochs (gray boxes) exceeding 6 times the golden SDs. (C) Commonly clean epochs (green) for participant pairs, used to calculate TIs across anterior (blue), central (red), and posterior (yellow) brain areas (D). Statistical Analysis

Because the TeamSTEPPS scores for each profession were independently assessed by 2 trained raters, we evaluated interrater reliability using the intraclass correlation coefficient (ICC; [48]). We selected a 2-way random-effects model, which assumes that both raters and participants were randomly chosen, to generalize the reliability estimates to any trained raters. Given the resource-intensive nature of rater training, we were focused on estimating the reliability of scores if only one rater was used. Accordingly, we adopted the "single rater" type and the "absolute agreement" definition, following the reporting guidelines proposed by Koo and Li [49]. The ICC was calculated using the *icc* function from the *irr* package (version 0.84.1 [50]) in R software (version 4.3.2; R Foundation for Statistical Computing), with the selected model, type, and definition options, while other parameters were set to default. To aid interpretation of ICC values, we applied Cicchetti's [51] thresholds, categorizing reliability as excellent (ICC=0.75-1.00), good (0.60-0.74), fair (0.40-0.59), and poor (<0.40). We also note that Koo and Li [49] proposed an alternative system in which ICC values <0.5, 0.5-0.75, 0.75-0.9, and >0.9 correspond to poor, moderate, good, and excellent reliability, respectively.

Since the study involved 2 variables (TeamSTEPPS and TI), analyses were performed with multivariate outliers, which were identified using the Minimum Covariance Determinant [52] using the *MASS* package (version 7.3.60.0.1 [53]) in R software (version 4.3.2) with 75% of the samples regarded as the minimum number of "good" samples and an α level of .001. Correlation between both variables was assessed using the Pearson correlation for 36 cases: a total of 6 for the TeamSTEPPS scores (5 topics and 1 overall), 3 for the brain areas (anterior, central, and posterior), and 2 for the frequency bands (all frequency bands and the alpha frequency band). To control for Type I error, the Benjamini and Hochberg procedure [54,55] was applied for multiple comparison with a combined threshold of $P<.05$.

Sample Size Justification

As part of the larger study [26,27], our sample size of 30 sessions aligned with Reinero's [8] study, which included a

total of 44 groups. A total of 30 sessions in this study yielded 180 observations (90 participants × 2 sessions), which is comparable to the 176 observations (4 participants × 44 groups) reported in Reinero's [8] study. With a desired statistical power of 0.8 and a sample size of 30 sessions, we calculated the minimum detectable effect size for correlation to be 0.49 using the formula provided elsewhere [56].

Ethical Considerations

The study was approved by the Institutional Review Board of the Faculty of Medicine at Chulalongkorn University (COA No 1085/2022). All participants provided written informed consent to participate. Participants who completed the experiment received THB 1000 (US $30.27).

Results

Demographic

We included a total of 85 students, with a mean age of 21.87 (SD 1.17) years, a mean grade point average of 3.21 (SD 0.38), and a mean PHQ-9 score of 3.49 (SD 2.54). Of these, there were 11 radiological technologists, 15 medical technologists, 15 medical doctors, 15 pharmacists, 14 circulation nurses, and 15 airway nurses. A total of 20 sessions had complete EEG activities of all 6 simulated professions. Table 2 presents the unweighted demographic characteristics of the included participants for each simulated profession. Of the 59 women (69% of the total sample), 8 (14%) were radiological technologists, 12 (20%) were medical technologists, 4 (7%) were medical doctors; 7 (12%) were pharmacists; 13 (22%) were circulation nurses; and 15 (25%) were airway nurses. A total of 13 (15%) students were administered a 10 mg dose of oral dimenhydrinate.

Professions Tend to Perform Best in Situation Monitoring and Worst in Mutual Support

Table 1 presents descriptive statistics of the TeamSTEPPS scores, with each simulated profession assessed independently by 2 raters (Rater 1 and Rater 2). A total of 12 raters were involved in the study. The statistics were calculated from 22 sessions of 11 radiological technologists, 30 sessions of 15 medial technologists, 30 sessions of 15 medical doctors, 30 sessions of 15 pharmacists, 30 sessions of 15 airway nurses, and 28 sessions of 14 circulation nurses. To enable comparisons across professions and to compute the group TeamSTEPPS score, participants' scores were scaled to a range between 0 and 1, since the score ranges varied by topic and profession (Table 1, "Range" rows). This resulted in the Scaled AVG values in Table 1, where higher values indicate better performance.

The average interrater agreement for the TeamSTEPPS scores, as measured by the ICC, was good across the 5 topics and 6 professions (mean 0.73, SD 0.18; range 0.32-0.999), with excellent agreement for the overall score (mean 0.87, SD 0.09; range 0.75-0.99). The lowest ICC was 0.32 for mutual support within the circulation nurse profession, whereas the highest was 0.999 for leadership within the medical technologist profession.

Team structure yielded the highest average agreement across professions (mean 0.86, SD 0.13; range 0.64-0.997), while mutual support had the lowest (mean 0.60, SD 0.25; range 0.32-0.94). Among professions, medical technologists had the highest overall agreement (mean 0.98, SD 0.03; range 0.94-0.999), and pharmacists had the lowest (mean 0.59, SD 0.14; range 0.43-0.78). For radiological technologists, team structure showed the highest ICC and mutual support the lowest. For medical technologists, leadership scored highest and mutual support lowest. For medical doctors, communication had the highest agreement and situation monitoring the lowest. For pharmacists, circulation nurses, and airway nurses, team structure showed the highest ICC, while situation monitoring (pharmacists and airway nurses) and mutual support (circulation nurses) were lowest.

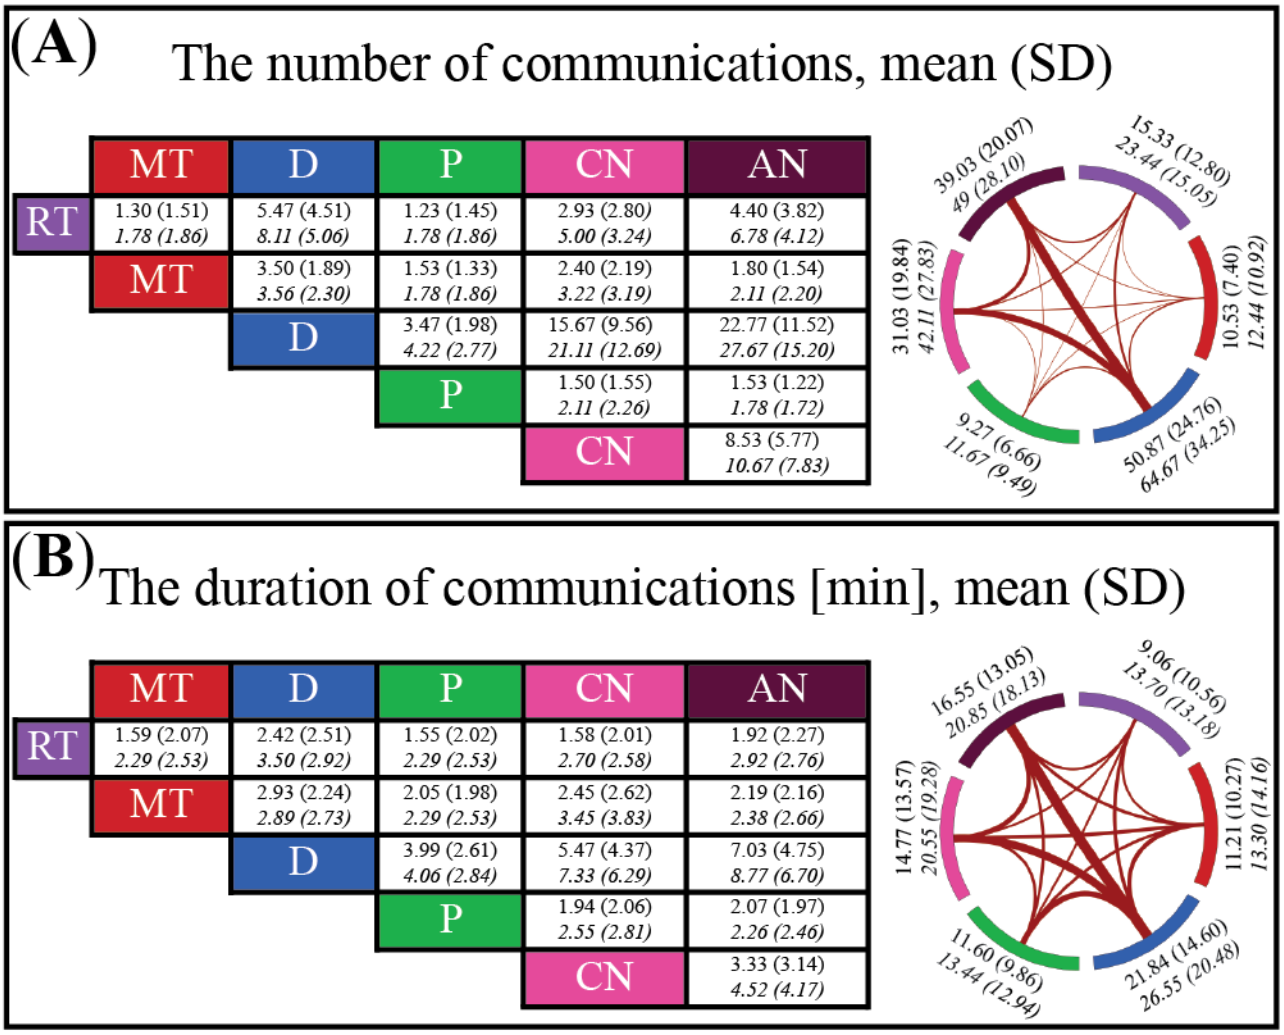
The results of the TeamSTEPPS performance comparison among professions across topics were summarized in the Scaled AVG rows of Table 1. Medical doctors demonstrated the highest performance in both team structure and situation monitoring compared to other professions. Pharmacists excelled in communication and leadership, while airway nurses performed best in mutual support. Notably, all professions exhibited their lowest Scaled AVG scores in mutual support, except for airway nurses, who had the lowest in communication. Each profession showed distinct strengths in different topics: radiological technologists and circulation nurses excelled in team structure; medical technologists, medical doctors, and airway nurses in situation monitoring, and pharmacists in communication.

Table 1 presents the group TeamSTEPPS scores for the 6 simulated professions across all 20 sessions and for the subset of 9 sessions in which all 6 student TIs were present. In both analyses, the lowest group Scaled AVG value was observed in mutual support, while the highest was observed in situation monitoring for the 20 sessions and in team structure for the 9 sessions. This indicated that the group performed worst in mutual support and best in situation monitoring across the 20 sessions.

Scenario Dominated by Communication Between Medical Doctors and Airway Nurse Professions

We examined the characteristics of communications between professions during the virtually simulated scenario, focusing on frequency and duration. As shown in Figure 5, the medical doctor and airway nurse professions communicated most frequently, with an average of 22.77 (SD 11.52) communications across 30 sessions and 27.67 (SD 15.20) across 9 sessions. Their communications also lasted the longest, averaging 7.03 minutes (SD 4.75 minutes) for the 30 sessions and 8.77 minutes (SD 6.70 minutes) for the 9 sessions. In contrast, communications between the radiological technologist and pharmacist professions were the least frequent (mean 1.23, SD 1.45) and shortest (mean 1.55 minutes, SD 2.02 minutes) across 30 sessions. In the 9 sessions, the shortest communication duration occurred between pharmacist and airway nurse professions (mean 2.26 minutes, SD 2.46 minutes), while the least frequent communications were observed between the following pairs: radiological technologist and medical technologist, radiological technologist and pharmacist, medical technologist and pharmacist, and pharmacist and airway nurse (all mean 1.78, SD 1.86).

Figure 5. Descriptive statistics of communications between participants. (A) The number of communications among 6 professions (left) and a connectogram (right) where thicker lines indicate more frequent communications. (B) Communication duration in minutes (left) and a connectogram (right) where thicker lines indicate longer durations. Numbers around connectograms indicate totals per profession. Italicized numbers denote complete groups in which all 6 student total interdependence (TI) were present. AN: airway nurse; CN: circulation nurse; D: medical doctor; MT: medical technologist; P: pharmacist; RT: radiological technologist.



The Alpha-Band Communication TI Deviates More From Baseline Than All Frequency Bands

Table 3 presents descriptive statistics of the communication TI for students across all frequency bands and specifically for the alpha frequency band, in the anterior, central, and posterior brain areas. Data are reported for each profession over the 30 sessions (total sessions) and for the 9 sessions (complete subset), representing the sessions in which the student TI of all 6 simulated professions was fully available.

The absolute values of the alpha-band communication TI of a student were larger than those of all frequency bands in most cases: 78% (14/18) during the 30 sessions and 67% (12/18) during the 9 sessions across the 6 professions and 3 brain areas. In the anterior brain area, 83% (5/6) of the professions showed higher alpha-band values during the 30 sessions, and 67% (4/6) during the 9 sessions. In the central brain area, this trend persisted for 83% of the professions in both sets, whereas in the posterior brain area, it was 67% for the 30 sessions and 50% for the 9 sessions. These results suggest that the alpha-band communication TI of a student deviated more from baseline and conveyed more information about brain-to-brain synchronization than the all frequency-bands communication TI.

We compared the absolute values of the alpha-band communication TI of a student across the 3 brain areas for each profession. In the 30 sessions, the central brain area exhibited larger values than the anterior and posterior areas in 67% (4/6) of professions, while the posterior area showed larger values in 33% (2/6) of professions, and no profession showed larger values in the anterior area. In the 9 sessions, larger values were observed in the anterior, central, and posterior brain areas in 33% (2/6), 17% (1/6), and 50% (3/6) of professions, respectively. The 30-session results suggest that the alpha-band communication TI in the anterior brain area may least represent brain-to-brain synchronization, while the 9-session results suggest a moderate representation in the anterior brain area.

Table 3. Descriptive statistics of the communication total interdependence of a student. Please note that, statistics were calculated after removing outliers.

Group TI Correlates With Group TeamSTEPPS Score

In this section, we present the correlations between TeamSTEPPS and TI after removing outliers using the Minimum Covariance Determinant method and correcting for multiple comparisons with the Benjamini and Hochberg procedure. The TeamSTEPPS scores included 5 topics—team structure, communication, leadership, situation monitoring, and mutual support—along with an overall score. The TI considered here comprised both the student TI and the group TI.

Initially, we examined the correlations between the TeamSTEPPS scores and the student TI. For all 6 simulated professions across both the all frequency and alpha bands, the correlations were weak and not statistically significant (all adjusted $P \geq .05$; Figures S2-S7 in Multimedia Appendix 7), except for the medical technologist simulated profession, which showed a significant negative correlation with the team structure topic in the alpha band at the anterior brain area (r=–0.76 adjusted P<.001). Combining data from all 6 simulated professions also resulted in weak and not statistically significant correlations for both frequency bands (adjusted P>.99; Figure S1 in Multimedia Appendix 7).

Second, we examined the correlations between the group TeamSTEPPS scores and the group TI, with results presented in Figure 6. This figure shows scatter plots illustrating the associations between the group TeamSTEPPS scores and the group TI for all frequency bands (blue) and the alpha frequency band (red) in the anterior (top row), central (middle), and posterior (bottom row) brain areas. The scatter plots are overlaid with the best-fit lines calculated using the least-squares method (*polyfit* function of MATLAB, The MathWorks, Inc). Out of the 30 sessions, a total of 9 sessions had complete student TI

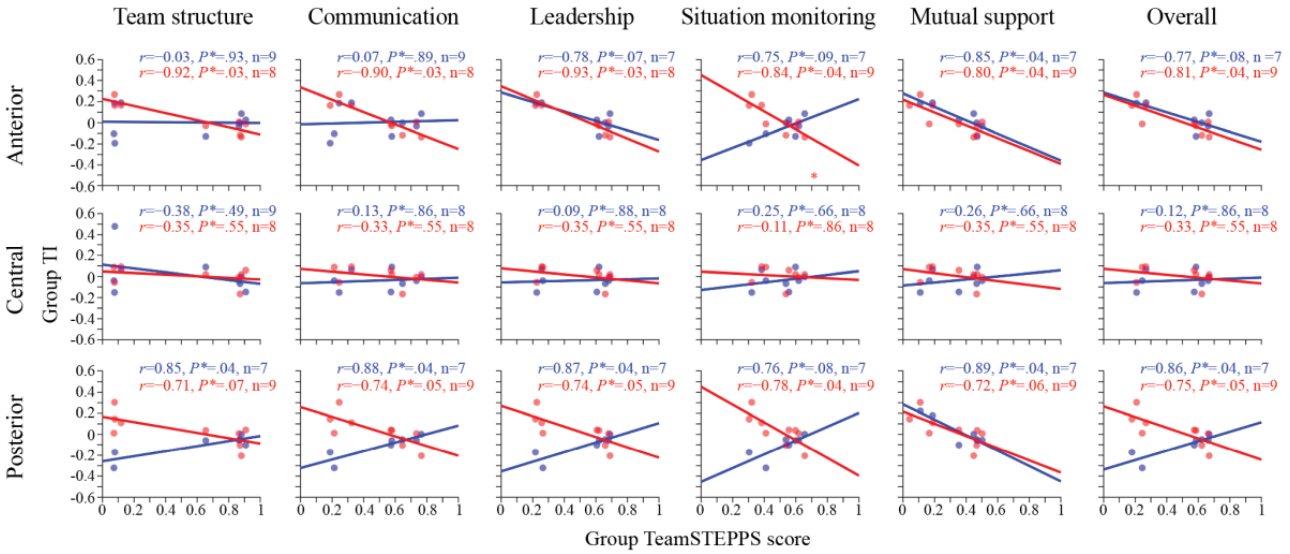
data for all 6 simulated professions, resulting in well-defined group TIs. Note that the number of sessions shown in the scatter plots may be lower than 9 due to the outlier screening procedure.

In the anterior brain area (Figure 6, top row), the alpha frequency band demonstrated strongly negative and statistically significant correlations with all 5 TeamSTEPPS topics, including the overall score: r=–0.92, adjusted P=.03 for team structure; r=–0.90, adjusted P=.03 for communication; r=–0.93, adjusted P=.03 for leadership; r=–0.84, adjusted P=.04 for situation monitoring; r=–0.80, adjusted P=.04 for mutual support; and r=–0.81, adjusted P=.04 for the overall score. In contrast, all frequency bands yielded strongly negative but nonstatistically significant correlations for the other topics, except for mutual support: r=–0.03, adjusted P=.93 for team structure; r=0.07, adjusted P=.89 for communication; r=–0.78, adjusted P=.07 for leadership; r=0.75, adjusted P=.09 for situation monitoring; r=–0.85, adjusted P=.04 for mutual support; and r=–0.77, adjusted P=.08 for the overall score.

In the central brain area (Figure 6, middle row), both all frequency bands and the alpha frequency band exhibited weak, nonstatistically significant correlations for all 5 topics including the overall score, with minimum adjusted P=.49 and a maximum absolute r=0.38.

In the posterior brain area (Figure 6, bottom row), all frequency bands displayed strongly positive and statistically significant correlations for team structure (r=0.85, adjusted P=.04), communication (r=0.88, adjusted P=.04), leadership (r=0.87, adjusted P=.04), and the overall score (r=0.86, adjusted P=.04). There were also strongly negative and statistically significant correlations for mutual support (r=–0.89, adjusted P=.04) and a strongly positive but nonstatistically significant correlation for situation monitoring (r=0.76, adjusted P=.08). The alpha frequency band in the posterior brain area showed strongly negative and statistically significant correlations for situation monitoring (r=–0.78, adjusted P=.04), but strongly negative and nonstatistically significant correlations for team structure (r=–0.71, adjusted P=.07), communication (r=–0.74, adjusted P=.05), leadership (r=–0.74, adjusted P=.05), mutual support (r=–0.72, adjusted P=.06), and the overall score (r=–0.75, adjusted P=.05).

Figure 6. Anterior group total interdependence (TI) in the alpha band negatively correlated with group Team Strategies and Tools to Enhance Performance and Patient Safety (TeamSTEPPS) scores. Scatter plots show relationships between group TI and TeamSTEPPS scores for anterior (top), central (middle), and posterior (bottom) brain areas, across all frequency bands (blue) and only the alpha band (red). Columns represent TeamSTEPPS domains, with the last column showing their sum. Legends display Pearson correlation (r), adjusted P value (P*), and sample size after excluding outliers (n). Best-fit least-squares lines are shown.



Discussion

Principal Findings

This study explored the correlation between brain-to-brain synchronization, measured by the TI, and team performance, evaluated using the TeamSTEPPS scores, in an online virtual SIMBIE setting where face-to-face communication was absent. At the individual level, no significant correlations were found between participants' synchronization with their team members (measured by the student TI) and their TeamSTEPPS scores (all adjusted P≥.05). These findings are consistent with previous studies [57,58], which similarly reported an absence of brain-to-brain synchronization when face-to-face interactions—crucial mechanisms such as eye contact, important for establishing trust and enhancing synchrony [59]—were missing.

However, at the team level, we identified strongly negative, statistically significant correlations between the group TIs and the group TeamSTEPPS scores, particularly in the anterior brain region (mean −0.87, SD 0.06; range −0.93 to −0.8). These findings are counterintuitive and contrast with our initial hypothesis, as higher team performance is generally associated with greater brain-to-brain synchronization [8]. To better understand this result, we examined the assessment method: team performance was evaluated using the TeamSTEPPS scores, which heavily rely on effective verbal communication [28]. Our findings tentatively suggest that a high degree of brain-to-brain synchronization does not necessarily correspond to improved

team performance. Conversely, at the team level, strongly positive, statistically significant correlations were observed between the group TIs based on all frequency bands and the group TeamSTEPPS scores—including the overall score and most topics—particularly in the posterior brain region.

Comparison With Previous Work

To our knowledge, no previous studies have examined the correlation between EEG-based brain-to-brain synchronization and TeamSTEPPS scores in an online hexad virtual SIMBIE setting without face-to-face communication. This study provides a novel contribution by incorporating a broader set of 6 participants and addressing an important gap in the literature on team-based interactions, using a cost-effective EEG device for analysis.

Exploring the Discrepancy: Negative Correlation of Anterior Alpha Band With TeamSTEPPS Performance and the Role of Intermittent Synchronization in Hexad Multi-Person Teams

Previous studies generally reported a positive correlation between brain-to-brain synchronization and team performance using basic social interaction tasks, such as Lego assembly, typically conducted in face-to-face dyadic groups and using high-cost methods, including functional near-infrared spectroscopy, near-infrared spectroscopy–based hyperscanning, and resource-intensive EEG studies [8,18,60-63]. In contrast, this study observed strongly negative, statistically significant correlations between team brain-to-brain synchronization—measured by the group TIs based on the anterior alpha band—and team performance assessed using the group TeamSTEPPS scores, including all 5 individual domains and their overall sum. By comparison, group TIs in the posterior frequency bands showed strongly positive, statistically significant correlations with team performance in nearly all individual domains and the overall sum.

We speculate that the discrepancy between the negative correlations observed in this study based on the anterior alpha band and the positive correlations reported in previous studies may result from the complexity of more-than-two-person communication in this study and the nature of the TeamSTEPPS scores, in contrast to previous studies focused on dyadic interactions [61-63]. For instance, compared to face-to-face dyads, groups with more than 2 individuals exhibit distinct patterns in verbal communication and nonverbal behaviors (eg, eye gaze) [64,65], which require intermittent synchronization—the brain's ability to shift focus among individuals—to maintain effective communication and coordination [66,67]. Intermittent synchronization in groups of more than 2 members was also observed in Stevens et al's [17,21] studies, which used mannequin-based group simulations with face-to-face interactions. These studies reported that triad groups exhibiting high TeamSTEPPS scores demonstrated elevated Shannon entropy of neurodynamic symbols derived from neural activity at the 10-Hz brain rhythm. Because the 10-Hz rhythm falls within the alpha frequency band and is associated with attention regulation, high Shannon entropy of the corresponding neurodynamic symbols likely reflects the waxing and waning of group members' attention during the simulation.

In our experimental setting, where 6 participants worked as a team, the brain's ability to engage in intermittent synchronization was crucial for effective communication and coordination [66,67]. Over synchronization within a team of more than 2 members may be detrimental to team performance, potentially leading to groupthink, a phenomenon in which members prioritize harmony and consensus over critical thinking and individual opinions [67,68].

The TeamSTEPPS scores rely heavily on effective verbal communication to establish a shared mental model of team tasks, strategies, and goals, which is critical for enhancing situational awareness and overall team performance [28,69-71]. TeamSTEPPS promotes an ideal team typology that requires intermittent synchronization—the ability to shift focus and support shared decision-making [72]. However, over synchronization, or an inability to shift focus among more-than-two team members, may disrupt communication and lead to groupthink [67,68]. In such cases, directive leadership and hierarchical structures within health care teams can prioritize consensus at the expense of independent critical thinking, potentially resulting in negative outcomes and impeding shared decision-making [68]. Groupthink, or cohesive typology, relies on a lower cognitive level than a shared mental model or facilitated team structure [72]. This may explain why higher brain-to-brain synchronization, or over-synchronization, as measured by group TIs, does not necessarily translate into optimal team performance as assessed by the TeamSTEPPS scores.

Anterior Alpha Band Synchronization: A Key Indicator for TeamSTEPPS Performance and Shared Attention in Hexad Teams Without Face-to-Face Interaction

The statistically significant correlations between brain-to-brain synchronization at the team level and TeamSTEPPS performance were primarily observed in the anterior brain areas, particularly in the alpha band. In other words, the anterior electrodes provided the most reliable measurements of TeamSTEPPS performance both overall and across each of the 5 domains, compared to the central and posterior electrodes. These findings align with previous studies that emphasize the critical role of the dorsomedial prefrontal cortex, which is associated with the perception of intention [73,74] and theory of mind, the ability to interpret others' mental states [75,76], as well as the frontopolar region, a part of the prefrontal cortex, during social interactions [77,78]. However, our results differ from other studies that identified different brain regions, such as the right temporo-parietal junction, as being highly activated during social interaction [57,79]. This discrepancy may arise from variations in the experimental conditions and the nature of tasks used [10].

Unlike the alpha band (8-12 Hz), the delta (1.5-4 Hz [80]), theta (4-8 Hz [81]), and beta (14-30 Hz [82]) bands were not analyzed individually due to limited theoretical support, as their primary functions are less relevant in studies focused on teamwork and

attention. Supporting our findings, previous research has identified a relationship between brain-to-brain synchronization in the alpha band and interactional synchrony during social interactions [61,63,83-87]. While some studies suggested that the gamma band (30-80 Hz) may also reflect brain-to-brain synchronization and shared intentions [88], the sampling rate of our EEG device (125 Hz), with a Nyquist frequency of 62.5 Hz limited our analysis to frequencies up to the beta band (14-30 Hz), thus preventing examination of the gamma band. Our emphasis on the alpha band is substantiated by its established roles in attention regulation [44,45,89,90] and cognitive control [46,47]. The alpha band has been extensively studied in contexts such as relaxation [91], inhibitory control [92], emotional processing [93], mental health [94], and sleep [95], making it a versatile marker for various cognitive processes. Our findings further highlight the value of the alpha band as an indicator of fluctuations in attention and focus during team-based activities as measured by TeamSTEPPS.

Overcoming Subjectivity in TeamSTEPPS Assessment: The Potential of Anterior Alpha Band EEG Synchronization in SIMBIE Scenarios

Figure 5 highlights differences in communication duration among participants, with medical doctors having the longest duration, which may explain their higher TeamSTEPPS scores. In contrast, radiological technologists, with the shortest communication duration, may have lacked closed-loop communication and sufficient identification, impacting critical information sharing as emphasized by the "Introduction, Situation, Background, Assessment, Recommendation" guidelines [96], and resulting in lower TeamSTEPPS scores. Interestingly, despite limited communication duration, the pharmacists achieved a relatively high TeamSTEPPS score. This may be due to the scenario design, where the pharmacist's role involved gathering medication history from a nonplayer character acting as a family member, thereby boosting TeamSTEPPS scores despite minimal communication with the team. However, no significant correlation was observed between the communication TI of a pair and communication duration, except for a low-value correlation in the central brain area within the alpha frequency band (Figure S1 in Multimedia Appendix 8).

The TeamSTEPPS scores in this study were derived from both verbal communications and nonverbal behaviors. The ICC values for the situation monitoring and mutual support domains were the lowest among the 5 domains (Table 1), likely due to their reliance on nonverbal behaviors and the need for experienced raters to assess them accurately. Examples include monitoring and checking patient's vital signs before, during, and after intubation, during X-ray procedures, and before intensive care unit transfer, as well as mutual assistance tasks such as raising bed rails and assisting with donning personal protective equipment. These findings indicate that assessing situation monitoring and mutual support with human raters is inherently limited by the subjectivity required to evaluate nonverbal behaviors [97]. However, EEG brain-to-brain synchronization, particularly in the anterior alpha band, offers a promising alternative method to support and enhance the prediction of TeamSTEPPS performance across all domains (Figure 6). The inherent subjectivity of human raters in evaluating situation monitoring and mutual support domains presents a challenge that could be intriguingly addressed by leveraging measures from the anterior alpha band. Previous studies [98-101] have used alpha-band EEG to measure individual situation awareness in real time. In contrast, our findings emphasize the potential of anterior alpha-band synchronization as a group-level metric, offering a fresh perspective on assessing team dynamics and collaborative performance.

Posterior All-Band Synchronization as a Potential Marker for Certain TeamSTEPPS Domains and Task-Dependent Roles in Hexad Teams Without Face-to-Face Interaction

Our results revealed strong positive and statistically significant correlations between the posterior group TIs based on all frequency bands (1-20 Hz, encompassing partial delta, theta, alpha, and partial beta) and the group TeamSTEPPS scores across most domains (r=0.76-0.88). Notably, the mutual support domain deviated from this pattern, showing a strong negative correlation (r=−0.89). The positive correlations between team performance and brain-to-brain synchronization across all frequency bands align with previous studies [8,14], which hypothesized that brain-to-brain synchronization is modulated by shared attention among team members. However, our results based on the posterior alpha band, which has a putative role in attention [44,45,89,90], showed the negative correlations that contrasted both with the posterior all frequency band results in this study and with previous studies based on all frequency bands.

Grounded in previous findings, the delta, theta, and beta frequency bands have well-known functional roles beyond attention—for example, levels of consciousness for the delta band [102], cognitive performance for the theta band [103], and motor control and execution for the beta band [104]. Our results tentatively suggest that in the complex interactions among the 6 team members in this study, brain-to-brain synchronization across all frequency bands cannot be explained solely by the shared attention mechanism. Therefore, we recommended that future research investigate brain-to-brain synchronization for each frequency band separately to understand their functional roles during cooperation and social interaction in teams with a larger number of participants, as in this study.

A recent study by Reinero et al [8] explored the relationship between team performance on problem-solving tasks and interbrain synchrony within a group of 4 participants. They found that higher interbrain synchrony, reflecting stronger connections among teammates, led to better performance on economic games and most problem-solving tasks. In contrast, this study found that higher interbrain synchrony correlated with lower TeamSTEPPS performance. Several factors may explain this difference. First, this study was conducted in a virtual environment without face-to-face interaction, which is known to reduce interbrain synchrony [8,57,58]. Second, our tasks required critical thinking and rapid, shared decision-making under time constraints, making effective verbal

communication essential. With a larger team of 6—exceeding the arguably optimal team size of 4 [105]—intermittent synchronization, or the brain's ability to shift focus among teammates, was crucial. Over interbrain synchrony may have disrupted this focus shifting, impeding team performance. In the study by Reinero et al [8], however, the team had fewer time pressures and communicated through private online chat, making intermittent synchronization less critical and allowing high interbrain synchrony to enhance performance. Our findings, together with those of Kikuchi et al [58] and Czeszumski et al [10], suggest that both the context of brain-to-brain synchronization and task characteristics are important factors in the relationship between brain-to-brain synchronization and team performance.

Strengths and Limitations

Excessive EEG noise during gameplay resulted in group TIs being available for only 45% (9/20) of sessions. Although correlations between group TIs and the TeamSTEPPS scores were statistically significant after correction for multiple comparisons, a minimum of 30 sessions is typically recommended to achieve meaningful correlations [106]. To account for potential data loss of up to 55% under similar conditions, we recommend that researchers plan for at least 67 sessions (100×30/45).

This study focused on healthy participants by excluding individuals with neurological, psychiatric, or substance use disorders, which are known to alter social cognition [107], emotional processing [108], or attentional processing [109]—mechanisms fundamental to brain-to-brain synchronization [110]. Several studies have reported that such disorders can influence brain-to-brain synchronization between individuals during various tasks. For instance, Deng et al [111] conducted an EEG hyperscanning study examining brain-to-brain synchronization during an emotional processing task in 25 parent-adolescent pairs with social anxiety, and found that the adolescents' level of social anxiety modulated the synchronization. Similarly, Wang et al [112] reported that the severity of autism spectrum disorder in children affected brain-to-brain synchronization during a cooperative task with their parent, although Kruppa et al [113] found no such modulation. Therefore, the applicability of our findings should be interpreted with caution in practical settings where screening for such disorders may not be feasible.

Time accuracy and precision are critical in brain-to-brain synchronization research. While our methodology produced statistically significant correlations and passed sanity checks, there is potential for further refinement. The first improvement is the Bluetooth connection between the EEG data-acquisition device and the PC. A higher baud rate can reduce transmission time but it also increases vulnerability to errors from electromagnetic interference. In this study, we set the baud rate to 115,200 bits per second, which theoretically allows a 24-bit data point to be transferred in 0.2083 milliseconds. However, factors such as distance, interference, Bluetooth overhead, and system delays in Windows 10 can extend transmission times to 0.6-10 milliseconds [114]. Despite these latency variations, BrainFlow software (version 4.9.0 [41]) maintained the correct order of data points. The second improvement involves better alignment of the 6 recorded screen footages. In this study, we manually aligned the footages using commercial software, which introduced the risk of human error, potentially causing partial loss of verbal communication data and related EEG information. We recommend real-time audio logging for both senders and receivers during virtual simulations to accurately capture team audio profiles. The third improvement focuses on enhancing the accuracy of the local Unix time. We used the C# DateTime function, which can differ from real time by approximately 10 milliseconds [115]. Implementing dedicated external hardware to synchronize time across EEG devices and team PCs would enhance both accuracy and precision.

In this study, we used a fully manual method to reject artifact portions of EEG signals. This approach poses several challenges: (1) potential data bias, (2) time consumption for large-scale studies, (3) reliance on EEG specialists, and (4) limited practicality for real-world applications. Artifact rejection remains a significant bottleneck in EEG data preprocessing, as unaddressed noise and artifacts can impair subsequent analysis. Despite its importance, there has been no consensus within the EEG community on effective artifact management. Recently, various tools and techniques for semiautomatic artifact rejection during offline analysis have emerged, such as the Clean Rawdata EEGLAB plug-in [116,117], Autoreject [118], FASTER [119], the Riemannian Potato technique [120], and the Robust Regression technique [121]. However, these methods often require manual parameter tuning, which can vary depending on the dataset.

Simulator sickness is a common issue in virtual simulations [122]. In this study, of the 90 participants, 13 (14%) took dimenhydrinate before the experiments to prevent nausea, vomiting, and dizziness associated with simulator sickness [123]. While dimenhydrinate can cause side effects such as drowsiness and hyperactivity, which may potentially impact EEG signals [29], Hu [124] reported no changes in peak frequency or the percentage distribution of the alpha band. Therefore, we speculate that our primary finding—the correlation between the alpha group TIs and the group TeamSTEPPS scores—was likely unaffected by dimenhydrinate, though it may have influenced results based on all frequency bands.

Our analysis approach evaluates the normalized TI immediately after each communication, rather than waiting until the end of the entire session. This allows for near real-time computation, making the method practical for real-world applications. This approach requires extensive computation, involving 1000 permutations to construct the TI empirical distribution for normalization. A small percentage of these distributions (175/4224, 4.14%) did not pass the Kolmogorov-Smirnov normality test, suggesting that a higher number of permutations may be needed, which would further increase computational demands.

This study was conducted in a single-room lab without electromagnetic shielding, where all 6 participants shared the same space due to facility limitations. This setup introduced unavoidable environmental factors, such as shared sounds,

visuals, and potential interference from external electromagnetic sources, which may have affected EEG signals [125-127]. To reduce spurious brain-to-brain synchronization from these external influences, we recommend that future studies place each participant in a separate, electromagnetically shielded room.

Future Research

Building on this study and considering the non-face-to-face context of the online hexadic virtual SIMBIE, we recommended using alpha-band activity in the anterior brain regions to evaluate TeamSTEPPS scores. This approach showed significant associations with all 5 TeamSTEPPS domains and provides a valuable framework for understanding shared attention and the development of shared mental models. Additionally, focusing on the anterior brain region is practical because affordable EEG devices with anterior electrodes are readily available, making this method cost-effective and widely accessible for broader applications.

Can we enhance the correlation between EEG brain-to-brain synchronization and TeamSTEPPS scores in virtual simulations or real-life practice to address the challenges of subjective TeamSTEPPS evaluations by raters? Our current methodology relies on verbal communication within a team of at least 2 collaborators to compute TIs. However, the TeamSTEPPS scores also encompass nonverbal components, such as early stages of situation monitoring (eg, visual attention) and mutual support in actions that are not captured by our TI calculations. Future studies could improve TIs by incorporating screen footage segments representing situation monitoring and mutual support, providing a more comprehensive analysis of both verbal and nonverbal components of TeamSTEPPS scores. In real-life clinical practice, it may be feasible to estimate the TeamSTEPPS scores in real-time using affordable, compact EEG devices positioned near the anterior brain region, enabling broader generalizability and practical application across various settings.

Conclusions

This study found no correlations between individual brain-to-brain synchronization, as measured by the student TI, and individual TeamSTEPPS performance during online virtual SIMBIE sessions without face-to-face communication. However, at the group level, strongly negative, statistically significant correlations were primarily observed in the alpha band in the anterior brain region between the group TI and the group TeamSTEPPS scores among teams of 6 multiprofessional students. These findings highlight the potential of EEG-based brain-to-brain synchronization analysis as an emerging tool for a more objective measure of TeamSTEPPS dynamics than subjective human evaluations, offering a novel approach to support TeamSTEPPS assessments with trend-based, quantitative, real-time feedback—ultimately enhancing team performance and patient safety.

Acknowledgments

This research was funded by the Second Century Fund, Chulalongkorn University. The authors thank the TeamSTEPPS raters for their invaluable contributions: Chulaluk Jaipang, Jiraphan Ritsamdang, Dr Khrongwong Musikatavorn, Dr Kanyarat Susantitaphong, Dr Navaporn Worasilchai, Noppawan Boonbumrong, Dr Nuntaree Chaichanawongsaroj, Dr Sararas Khongwirotphan, Sawitree Suayod, Dr Sunisa Seephom, and Sirikanyawan Srikasem. Their dedication and expertise were instrumental to the success of this study. The authors also thank the Chulalongkorn Healthcare Advanced Multi-Profession Simulation Center, Surachai Pianpetchlert, and research assistants—Chaiwat Takkanat, Chayanit Trakulpipat, Kitnipat Boonydhammakul, Nuttarin Panswad, Sirisopha Suwanchinda, Sutasinee Chaidej, Thanes Yunirundorn, Thanyared Sangsawad, Wallop Boonkua, and Werasak Boonwong—for their support in data collection and IT assistance. Special thanks to Dr Zarina Sadad for help with rater training, Dr Chaipat Chunharas and Dr Solaphat Hemrungrojn for advice on EEG devices, and Dr Mary Kay Smith for TeamSTEPPS training. Finally, the authors thank Dr Diego Reinero and Dr Jay Van Bavel for their valuable discussions.

During the preparation of this study, the authors used ChatGPT-4o and ChatGPT-5 to check and correct grammatical errors, refine language, and suggest alternative reader-friendly synonyms during the manuscript writing process. After using these tools, the authors reviewed and edited the content as needed and take full responsibility for the content of the publication.

A preliminary version of this study was presented at the Society for Simulation in Europe conference on June 19, 2024 in Prague, Czech Republic. This study provides a comprehensive reanalysis with significant updates.

Abstract

Medical education has not traditionally recognized patient safety as a core subject. To foster a culture of patient safety and enhance psychological safety, it is essential to address the barriers and facilitators that currently impact the development and delivery of medical education curricula. The aim of including patient safety and psychological safety competencies in education curricula is to insert these into the genome of the modern health care worker.

(JMIR Med Educ 2025;11:e68046) doi:10.2196/68046

KEYWORDS

patient safety; psychological safety; medical curriculum; professional competence; clinical competence

It has been over 25 years since the beginning of the active development of the patient safety movement, during which the theories and methods of patient safety science have evolved. We now understand the key drivers and practices for safer care [1], and while there have been many achievements and successes in implementation, transfer to different contexts, reliability, and sustainability remain challenging.

One of the underlying problems is that the health care workforce has limited training in the theories and methods of patient safety and insufficient training in improvement or implementation science. Developing sustainable changes in the way we approach patient safety requires radically rethinking how we educate the health care workforce of the future, so that patient safety becomes integrated into the way they work, that is, part of the genome of a modern health care worker.

In the past, patient safety was presumed to be synonymous with being a professional, so it was implicit that on completing medical or nursing education, one would be safe. This clearly is not the case. The paper by Carillo et al [2] approaches this challenge from the perspective of the critical practice of psychological safety in the workforce as the foundation for safer care. They first assessed the current status of training programs for medical students and trainees across Europe, with regard to the acquisition of knowledge, skills, and attitudes about patient safety. This was followed by the development of a suggested set of competencies for psychological safety that should be acquired during training programs. The curriculum is a valuable addition to our understanding of foundations for safer care. The focus on psychological safety as a key competency of patient safety training, rather than a mere focus on knowledge, is a novel approach to the curriculum. Additionally, it can form the basis of a better response to the second victim following an adverse event. Several themes arose from the paper that should be considered.

First, the focus on psychological safety changes the focus of education, shifting away from concentrating only on knowledge acquisition, as in other curricula such as the World Health Organization (WHO) [3] patient safety curriculum, which is under review. A modern patient safety curriculum needs to specify the learner outcomes of knowing what to do and how to generate feelings of being psychologically safe when applying safety science in the workplace to create safer clinical teams. This will be essential for the delivery of the WHO Patient Safety Global Action Plan [4].

Second, a patient safety curriculum cannot stand alone outside the wider concepts of quality in health care. This is an ongoing debate, but many other domains of quality impact the safe delivery of care. Therefore, a patient safety curriculum should be part of a comprehensive set of competencies that facilitate the implementation of patient safety improvement initiatives. Knowledge and skills of improvement methodology and implementation science are essential, and there are examples

of frameworks that achieve this goal for comprehensive quality in health care [5]. Equally, psychological safety influences the success of improvement efforts, implementation efforts, and innovation, all of which depend on being able to speak openly and share new ideas without fear.

Third, it should be determined whether one can engender psychological safety via a training program alone and whether a program is the sole foundation on which a safe system can be built. Organizational culture is fundamental for psychological safety. Psychological safety can only thrive within a team or organization that has a culture of safety that includes a focus on communication, feedback, respect, and trust [6]. Although this is part of the program suggested, there is often a disconnect between the theoretical classroom and trainees' lived experiences. Psychological safety requires positive team and organizational relationships that facilitate team members being safe [7]. The proposed framework for psychological safety includes structural, interpersonal, and individual factors that extend beyond education and depend heavily on leadership. Applying this in practice is challenging [8].

Fourth, to create a strategy for safer care delivery, we need to consider the reasons why medical education has not made patient safety an integral part of the curriculum, despite growing evidence of interventions that decrease harm and create a safer health care environment. Most academic institutions remain hierarchical and are steeped in the traditional medical model of teaching. Reasons for the reluctance to incorporate patient safety include lack of awareness of the emerging science, lack of leadership prioritization, curriculum overload, and competition with other emerging sciences [9]. For the proposed curriculum to succeed, these challenges need to be addressed head-on, and a radical rethink of medical education is required.

Finally, we need to consider the efficacy of patient safety training to make a difference. Two systematic reviews indicate the heterogeneity of papers that assess the effectiveness of patient safety education programs. The link between education and improved clinical outcomes is not strong [10]. There appears to be a disconnect between undergraduate patient safety training and what happens in the clinical setting [11]. This indicates the need for training programs to be integrated into postgraduate and undergraduate programs. It also suggests the need for early evaluation of any new program to ensure that what is imagined is being achieved.

In conclusion, Carillo et al [2] have shown a way forward for patient safety training. The challenge will be implementation within traditional medical education curricula. Perhaps the solution to this could be coproduced by educators, trainees, and patients rather than created by experts and mentors alone. Even though the goal must be transformation in how patient safety is considered within medical education, we can start to create the conditions for these competencies to thrive at our next classroom meeting, simulation session, team huddle, or handover. Imagine the power of a senior clinician openly sharing their vulnerability of not being able to know everything that is required to be safe, inviting respectful dissent, and graciously embracing difficult news. That is the improvement way!
