JMIR Medical Education

Impact Factor (2024): 3.2
Volume 11 (2025) ISSN 2369-3762 Editor-in-Chief: Blake J. Lesselroth, MD, MBI, FACP, FAMIA

Contents

Original Papers

Development and Validation of a Large Language Model–Based System for Medical History-Taking Training: Prospective Multicase Study on Evaluation Stability, Human-AI Consistency, and Transparency (e73419)
Yang Liu, Chujun Shi, Liping Wu, Xiule Lin, Xiaoqin Chen, Yiying Zhu, Haizhu Tan, Weishan Zhang. 16

Utility of Generative Artificial Intelligence for Japanese Medical Interview Training: Randomized Crossover Pilot Study (e77332)
Takanobu Hirosawa, Masashi Yokose, Tetsu Sakamoto, Yukinori Harada, Kazuki Tokumasu, Kazuya Mizuta, Taro Shimizu. 35

Leveraging Large Language Models for Simulated Psychotherapy Client Interactions: Development and Usability Study of Client101 (e68056)
Daniel Cabrera Lozoya, Mike Conway, Edoardo Sebastiano De Duro, Simon D'Alfonso. 46

Collaborative Development of Feedback Concept Maps for Virtual Patient–Based Clinical Reasoning Education: Mixed Methods Study (e57331)
Anja Mayer, Inga Hege, Andrzej Kononowicz, Anja Müller, Małgorzata Sudacka. 64

Exploring the Implementation of Multiple Telementoring ECHO Programs From an Institutional and Organizational Perspective: Qualitative Study (e75844)
M Pagé, Élise Develay, Annie Talbot, Rania Khemiri, Claire Wartelle-Bladou. 496

Investigating Learning Effects Through the Implementation of Teledermatology Consultations Among General Practitioners in Germany: Mixed Methods Process Evaluation (e65915)
Andreas Polanc, Inka Roesel, Elke Feil, Peter Martus, Stefanie Joos, Roland Koch. 509

Impact of Motivational Interviewing Education on General Practitioners' and Trainees' Learning and Diabetes Outcomes in Primary Care: Mixed Methods Study (e75916)
Isaraporn Thepwongsa, Pat Nonjui, Radhakrishnan Muthukumar, Poompong Sripa. 525

Using Web-Based Continuing Education to Improve New Diagnoses of Alzheimer Disease in Claims Data: Retrospective Case-Control Study (e72000)
Katie Lucero, Thomas Finnegan, Soo Borson. 545

Exploring Health Care Professionals' Perspectives on Education, Awareness, and Preferences for Digital Educational Resources to Support Transgender, Nonbinary, and Intersex Care: Interview Study (e67993)
Sravya Katta, Nadia Davoody. 553

A Web-Based Training Intervention for Primary Care Providers on Preparing Patients for Cancer Treatment Decisions and Conversations About Clinical Trials: Evaluation of a Pilot Study Using Mixed Methods and Follow-Up (e66892)
Naomi Parker, Margo Michaels, Carla Fisher, Alyssa Crowe, Elisa Weiss, Maria Sae-Hau, Jason Arnold, Andrea Cassells, Domenic Durante, Ji-Hyun Lee, Raymond Vega, Ana Natale-Pereira, Taylor Vasquez, Zhongyue Zhang, Carma Bylund. 576

Pharmacists' Attitudes, Perceptions, and Preferences Regarding Continuing Education: Cross-Sectional Study in Vietnam (e77013)
Trung Vo, Phuoc Le, Hien Tran, Hieu Nguyen, Thoai Nguyen, Trang Huynh, Bay Vo. 598

Evaluation of an Interdisciplinary Educational Program to Foster Learning Health Systems: Education Evaluation (e54152)
Sathana Dushyanthen, Nadia Zamri, Wendy Chapman, Daniel Capurro, Kayley Lyons. 615

Motivational Framing Strategies in Health Care Information Security Training: Randomized Controlled Trial (e73245)
Thomas Keller, Julia Warwas, Julia Klein, Richard Henkenjohann, Manuel Trenz, Simon Trang. 629

Using AI-Based Virtual Simulated Patients for Training in Psychopathological Interviewing: Cross-Sectional Observational Study (e78857)
Daniel García-Torres, César Fernández, José Mira, Alexandra Morales, María Vicente. 645

Assessing and Improving Study Skills Support in Medical Education Through a Student-Staff Partnership: Mixed Methods Approach (e65053)
Nicole Tay, Anaïs Deere, Dhivya Ilangovan, Carys Phillips, Emma Kelley. 662

Recruiting Medical, Dental, and Biomedical Students as First Responders in the Immediate Aftermath of the COVID-19 Pandemic: Prospective Follow-Up Study (e63018)
Nicolas Schnetzler, Victor Taramarcaz, Tara Herren, Eric Golay, Simon Regard, François Mach, Amanta Nasution, Robert Larribau, Melanie Suppan, Eduardo Schiffer, Laurent Suppan. 672

Comparison of Learning Outcomes Among Medical Students in Thailand to Determine the Right Time to Teach Forensic Medicine: Retrospective Study (e57634)
Ubon Chudoung, Wilaipon Saengon, Vichan Peonim, Wisarn Worasuwannarak. 685

Understanding Community Health Care Through Problem-Based Learning With Real-Patient Videos: Single-Arm Pre-Post Mixed Methods Study (e68743)
Kiyoshi Shikino, Kazuyo Yamauchi, Nobuyuki Araki, Ikuo Shimizu, Hajime Kasai, Tomoko Tsukamoto, Hiroshi Tajima, Yu Li, Misaki Onodera, Shoichi Ito. 692

Organizational Leaders' Views on Digital Health Competencies in Medical Education: Qualitative Semistructured Interview Study (e64768)
Humairah Zainal, Xin Xiao Hui, Julian Thumboo, Fong Kok Yong. 704

Educational Effectiveness of a 5-Country Virtual Exchange Program for Internationalization in Occupational Therapy Education: Mixed Methods Study (e77564)
Natsuka Suyama, Kaoru Inoue, Norikazu Kobayashi, Anuchart Kaunnil, Supatida Siangchin, Muhammad Sahid, Erayanti Saloko, Sk Moniruzzaman. 718

Exploration and Practice of the First Clinical Medical Postdoctoral Program in China: Retrospective, Nonrandomized, Controlled Study (e65622)
Lingda Zhang, Lianghong Sun, Honglei Li. 737

Comparison of Physician Assistant and Medical Students' Clinical Reasoning Processes Using an Online Patient Simulation Tool to Support Clinical Reasoning (eCREST): Mixed Methods Study (e68981)
Alistair Thorpe, Angelos Kassianos, Ruth Plackett, Vinodh Krishnamurthy, Maria Kambouri, Jessica Sheringham. 745

A Brief Web-Based Person-Centered Care Group Training Program for the Management of Generalized Anxiety Disorder: Feasibility Randomized Controlled Trial in Spain (e50060)
Vanesa Ramos-García, Amado Rivero-Santana, Wenceslao Peñate-Castro, Yolanda Álvarez-Pérez, Andrea Duarte-Díaz, Alezandra Torres-Castaño, María Trujillo-Martín, Ana González-González, Pedro Serrano-Aguilar, Lilisbeth Perestelo-Pérez. 757

Faculty Perceptions on the Roles of Mentoring, Advising, and Coaching in an Anesthesiology Residency Program: Mixed Methods Study (e60255)
Sydney Nykiel-Bailey, Kathryn Burrows, Bianca Szafarowicz, Rachel Moquin. 769

Performance of Plug-In Augmented ChatGPT and Its Ability to Quantify Uncertainty: Simulation Study on the German Medical Board Examination (e58375)
Julian Madrid, Philipp Diehl, Mischa Selig, Bernd Rolauffs, Felix Hans, Hans-Jörg Busch, Tobias Scheef, Leo Benning. 780

Visual Learning in Electrocardiography Training for Medical Residents: Comparative Intervention Study (e73328)
Heng-You Sung, Feng-Ching Liao, Shu-I Lin, Han-En Cheng, Chun-Wei Lee. 793

e-Learning in Phoniatrics and Speech-Language Pathology: Exploratory Analysis of Free Access Tools in Augmentative and Alternative Communication (e63392)
Jessica Büchs, Christiane Neuschaefer-Rube. 800

Evolution of Learning Styles in Surgery Comparing Residents and Teachers: Cross-Sectional Study (e64767)
Gabriela Gouvea Silva, Carlos da Silva Costa, Bruno Cardoso Gonçalves, Luiz Vianney Saldanha Cidrão Nunes, Emerson Roberto dos Santos, Natalia Almeida de Arnaldo Rodriguez Castro, Alba de Abreu Lima, Vânia Sabadoto Brienze, Antônio Oliani, Júlio André. 812

Exploring Connections Between Mental Health, Burnout, and Academic Factors Among Medical Students at an Iranian University: Cross-Sectional Questionnaire Study (e58008)
Elham Faghihzadeh, Ali Eghtesad, Muhammad Fawad, Xiaolin Xu. 820

Barriers to and Facilitators of Implementing Team-Based Extracorporeal Membrane Oxygenation Simulation Study: Exploratory Analysis (e57424)
Joan Brown, Sophia De-Oliveira, Christopher Mitchell, Rachel Cesar, Li Ding, Melissa Fix, Daniel Stemen, Krisda Yacharn, Se Wong, Anahat Dhillon. 831

Game-Based Assessment of Cognitive Abilities and Personality Characteristics for Surgical Resident Selection: A Preliminary Validation Study (e72264)
Noa Gazit, Gilad Ben-Gal, Ron Eliashar. 845

Trends in the Japanese National Medical Licensing Examination: Cross-Sectional Study (e78214)
Yuki Morimoto, Kiyoshi Shikino, Yukihiro Nomura, Shoichi Ito. 859

Evaluation of the Inverted Classroom Approach in a Case-Study Course on Antithrombotic Drug Use in a PharmD Curriculum: French Monocentric Randomized Study (e67419)
Georges Jourdi, Mayssa Selmi, Pascale Gaussem, Jennifer Truchot, Isabelle Margaill, Virginie Siguret. 878

Balancing Academics and Life: Qualitative Study of Health Professions Students' Perceptions of a Four-Day Academic Week in the United Arab Emirates (e67775)
Ashokan Arumugam, Jacqueline Dias, Sangeetha Narasimhan, Raneen Qadah, Reime Shalash, Taif Omran, Bashair Mussa, Basema Saddik, Nadia Al Mazrouei, Sivapriya Ramakrishnan. 891

Evaluating Tailored Learning Experiences in Emergency Residency Training Through a Comparative Analysis of Mobile-Based Programs Versus Paper- and Web-Based Approaches: Feasibility Cross-Sectional Questionnaire Study (e57216)
Hsin-Ling Chen, Chen-Wei Lee, Chia-Wen Chang, Yi-Ching Chiu, Tzu-Yao Hung. 904

Acceptance of AI-Powered Chatbots Among Physiotherapy Students: International Cross-Sectional Study (e76574)
Salwa El-Sobkey, Kerolous Kelini, Mahmoud ElKholy, Tayseer Abdeldayem, Mariam Abdallah, Dina Mohamed, Aya Fawzy, Yomna Ahmed, Ayman El Khatib, Hind Khalid, Balkhis Shaik, Ana Anjos, Mutasim Alharbi, Karim Fathy, Khaled Takey. 916

Paradox of AI in Higher Education: Qualitative Inquiry Into AI Dependency Among Educators in Palestine (e74947)
Anas Alhur, Zuheir Khlaif, Bilal Hamamra, Elham Hussein. 930

Preclinical Medical Students' Perspectives and Experiences With Structured Web-Based English for Medical Purposes Courses: Cross-Sectional Study (e65779)
Radhakrishnan Muthukumar, Isaraporn Thepwongsa, Poompong Sripa, Bangonsri Jindawong, Kamonwan Jenwitheesuk, Surapol Virasiri. . . 9 4 8

Health Workers' Perspectives on Mobile Health Care Learning Stickiness: Mixed Methods Study (e63827)
Sabila Nurwardani, Putu Handayani. 962

Training Gaps in Digital Skills for the Cancer Health Care Workforce Based on Insights From Clinical Professionals, Nonclinical Professionals, and Patients and Caregivers: Qualitative Study (e78490)
David Liñares, Theologia Tsitsi, Noemí López-Rey, Wilfredo Guanipa-Sierra, Susana Aldecoa-Landesa, Carme Carrión, Daniela Cabutto, Deborah Moreno-Alonso, Clara Madrid-Alejos, Andreas Charalambous, Ana Clavería. 983

Impact of Learner Autonomy on the Performance in Voluntary Online Cardiac Auscultation Courses: Prospective Self-Controlled Study (e78363)
Yudong Fang, Ligang Fang, Xue Lin. 999

Student Satisfaction in Social Media–Based Learning Environments: Development, Validation, and Psychometric Evaluation of the CuSAERS (Questionnaire of Satisfaction With Educational Activities Performed on Social Media) (e73805)
Roy La Touche, Álvaro Reina-Varona, Mónica Grande-Alonso, José León-Hernández, Joaquín Pardo-Montero, Néstor Requejo-Salinas, Raúl Ferrer-Peña, Alba Paris-Alemany. 1008

Factors Influencing Educators' Perspectives on Accepting Extended Reality in Health Care Education: Qualitative Study (e65042)
Zuheir Khlaif, Nisreen Salama, Bilal Hamamra, Allam Mousa. 1022

Assessing ChatGPT's Capability as a New Age Standardized Patient: Qualitative Study (e63353)
Joseph Cross, Tarron Kayalackakom, Raymond Robinson, Andrea Vaughans, Roopa Sebastian, Ricardo Hood, Courtney Lewis, Sumanth Devaraju, Prasanna Honnavar, Sheetal Naik, Jillwin Joseph, Nikhilesh Anand, Abdalla Mohammed, Asjah Johnson, Eliran Cohen, Teniola Adeniji, Aisling Nnenna Nnaji, Julia George. 1038

Virtual Reality Simulation for Undergraduate Nursing Students for Care of Patients With Infectious Diseases: Mixed Methods Study (e64780)
Wen Chang, Chun-Chih Lin, Julia Crilly, Hui-Ling Lee, Li-Chin Chen, Chin-Yen Han. 1051

Effectiveness of a 5G Local Area Network–Based Digital Microscopy Interactive System: Quasi-Experimental Design (e70256)
Jie Xu, Jihong Sha, Song Jia, Jiao Li, Lei Xu, Zhihua Shao. 1064

Pass/Fail Versus Tiered Grades and Academic Performance in Undergraduate Medical Education: Crossover Study (e74975)
Boris Modrau, Karina Kirk, Sinan Said, Carsten Bjarkam, Lone Sunde, Jacob Bodilsen, Jakob Dal, Jette Kristensen, Jeppe Emmersen, Mike Astorp, Stig Andersen. . . . 1075

Insights Into History and Trends of Teaching and Learning in Stomatology Education: Bibliometric Analysis (e66322)
Ziang Zou, Linna Guo. . . . 1084

Digital Literacy Training for Digitalization Officers ("Digi-Managers") in Outpatient Medical and Psychotherapeutic Care: Conceptualization and Longitudinal Evaluation of a Certificate Course (e70843)
Anne Mainz, Timo Neunaber, Paula D'Agnese, Alexander Eid, Tanja Galla, Christoph Ellers, Sven Meister. . . . 1099

Mapping the Evolution of China's Traditional Chinese Medicine Education Policies: Insights From a BERTopic-Based Descriptive Study (e72660)
Tao Yang, Fan Yang, Yong Li. . . . 1112

Mono-Professional Simulation-Based Obstetric Training in a Low-Resource Setting: Stepped-Wedge Cluster Randomized Trial (e54911)
Anne van Tetering, Ella de Vries, Peter Ntuyo, E van den Heuvel, Annemarie Fransen, M van der Hout-van der Jagt, Imelda Namagembe, Josaphat Byamugisha, S Oei. . . . 1129

Implementation Outcomes of Reusable Learning Objects in Health Care Education Across Three Malaysian Universities: Evaluation Using the RE-AIM Framework (e63882)
Hooi Lim, Chin Teo, Yew Lee, Ping Lee, Kuhan Krishnan, Zahiruddin Abu Hassan, Phelim Yong, Wei Yap, Renukha Sellappans, Enna Ayub, Nurhanim Hassan, Sazlina Shariff Ghazali, Nurul Nasharuddin, Puteri Jahn Kassim, Faridah Idris, Klas Karlgren, Natalia Stathakarou, Petter Mordt, Stathis Konstantinidis, Michael Taylor, Cherry Poussa, Heather Wharrad, Chirk Ng. . . . 1140

Resident Physician Recognition of Tachypnea in Clinical Simulation Videos in Japan: Cross-Sectional Study (e72640)
Kiyoshi Shikino, Yuji Nishizaki, Sho Fukui, Koshi Kataoka, Daiki Yokokawa, Taro Shimizu, Yu Yamamoto, Kazuya Nagasaki, Hiroyuki Kobayashi, Yasuharu Tokuda. . . . 1155

Awareness and Attitude Toward Artificial Intelligence Among Medical Students and Pathology Trainees: Survey Study (e62669)
Anwar Rjoop, Mohammad Al-Qudah, Raja Alkhasawneh, Nesreen Bataineh, Maram Abdaljaleel, Moayad Rjoub, Mustafa Alkhateeb, Mohammad Abdelraheem, Salem Al-Omari, Omar Bani-Mari, Anas Alkabalan, Saoud Altulaih, Iyad Rjoub, Rula Alshimi. . . . 1166

Reviewing Mobile Apps for Teaching Human Anatomy: Search and Quality Evaluation Study (e64550)
Guadalupe Rivera García, Miriam Cervantes López, Juan Ramírez Vázquez, Arturo Llanes Castillo, Jaime Cruz Casados. . . . 1174

Exploring Gender Perspectives in Medical Education: Latent Semantic Analysis of Israeli First-Year Medical Students' Reflections (e78371)
Rola Khamisy-Farah, Raymond Farah, Haneen Jabaly-Habib, Yara Nakhleh Francis, Nicola Bragazzi. . . . 1192

Enhancing Clinical Competencies Through Peer Role-Play in Oncology Graduate Students: Mixed Methods Study (e79771)
Yao Wang, Feixiang Wang, Gaojie Liu, Yuqing luo, Hongjun Ba, Jie Long. . . . 1210

Effectiveness of a Fully Online Scientific Research Works Peer Support Group Model for Research Capacity Building Through Conducting Systematic Reviews Among Health Care Professionals: Retrospective Cohort Studies (e78862)
Yuki Kataoka, Ryuhei So, Masahiro Banno, Yasushi Tsujimoto, SRWS-PSG Mentors. . . . 1218

Using Electronic Health Data to Deliver an Adaptive Online Learning Solution to Emergency Trainees: Mixed Methods Pilot Study (e65287)
Anna Janssen, Andrew Coggins, James Tadros, Deleana Quinn, Amith Shetty, Tim Shaw. . . . 1231

Engaging Undergraduate Medical Students With Introductory Research Training via an Educational Escape Room: Mixed Methods Evaluation (e71339)
Bastien Le Guellec, Victoria Gauthier, Rémi Lenain, Alexandra Nuytten, Luc Dauchet, Brigitte Bonneau, Erwin Gerard, Claire Castandet, Patrick Truffert, Marc Hazzan, Philippe Amouyel, Raphaël Bentegeac, Aghiles Hamroun. 1250

Gamified Learning in a Virtual World for Undergraduate Emergency Radiology Education: Quasi-Experimental Study (e68518)
Alba Pérez-Baena, Teodoro Rudolphi-Solero, Rocío Lorenzo-Álvarez, Miguel Ruiz-Gómez, Francisco Sendra-Portero. 1270

Integrated e-Learning for Shoulder Anatomy and Clinical Examination Skills in First-Year Medical Students: Randomized Controlled Trial (e62666)
Roland Koch, Lena Gassner, Navina Gerlach, Teresa Festl-Wietek, Bernhard Hirt, Stefanie Joos, Thomas Shiozawa. 1287

E-Learning for Pediatric Emergency Department Staff in Point-of-Care Electroencephalogram Interpretation: Prospective Cohort Study (e69395)
Leopold Simma, Maurice Schneeberger, Stefanie von Felten, Michelle Seiler, Georgia Ramantani, Bigna Bölsterli. 1305

Evaluation and Uptake of an Online ADHD Psychoeducation Training for Primary Care Health Care Professionals: Implementation Study (e59365)
Blandine French, Hannah Wright, David Daley, Elvira Perez Vallejos, Kapil Sayal, Charlotte Hall. 1317

Making Medical Education Courses Visible: Theory-Based Development of a National Database (e62838)
Andi Gashi, Monika Brodmann Maeder, Eva Hennel. 1326

Large Language Models in Biochemistry Education: Comparative Evaluation of Performance (e67244)
Olena Bolgova, Inna Shypilova, Volodymyr Mavrych. 1341

Medical Students' Acceptance of Tailored e–Mental Health Apps to Foster Their Mental Health: Cross-Sectional Study (e58183)
Catharina Grüneberg, Alexander Bäuerle, Sophia Karunakaran, Dogus Darici, Nora Dörrie, Martin Teufel, Sven Benson, Anita Robitzsch. . .
1 3 5 1

Integration of an Audiovisual Learning Resource in a Podiatric Medical Infectious Disease Course: Multiple Cohort Pilot Study (e55206)
Garrik Hoyt, Chandra Bakshi, Paramita Basu. 1362

Performance of ChatGPT-3.5 and ChatGPT-4 in the Taiwan National Pharmacist Licensing Examination: Comparative Evaluation Study (e56850)
Ying-Mei Wang, Hung-Wei Shen, Tzeng-Ji Chen, Shu-Chiung Chiang, Ting-Guan Lin. 1373

Guidelines for Patient-Centered Documentation in the Era of Open Notes: Qualitative Study (e59301)
Anita Vanka, Katherine Johnston, Tom Delbanco, Catherine DesRoches, Annalays Garcia, Liz Salmi, Charlotte Blease. 1383

Implementing the H&P 360 in Three Medical Institutions: Usability Study (e66221)
Rupinder Hayer, Joyce Tang, Julia Bisschops, Gregory Schneider, Kate Kirley, Tamkeen Khan, Erin Rieger, Eric Walford, Irsk Anderson, Valerie Press, Brent Williams. 1395

Comparing the Perceived Realism and Adequacy of Venipuncture Training on an in-House Developed 3D-Printed Arm With a Commercially Available Arm: Randomized, Single-Blind, Cross-Over Study (e71139)
Susan Brouwer de Koning, Amy Hofman, Sonja Gerber, Vera Lagerburg, Michelle van den Boorn. 1408

Resilience Training Web App for National Health Service Keyworkers: Pilot Usability Study (e51101)
Joanna Burrell, Felicity Baker, Matthew Bennion. 1419

Development of a Clinical Clerkship Mentor Using Generative AI and Evaluation of Its Effectiveness in a Medical Student Trial Compared to Student Mentors: 2-Part Comparative Study (e76702)
Hayato Ebihara, Hajime Kasai, Ikuo Shimizu, Kiyoshi Shikino, Hiroshi Tajima, Yasuhiko Kimura, Shoichi Ito. . . . 1426

Evaluating the Performance of DeepSeek-R1 and DeepSeek-V3 Versus OpenAI Models in the Chinese National Medical Licensing Examination: Cross-Sectional Comparative Study (e73469)
Weiping Wang, Yuchen Zhou, Jingxuan Fu, Ke Hu. . . . 1442

Evaluation of a Simulation Program for Providing Telenursing Training to Nursing Students: Cohort Study (e67804)
Ola Ali-Saleh, Layalleh Massalha, Ofra Halperin. . . . 1453

Global Trends in Cadaver Donation and Medical Education Research: Bibliometric Analysis Based on VOSviewer and CiteSpace (e71935)
Xianxian Zhou, Hua Xiong, Yi Wen, Fang Li, Dexi Hu. . . . 1463

Text Message (SMS) Microlearning for Tobacco Use Disorder: Pre-Post Pilot Study of Clinician Confidence (e73821)
Zehra Dhanani, Veena Dronamraju, Jamie Garfield. . . . 1486

Distance Learning During the COVID-19 Lockdown and Self-Assessed Competency Development Among Radiology Residents in China: Cross-Sectional Survey (e54228)
Peicheng Wang, Ziye Wu, Jingfeng Zhang, Yanrong He, Maoqing Jiang, Jianjun Zheng, Zhenchang Wang, Zhenghan Yang, Yanhua Chen, Jiming Zhu. . . . 1493

Comparison of an Emergency Medicine Asynchronous Learning Platform Usage Before and During the COVID-19 Pandemic: Retrospective Analysis Study (e58100)
Blake Briggs, Madhuri Mulekar, Hannah Morales, Iltifat Husain. . . . 1509

Innovative Mobile App (CPD By the Minute) for Continuing Professional Development in Medicine: Multimethods Study (e69443)
Peter Slinger, Maram Omar, Sarah Younus, Rebecca Charow, Michael Baxter, Craig Campbell, Meredith Giuliani, Jesse Goldmacher, Tharshini Jeyakumar, Inaara Karsan, Janet Papadakos, Tina Papadakos, Alexandra Rotstein, May-Sann Yee, Asad Siddiqui, Marcos Restrepo, Melody Zhang, David Wiljer. . . . 1518

Exploring Social Media Use Among Medical Students Applying for Residency Training: Cross-Sectional Survey Study (e59417)
Simi Jandu, Jennifer Carey. . . . 1533

Ethical Use of Social Media and Sharing of Patient Information by Medical Students at a University Hospital in Saudi Arabia: Cross-Sectional Survey (e57812)
Sara Farsi, Alaa Sabbahi, Deyala Sait, Raghad Kabli, Ghaliah Abduljabar. . . . 1543

Instagram as a Tool to Improve Human Histology Learning in Medical Education: Descriptive Study (e55861)
Alejandro Escamilla-Sanchez, Juan López-Villodres, Carmen Alba-Tercedor, María Ortega-Jiménez, Francisca Rius-Díaz, Raquel Sanchez-Varo, Diego Bermúdez. . . . 1553

Virtual Standardized Patients for Improving Clinical Thinking Ability Training in Residents: Randomized Controlled Trial (e73196)
Liyuan Xu, Qinrong Xu, Chunya Liu, Baozhen Chen, Chunxia Wang. . . . 1567

Exploring the Role of Immersive Virtual Reality Simulation in Health Professions Education: Thematic Analysis (e62803)
Jordan Talan, Molly Forster, Leian Joseph, Deepak Pradhan. . . . 1579

Knowledge Mapping and Global Trends in Simulation in Medical Education: Bibliometric and Visual Analysis (e71844)
Hongjun Ba, Lili Zhang, Xiufang He, Shujuan Li. . . . 1591

Global Disparities in Simulation-Based Learning Performance: Serial Cross-Sectional Mixed Methods Study (e52332)
Kashish Malhotra, Harshin Balakrishnan, Emily Warmington, Vina Soran, Francesca Crowe, Dengyi Zhou, SIMBA AND CoMICs Team, Punith Kempegowda. . . . 1601

Health Care Professionals' Knowledge, Attitude, Practice, and Infrastructure Accessibility for e-Learning in Ethiopia: Cross-Sectional Study (e65598)
Sophie Rossner, Muluken Gizaw, Sefonias Getachew, Eyerusalem Getachew, Alemnew Destaw, Sarah Negash, Lena Bauer, Eva Hermann, Abel Shita, Susanne Unverzagt, Pablo Santos, Eva Kantelhardt, Eric Kroeber. . . . 1612

Effectiveness of an Interactive Web-Based Clinical Practice Monitoring System on Enhancing Motivation in Clinical Learning Among Undergraduate Nursing Students: Longitudinal Quasi-Experimental Study in Tanzania (e45912)
Patricia Herman, Stephen M Kibusi, Walter C Millanzi. . . . 1627

Deconstructing Participant Behaviors in Virtual Reality Simulation: Ethnographic Analysis (e65886)
Daniel Loeb, Jamie Shoemaker, Kelly Ely, Matthew Zackoff. . . . 1647

A Virtual Simulator to Improve Weight-Related Communication Skills for Health Care Professionals: Mixed Methods Pre-Post Pilot Feasibility Study (e65949)
Fiona Quigley, Leona Ryan, Raymond Bond, Toni McAloon, Huiru Zheng, Anne Moorhead. . . . 1660

Media-Induced and Psychological Factors That Foster Empathy Through Virtual Reality in Nursing Education: 2×2 Between-Subjects Experimental Study (e59083)
Kuo-Ting Huang, Zexin Ma, Lan Yao. . . . 1672

Case-Based Virtual Reality Simulation for Severe Pelvic Trauma Clinical Skill Training in Medical Students: Design and Pilot Study (e59850)
Peng Teng, Youran Xu, Kaoliang Qian, Ming Lu, Jun Hu. . . . 1683

Extended Reality–Enhanced Mental Health Consultation Training: Quantitative Evaluation Study (e64619)
Katherine Hiley, Zanib Bi-Mohammad, Luke Taylor, Rebecca Burgess-Dawson, Dominic Patterson, Devon Puttick-Whiteman, Christopher Gay, Janette Hiscoe, Chris Munsch, Sally Richardson, Mark Knowles-Lee, Celia Beecham, Neil Ralph, Arunangsu Chatterjee, Ryan Mathew, Faisal Mushtaq. . . . 1700

Exploring the Impact of the COVID-19 Pandemic on Learning Experience, Mental Health, Adaptability, and Resilience Among Health Informatics Master's Students: Focus Group Study (e63708)
Nadia Davoody, Natalia Stathakarou, Cara Swain, Stefano Bonacina. . . . 1718

Feedback From Dental Students Using Two Alternate Coaching Methods: Qualitative Focus Group Study (e68309)
Lulwah Alreshaid, Rana Alkattan. . . . 1741

Alignment Between Classroom Education and Clinical Practice of Root Canal Treatment Among Dental Practitioners in China: Cross-Sectional Study (e65534)
XinYue Ma, JingShi Huang. . . . 1751

Enhancing Preclinical Training for Removable Partial Dentures Through Participatory 3D Simulation: Development and Usability Study (e71743)
Yikchi Siu, Hefei Bai, Jung-Min Yoon, Hongqiang Ye, Yunsong Liu, Yongsheng Zhou. . . . 1763

A Large-Scale Multispecialty Evaluation of Web-Based Simulation in Medical Microbiology Laboratory Education: Randomized Controlled Trial (e72495)
Lei Xu, Xichuan Deng, Tingting Chen, Nan Lu, Yuran Wang, Jia Liu, Yanan Guo, Zeng Tu, Yuxin Nie, Yeganeh Hosseini, Yonglin He. 1776

Open-Access Web-Based Gamification in Pharmacology Education for Medical Students: Quasi-Experimental Study (e73666)
Lujain Aloum, Halah Ibrahim, Senthil Rajasekaran, Eman Alefishat. 1787

Guidelines for Rapport-Building in Telehealth Videoconferencing: Interprofessional e-Delphi Study (e76260)
Paula Koppel, Jennie De Gagne, Michelle Webb, Denise Nepveux, Janelle Bludorn, Aviva Emmons, Paige Randall, Neil Prose. 1809

The Evolution of Medical Student Competencies and Attitudes in Digital Health Between 2016 and 2022: Comparative Cross-Sectional Study (e67423)
Paula Veikkolainen, Timo Tuovinen, Petri Kulmala, Erika Jarva, Jonna Juntunen, Anna-Maria Tuomikoski, Merja Männistö, Teemu Pihlajasalo, Jarmo Reponen. 1827

Refining Established Practices for Research Question Definition to Foster Interdisciplinary Research Skills in a Digital Age: Consensus Study With Nominal Group Technique (e56369)
Jana Sedlakova, Mina Staniki , Felix Gille, Jürgen Bernard, Andrea Horn, Markus Wolf, Christina Haag, Joel Floris, Gabriela Morgenshtern, Gerold Schneider, Aleksandra Zumbrunn Wojczy ska, Corine Mouton Dorey, Dominik Ettlin, Daniel Gero, Thomas Friemel, Ziyuan Lu, Kimon Papadopoulos, Sonja Schläpfer, Ning Wang, Viktor von Wyl. 1841

Global Health care Professionals' Perceptions of Large Language Model Use In Practice: Cross-Sectional Survey Study (e58801)
Ecem Ozkan, Aysun Tekin, Mahmut Ozkan, Daniel Cabrera, Alexander Niven, Yue Dong. 1856

Quantifying Emergency Medicine Residency Learning Curves Using Natural Language Processing: Retrospective Cohort Study (e82326)
Carl Preiksaitis, Joshua Hughes, Rana Kabeer, William Dixon, Christian Rose. 1869

AI-Generated "Slop" in Online Biomedical Science Educational Videos: Mixed Methods Study of Prevalence, Characteristics, and Hazards to Learners and Teachers (e80084)
Eric Jones, Jane Newman, Boyun Kim, Emily Fogle. 1882

Application of AI Communication Training Tools in Medical Undergraduate Education: Mixed Methods Feasibility Study Within a Primary Care Context (e70766)
Chris Jacobs, Hans Johnson, Nina Tan, Kirsty Brownlie, Richard Joiner, Trevor Thompson. 1901

Large Language Models for the National Radiological Technologist Licensure Examination in Japan: Cross-Sectional Comparative Benchmarking and Evaluation of Model-Generated Items Study (e81807)
Toshimune Ito, Toru Ishibashi, Tatsuya Hayashi, Shinya Kojima, Kazumi Sogabe. 1915

Novel Blended Learning on Artificial Intelligence for Medical Students: Qualitative Interview Study (e65220)
Zoe Oftring, Kim Deutsch, Daniel Tolks, Florian Jungmann, Sebastian Kuhn. 1926

Chatbots' Role in Generating Single Best Answer Questions for Undergraduate Medical Student Assessment: Comparative Analysis (e69521)
Enjy Abouzeid, Rita Wassef, Ayesha Jawwad, Patricia Harris. 1942

Role of Artificial Intelligence in Surgical Training by Assessing GPT-4 and GPT-4o on the Japan Surgical Board Examination With Text-Only and Image-Accompanied Questions: Performance Evaluation Study (e69313)
Hiroki Maruyama, Yoshitaka Toyama, Kentaro Takanami, Kei Takase, Takashi Kamei. 1953

Performance Evaluation of 18 Generative AI Models (ChatGPT, Gemini, Claude, and Perplexity) in 2024 Japanese Pharmacist Licensing Examination: Comparative Study (e76925)
Hiroyasu Sato, Katsuhiko Ogasawara, Hidehiko Sakurai. . . . 1963

Perception of Medical Undergraduates on Artificial Intelligence in Medical Education: Qualitative Exploration (e73798)
Thilanka Seneviratne, Kaumudee Kodikara, Isuru Abeykoon, Wathsala Palpola. . . . 1979

Impact of Prompt Engineering on the Performance of ChatGPT Variants Across Different Question Types in Medical Student Examinations: Cross-Sectional Study (e78320)
Ming-Yu Hsieh, Tzu-Ling Wang, Pen-Hua Su, Ming-Chih Chou. . . . 1990

ChatGPT in Medical Education: Bibliometric and Visual Analysis (e72356)
Yuning Zhang, Xiaolu Xie, Qi Xu. . . . 1999

AI's Accuracy in Extracting Learning Experiences From Clinical Practice Logs: Observational Study (e68697)

Abstract

Background: History-taking is crucial in medical training. However, current methods often lack consistent feedback and standardized evaluation and have limited access to standardized patient (SP) resources. Artificial intelligence (AI)–powered simulated patients offer a promising solution; however, challenges such as human-AI consistency, evaluation stability, and transparency remain underexplored in multicase clinical scenarios.

Objective: This study aimed to develop and validate the AI-Powered Medical History-Taking Training and Evaluation System (AMTES), based on DeepSeek-V2.5 (DeepSeek), to assess its stability, human-AI consistency, and transparency in clinical scenarios with varying symptoms and difficulty levels.

Methods: We developed AMTES, a system using multiple strategies to ensure dialog quality and automated assessment. A prospective study with 31 medical students evaluated AMTES's performance across 3 cases of varying complexity: a simple case (cough), a moderate case (frequent urination), and a complex case (abdominal pain). To validate our design, we conducted systematic baseline comparisons to measure the incremental improvements from each level of our design approach and tested the framework's generalizability by implementing it with an alternative large language model (LLM) Qwen-Max (Qwen AI; version 20250409), under a zero-modification condition.

Results: A total of 31 students practiced with our AMTES. During the training, students generated 8606 questions across 93 history-taking sessions. AMTES achieved high dialog accuracy: 98.6% (SD 1.5%) for cough, 99.0% (SD 1.1%) for frequent urination, and 97.9% (SD 2.2%) for abdominal pain, with contextual appropriateness exceeding 99%. The system's automated assessments demonstrated exceptional stability and high human-AI consistency, supported by transparent, evidence-based rationales. Specifically, the coefficients of variation (CV) were low across total scores (0.87% - 1.12%) and item-level scoring (0.55% - 0.73%). Total score consistency was robust, with the intraclass correlation coefficients (ICCs) exceeding 0.923 across all scenarios, showing strong agreement. The item-level consistency was remarkably high, consistently above 95%, even for complex cases like abdominal pain (95.75% consistency). In systematic baseline comparisons, the fully-processed system improved ICCs from 0.414/0.500 to 0.923/0.972 (moderate and complex cases), with all CVs ≤1.2% across the 3 cases. A zero-modification implementation of our evaluation framework with an alternative LLM (Qwen-Max) achieved near-identical performance, with the item-level consistency rates over 94.5% and ICCs exceeding 0.89. Overall, 87% of students found AMTES helpful, and 83% expressed a desire to use it again in the future.

Conclusions: Our data showed that AMTES demonstrates significant educational value through its LLM-based virtual SPs, which successfully provided authentic clinical dialogs with high response accuracy and delivered consistent, transparent educational feedback. Combined with strong user approval, these findings highlight AMTES's potential as a valuable, adaptable, and generalizable tool for medical history-taking training across various educational contexts.

KEYWORDS

large language models; medical history-taking; structured evaluation; evaluation stability; human-AI consistency; evaluation transparency; virtual standardized patient; DeepSeek; Qwen; cross-model generalizability

Introduction

History-taking is fundamental to clinical practice and one of the clinicians' most frequently performed tasks [1]. Although technological advances in assessing patients have proliferated, history-taking remains the most crucial, cost-effective technique [2]. Therefore, enhanced training in medical history-taking is crucial for both improving disease diagnosis accuracy [3-5] and fostering the development of competent physicians [6].

Standardized patients (SPs) effectively teach and evaluate history-taking skills by ensuring structured learning experiences. The training process for SPs is rigorous, time-consuming, and resource-intensive [7,8]. Consequently, the availability of qualified SPs is limited [7]. During SP-based teaching and evaluation, subjective factors are an unavoidable influence [9]. Existing literature suggests SP feedback is highly variable in terms of its content and quality [10,11]. These factors pose a significant challenge to implementing effective one-on-one history-taking training.

The rapid evolution of artificial intelligence (AI) technology, especially with the emergence of large language models (LLMs), has demonstrated significant potential in medical education [12-16]. LLMs can act as virtual standardized patients (VSPs) [12,17-19] and create a human-like conversational experience [12,20]. In addition, the web-based system is accessible at any time, allows repeated practice, and significantly reduces teaching costs. However, feedback is the cornerstone of medical education and is crucial for the continuous learning of trainees [21]. Therefore, a system that only provides interactive practice without structured feedback may fail to meet the instructional needs.

Encouragingly, LLMs can also provide instant feedback. A recent single-case study has shown that an LLM-powered VSP can not only provide accurate interactions but also implement structured evaluations with high human-AI consistency for most assessment items, while identifying a subset of items where further alignment could significantly enhance performance [22]. The inherent scalability and personalization capabilities of LLMs may address the inefficiencies and inconsistencies associated with traditional feedback, holding the promise of democratizing high-quality learning experiences. These findings offer preliminary evidence for applying LLMs to evaluate medical history-taking training.

Despite these promising developments, implementing AI as VSPs presents several challenges and technical limitations, particularly in providing real-time educational feedback [23]. First, while some preliminary studies have explored LLMs in medical history-taking evaluation, there remains a gap in research investigating multiple cases of varying difficulty levels across different clinical scenarios. Specifically, given the diversity of disease types in clinical practice and the variations in content and evaluation standards for history-taking across different diseases, further exploration is required to assess their applicability and effectiveness in a broader range of clinical settings.

Second, LLMs may generate "hallucinations," producing information that appears reasonable but is incorrect [24], leading to different responses to the same query. Even the most advanced models may struggle to handle complex or highly specialized inputs, affecting the accuracy of their outputs. Furthermore, their decision-making process lacks transparency, resulting in users unable to understand the basis on which they draw conclusions, presenting a "black box" problem [25,26]. This black box characteristic raises doubts about their evaluation results. Research shows that the transparency and credibility of evaluation feedback significantly influence learner acceptance, particularly for AI-generated feedback, which requires clear evaluation criteria and frameworks [23].

Moreover, these risks highlight the importance of adding an extra layer of validation, especially for complex teaching tasks that directly affect patient diagnosis and treatment. It is evident that current LLMs cannot yet be solely relied upon in the fields of education and research. Therefore, to identify and prevent these safety risks, developing a systematic assessment system with broad adaptability is particularly important [27]. Consequently, when developing LLM-powered evaluation systems, special attention must be paid to making the evaluation process transparent and standardized. Finally, the stability of LLM-generated evaluations remains to be characterized, which is a critical factor for long-term application in teaching.

To address these gaps, we developed the AI-Powered Medical History-Taking Training and Evaluation System (AMTES). This study describes its development and rigorously evaluates its dialog quality, evaluation stability, human-AI consistency, and transparency across 3 clinical cases of varying complexity. We also validated our design through systematic baseline and cross-model comparisons.

Methods

System Design and Implementation of AMTES

Overview of AMTES

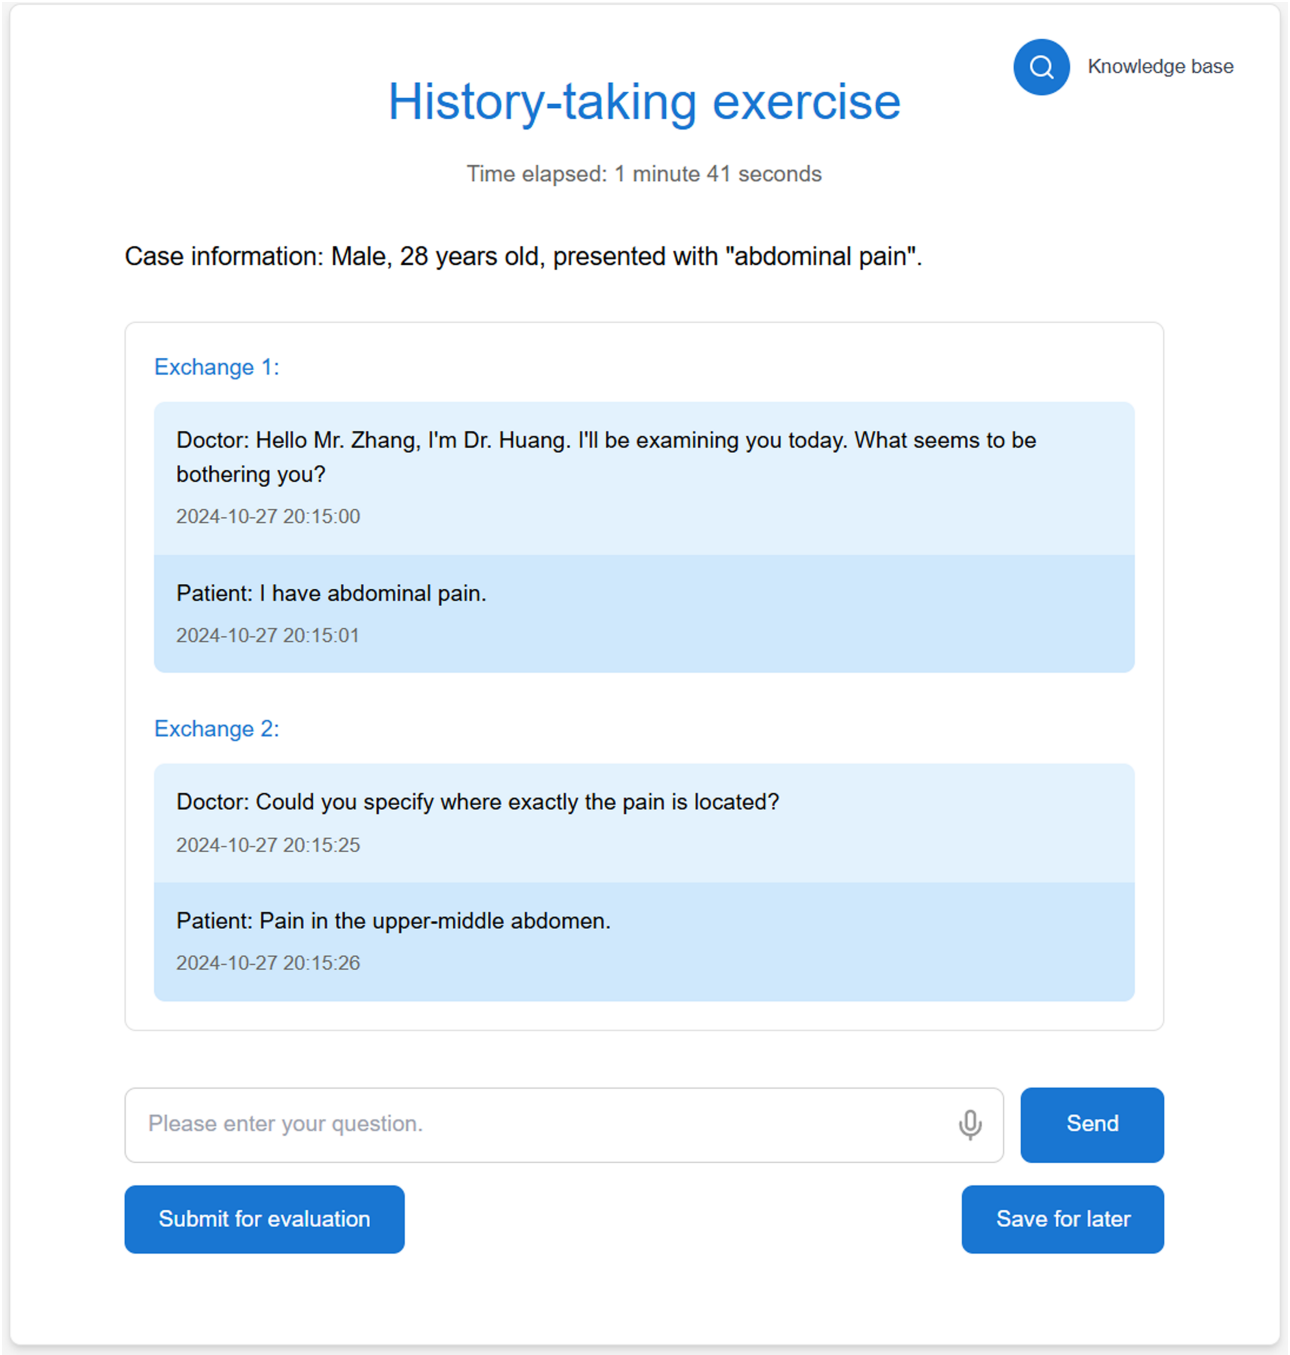
AMTES is a web-based system developed using the ASP.NET framework (Microsoft) with a Browser/Server architecture. The system seamlessly integrates the DeepSeek-V2.5 (DeepSeek) application programming interface (API), a sophisticated Chinese LLM. This model was selected after demonstrating superior performance for our specific medical dialog tasks in preliminary tests against other domestic models available during the study's implementation phase, thereby best fulfilling the project's technical and accessibility requirements. DeepSeek-V2.5 features an advanced architecture with 236 billion parameters and supports an extensive context window of up to 128,000 tokens, enabling robust natural language understanding and complex reasoning capabilities across extended conversations. The AMTES software has been granted

the Computer Software Copyright Registration Certificate by the National Copyright Administration of China (Registration No. 14651073).

System Modules

AMTES consists of two core modules: (1) the conversational Dialog Module (Figure 1), which enables multiround history-taking conversations with a VSP while recording all interactions for evaluation; (2) the Automated Evaluation Feedback Module, which analyzes dialog records using LLM technology to generate structured feedback. These 2 modules constitute the core of the system: simulation (conversational dialog) and assessment (automated evaluation).

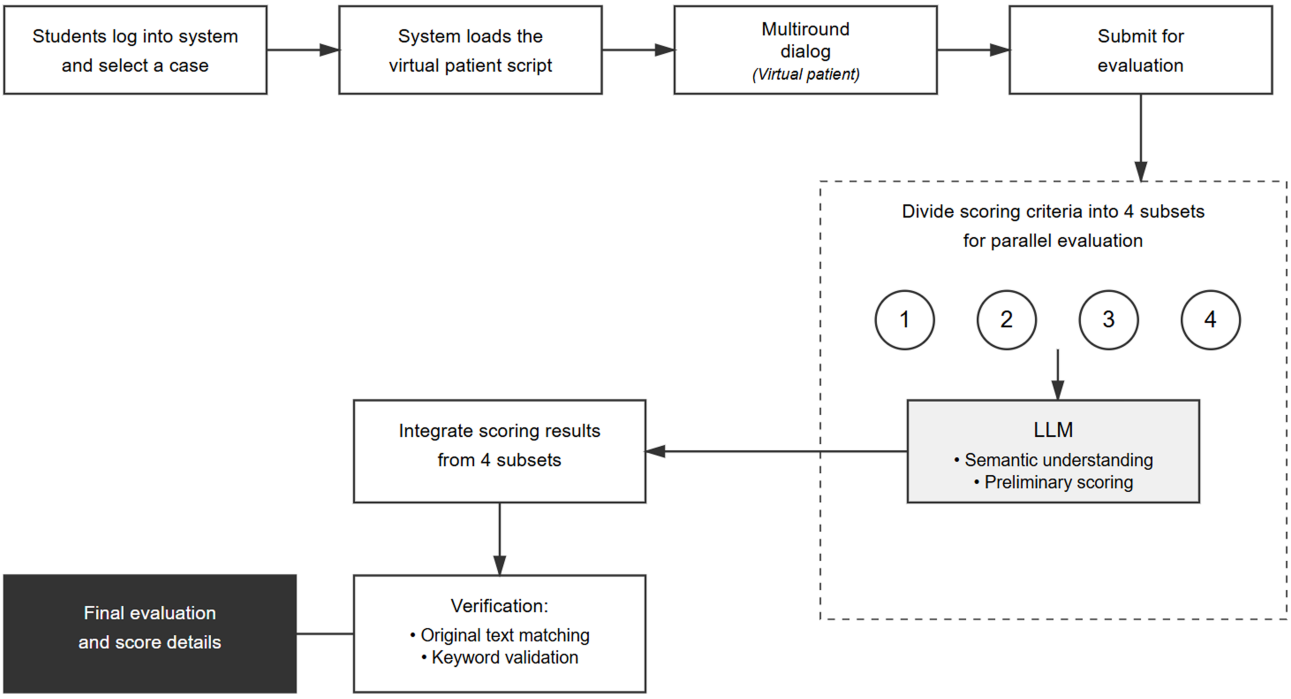
Figure 1. History-taking interface showing the chat environment where students interact with the virtual standardized patient.



System Workflow

The complete system workflow, from student login through final evaluation delivery, is illustrated in Figure 2. A granular, step-by-step description of each stage is provided in Multimedia Appendix 1.

Figure 2. System workflow diagram illustrating the complete medical history-taking training and evaluation process in the Artificial Intelligence–Powered Medical History-Taking Training and Evaluation System. LLM: large language model



System Design Strategies

This subsection elaborates on the underlying principles and innovations guiding AMTES's development.

Framework Objectives and Implementation Strategies

To ensure AMTES meets clinical education requirements, we implemented a comprehensive design framework with specific strategies aimed at achieving system reliability, human-AI consistency, and evaluation transparency (Table 1). System design framework and implementation strategies present this multifaceted framework in a structured format designed to clearly delineate each objective, the strategies used, and their specific implementation methods. These strategies were engineered specifically to address the key LLM challenges of transparency and hallucination identified in the introduction, ensuring the system's reliability and trustworthiness.

Table . System design framework and implementation strategies.

Core objective and strategy	Key methods	Specifications and examples
A. Reliability assurance (ensuring accurate and stable system outputs)		
Minimizing randomness	Lower the temperature parameter of the LLM's[a] API[b]	Dialog: set temperature as 0.05; assessment: set temperature as 0.0
Implementing multilevel verification[c]	1. Original-text matching: verifies whether the LLM-cited dialog exists verbatim in the original dialog 2. Keyword validation: confirms the presence of predefined mandatory keywords within the cited evidence	The specific strategy is in Multimedia Appendix 2
Parallelizing evaluations[d]	Split scoring items into 4 subsets for parallel LLM queries	Benefits: enables evidence-based scoring by circumventing token limits; reduces evaluation time through parallel processing
B. Human-AI Consistency (aligning AI evaluations with expert judgment)		
Decomposition for standardization	Complex scoring items decomposed into smaller, unambiguous sub-items to improve LLM execution accuracy	For example, original: "persistent moderate-to-severe burning abdominal pain"→ 3 sub-items: 1. Pain is burning in nature 2. Pain is moderate to severe 3. Pain is persistent
Disambiguation via guidelines	Detailed evaluation guidelines for contextual differentiation and terminology clarification	For example, context: "initial dull pain" versus "current burning pain"; terminology: "petechiae"=small red hemorrhagic spots
Few-shot examples	Uses in-prompt examples to demonstrate correct scoring	The complete prompt is available in Multimedia Appendix 3
C. Transparency enhancement (making evaluation processes traceable and verifiable)		
Evidence-based scoring[e]	Prompt engineering compels LLM to cite specific dialog text and explain the rationale for transparent decision-making	The complete prompt is available in Multimedia Appendix 3, "Final Output Format" section
Structured feedback	Organizes feedback hierarchically, from overall metrics down to item-level specifics	Hierarchy: overall performance → category analysis → item details → dialog links

[a]LLM: large language model

[b]API: application programming interface

[c]Multilevel verification mechanism (strategy A) represents a key innovation in handling large language model hallucinations through systematic validation protocols. This approach ensures reliability by implementing multiple checkpoints throughout the evaluation process (see Multimedia Appendix 2 for detailed implementation).

[d]Parallel evaluation architecture (strategy A) aims to improve computational efficiency while enabling comprehensive evidence-based scoring within token constraints.

[e]Evidence-based scoring framework ensures full traceability of artificial intelligence decision-making processes through mandatory citation requirements. Every evaluation decision must be supported by explicit dialog evidence.

Strategy Development and Refinement

The design strategies described above were not developed in isolation but emerged through an iterative development process. Over a 2-month period, a multidisciplinary team comprising 4 clinical instructors, 6 medical students, and 2 engineers extensively tested the system with 3 clinical cases. Through this collaborative process, the AMTES system itself, along with the dialog scripts, prompts, scoring standards, and evaluation guidelines, underwent continuous refinement based on practical insights and user feedback. This iterative approach resulted in a comprehensive set of evaluation rules and a well-structured bank of few-shot examples, establishing a solid foundation for the formal validation studies.

Construction of the Clinical Case Bank

Three representative cases were prepared by 5 senior clinical experts, aligned with the national medical licensing examination syllabus. They were chosen as the clinical conditions for the simulation due to their relevance to the material being taught at the time. This alignment ensured that the scenario was both clinically pertinent and integrated with the participants' ongoing coursework in basic sciences and clinical disciplines.

This bank includes 3 cases:

- Case 1: an 18-year-old male presenting with a chief complaint of recurrent cough. (This is a common respiratory system disease, characterized by a short course and typical symptoms. Difficulty: simple.)

- Case 2: a 27-year-old female presenting with a chief complaint of frequent urination. (This case pertains to a common urinary system disease, complicated by patient anxiety and a recurrent history from 6 months previous. Difficulty: moderate.)
- Case 3: a 28-year-old male presenting with a chief complaint of recurrent abdominal pain involving a gastrointestinal system disease. (This case involves a chronic digestive system disease, notable for its recurrent nature and the recent development of complications. Difficulty: complex.)

Each case includes detailed scripts covering the background introduction, patient profile, comprehensive medical history content, and proactively asked questions. The history content comprehensively covers the chief complaint, present illness, past history, personal history, marital history, reproductive history, family history, and, for female patients, menstrual history.

Scoring items were established and points allocated based on the clinical significance and teaching objectives of each medical history segment, with each scoring item clearly corresponding to a single evaluation criterion. The total score is 70 points, with the current medical history accounting for 45 - 50 points. Each scoring item is assigned different scores based on its diagnostic value, ranging from 2 points to 0.5 points. The number of scoring items for the 3 cases was 66 for the cough case, 59 for the frequent urination case, and 67 for the abdominal pain case.

Study Design and Validation Framework

Participants

Between September 2024 and November 2024, 31 third-year medical students (16 females, 15 males) from Shantou University Medical College undergoing diagnostic training were recruited. All participants had received theoretical training on medical history-taking. The inclusion criteria were possession of an electronic device and voluntary participation in the teaching trial. All participants provided informed consent, agreed to the use of their data for research purposes, and were provided with a login account with instructions on using AMTES. No participant was excluded from the final analysis.

Validation Approach

To rigorously evaluate AMTES, we conducted validation in 3 sequential phases, using 3 complementary strategies to comprehensively assess the system's performance, stability, and generalizability. Given the pedagogical imperative to protect students' learning experiences, all participants interacted with the fully processed system. Baseline and generalizability comparisons were conducted retrospectively using stored dialog records, ensuring educational quality while maintaining methodological rigor.

Implementation Phases

Phase 1 (Weeks 1 - 3)

Thrity-one students completed 3 history-taking sessions (cough → frequent urination → abdominal pain) and received immediate feedback from the fully-processed system. Posttraining questionnaires were administered to collect student feedback on system usability.

Phase 2

All 93 dialog records were collected, followed by 9 additional rounds of automated assessment to complete the 10 runs required for the comprehensive performance test. Subsequently, teachers not only manually scored the 93 dialog records based on the rubric but also evaluated the quality of the VSP's conversational dialog responses. The validation work was conducted by 2 senior teachers who were independent of the case development team in order to ensure the reliability of the evaluations.

Phase 3

We rescored the same 93 records to perform 2 main analyses. First, a Systematic Baseline Comparison Test was conducted across 3 versions of system: baseline, core-optimized, and fully processed systems. Second, a Cross-Model Generalizability Test was run using the Qwen-Max (version 20250409) model. Since our participants are native Chinese speakers, all interactions with AMTES were conducted in Chinese. The data and screenshots were then translated into English for presentation.

Validation Strategies Used

The following 3 strategies were used during the implementation phases described above.

Comprehensive Performance Test

The fully processed system was executed 10 times per student record to quantify evaluation stability, human-AI consistency, and transparency.

Systematic Baseline Comparison

To quantify the contribution of our distinct optimization layers, we conducted a baseline comparison. A 3-level approach was necessary because several of our core strategies are technically interdependent and could not be tested in isolation (eg, our evidence-based scoring strategy, which requires extensive dialog citation, is only feasible through parallel subevaluation to avoid exceeding the LLM's token limits; in turn, our final postverification stage actively uses this cited evidence to perform its validation checks). Therefore, we designed the study to compare 3 logically sequenced system versions on identical dialog data, representing distinct stages of optimization.

- Baseline system (minimal prompting): this represents the out-of-the-box performance of the LLM, using only a minimal prompt and sequential processing without any of our custom strategies.
- Core-optimized system (enhanced prompt and parallel processing): this version incorporates our full suite of optimization strategies that are applied during the LLM evaluation process. It includes our entire prompt architecture (eg, structured prompts, few-shot examples, evidence-based scoring; see Multimedia Appendix 3 for the complete integrated prompt) and the parallel subevaluation mechanism, which function as a synergistic whole. This stage is designed to isolate the impact of sophisticated

prompting and system architecture, but it explicitly excludes any postprocessing of the LLM's output.
- Fully processed system (with postprocessing verification): this represents the complete, fully processed AMTES system. It builds directly on core-optimized system by adding the final, critical layer of our multilevel verification mechanisms (ie, original-text matching and keyword validation) to the output generated in the previous stage. Comparing this to the previous system allows us to precisely measure the incremental gain achieved by our postprocessing verification strategies.

Cross-Model Generalizability Test

To assess the robustness and adaptability of our evaluation framework, we implemented the complete AMTES system using Qwen-Max, an alternative LLM, without modifying any prompts, evaluation strategies, or system parameters. This testing aimed to demonstrate that our design approach could generalize across different LLM platforms, which is crucial for educational institutions that may need to adapt to various AI technologies.

Outcome Metrics

To rigorously assess AMTES, we defined the following key outcome metrics and their measurement criteria.

Stability

This evaluates the consistency of AMTES evaluations across 10 repeated assessments. We calculated the coefficient of variation (CV) for total scores and the counts of scoring items where AMTES's evaluation matched human scoring (Human-AMTES Matched Item Counts). CV values ≤10% indicated minimal variation, 10%<CV≤20% indicated moderate variation, and CV >20% indicated significant variation.

Human-AI Consistency

This refers to the degree of agreement between evaluations by human experts and those generated by the AI system (AMTES) for the same student performance. We measured this consistency at 2 levels:

- Total score level: we assessed consistency by examining the intraclass correlation coefficient (ICC) and Pearson *r* between the overall scores assigned by human experts and the AI system, using human scoring as the benchmark. ICC values ≥0.75 were considered indicative of good reliability, and values ≥0.90 were regarded as highly consistent. For Pearson *r*, values of 0.50 - 0.70 were considered moderate, 0.70 - 0.90 indicated strong, and >0.90 indicated very strong.
- Item level: for human-AI consistency in item-level scoring, we quantified it using the following metrics.

$$\text{Mean Difference Items} = |\text{Human Scoring Items} - \text{AI Scoring Items}|$$

$$\text{Item-Level Consistency} = \text{Total Items} - \text{Mean Difference Items} \text{Total Items} \times 100\%$$

Transparency

Transparency was defined qualitatively per report: every scoring item had to (1) include a verbatim dialog citation with its rationale and (2) pass both stages of automated verification (original-text matching and keyword checks).

Statistical Analysis

The study data were analyzed using SPSS 24.0 (SPSS Inc). The Shapiro-Wilk normality test was conducted to examine whether the collected data followed a normal distribution. Values were presented as the mean (SD) for normally distributed data. In terms of dialog quality, the one-way ANOVA was performed to determine differences in the accuracy and appropriateness of AMTES responses across the 3 case scenarios. The CV was calculated to measure the system stability. The consistency at the total score level was assessed using the ICC and Pearson *r*. At the item level, the mean difference items and item-level consistency were calculated to evaluate the average discrepancy. Statistical significance for all tests was set at $P<.05$.

Ethical Considerations

This study received ethical approval from the Ethics Committee of Shantou University Medical College (approval number: SUMC-2024 - 079). All procedures were conducted in accordance with the principles of the Declaration of Helsinki and complied with relevant Chinese laws and institutional ethical standards. Prior to participation, all subjects provided written informed consent. Participants were fully informed of the study's purpose, procedures, and data handling methods and were explicitly told that they could withdraw from the study at any time without penalty. To ensure the privacy and confidentiality of participants, all data were anonymized. Personally identifiable information was removed from the research data, and all files were securely stored in password-protected documents accessible only to the research team. No compensation was provided to the participants for their involvement in this study.

Results

Participant Demographics

There were 16 (52%) females and 15 (48%) males in this study. All participants were enrolled in the same stage of their diagnostics curriculum and had the experience of learning theoretical knowledge but lacked practical experience in simulated patient history-taking. The study achieved a 100% completion rate, with no dropouts, and all participants were included in the final analysis.

Analysis of AMTES's Conversational Dialog Quality

A descriptive analysis was performed on all conversational dialog records between the 31 students and AMTES across 3 clinical case scenarios to assess the quality of AMTES's conversational dialog performance. The students completed a total of 93 history-taking sessions, generating 8606 questions (cough scenario: 2383; frequent urination: 2818; abdominal pain: 3405). The system's response rate was 100%.

The accuracy rates (respond in accordance with the case script) of AMTES's replies were as follows: 98.6% (SD 1.5%) for cough, 99.0% (SD 1.1%) for frequent urination, and 97.9% (SD 2.2%) for abdominal pain. The proportion of contextually appropriate responses from AMTES was consistently high: 99.74% (SD 0.67%) for cough, 99.09% (SD 1.14%) for frequent urination, and 99.36% (SD 1.03%) for abdominal pain.

Despite occasional participant errors, such as spelling mistakes, AMTES demonstrated the ability to accurately interpret and respond to the majority of these questions. Specifically, in the cough scenario, out of 28 erroneous questions, AMTES correctly interpreted and responded to 26; in frequent urination, out of 40 erroneous questions, 32 were correctly handled; and in abdominal pain, 12 out of 15 erroneous questions were correctly addressed by AMTES (Table 2).

Table . Quality analysis of Artificial Intelligence (AI)–Powered Medical History-Taking Training and Evaluation System conversational dialog.

Case	Cough (n=31)	Frequent urination (n=31)	Abdominal pain (n=31)	*P* value
Response accuracy (%)[a], mean (SD)	98.60 (1.5)	99 (1.1)	97.90 (2.2)	.04
Number of questions asked, mean (SD)	76.87 (21.22)	90.9 (21.56)	109.84 (28.83)	<.001
Information appropriateness rate (%)[b], mean (SD)	99.74 (0.67)	99.09 (1.14)	99.36 (1.03)	.03
Number of incorrect student questions, n	28	40	15	—[c]
Number of questions correctly understood and answered by AMTES[d, e], n	26	32	12	—

[a]Response accuracy (%) denotes the proportion of system responses evaluated as entirely correct relative to the total number of valid AI-generated answers in that scenario.

[b]Information appropriateness rate (%) refers to the percentage of system responses deemed relevant and contextually appropriate to the questions asked.

[c]Not available.

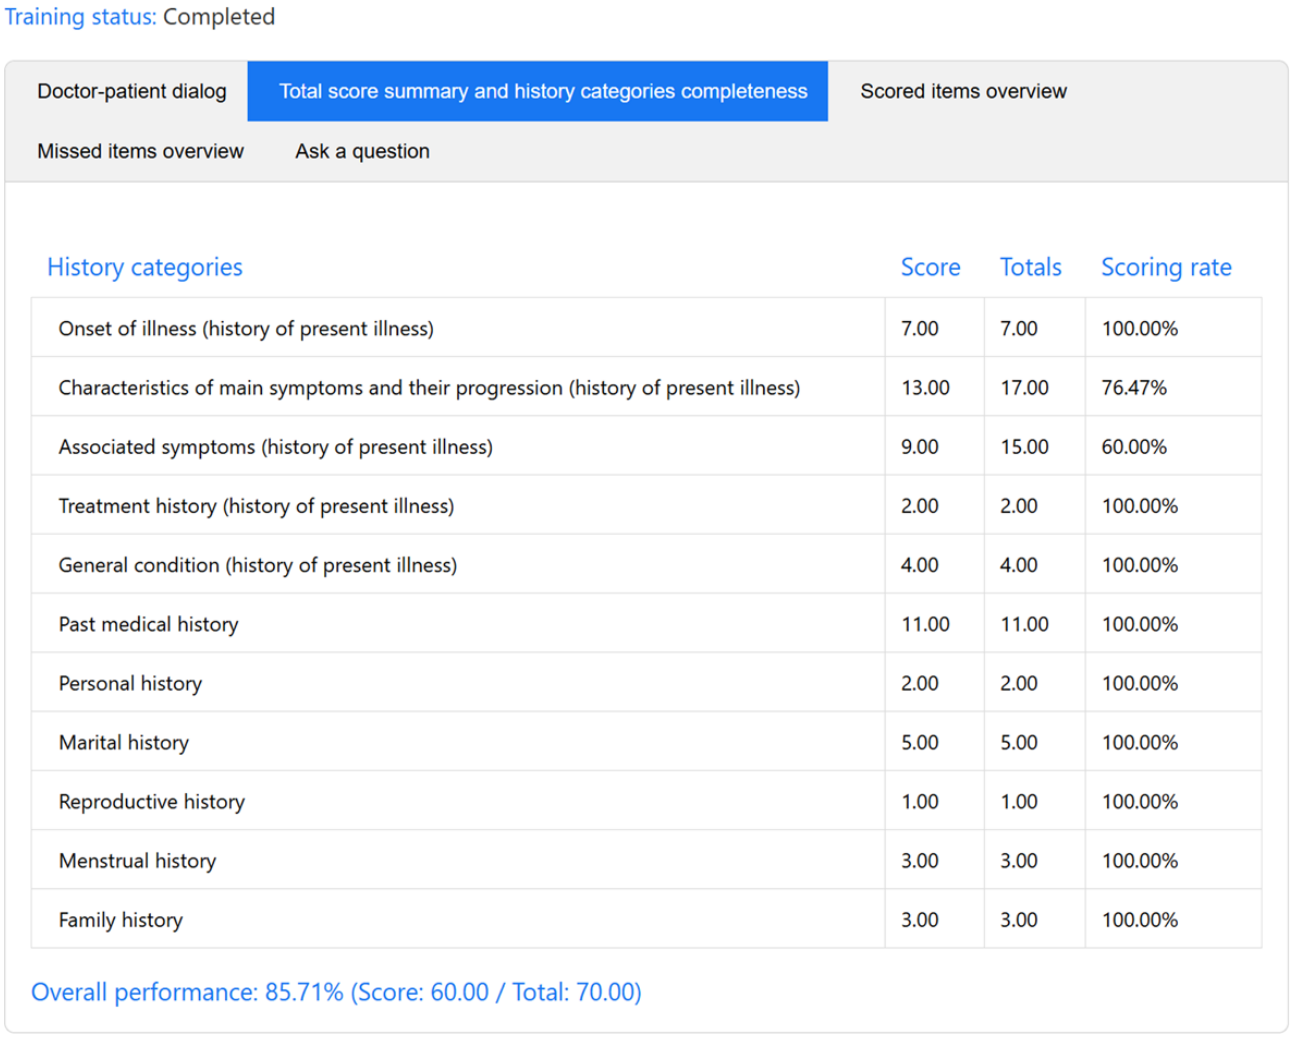
[d]AMTES: Artificial Intelligence–Powered Medical History-Taking Training and Evaluation System.

[e]The number of questions correctly understood and answered by AMTES shows how many of those erroneous questions were still accurately interpreted and properly answered by AMTES.

AMTES Provided Transparent and Structured Evaluation Reports

After automatically evaluating each student's history-taking session, AMTES generated comprehensive feedback reports that included the following components: doctor-patient dialog records, total score per attempt, completeness percentages for each history category, an overview of scored items, and an overview of missed items, thereby comprehensively presenting the evaluation feedback (Figure 3). The history categories included chief complaint, history of present illness, past medical history, personal history, menstrual history, reproductive history, family history, and other relevant sections.

Figure 3. Artificial Intelligence–Powered Medical History-Taking Training and Evaluation System comprehensive feedback report showing the structured evaluation components.



Importantly, across all 93 history-taking records, every feedback report met the predefined transparency criteria. The scoring items displayed specific scoring criteria with clear rationales, containing verbatim dialog citations along with explicit explanations of how the cited text satisfied the corresponding scoring standard (Figure 4). System logs confirmed that all displayed items passed both the original-text matching and keyword checks; items that lacked direct evidence or failed validation were automatically removed and were never shown to students.

Figure 4. Scoring items and rationale display showing how the system justifies scores.

Number	Scoring items	Category	Points earned	Scoring rationale
1	Chief complaint of abdominal pain	Onset of illness (history of present illness)	2	Doctor's question: "Hello Mr. Zhang, I'm Dr. Huang. I'll be examining you today. What seems to be bothering you?" Patient's response: "I have abdominal pain." Scoring rationale: Doctor explicitly inquired about the chief complaint, patient directly reported abdominal pain.
2	Precipitating factor: alcohol consumption at business dinner	Onset of illness (history of present illness)	2	Doctor's question: "Was there anything that might have triggered the abdominal pain a week ago? Patient's response: "I had been drinking heavily at a business dinner." Scoring rationale: Doctor explicitly asked about potential triggers, patient directly identified alcohol consumption.
3	Onset of present abdominal pain was one week ago	Characteristics of main symptoms and their progression (history of present illness)	1	Doctor's question: "When did the pain start?" Patient's answer: "It started a week ago." Scoring rationale: Doctor explicitly asked about onset timing, patient directly specified one week ago.
4	Character of pain described as burning	Characteristics of main symptoms and their progression (history of present illness)	2	Doctor's question: "Can you describe the nature of the pain? For example, is it a burning sensation or a sharp, cutting pain?" Patient's response: "It's a burning pain" Scoring rationale: Doctor explicitly asked about pain character, patient directly identified burning sensation.
5	Pain location in upper-middle abdomen	Characteristics of main symptoms and their progression (history of present illness)	1	Doctor's question: "Could you specify where exactly the pain is located?" Patient's answer: "Pain in the upper-middle abdomen." Patient's response: Doctor explicitly asked about pain location, patient directly specified upper-middle abdomen.
6	Pain intensity moderate to severe, rated 5-6/10	Characteristics of main symptoms and their progression (history of present illness)	2	Doctor's question: Doctor's question: "On a pain scale of 1 to 10, where 10 represents the most severe pain, how would you rate your pain?" Patient's response: "5 to 6" Scoring rationale: Doctor explicitly asked about pain intensity, patient directly rated it as 5-6/10.

Furthermore, AMTES implemented comprehensive logging of the evaluation process, capturing inputs, outputs, scoring results, and error data for each interaction. This logging facilitated subsequent verification, analysis, and system refinement. Therefore, the AMTES assessment process remained fully traceable and interpretable, providing learners with clear and reliable justifications for each awarded point.

AMTES Demonstrates High Stability and Repeatability in Evaluations

The stability and reliability of the system were confirmed by consistently low CVs at multiple levels of analysis. At the total score level, the average CVs were 0.87%, 1.12% and 1.07% for cough, frequent urination, and abdominal pain cases, respectively. At the item level, the CVs were exceptionally low, with averages of 0.55% (cough), 0.73% (frequent urination),

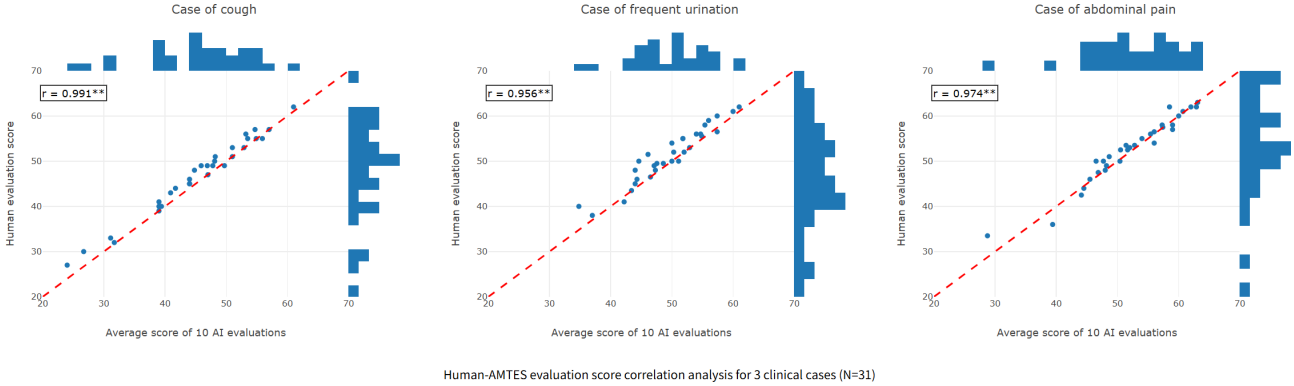
and 0.67% (abdominal pain) using human evaluations as the benchmark. At the specific history category level, the "chief complaint" category notably achieved a CV of 0 in both the cough and abdominal pain cases, indicating perfect consistency. Even the categories with the highest variability, such as "present history," maintained very low CVs (eg, 0.65% and 0.95%). These consistently low CV values across all levels of analysis robustly demonstrate that AMTES provides highly stable and reliable structured evaluations. All detailed CV data, including ranges and category-specific breakdowns, are presented in Multimedia Appendix 4.

Human-AI Consistency in Structured Evaluation

Human-AI Consistency at Total Score Level

Excellent consistency was observed between the total scores assigned by AMTES and human evaluators. The ICC exceeded 0.923 across all 3 clinical scenarios, indicating a high level of agreement between the AI and human experts. This strong positive relationship was further supported by high Pearson *r* (Figure 5). A detailed breakdown of the mean scores, SD, and specific ICC values with 95% CIs for each case is available in Multimedia Appendix 4.

Figure 5. Human-AMTES evaluation score correlation analysis showing strong positive correlations across all 3 cases. AI: artificial intelligence. AMTES: Artificial Intelligence–Powered Medical History-Taking Training and Evaluation System. ***P*<.01.



Human-AI Consistency at Item Level

The primary metric for evaluating human-AI consistency is the item-level consistency, which directly reflects the proportion of scoring items where AMTES and human evaluators agree. This metric provides a more accurate assessment of evaluation quality than total score comparisons, as it avoids the confounding effect where errors in opposite directions might cancel out. Across all 3 cases, not only was the mean difference items less than 3, but the item-level consistency was also remarkably high, exceeding 95% in all scenarios. Even in the most complex abdominal pain case, the system maintained an item-level consistency rate of 95.75%, demonstrating its robustness in nuanced evaluations (Table 3). Overall, AMTES demonstrated high consistency with human evaluations across multiple case scenarios.

Table . Discrepancy and consistency analysis of human-AMTES[a] matched item counts by case groups.

Case	Total items, n	Mean difference items, mean (SD)	Item-level consistency, %
Cough (n=31)	66	1.89 (1.49)	97.13
Frequent urination (n=31)	59	2.06 (1.36)	96.50
Abdominal pain (n=31)	67	2.85 (1.56)	95.75

[a]AMTES: Artificial Intelligence–Powered Medical History-Taking Training and Evaluation System.

Student Questionnaire

All 31 distributed questionnaires were returned (response rate: 100%). The results are displayed in Table 4. When considering whether the AMTES is helpful, a large proportion of students agreed (n=14, 45%) or strongly agreed (12, 39%). A significant portion (n=14, 45%) strongly agreed, and 11 (35%) agreed with the notion that the feedback and evaluation are very valuable. Furthermore, 11 (35%) students agreed and 15 (48%) strongly agreed that they would like to use the AMTES in the future. When asked whether they would like to recommend this AMTES to others, 11 (35%) agreed and 17 (55%) strongly agreed, while only 1 (3%) student disagreed and none strongly disagreed.

Table . Results of student questionnaire feedback.

Item	Students responding (n=31), n (%)				
	Strongly agree	Agree	Neutral	Disagree	Strongly disagree
AMTES[a] is helpful as an additional tool	12 (39)	14 (45)	4 (13)	1 (3)	0 (0)
Feedback and evaluation are very valuable	14 (45)	11 (35)	5 (16)	1 (3)	0 (0)
Would like to use the AMTES in the future	15 (48)	11 (35)	4 (13)	1 (3)	0 (0)
Would like to recommend this AMTES to others	17 (55)	11 (35)	2 (6)	1 (3)	0 (0)

[a]AMTES: Artificial Intelligence–Powered Medical History-Taking Training and Evaluation System.

Baseline Comparison Analysis

The baseline comparison revealed substantial and consistent improvements across multiple dimensions, as detailed in Table 5.

Table . Baseline comparison of system performance across implementation levels and cross-model generalizability test results using Qwen-Max.

Metric and case	Baseline system	Core-optimized system	Fully-processed system	Relative change (%) baseline→fully-processed	LLM[a] backend Qwen-Max	Δ (Qwen - DeepSeek)
CV[b] (%), mean (range)						
Cough (n=31)	2.09 (0 - 8.66)	1.78 (0 - 5.71)	0.87 (0 - 2.78)	−58.3	1.71 (0 - 3.93)	+0.84
Frequent urination (n=31)	1.68 (0 - 8.22)	3.02 (0 - 14.99)	1.12 (0 - 7.64)	−33.3	2.90 (1.10 - 6.05)	+1.78
Abdominal pain (n=31)	0.57 (0 - 4.12)	0.98 (0 - 2.96)	1.07 (0 - 3.78)	+87.7	2.19 (0.63 - 4.91)	+1.12
Mean difference items, mean (SD)						
Cough (n=31)	4.83 (2.28)	4.60 (2.28)	1.89 (1.49)	−60.9	2.24 (1.14)	+0.35
Frequent urination (n=31)	7.92 (2.56)	4.83 (2.86)	2.06 (1.36)	−74.0	2.86 (1.59)	+0.80
Abdominal pain (n=31)	9.44 (3.86)	4.05 (2.17)	2.85 (1.56)	−69.8	3.71 (2.18)	+0.86
Item-level consistency, %						
Cough (n=31)	92.69	93.03	97.13	+4.8	96.60	−0.53
Frequent urination (n=31)	86.58	91.82	96.50	+11.5	95.14	−1.36
Abdominal pain (n=31)	85.92	93.96	95.75	+11.5	94.45	−1.30
ICC[c] (95% CI)						
Cough (n=31)	0.866 (0.785 - 0.942)	0.864 (0.747 - 0.931)	0.978 (0.955 - 0.989)	+12.9	0.970 (0.938 - 0.985)	-0.008
Frequent urination (n=31)	0.414 (0.023 - 0.702)	0.663 (0.445 - 0.815)	0.923 (0.849 - 0.962)	+122.9	0.893 (0.792 - 0.947)	+0.030
Abdominal pain (n=31)	0.500 (0.044 - 0.775)	0.897 (0.803 - 0.948)	0.972 (0.943 - 0.986)	+94.4	0.973 (0.945 - 0.987)	+0.001
Pearson *r*						
Cough (n=31)	0.953	0.944	0.991	+4.0	0.983	−0.008
Frequent urination (n=31)	0.768	0.785	0.956	+24.5	0.969	+0.013
Abdominal pain (n=31)	0.866	0.948	0.974	+12.5	0.973	−0.001

[a]LLM: large language model.

[b]CV: coefficients of variation.

[c]ICC: intraclass correlation coefficient.

Enhanced Evaluation Stability

For the cough case, CV saw a substantial 58.3% reduction, moving from a mean of 2.09% (baseline system) to 0.87% (fully processed system), indicating minimal variation. While frequent urination also showed a 33.3% reduction (1.68% to 1.12%), abdominal pain presented a unique trend, with CV increasing from 0.57% (baseline system) to 1.07% (fully processed system), suggesting increased variability in this most complex scenario despite overall alignment gains.

Significant Improvements in Human-AI Consistency

The optimization process yielded remarkable gains in human-AI alignment across multiple metrics. For detailed data, please refer to Table 5.

Item-Level Consistency

Our optimization efforts yielded significant gains in item-level human-AI consistency. Across all cases, the mean number of discrepant items saw reductions ranging from 60.9% to 74.0%. This was accompanied by a notable rise in the item-level consistency, which climbed from 85.92% - 92.69% (baseline) to a consistently high 95.75% - 97.13% (fully processed system). These improvements consistently showed incremental

gains from the baseline system to core-optimized system and then to the final fully processed system (Table 5).

Total Score-Level Consistency

Total score-level consistency demonstrated even more striking improvements, with both the ICC and Pearson *r* showing significant positive changes.

The ICC values experienced exceptional growth, particularly as case difficulty increased, showcasing the optimization's pronounced effect on alignment in more complex scenarios. For instance, the ICC for frequent urination surged by an impressive 122.9% (from 0.414 to 0.923), transforming from weak to highly consistent. Similarly, abdominal pain saw a 94.4% increase (from 0.500 to 0.972), also achieving high consistency. Even for the cough case, ICC improved by 12.9% (from 0.866 to 0.978), reaching near-perfect consistency. The progressive nature of these gains was clear across all versions of the systems (Table 5).

Correlation strength, as indicated by Pearson *r*, consistently improved across all cases. It moved from a strong correlation for cough (0.953) to nearly perfect (0.991), and from moderate and strong to very strong for frequent urination (0.768 to 0.956) and abdominal pain (0.866 to 0.974). This further confirms a much tighter alignment, with noticeable steps of improvement from each optimization layer (Table 5).

Cross-Model Generalizability Validation

Upon replacing DeepSeek-V2.5 in the AMTES system with Qwen-Max, the item-level consistency remained high (94.45% - 96.60%), confirming its excellent reliability. Notably, in the more challenging abdominal pain case, it demonstrated high human-AI consistency, with a Pearson *r* reaching 0.969. Despite a slight increase in the average number of differing items (18.5% - 38.8% increase, or 0.35 - 0.86 additional items) with Qwen-Max, the absolute difference remained very small, and the item-level consistency rate only saw a minor decrease of 0.53% - 1.36% (Table 5). Therefore, this cross-model validation provides strong evidence supporting the effectiveness of the AMTES system framework.

Discussion

Principal Findings and Methodological Innovations

In this study, we successfully developed the AMTES. Our findings demonstrate that through our comprehensive framework of integrated design strategies, AMTES effectively simulates patient interactions across 3 cases of varying difficulty, providing high-quality dialog and transparent, evidence-based feedback. Critically, its evaluations achieved exceptional stability (mean CV <1.20%) and high human-AI consistency (mean ICC >0.923). This remarkable stability and consistency demonstrate that AMTES holds significant potential as a history-taking training tool in medical education. The use of AMTES as a standardized patient offers a more accessible alternative to traditional human standardized patients, potentially enhancing access to medical training, especially in resource-limited settings. The positive student reception further supports its significant potential as an engaging history-taking training tool.

The key to achieving these robust results lies in our systematic approach, which extends beyond conventional prompt optimization to encompass a multistage strategic framework. Pre-evaluation, we implemented "Decomposition for Standardization" to break down complex tasks and "Disambiguation via Guidelines" to ensure input clarity. During the evaluation, we architected a "Parallelizing Evaluations" mechanism. This architecture segments the scoring task into multiple concurrent sub-queries, which not only circumvents token limit constraints in long-context scenarios but also significantly enhances processing throughput. Post-evaluation, a "Multi-level Verification" mechanism was deployed to cross-reference and validate the preliminary results, ensuring the accuracy and reliability of the final output. It is this organic integration of strategies across the entire workflow that provided the foundation for AMTES's superior performance.

Empirical Performance Results and Comparison With Previous Work

High-quality doctor-patient interaction is crucial in history-taking training. AMTES addresses the need for patient simulation through the integration of a LLM DeepSeek-V2.5. Through rule restrictions and multiple validations, AMTES mitigated the "hallucination" issue commonly associated with LLMs in complex dialogs, as well as the occurrence of unreliable answers stemming from their strong reasoning abilities, as noted in previous studies [12]. Our results show that response accuracy and information appropriateness are highest in the simplest cases among 3 different levels of difficulty, at 98.6% (SD 1.5%) and 99.74% (SD 0.67%). These response accuracy rates are on par with those of ChatGPT-powered systems [22,28]. In addition, our findings thus confirm that LLM-powered systems exhibit high accuracy and completeness, with accuracy slightly lower for higher difficulty compared to lower difficulty. This observation is consistent with findings from other studies [28].

Experimental data demonstrate that the fully processed system exhibits exceptional stability in repeated structured evaluations across 3 distinct cases. The CVs of total scores are low-cough: 0.87% (range 0% - 2.78%); frequent urination: 1.12% (range 0% - 7.64%); abdominal pain: 1.07% (range 0% - 3.78%). Moreover, the system shows low CVs in both item-level scoring and across history categories. Furthermore, AMTES demonstrates high consistency with human evaluations in both total score level and item-level assessments, thereby confirming the system's significant reliability and accuracy. This accuracy surpasses that reported for virtual patient systems in previous studies [29-31] and, in some aspects, exceeds the human-AI consistency of ChatGPT-4.0-driven systems [22].

Optimization Impact and Cross-Model Generalizability

Our baseline comparison analysis provides empirical evidence for the value of systematic optimization in LLM-powered educational tools. The progressive improvements from baseline system to fully processed system, particularly the dramatic enhancements in human-AI consistency for complex cases (ICC

improving from 0.500 to 0.972 for abdominal pain), demonstrate that sophisticated prompt engineering and verification mechanisms can transform unreliable LLM outputs into clinically acceptable evaluations. Most notably, the differential impact across case complexities, with the greatest improvements observed in the most challenging scenarios, suggests that our optimization strategies are particularly valuable for nuanced clinical assessments where raw LLMs struggle most. These findings offer practical guidance for institutions, rather than accepting out-of-the-box LLM performance, investing in comprehensive optimization can yield evaluation tools that approach human-level consistency.

Beyond demonstrating the importance of optimization, our framework also exhibits remarkable cross-model adaptability. Validation experiments with the new large-language model Qwen-Max demonstrated that, without any prompt modifications, our system could still provide transparent, stable, and highly accurate structured evaluations. The success of this experiment challenges the common assumption that LLM-powered systems require extensive customization for each model. This finding indicates that a well-designed evaluation framework can achieve a level of abstraction that transcends specific model architectures, and its cross-model generalizability suggests great potential for medical education applications. Educational institutions often face constraints in technology choices due to institutional policies, regional regulations, or resource limitations. Although our preliminary findings suggest that the evaluation framework may not be entirely dependent on a specific LLM, further validation across diverse platforms is needed to confirm this architectural flexibility. If fully realized, such adaptability could potentially facilitate broader adoption of AI-driven educational tools in varied educational settings. These findings suggest that a one-size-fits-all approach to implementing LLMs in education is suboptimal; instead, investing in a structured, multi-layered optimization and verification framework is critical to unlocking their full potential as reliable assessment tools.

Educational Value and Student Feedback

Evaluation and feedback are critical in clinical education [32], and particularly structured and procedural assessments, which positively impact teaching and student learning [33]. Therefore, through continuous prompt optimization, our fully processed system not only outputs structured scores but also provides detailed rationales for each item-level score by citing specific dialogs from the text, addressing the inherent opacity of scoring reasons in traditional SP programs and existing virtual patient systems. By providing clear evidence for each scoring decision, AMTES helps students understand not only what they missed but also why specific items are important for comprehensive history-taking. This transparency is crucial for building trust in AI-based educational tools and supporting effective learning.

Students who participated in the study provided positive feedback. Among them, 11 (35%) students agreed and 14 (45%) strongly agreed that the system's evaluation function is valuable. 11 (35%) students agreed and 15 (48%) strongly agreed to continue using the AMTES system for history-taking practice. Moreover, the majority of students were willing to recommend the system to their peers. The strong performance of AMTES across 3 cases of different difficulties and disease types, along with positive user feedback, highlights its potential adaptability to a broader range of clinical scenarios. This matches studies showing that AI in health care can help develop communication skills, critical thinking, and clinical reasoning abilities through good interactions and clear feedback [34]. In addition, studies confirm that practice in virtual environments helps improve skills and confidence in real-world clinical encounters [35,36], suggesting that tools like AMTES can optimize educational resources while maintaining educational quality.

AMTES Positioning and Application Prospects

Specifically, AMTES breaks through traditional training resource limitations and accessibility barriers by offering 24/7 learning support, personalized learning experiences, and tailored-structured feedback independent of standardized patient availability. This continuous accessibility and tailored response capability are key strengths of LLMs in medical education [37], potentially supporting student learning efficiency and skill acquisition. AMTES represents a significant advancement in history-taking education, but it is designed to complement rather than replace traditional standardized patient (SP) training. Given the focus of AMTES on evaluating the completeness of history-taking, it is evident that AMTES excels at providing continuous availability for early-stage skill development, allowing students to practice at their own pace and receive consistent, item-level feedback throughout their learning journey. However, the system currently lacks the ability to simulate nonverbal communication (such as facial expressions and body language) and cannot provide emotional understanding and ethical guidance in its feedback - elements which are unique strengths of human SP interactions. While LLMs demonstrate decision-making capabilities, their potential as a replacement for evidence-based professional teaching remains to be fully explored [37]. Therefore, the successful integration of LLMs in medical education feedback, as exemplified by AMTES, is unlikely to lead to the complete replacement of human educators; instead, it may facilitate a redistribution of human effort to areas where it's most impactful [38].

Limitations and Future Prospects

We acknowledge that this study has several limitations, which, in turn, provide clear directions for our future research.

First, from a methodological perspective, a key limitation is the retrospective nature of our baseline comparisons. This was a deliberate ethical choice, grounded in the pedagogical imperative to protect the student learning experience. Exposing learners to a potentially unoptimized baseline system risked undermining their motivation and trust, so we prioritized providing all participants with the most reliable and educationally beneficial version of the system. However, we acknowledge this precludes a direct, prospective comparison of learning outcomes between the different system versions. Future research could use a randomized controlled trial design to provide more definitive evidence on the educational impact of each optimization layer.

Second, the current system's inability to simulate or interpret nonverbal communication (eg, facial expressions and body

language) represents a significant shortcoming in achieving the full fidelity of patient-physician interactions. Maintaining a warm and friendly communication style and expressing empathy are particularly crucial for establishing effective doctor-patient relationships. Empathy, as a core competency in doctor-patient interactions [39], has proven highly effective in improving patient satisfaction, treatment outcomes [40], and generating positive health care results [41,42]. To address this gap, future work will focus on integrating cutting-edge multimodal technologies, such as virtual reality (VR), augmented reality (AR), and expressive speech synthesis, to create a more holistic and immersive simulation environment.

Finally, the scope of our validation needs to be broadened. The current evaluation was conducted not only with a limited sample size but was also confined to 2 prominent Chinese LLMs (DeepSeek and Qwen). To comprehensively establish the generalizability of our framework, a crucial future endeavor will be 2-fold: first, to expand our validation dataset with more diverse cases from multiple institutions; and second, to apply our framework to leading international models (eg, the GPT series [OpenAI], Claude [Anthropic]) and evaluate it in different linguistic contexts, such as English.

By systematically addressing these limitations, we are confident that the system has the potential to evolve into a more robust and comprehensive next-generation tool for medical education.

Conclusion

AMTES, built on a framework of transparent and verifiable evaluation, achieves high stability and human-AI consistency. To our knowledge, this is the first study to systematically evaluate an LLM-powered history-taking evaluation system across multiple disease scenarios while providing empirical validation of design strategies through baseline comparisons and demonstrating cross-model generalizability. By providing students with consistent, evidence-based feedback, AMTES is positioned as a valuable complementary tool in medical education, though further validation in diverse settings would strengthen these conclusions.

Data Availability

The datasets generated or analyzed during this study are available from the corresponding author on reasonable request.

Authors' Contributions

WZ was responsible for the conceptualization and project administration of the study, in addition to developing the software system and contributing to formal analysis. YL handled the development of the research methodology, conducted the investigation, performed data analysis, and prepared the original manuscript draft. CS contributed to the methodology, supervised the research team, managed the project, and secured funding. HT focused on developing the analytical methodology, performed formal statistical analysis, and was responsible for data visualization. LW contributed to the conceptualization and design of the study, also assisting with project management. XL and XC contributed to the conceptual framework and study design. YZ was responsible for data curation and contributed to the data analysis. YL and CS contributed equally to this work and are co-first authors; HT and WZ contributed equally to this work and are co-corresponding authors.

Abstract

Background: The medical interview remains a cornerstone of clinical training. There is growing interest in applying generative artificial intelligence (AI) in medical education, including medical interview training. However, its utility in culturally and linguistically specific contexts, including Japanese, remains underexplored. This study investigated the utility of generative AI for Japanese medical interview training.

Objective: This pilot study aimed to evaluate the utility of generative AI as a tool for medical interview training by comparing its performance with that of traditional face-to-face training methods using a simulated patient.

Methods: We conducted a randomized crossover pilot study involving 20 postgraduate year 1‐2 physicians from a university hospital. Participants were randomly allocated into 2 groups. Group A began with an AI-based station on a case involving abdominal pain, followed by a traditional station with a standardized patient presenting chest pain. Group B followed the reverse order, starting with the traditional station for abdominal pain and subsequently within the AI-based station for the chest pain scenario. In the AI-based stations, participants interacted with a GPT-configured platform that simulated patient behaviors. GPTs are customizable versions of ChatGPT adapted for specific purposes. The traditional stations involved face-to-face interviews with a simulated patient. Both groups used identical, standardized case scenarios to ensure uniformity. Two independent evaluators, blinded to the study conditions, assessed participants' performances using 6 defined metrics: patient care and communication, history taking, physical examination, accuracy and clarity of transcription, clinical reasoning, and patient management. A 6-point Likert scale was used for scoring. The discrepancy between the evaluators was resolved through discussion. To ensure cultural and linguistic authenticity, all interviews and evaluations were conducted in Japanese.

Results: AI-based stations scored lower across most categories, particularly in patient care and communication, than traditional stations (4.48 vs 4.95; *P*=.009). However, AI-based stations demonstrated comparable performance in clinical reasoning, with a nonsignificant difference (4.43 vs 4.85; *P*=.10).

Conclusions: The comparable performance of generative AI in clinical reasoning highlights its potential as a complementary tool in medical interview training. One of its main advantages lies in enabling self-learning, allowing trainees to independently practice interviews without the need for simulated patients. Nonetheless, the lower scores in patient care and communication underline the importance of maintaining traditional methods that capture the nuances of human interaction. These findings support the adoption of hybrid training models that combine generative AI with conventional approaches to enhance the overall effectiveness of medical interview training in Japan.

artificial intelligence; generative artificial intelligence; medical interview training; mock patient; simulation education

Introduction

Medical Interview Training

Medical interview training is an essential part of medical education, significantly influencing clinical competence, patient satisfaction, and treatment outcomes [1-5]. Effective medical interviewing skills are crucial not only for accurate diagnosis but also for establishing trust and rapport among health care professionals, patients, and their families [6-11]. For example, several studies revealed that proper diagnoses can often be made based mainly on an effective medical interview rather than investigations [12,13]. These findings highlighted the pivotal role of communication skills in clinical practice.

Barriers to Medical Interview Training

Despite its importance, medical interview training often faces several barriers [14]. For instance, traditional training methods typically involve simulated patient interactions, which are resource-intensive, requiring substantial time commitments from both medical trainees and educators [15]. While simulation training can provide valuable experiential learning [16-18], its scalability is often limited by resource and financial constraints [19-22]. Consequently, medical students and junior physicians may not receive sufficient opportunities for comprehensive and repeated practice, limiting their development of essential communication and clinical reasoning skills [23,24].

Potential of Artificial Intelligence for Medical Interview Training

In response to these challenges, artificial intelligence (AI) has emerged as a promising tool in medical education [25-28]. Until recent breakthroughs, AI performance remained inadequate due to technical limitations [29]. However, the current development of suitable technologies, including Compute Unified Device Architecture and advanced graphics processing units, has remarkably enhanced AI capabilities [30-33]. AI-driven platforms offer scalable, consistent, and flexible training experiences that allow trainees to practice extensively [34]. These tools have the potential to bridge gaps in access to traditional training by enabling frequent, independent practice [35,36].

Potential of Generative AI for Medical Interview Training

Generative AI, a subset of AI that generates human-like responses and interactions [37,38], presents exciting potential for medical interview training [39,40]. It often incorporates natural language processing and large language models, which enable it to generate and respond to human dialogue in contextually appropriate ways [41,42]. Unlike traditional training methods, generative AI can simulate diverse and complex patient scenarios, providing interactive, responsive, and personalized feedback [43]. This capability not only enhances clinical reasoning but also facilitates self-learning, allowing students to practice repeatedly at their convenience [44-46].

Prior Work

Recent studies have explored the application of generative AI in medical interview training, particularly in the context of Objective Structured Clinical Examinations (OSCEs). For example, research in Japan reported that GPT-4 (legacy) based stations outperformed traditional stations for medical students [47]. However, direct comparison with previous work is limited by differences in AI versions, participant populations, clinical cases, and study designs. Further, earlier studies found that previous versions of GPT occasionally generated implausible responses [48,49]. Additionally, the comparative performance between ChatGPT-4 (legacy) and human physicians in conducting medical interviews revealed comparable aggregate scores across 5 components on the 5-Likert scale (15/25 vs 15/25; $P<.28$) [50].

Research Gap and Aim of the Study

Despite these advances, there is still a lack of research evaluating the utility of generative AI tools in Japanese clinical contexts. Cultural and linguistic nuances, including Japanese, play a significant role in effective communication [51-53]. However, there is a lack of enough research evaluating the effectiveness and adaptability of generative AI tools within the Japanese clinical context. To the best of our knowledge, there is limited research regarding the effectiveness and applicability of generative AI-driven training tools for Japanese medical trainees [47]. Therefore, this study aimed to evaluate the utility and limitations of generative AI by comparing AI-driven medical interview scenarios with traditional mock patient interactions among postgraduate physicians in Japan.

Methods

Setting

This pilot study was conducted in the Department of Diagnostic and Generalist Medicine (general internal medicine [GIM]) at Dokkyo Medical University, Tochigi, Japan.

To minimize variability in participants' medical interview skills, a randomized crossover design was used [54]. All interviews and evaluations were conducted in Japanese to preserve cultural and linguistic integrity. The study consisted of 3 main components: participant recruitment, medical interview implementation, and interview evaluation. This study adhered to the CONSORT-EHEALTH (Consolidated Standards of Reporting Trials of Electronic and Mobile Health Applications and Online Telehealth) guidelines (the CONSORT-EHEALTH checklist is provided in Checklist 1).

Ethical Considerations

Ethics approval was obtained from the Institutional Review Board at Dokkyo Medical University Hospital (number R-79 - 14J). The research adhered strictly to the Helsinki Declaration guidelines to ensure ethical conduct in human participant research.

Participant Inclusion

Participants included postgraduate year 1 - 2 physicians rotating through the GIM department at Dokkyo Medical University

Hospital between April 2024 and January 2025. All eligible physicians during this period were invited to participate. Exclusion criteria included hearing loss or unwillingness to attend the research. Before enrollment, all participants received detailed explanations regarding the study's objectives, procedures, and confidentiality protocols from researchers. Written informed consent was obtained from each participant.

Medical Interview

Overview

Participants were randomly allocated into 2 groups through block randomization to ensure an equal group size [55]. The random allocation sequence was generated by an independent researcher (KM) using Microsoft Excel. This ensured balanced distribution and minimized potential confounding from individual differences.

Each participant completed 2 types of medical interview stations—an AI-based station using the GPTs platform and a traditional station with face-to-face interviews with a trained actor simulating the patient (simulated patient). The 2 stations covered separate clinical cases: abdominal pain and chest pain. In the AI-based stations, participants typed their questions and responses into a laptop computer to interact with the GPTs platform. In the traditional stations, participants engaged in spoken conversation with a simulated patient to conduct the medical interview.

Participants in Group A started with the AI-based interview on abdominal pain, followed by the traditional interview on chest pain. Group B began with the traditional interview on abdominal pain and proceeded to the AI-based interview on chest pain.

Station Structure

Both the AI-based and traditional stations followed an identical structure based on The OSCE [56]. Initially, participants reviewed the simulated patient's basic information for 1 minute. The medical interview, including questions relevant to physical examination, was conducted over 15 minutes. Physical examinations were not actually performed in either station due to maintaining consistency with the text-based interaction in the AI-based station. Following the medical interview, participants had 6 minutes to formulate an assessment and plan. Brief feedback and learning points were then provided for several minutes, after which the participants moved to the next station.

GPTs Setting

GPTs are custom versions of ChatGPT that we can adjust for a specific purpose without programming [57]. In this study, the systems were configured to simulate a patient based on detailed case information provided in Japanese. Importantly, the GPTs were not trained or fine-tuned in the Japanese medical language. The systems did not provide a final diagnosis, even if participants asked. Furthermore, if a participant inputted medical jargon [58], GPTs responded with queries such as "What is XXX?" to simulate realistic patient confusion. Additional configuration with translation in English details is provided in Multimedia Appendix 1.

Simulated Patient

The traditional simulated patient interviews were conducted by researcher TH, who was trained to ensure consistency in responses and demeanor. This approach was chosen because the researcher serves not only as a trained actor simulating symptoms but also as an educator providing brief feedback to the participants at the end of each session. Identical clinical scenarios were used across both groups, based on a widely used and standardized textbook for medical interview training [59].

Evaluation for Medical Interview

Traditional stations were video-recorded and transcribed. AI-based stations used the saved text logs. For consistency in evaluation, the transcriptions were refined to match the same structures between stations. For example, headers labeled as "GPTs" in the AI-based stations were changed to "Patient." Self-introduction parts were removed. The corresponding text files were also anonymized. Sample transcript with translation in English is available in Multimedia Appendix 2.

Two experienced physicians, MK and TSa, independently evaluated the transcripts. The evaluators did not take part in the previous participant recruitment and medical interview implementation. Evaluators used a structured scoring system using a 6-point Likert scale, where 1 is inferior and 6 is excellent. Assessments were based on six key domains: (1) patient care and communication skills, (2) thoroughness of history-taking, (3) physical examination proficiency, (4) accuracy and clarity of transcription, (5) clinical reasoning capability, and (6) overall patient management strategies. The discrepancy was resolved through discussion. Evaluators were blinded to interview methods and participant identity. They assessed transcripts in random order. The scoring system is also based on The OSCE [56,60].

Statistical Analysis

Outcome

The primary outcomes were the comparison of mean scores between AI-based and traditional stations for the whole and each assessment component. The secondary outcome measures involved comparisons within each clinical case, abdominal pain, and chest pain, by interview style.

Data Collection

Baseline characteristics data were collected, including years since obtaining a degree in medicine and sex. All medical interviews were also recorded to ensure accurate transcription: traditional stations were video-recorded, and AI-based stations preserved the conversation logs as text.

Analysis

For both primary and secondary outcomes, scores on the 6-point Likert scale were presented as mean with 95% CIs. To assess the appropriateness of statistical tests, the normality of the paired score differences between AI-based and traditional stations was checked using the Shapiro-Wilk test [61]. As the score differences were not normally distributed, the Mann-Whitney *U* test was used as the primary method for comparing paired outcomes between the 2 stations. A *P* value <.05 was considered

statistically significant. For reference, the 95% CIs are provided to supplement the *P* values (Multimedia Appendix 3 contains detailed normality test results and detailed mean difference).

Continuous variable related to participant characteristics is presented as medians and IQRs and compared using the Mann-Whitney *U* test. The categorical variable was compared using the Fisher exact test. All statistical analyses were conducted using R (version 4.2.2; The R Foundation for Statistical Computing) for MacOS X.

Results

Participants Characteristics

A total of 20 postgraduate physicians were enrolled (Figure 1). Among them, 11 (56%) physicians were first year after graduation, while 9 (45%) physicians were in their second year. Two (10%) female participants were included. There were no statistical differences in participant characteristics between group A and group B, as shown in Table 1.

Figure 1. The flow chart includes participants and allocating the groups.

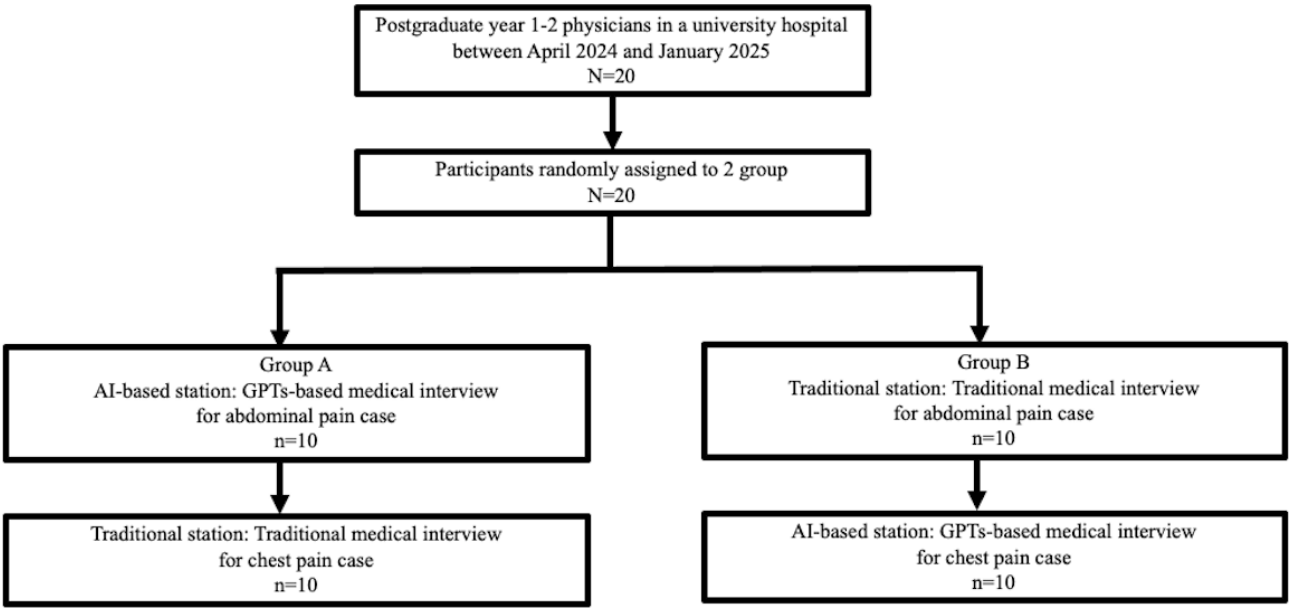

Table . Participants' characteristics.

Variable	Group A (N=10)	Group B (N=10)	*P* value
Female, n (%)	0 (0)	2 (20)	.47[a]
Years after graduation (years), median (IQR)	1.5 (1.0)	1.0 (1.0)	.69[b]

[a]Fisher exact test.

[b]Mann-Whitney *U* test.

Evaluation Outcomes

Performance scores were compared between the AI-based and traditional stations across overall and 6 assessment domains, as shown in Table 2. Overall, the total score was 4.89 in the AI-based stations compared with 5.47 in the traditional stations (*P*<.001).

Table . Performance scores were compared between the artificial intelligence–based and traditional stations across overall and 6 assessment domains.

Scoring system with a 6-point Likert scale	Artificial intelligence–based (GPTs) stations (N=20[a]), 95% CI	Traditional stations (N=20[a]), 95% CI	*P* value[b]
Overall	4.89 (4.74 - 5.04)	5.47 (5.35 - 5.58)	<.001
Patient care and communication	5.05 (4.73 - 5.37)	5.45 (5.06 - 5.84)	.04
History taking	4.90 (4.69 - 5.11)	5.30 (4.96 - 5.65)	.04
Physical examination	5.10 (4.73 - 5.47)	5.80 (5.61 - 5.99)	.001
Accuracy and clarity of transcription	4.70 (4.36 - 5.05)	5.40 (5.16 - 5.64)	.002
Clinical reasoning	4.75 (4.23 - 5.27)	5.30 (4.96 - 5.64)	.13
Management	4.85 (4.34 - 5.36)	5.55 (5.31 - 5.79)	.02

[a]Crossover participants with 10 chest paincasese and 10 abdominal paincasese.

[b]Mann-Whitney *U* test.

AI-based stations yielded slightly lower scores in patient care and communication (mean score: 5.05 vs 5.45; *P*=.04). Scores in other domains such as history taking (4.90 vs 5.30; *P*=.04), physical examination (5.10 vs 5.80*; P*=.001), accuracy and clarity of transcription (4.70 vs 5.40; *P*=.002), and management (4.85 vs 5.55; *P*=.02) also trended lower for the AI-based stations. In contrast, the domain of clinical reasoning showed no significant difference between AI-based and traditional stations (4.75 vs 5.30; *P*=.13).

Subgroup Analysis

Overview

Subgroup analyses were performed to compare the AI-based and traditional stations for each clinical case individually. The initial case presented to participants was abdominal pain, followed sequentially by a chest pain case.

Abdominal Pain Cases

For the abdominal pain case, as shown in Table 3, the overall score was significantly lower in the AI-based stations compared with the traditional stations (4.70 vs 5.48; *P*<.001). Notably, scores for clinical reasoning (4.30 vs 5.50; *P*=.01) and accuracy and clarity of the transcript (4.40 vs 5.40; *P*=.009) were significantly lower in the AI-based stations. While other domains such as patient care and communication (5.00 vs 5.60; *P*=.06), physical examination (5.20 vs 5.80; *P*=.06), and management (4.60 vs 5.50; *P*=.07) were lower in the AI-based stations than the traditional stations, these did not reach statistical significance.

Table . Subgroup analysis for abdominal pain cases compared the artificial intelligence-based and traditional stations across overall and 6 assessment domains.

Scoring system with a 6-point Likert scale	Artificial intelligence-based (GPTs) stations (N=10), 95% CI	Traditional stations (N=10), 95% CI	*P* value[a]
Overall	4.70 (4.47 - 4.93)	5.48 (5.31 - 5.66)	<.001
Patient care and communication	5.00 (4.52 - 5.48)	5.50 (4.80 - 6.20)	.06
History taking	4.70 (4.35 - 5.05)	5.20 (4.54 - 5.86)	.17
Physical examination	5.20 (4.64 - 5.76)	5.80 (5.50 - 6.10)	.06
Accuracy and clarity of transcription	4.40 (3.78 - 5.00)	5.40 (5.03 - 5.77)	.009
Clinical reasoning	4.30 (3.54 - 5.06)	5.50 (5.12 - 5.88)	.01
Management	4.60 (3.70 - 5.50)	5.50 (5.12 - 5.88)	.07

[a]Mann-Whitney *U* test.

Chest Pain Cases

In the case of chest pain, as shown in Table 4, the AI-based stations scored slightly lower in overall scores compared with those in the traditional stations (5.08 vs 5.45; *P*=.004). Physical examination skills were also significantly lower in the AI-based stations (5.00 vs 5.80; *P*=.009). Other domains, including patient care and communication (5.10 vs 5.40; *P*=.37), history taking (5.10 vs 5.40; *P*=.14), and transcription clarity (5.00 vs 5.40; *P*=.09), demonstrated trends in favor of the traditional stations but did not reach significance. Clinical reasoning scores were comparable between the 2 stations (5.10 vs 5.20; *P*=.72), indicating consistent reasoning performance regardless of the interview modality.

Table . Subgroup analysis for chest pain cases compared the artificial intelligence–based and traditional stations across overall and 6 assessment domains.

Scoring system with a 6-point Likert scale	Artificial intelligence-based (GPTs) stations (N=10), 95% CI	Traditional stations (N=10), 95% CI	*P* value[a]
Overall	5.08 (4.90 - 5.27)	5.45 (5.29 - 5.61)	.004
Patient care and communication	5.10 (4.57 - 5.63)	5.40 (4.90 - 5.90)	.37
History taking	5.10 (4.87 - 5.33)	5.40 (5.03 - 5.77)	.14
Physical examination	5.00 (4.42 - 5.58)	5.80 (5.50 - 6.10)	.009
Accuracy and clarity of transcription	5.00 (4.66 - 5.34)	5.40 (5.03 - 5.77)	.09
Clinical reasoning	5.20 (4.46 - 5.94)	5.10 (4.47 - 5.73)	.72
Management	5.10 (4.47 - 5.73)	5.60 (5.23 - 5.97)	.20

[a]Mann-Whitney *U* test.

Discussion

Principal Findings

This study evaluated the utility of generative AI in medical interview training compared with traditional simulated patient interactions among postgraduate physicians in Japan. The principal findings indicate that while AI-based stations provide alternative training methods, they generally yield lower performance scores across several critical domains, including patient care and communication, thoroughness of history-taking, physical examination proficiency, accuracy and clarity of transcription, and management. Participants may have found it difficult to express empathy or engage in natural conversation through typed exchanges [62], limiting the development of interpersonal skills in the GPT stations. While generative AI demonstrates the potential for medical interview training, our findings suggest that it is best suited as a supplementary tool rather than a replacement for traditional simulated patient interactions. The lower performance observed in domains dependent on human interaction—such as communication and patient care—highlights current limitations in AI's ability to simulate empathy and nonverbal cues. Traditional stations, facilitated by trained actors or simulated patients, remain essential for developing advanced interpersonal and communication skills.

A key methodological aspect of this study was configuring the GPT instance to realistically simulate Japanese patient interactions. The GPTs were set up to operate entirely in Japanese, with patient cases, and presented in culturally appropriate language. To enhance authenticity, the system was instructed to respond using typical expressions. Furthermore, the GPTs were directed to avoid using medical terminology.

Despite the limitations in interpersonal skill development, domains such as clinical reasoning remained comparable between GPTs and traditional stations. This finding reinforces the potential of AI-based stations in supporting cognitive aspects of clinical assessment. This result highlights the enduring value of traditional stations, where human dynamics and emotional responsiveness can be authentically practiced and assessed.

Subgroup analyses further demonstrated these differences across specific clinical scenarios. In the abdominal pain case, AI-based stations scored significantly lower in overall performance, clinical reasoning, and transcription clarity. Although other domains like patient care and physical examination were also lower, they did not reach statistical significance. For the chest pain case, while the overall scores were also lower in the GPT stations, the difference was narrower, with physical examination skills showing the most significant disparity. Interestingly, a sub-analysis of abdominal pain cases revealed a significantly lower clinical reasoning score in the AI-based station. This disparity may be attributed to differences in case complexity or the broader differential diagnoses associated with abdominal presentations. In particular, abdominal pain may demand a nuanced interpretation of information [63], suggesting that the limited interactivity of the AI-based format may have constrained diagnostic reasoning. This finding, which was not apparent in the overall analysis, provides an important supplementary insight. It highlights the need to account for case-specific characteristics when selecting cases or designing AI-driven educational tools [64].

Limitations

Several limitations must be acknowledged. First, this study was designed as a feasibility and exploratory trial and was not fully powered or intended for formal hypothesis testing. The small sample size (n=20) and limited number of stations constrain the generalizability of the findings. The primary goal was to assess the feasibility and gather preliminary data to inform future larger-scale studies. Second, the study only included postgraduate physicians from a single institution, potentially restricting the diversity and representativeness of the findings. Results may not be directly applicable to undergraduate medical students, other health care professionals, or participants from different institutions or backgrounds. Third, the mode of interaction differed between AI, typed input, and traditional stations, spoken conversation, which may have inherently biased communication-related scores. Furthermore, physical examinations were not really performed in either station to unify the format for the text-based interaction in the AI-based station, which could have influenced how this domain was assessed. Fourth, the blinded evaluators may have been able to discern the interview modality indirectly, potentially introducing bias. Fifth, it should also be noted that there was some difference in difficulty between the abdominal pain and chest pain cases.

This discrepancy arose because it is inherently challenging to create cases of identical complexity based on different primary concerns. Such differences in case difficulty may have influenced performance results and should be considered when interpreting subgroup analyses. Finally, the study was conducted in a single language using only one generative AI platform, GPTs, limiting its applicability to other languages, cultural contexts, and AI technologies.

Comparison With Prior Work

The current findings expand upon the existing literature. Previous research on OSCEs in Japan found that GPT-4 (legacy) based stations outperformed traditional stations of medical students, with significantly higher total scores across 5 components of a 6-point Likert scale (28.1/31, vs 27.1/31; *P*=.01) [47]. Several differences between the previous study and the current findings limit direct comparison. These include variations in the AI versions used (GPT-4 legacy vs GPTs), participant demographics (medical students vs physicians), cases, and study design (nonrandomized vs randomized crossover).

In relation to the quality of simulated patient responses, previous research on GPT-3.5 and GPT-4 (legacy) indicated implausible response rates of 2% (14/842) and 0.7% (13/1894), respectively [48,49]. In this study using the latest GPTs, responses were almost entirely plausible, with only one instance where GPTs prematurely revealed full physical exam results. This highlights rare but relevant issues in prompt sensitivity.

These findings are particularly promising for resource-limited settings or educational scenarios where access to trained professionals for mock interviews is constrained [65]. However, caution remains warranted in extrapolating these outcomes to real-world clinical environments.

Future Direction

To expand the utility of generative AI in medical interview training, future research should aim for broader validation across diverse educational settings, languages, and digital technology platforms. Improvements in multimodal AI and the integration of voice-based interactions may enhance the realism and interpersonal aspects of AI simulations [66]. Multimodal AI processes and understands information from different types of data, including text, images, audio, video, and sometimes even sensor data [67]. Future investigations should also explore the longitudinal impacts of repeated practice with AI-driven tools to better evaluate the long-term benefits [68]. Additionally, studies comparing hybrid models—such as AI-assisted interviews followed by human debriefing—may offer insights into how best to combine the strengths of both methods [69,70].

Conclusions

This study provides important proof-of-concept evidence for the use of generative AI, specifically GPTs, as a tool in medical interview training among postgraduate physicians. While the AI-based (GPT) station underperformed compared with traditional stations across several domains, including patient care and communication, the performance in clinical reasoning was comparable. These results suggested that generative AI could serve as a supplemental tool for medical education in cognitive components of clinical assessment.

The practical implications for medical education are important. Generative AI can enable self-directed, scalable, and accessible medical interview practice. However, the current findings also reinforce the value of human interaction in developing nuanced communication and empathy. Therefore, the adoption of hybrid educational models may be particularly effective. This approach is the unique strength of combining AI and human educators in simulation-based learning environments.

Nevertheless, these conclusions are preliminary. The small sample size, single-institution setting, and limited number of clinical cases restrict the generalizability of our findings. The crossover design, differences in case complexity, modality of interaction (typed vs spoken), and the use of a single AI language model and language all further limit broad application. These feasibility findings warrant cautious interpretation and highlight the need for larger, multicenter, and longitudinal studies to establish comparative effectiveness and assess the long-term educational impact of AI-assisted training.

Future research should explore the integration of multimodal AI systems to enhance the realism and authenticity of patient simulations. Additionally, multiple institutional collaborations, broader participant demographics, and studies in other languages and contexts are needed to determine the true potential and limitations of AI in medical education.

Acknowledgments

This study was made possible using the resources from the Department of Diagnostic and Generalist Medicine, Dokkyo Medical University.

Authors' Contributions

TH, MY, TSa, YH, KT, KM, and TSh contributed to the study's conceptualization and design. TH served as a simulated patient, and MY was responsible for participant allocation using block randomization. MK and TSa independently evaluated the interview transcripts. TH conducted the statistical analyses and drafted the manuscript. YH, KT, and TSh provided critical revisions to the manuscript for intellectual content. All authors reviewed and approved the final version of the manuscript.

Abstract

Background: In recent years, large language models (LLMs) have shown a remarkable ability to generate human-like text. One potential application of this capability is using LLMs to simulate clients in a mental health context. This research presents the development and evaluation of Client101, a web conversational platform featuring LLM-driven chatbots designed to simulate mental health clients.

Objective: We aim to develop and test a web-based conversational psychotherapy training tool designed to closely resemble clients with mental health issues.

Methods: We used GPT-4 and prompt engineering techniques to develop chatbots that simulate realistic client conversations. Two chatbots were created based on clinical vignette cases: one representing a person with depression and the other, a person with generalized anxiety disorder. A total of 16 mental health professionals were instructed to conduct single sessions with the chatbots using a cognitive behavioral therapy framework; a total of 15 sessions with the anxiety chatbot and 14 with the depression chatbot were completed. After each session, participants completed a 19-question survey assessing the chatbot's ability to simulate the mental health condition and its potential as a training tool. Additionally, we used the LIWC (Linguistic Inquiry and Word Count) tool to analyze the psycholinguistic features of the chatbot conversations related to anxiety and depression. These features were compared to those in a set of webchat psychotherapy sessions with human clients—42 sessions related to anxiety and 47 related to depression—using an independent samples *t* test.

Results: Participants' survey responses were predominantly positive regarding the chatbots' realism and portrayal of mental health conditions. For instance, 93% (14/15) considered that the chatbot provided a coherent and convincing narrative typical of someone with an anxiety condition. The statistical analysis of LIWC psycholinguistic features revealed significant differences between chatbot and human therapy transcripts for 3 of 8 anxiety-related features: negations (t_{56}=4.03, P=.001), family (t_{56}=–8.62, P=.001), and negative emotions (t_{56}=–3.91, P=.002). The remaining 5 features—sadness, personal pronouns, present focus, social, and anger—did not show significant differences. For depression-related features, 4 of 9 showed significant differences: negative emotions (t_{60}=–3.84, P=.003), feeling (t_{60}=–6.40, P<.001), health (t_{60}=–4.13, P=.001), and illness (t_{60}=–5.52, P<.001). The other 5 features—sadness, anxiety, mental, first-person pronouns, and discrepancy—did not show statistically significant differences.

Conclusions: This research underscores both the strengths and limitations of using GPT-4-powered chatbots as tools for psychotherapy training. Participant feedback suggests that the chatbots effectively portray mental health conditions and are generally perceived as valuable training aids. However, differences in specific psycholinguistic features suggest targeted areas for enhancement, helping refine Client101's effectiveness as a tool for training mental health professionals.

KEYWORDS

medical education; mental health; chatbots; psychotherapy training; virtual client

Introduction

Background

Psychotherapy training requires a comprehensive approach, encompassing practical skill development through supervised sessions with clients or peer role-playing, along with the analysis and discussion of therapy sessions from experienced psychologists [1]. Optimal psychotherapy training ideally needs abundant practice opportunities coupled with immediate performance-based feedback [2]. However, both training methods, working with clients or using role-play, present significant challenges. The use of clients raises ethical concerns regarding patient welfare, particularly when inexperienced psychotherapists provide treatment, which can result in risks to

vulnerable individuals receiving suboptimal care. However, role-play scenarios, while more controlled, are resource-intensive. They face challenges such as finding suitable peers for role-playing and ensuring a consistent learning experience due to varying skill levels among participants.

The integration of natural language processing (NLP) in the field of mental health training offers potential solutions to challenges in client availability. Chatbots leveraging large language models (LLMs) can simulate human dialogue and offer a structured framework for task-oriented interactions [3]. Their evolving conversational abilities allow them to actively engage in dialogues, making them a promising educational tool in fields such as health care and medical education [4]. The use of chatbots as virtual patients in mental health training holds significant potential. Through prompt engineering techniques, chatbots can be configured to simulate diverse mental health conditions and behaviors. This capability makes them valuable assets for psychotherapy training in a controlled environment, thereby mitigating the risks associated with using real clients for training purposes. Additionally, chatbots offer the advantage of being readily accessible platforms for simulated therapeutic interactions at any time.

In this study, we present Client101, a web-based conversational platform that uses LLMs as chatbots to simulate the behavior of mental health clients. We used 2 distinct prompt configurations to generate 2 types of virtual clients: one simulating the experience of depression and the other representing individuals coping with generalized anxiety disorder (GAD). A total of 16 individuals with a background in psychotherapy (ie, clinical psychologists and qualified counselors) used the platform to evaluate it. The participant therapists were tasked with conducting single sessions with each of the 2 chatbots before completing a questionnaire. While no specific instructions were given, it was suggested to the participants that they use something like a single-session integrated cognitive behavioral therapy (SSI-CBT) approach [5].

Furthermore, we used the LIWC-22 (Linguistic Inquiry Word Count) software to measure psycholinguistic features of the sessions. This enabled us to examine whether the chatbots used linguistic indicators commonly associated with depression and GAD. Additionally, we conducted a comparative analysis between the psycholinguistic features of the sessions conducted with the virtual clients and those from single webchat therapy sessions typical of an online Australian mental health support service.

Study Aim

This study pursued 2 primary objectives. First, it aimed to assess psychotherapists' perceptions of the chatbot's ability to simulate client characteristics during sessions, using the questionnaire completed by the therapists. Second, it sought to assess the degree of divergence between synthetic and organic psychotherapy transcripts by identifying any statistically significant differences in specific psycholinguistic indicators. These 2 aims guided our investigation of the following research questions: (1) How well does Client101 simulate the language of psychotherapy clients? (2) How effective is Client101 as an educational tool for training therapists? and (3) What are Client101's limitations, and how can they be addressed?

Thus, our main contributions in this paper are as follows: (1) we built Client101, a web-based conversational platform that uses LLMs as chatbots to simulate the behavior of mental health clients; (2) we present a prompt engineering methodology to generate and evaluate counseling transcripts for simulated psychotherapy client interactions; (3) we performed a psycholinguistic analysis comparing depression and anxiety dimensions between therapy transcripts obtained from an online counseling service and therapy sessions using Client101; and (4) we present results from a preliminary questionnaire that gathered the perceptions and feedback of participant therapists via a set of Likert and open-ended items.

Related Work

Conversational Agents for Mental Health

The connection between chatbots and psychology can be traced to the creation of ELIZA, developed by computer scientist Weizenbaum [6] in the mid-1960s. The ELIZA system used reassembly and decomposition rules to act as a Rogerian psychotherapist (ie, based on the approach of humanistic psychology pioneer Carl Rogers). However, ELIZA was not intended to be a therapy chatbot. Rather, Weizenbaum developed ELIZA to explore interactions between humans and chatbots and to ultimately demonstrate what he saw as the superficiality of such interactions. It is in recent years, partly due to advances in NLP and partly due to the rise of digital mental health, that we have seen the emergence of conversational agents as mental health interventions [3].

Contrary to the prevalence of chatbots that serve as virtual therapists, there is scant lineage of chatbots that instead simulate an individual with mental health issues. In 1972, psychiatrist Colby et al [7] developed PARRY, a chatbot that simulated a person with paranoid schizophrenia. However, PARRY was not intended to serve as a therapy training tool. Rather, its purpose was to model and understand the thought processes and verbal expressions of paranoia, aiming to aid in psychiatric research and study. Since PARRY, little work has been done on the idea of developing chatbots to simulate individuals with mental health issues, particularly for training purposes.

ELIZA, PARRY, and many of the currently available chatbots that rely on predefined rules undermine their potential for therapeutic services by operating through simplistic pattern-matching mechanisms [8]. These systems generate responses by rigidly mapping user inputs to predetermined templates, which result in repetitive, noncontextual interactions that fail to capture the nuanced, dynamic nature of human communication [9]. Unlike humans who can intuitively interpret emotional subtexts, recognize implicit meanings, and respond with genuine empathy, these chatbots provide surface-level, algorithmic outputs that lack the depth, adaptability, and emotional intelligence critical for meaningful dialogue [9]. More recent NLP models, such as recurrent neural networks with long short-term memory (LSTM), generate text by learning from a large corpus of examples rather than relying on hand-crafted rules [10]. Tanana et al [2] developed ClientBot, a web-based

system that uses machine-based feedback for training counseling skills. The underlying NLP component of ClientBot was an LSTM recurrent neural network model trained on 2 distinct datasets. The first dataset consisted of a vast collection of movie and TV show subtitles, encompassing 1689 bitexts and totaling 2.6 billion sentences across 60 languages [11]. The second dataset included psychotherapy transcripts published by Alexander Street Press [12]. Since ClientBot was trained on a corpus of movie transcripts, its responses were sometimes contextually incoherent and often lacked the depth and length typical of a client in a psychotherapy session. As observed by Zhang et al [13], the lack of coherency and consistency in conversational agents results in an unsatisfying overall experience for human users.

Conversational agents struggle to keep an engaging conversation due to a lack of consistent personality [11] and the absence of an explicit long-term memory [10]. To address this issue, Zhang et al [13] developed the dataset "persona-chat dataset," a collection of 164,356 written utterances between crowd workers who were asked to communicate with each other while playing the part of a specific persona. While training LSTM models with this dataset enhances engagement during conversations between humans and chatbots, it was not designed to address the challenge of simulating a realistic mental health client.

Transformer-based generative models leverage self-attention mechanisms to capture long-range dependencies and contextual relationships, allowing them to produce coherent responses [14]. As a result, these models have been used as chatbots for educational applications, including medical training via simulated patient interactions [15]. Efficient prompt engineering, the process of iterating a generative artificial intelligence (AI) prompt to improve its effectiveness, plays a crucial role in creating a conversational agent that accurately mimics a patient. In the study by Stapleton et al [16], prompts were designed for GPT-3.5 Turbo to simulate a patient experiencing suicidal ideation. To achieve realistic conversations, their prompts built a persona detailing the patient's age, past experiences, and intrusive thoughts. When designing the prompts, the authors did not rely on licensed psychologists or psychiatrists, but instead they used the lived experiences of suicidal people as a reference. However, Demasi et al [17] stress the importance of engaging specialized users, such as mental health professionals, in system development and evaluation to achieve successful results. Hence, to achieve engaging and realistic conversations that accurately mimic mental health patients, we collaborated with mental health professionals in designing the prompts and incorporated a memory system into the chatbot to ensure cohesive and consistent interactions over long conversations.

Psycholinguistic Features

A crucial limitation of previous conversational agents for mental health is the lack of validation and grounding in psychological theory for the outputs they generate. Although NLP models have demonstrated remarkable performance in text generation, their effectiveness in mental health applications remains uncertain due to insufficient grounding in psychological theory [18]. To address this gap, our research involved evaluating the quality of the model-generated responses with the assistance of licensed psychologists. Additionally, we used the LIWC-22 [19], a tool designed to assess various psychosocial constructs within text, to evaluate if psycholinguistic features associated with depression and anxiety were present in the sessions generated by the chatbots. A statistical analysis was conducted to observe if there is a statistically significant difference between the psycholinguistic features of the Client101 simulated sessions and single webchat therapy sessions.

LIWC text analysis software has been used to identify linguistic markers of depression and anxiety. Eichstaedt et al [20] used language from Facebook posts of consenting individuals to predict depression recorded in electronic medical records, specifically major depression (*ICD* [*International Classification of Diseases*] codes 296.2) and depressive disorder (*ICD* codes 311). Using different linguistic markers, they could identify depressed patients with fair accuracy: area under the curve=0.69, approximately matching the accuracy of screening surveys benchmarked against medical records. The LIWC negative emotions, feel, sadness, anxiety, health, illness, mental, first-person singular, and discrepancy dictionaries were significantly associated with future depression status. LIWC psycholinguistic features have also shown promising results for remote screening of GAD. Rook et al [21] used linguistic features to predict clinically validated behavioral measures for GAD and self-reported sensitivity in behavioral avoidance or inhibition and behavioral approach. Significant positive correlations were found between scores from the GAD-7 measure and the following LIWC categories: negations, sadness, personal pronouns, present focus, social processes, family, negative emotions, and anger.

Methods

Client101 Platform

The Client101 platform was built using the Django framework and is hosted on an Amazon Web Services EC2 T2 Medium instance (2 vCPUs, 4 GiB RAM) running Ubuntu, with 32 GB of storage. The platform features 2 chatbots that users can engage with to simulate psychotherapy sessions. Each chatbot is tailored to mimic a client with a distinct mental health issue: one represents a person experiencing depression, while the other portrays someone struggling with anxiety. Once a chatbot is selected, psychologists can commence the therapy session using a standard chat interface, akin to those used for online messaging platforms. Alongside the chat interface, there is a text field available to enter any session notes, which can be used for reference and feedback. Additionally, there is a numerical field provided to rate the chatbot's session quality. The session transcript, along with a summary of the session, is stored in a database. If the therapist wishes to pause and then resume the session, the platform can retrieve the session and restart it from where the therapist left off. All session records are stored in an SQLite relational database on the Amazon Web Services instance. Refer to Figure 1 for an example of the user interface. Figure 2 presents excerpts from simulated therapy sessions between a user and chatbots programmed to simulate patients with anxiety (Alice) and depression (Luke).

Figure 1. Client101 user interface.

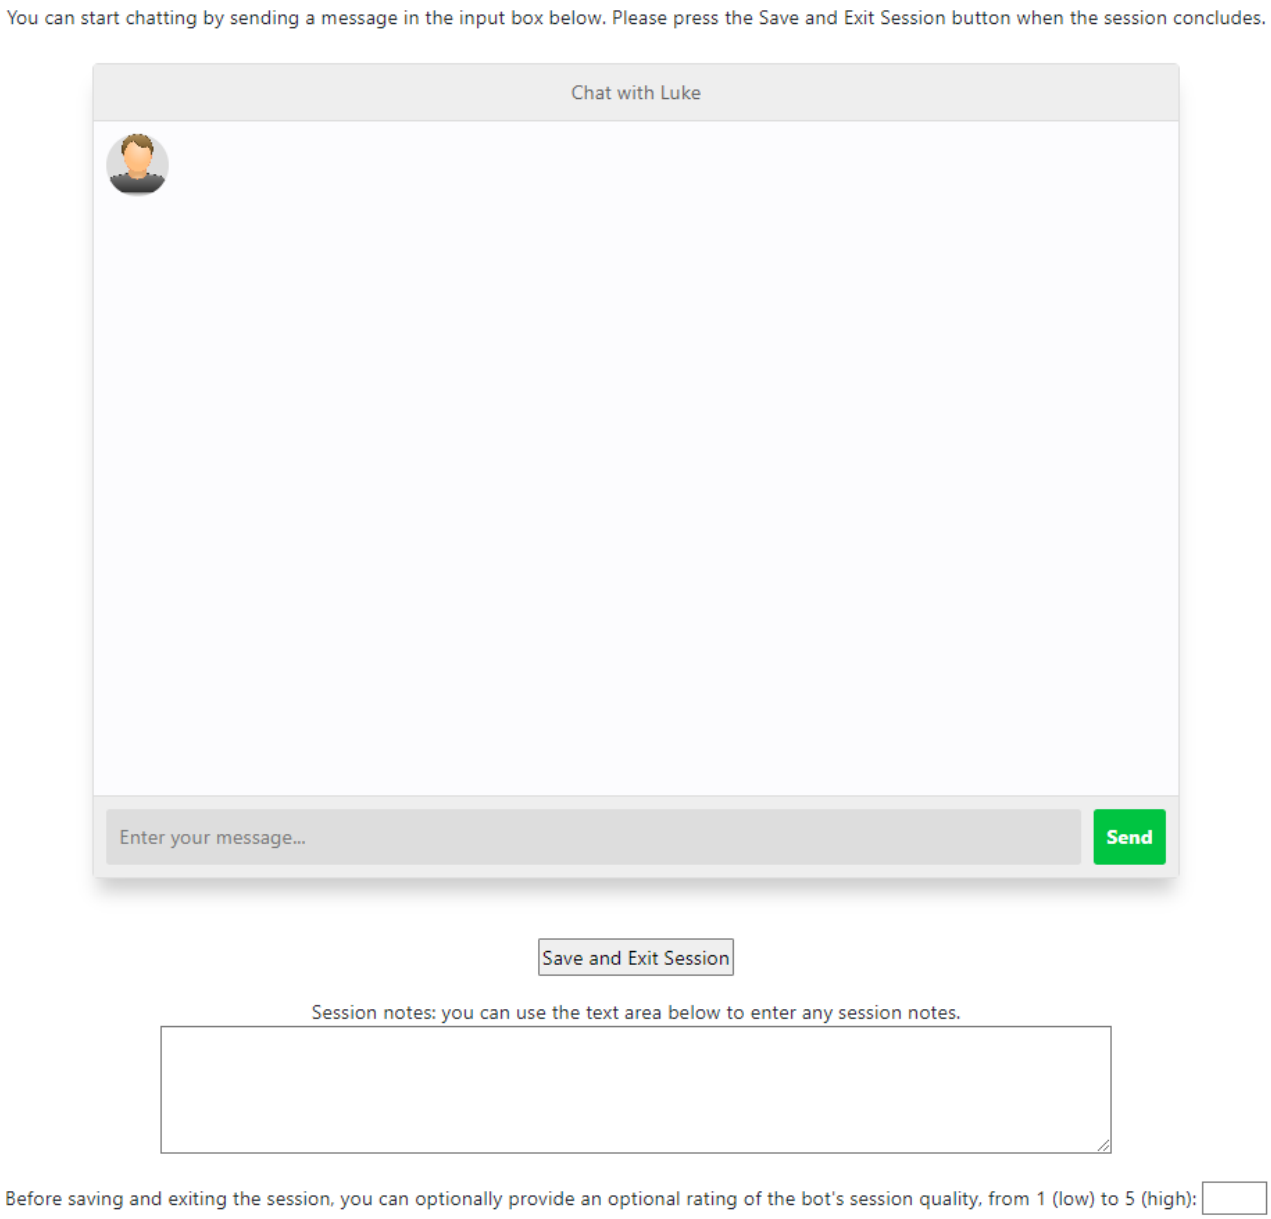

Figure 2. Simulated therapy sessions featuring the top image, of a therapist interacting with Alice, a chatbot portraying a patient with anxiety, and the bottom image, of a therapist engaging with Luke, a chatbot representing a patient with depression.

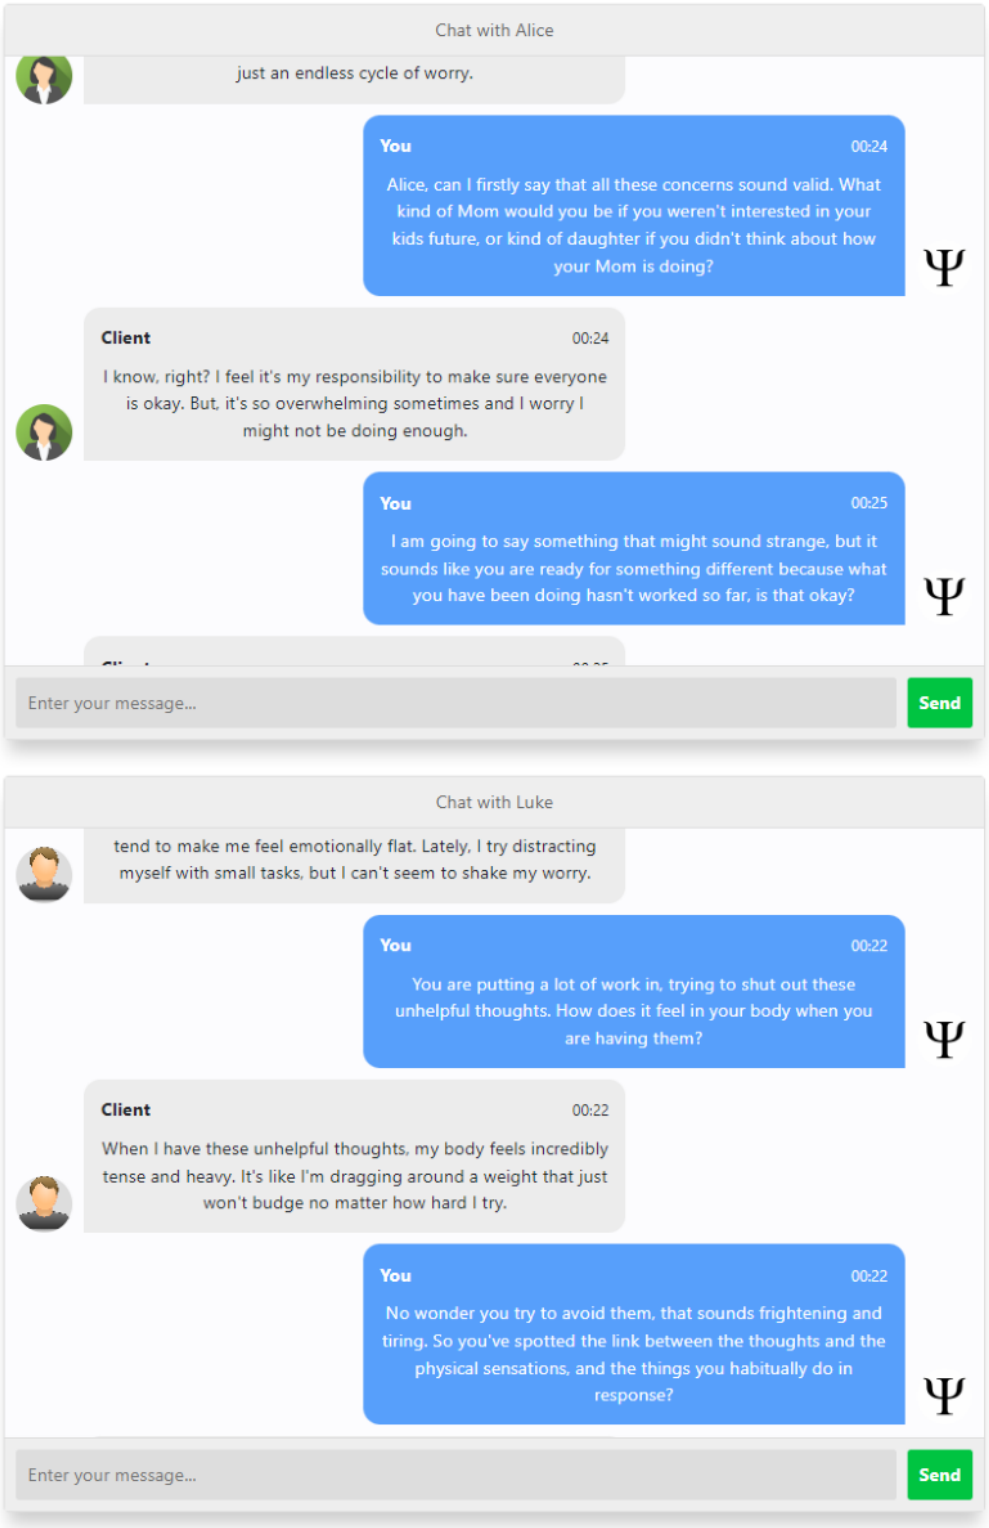

LLM-Driven Chatbots

Overview

The chatbots available on the Client101 platform used GPT-4 [22] as their LLM, accessed via OpenAI's paid application programming interface. The hyperparameters set for these models include a temperature of 1.0 and a presence penalty of 0. To aid the chatbots in simulating authentic patient interactions, we crafted prompts derived from psychotherapy case illustrations. To enhance the performance of our LLMs, we used the following prompt engineering techniques:

Memory-Assisted Prompt Editing

Inspired by Madaan et al [23], we paired our generative model with an external memory of previous messages. Previous messages were stored in the SQLite database and interfaced

with the LLM via a buffer. Such a memory allowed the LLMs to create better responses by referencing information from previous dialogues. The memory system included a summarizer module that condensed the content of prior messages, ensuring that the length of previous dialogues fit within the context window of the LLM.

Prompt Curation

The prompt design followed the role-play prompting technique [24], where the assigned role or persona provides context for the LLM's identity and background. The chatbots' personas were developed based on clinical vignettes from a psychology textbook [25], guidelines from the National Institute for Health and Care Excellence [26], and feedback from 2 colleagues with experience in psychotherapy. In collaboration with the psychologist, we conducted iterative prompt curation to develop high-quality prompts that effectively simulate mental health clients. A total of 5 sessions with the therapist were held to ensure optimal prompt quality and relevance. The finalized prompts for each chatbot were then used to configure the message-roles parameter in the chat completions application programming interface, with the role type set to developer. The prompts for each chatbot are available in Multimedia Appendix 1.

Human Evaluation

Overview

To assess the mental health professionals' perception of the chatbot's ability to simulate mental health client characteristics, we used a survey designed per the CHERRIES (Checklist for Reporting Results of Internet E-Surveys) [27]:

Design

This study targeted professionals in psychotherapy, specifically clinical psychologists, psychiatrists, and counselors. The survey was a postsession evaluation form completed by participants after interacting with the chatbots. Participants completed a 19-question survey evaluating the general quality of the chatbot, its ability to simulate the mental health condition in question (anxiety or depression), its characteristics in terms of acting as a client, and its suitability for use as a potential training tool.

Development and Testing

Questions 1 to 4 were adapted from the chatbot usability questionnaire [28], with modifications to specify that the chatbots represented psychotherapy clients. Questions 5 to 8 were custom-designed for this survey: questions 5 and 6 assessed whether therapists correctly identified the chatbot's simulated mental health condition, while questions 7 and 8 evaluated the chatbot's usability as an educational tool for trainee psychologists. Guided by the SSI-CBT framework [5], we formulated questions 9 to 18 to assess client characteristics typically observed in SSI-CBT sessions. These questions were reviewed by a mental health professional to ensure their relevance and clarity. Finally, question 19 was an open-ended prompt, allowing mental health professionals to provide additional insights, concerns, or suggestions not covered in the structured questions. Eight of these questions used a Likert scale with response options including "strongly agree," "agree," "neutral," "disagree," "strongly disagree," and "not applicable." Psychologists also had the option to provide additional comments regarding their responses to each question. All the questions are enumerated in Multimedia Appendix 2.

Recruitment Process and Sample Access

The survey was a closed survey, distributed exclusively via email to selected participants. Invitations were sent through direct email contact, with no open online advertisement or public recruitment. To ensure consistency in chatbot interactions, participants were provided with session procedure guidelines (Multimedia Appendix 3).

Survey Administration

The survey was administered electronically after each chatbot session. The questionnaire consisted of 19 questions, including 8 Likert scale-based questions and open-ended response options.

Response Rates

A total of 16 individuals participated, with 12 being clinical psychologists, 2 psychiatrists, and 2 counselors. Further, 13 participants completed sessions with both chatbots, while 3 engaged with only 1 chatbot. The total number of synthetic therapy transcripts generated was 29.

Preventing Multiple Entries

As participants were invited individually, 2 authors of this paper were able to track and verify that no participant submitted multiple entries.

Analysis

All completed surveys were analyzed, including those from participants who interacted with only 1 chatbot.

Therapy Transcript Dataset

To compare the Client101 sessions against therapy sessions involving human clients and therapists, we obtained psychotherapy transcripts from a 2020 study in which an on-demand online mental health chat service was embedded into a mental health web platform [29].

A total of 200 therapy transcripts were collected from this study. From this dataset, we selected sessions if they met one of the following conditions: (1) clients self-identified as experiencing symptoms of anxiety, depression, or both during the therapy session; (2) clients are participating or encouraged to participate in the anxiety or the depression pathways programs, each designed to offer comprehensive support and resources for managing their respective conditions; and (3) clients indicated in the pretherapy session questionnaire that their visit was related to anxiety or depression.

From this dataset, 42 sessions were related to anxiety and 47 sessions were related to depression.

LIWC Analysis

We used the LIWC software to extract psycholinguistic features from the synthetic and organic therapy sessions. An independent samples *t* test was conducted to compare the psycholinguistic features of the sessions with Client101 to those of the single webchat therapy sessions. The selected LIWC features were

based on studies that have identified them as markers of depression and anxiety [20,21]. These *t* tests aim to determine how realistic the Client101 content is in terms of psycholinguistic feature prevalence.

The psycholinguistic features corresponding to each mental health condition were obtained from the following LIWC-22 dictionaries: (1) depression: negative emotions, feel, sadness, anxiety, health, illness, mental, first-person singular, and discrepancy; (2) anxiety: negations, sadness, personal pronouns, present focus, social, family, negative emotions, and anger.

A power analysis was conducted to calculate the sufficient number of samples for a *t* test. With a statistical power of 0.8, a large effect size of 0.8, a type I error of 0.05, and an allocation ration of 2.4 between the organic therapy transcripts and the synthetic therapy transcripts, G*Power (version 3.1.9.6; Heinrich-Heine-Universität Düsseldorf) [30,31] determined that a *t* test would require 34 organic therapy transcripts and 14 synthetic therapy transcripts. We performed 1 *t* test for each psycholinguistic feature associated with each mental health condition, resulting in 9 *t* tests for the depression condition and 8 for the anxiety condition. To account for multiple comparisons, we applied the Bonferroni correction to adjust the *P* values.

Ethical Considerations

Ethics approval was obtained from the low and negligible risk 3B committee at the University of Melbourne Office of Research Ethics and Integrity (2024-27815-51746-4). Upon being provided with a plain language statement outlining the study and signing the consent form, participants were sent an email with guidelines on how to test and evaluate the platform. Session lengths were left to the discretion of the participants, resulting in an average session duration of 43 minutes. Participants were made aware that after the session, they needed to fill out a 19-question survey. To prevent multiple entries, the questionnaire responses contained participant names. This data was handled by investigator SD who had already contacted participants and was responsible for recruiting them. Questionnaire responses were subsequently anonymised for further usage by replacing individual names with identifiers of the form Px.

Results

Overview

In this section, we present our statistical findings derived from comparing the synthetic therapy transcripts from Client101 with the organic therapy transcripts that we obtained. We also report the survey responses from participants who used Client101. The subsequent section is dedicated to a comprehensive discussion and analysis of the implications arising from these outcomes.

Figure 3 compares the LIWC feature distributions related to anxiety in organic and synthetic therapy transcripts. Among the 8 anxiety-related features, 3 of them, negations (t_{56}=4.03, *P*=.001), family (t_{56}=–8.62, *P*=.001), and negative emotions (t_{56}=–3.91, *P*=.002), showed statistically significant differences between the organic and synthetic therapy transcripts. The remaining 5 features, including sadness, personal pronouns, present focus, social, and anger, did not show statistically significant differences. Figure 4 illustrates the survey responses from mental health professionals for the Alice chatbot.

Figure 3. Comparison of LIWC feature distributions associated with anxiety: Organic versus synthetic therapy transcripts. LIWC: Linguistic Inquiry and Word Count.

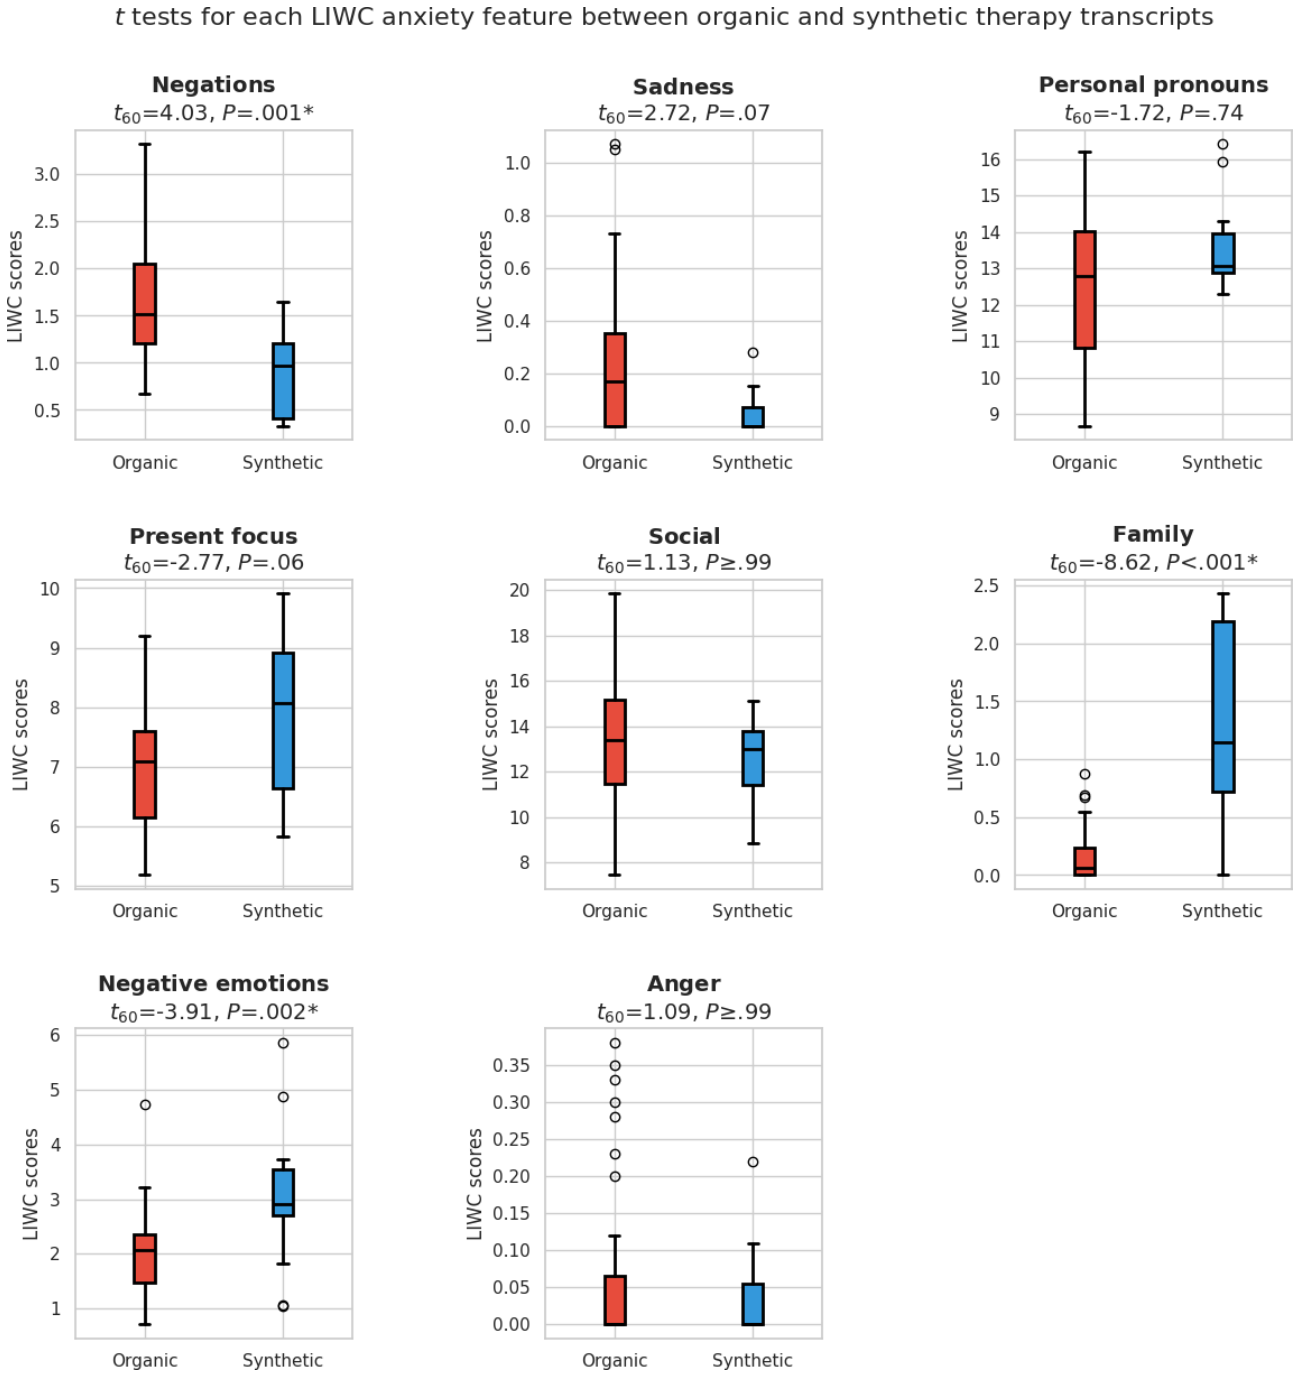

Figure 4. Likert scale responses for the Alice chatbot.

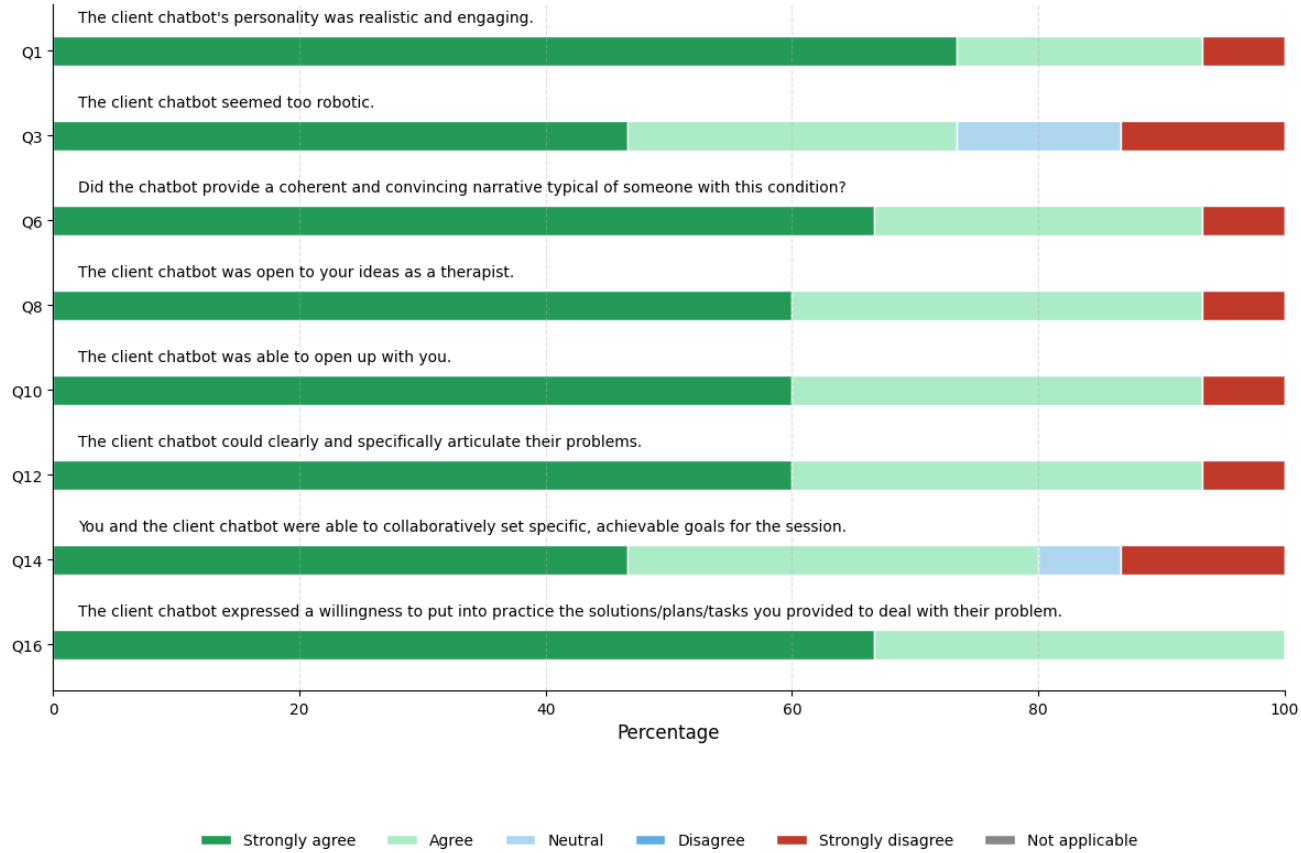

Figure 5 compares the LIWC feature distributions related to depression in organic and synthetic therapy transcripts. Among the 9 depression-related features, 4 of them, negative emotions (t_{60}=–3.84, P=.003), feeling (t_{60}=–6.40, P<.001), health (t_{60}=–4.13, P=.001), and illness (t_{60}=–5.52, P<.001), showed statistically significant differences between the organic and synthetic therapy transcripts. The remaining 5 features, including sadness, anxiety, mental, first personal pronouns, and discrepancy, did not show statistically significant differences. Figure 6 illustrates the survey responses from mental health professionals for the Luke chatbot.

Figure 5. Comparison of LIWC feature distributions associated with depression: Organic versus synthetic therapy transcripts. LIWC: Linguistic Inquiry and Word Count.

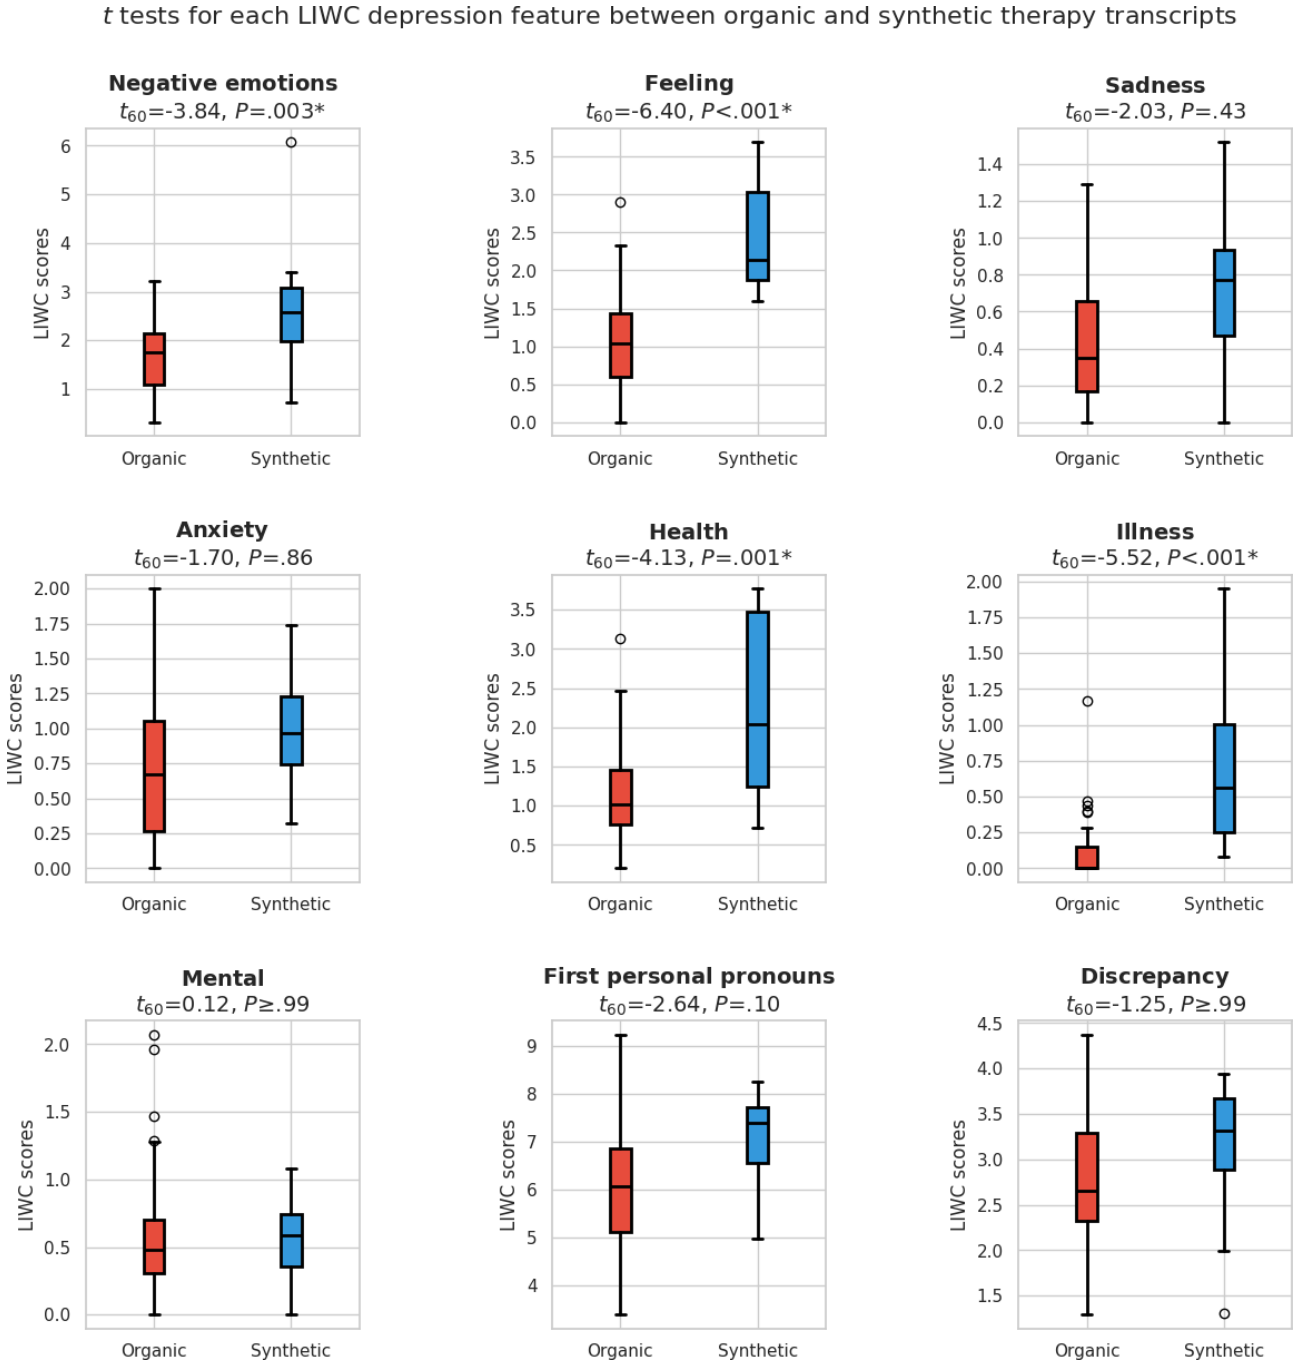

Figure 6. Likert scale responses for the Luke chatbot.

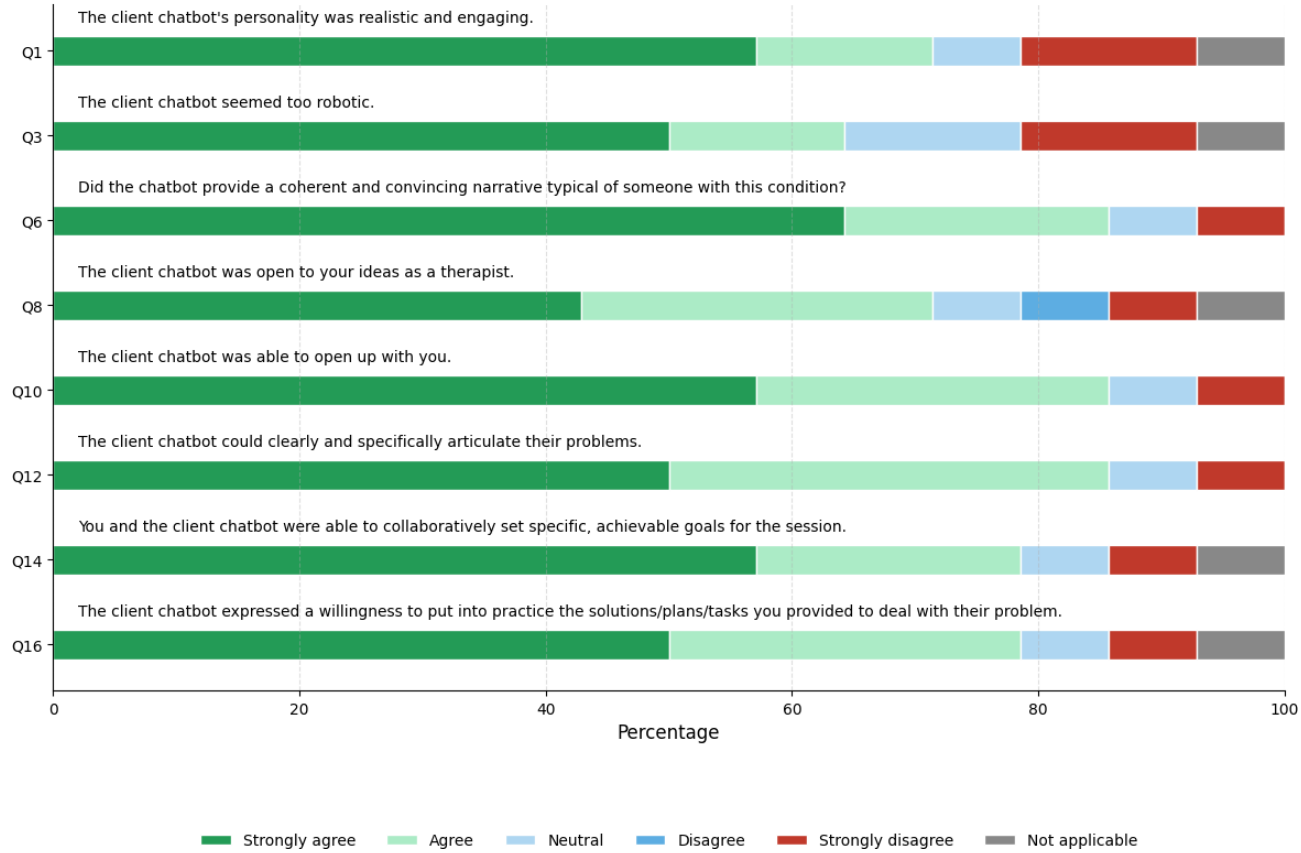

Alice Chatbot

When examining the anxiety-related LIWC features that showed statistically significant differences between organic and synthetic transcripts, the synthetic data exhibited higher values for all features except for negations. Chat-based language models are designed to be helpful and tend to comply with safe queries [32]. In contrast, patients sometimes refuse to engage in certain activities and may say no to therapists' requests or suggestions. This cooperative behavior in chatbots is further supported by survey results for questions 8, 10, 14, and 16, where 93% (14/15) of therapists agreed or strongly agreed for questions 8 and 10, 80% (12/15) for question 14, and 100% (15/15) for question 16 that the Alice chatbot is receptive and willing to collaborate. This is further corroborated by open-ended survey responses:

> *The client chatbot seemed too ready to engage, overly compliant*
>
> *The responses of the bot were appropriate in response to questions, however it was hard to tell whether the bot had learned to be very compliant and easy with the therapist, or if it was the personality of Alice.*

The *t* statistic with the largest magnitude of difference was observed for the family feature, which we attribute to the prompting components within the clinical vignette used to construct Alice's persona. This vignette includes references to concerns about a mother and her children. A common practice in single-session psychotherapy sessions is setting an agenda. This involves the therapist asking the patient what topics they would like to discuss during the session. When responding to such agenda-setting prompts, the Alice chatbot frequently mentions family members, as they are part of its prompt. This frequent reference to family contributes to a higher family score. This openness and specificity in discussing family issues is further supported by survey results for questions 10 and 12, where 93% (14/15) of psychologists agree or strongly agree that Alice can clearly articulate family issues. The following open-ended responses support these claims:

> *I found Alice's language sufficiently realistic for training purposes. Where Alice lacked realism was that she guided me back to the main issue more than a real client might if I took them off track.*
>
> *The bot was pretty good (always felt responsive, didn't get tripped up by spelling errors, or when I hit enter too soon) but felt a bit too clear, compliant, as well as a bit too repetitive. It represents a pretty nice client who can appropriately summarise their thoughts and experiences in an extremely clear way and then is eager to try whatever you give them.*

Despite the 3 anxiety features that showed a statistically significant difference between synthetic and organic transcripts, participants still found that the chatbots provided a coherent and convincing narrative typical of someone with anxiety. This is evident from survey results for questions 1 and 6, where approximately three-fourths of therapists agreed or strongly agreed that the chatbot conducted a realistic therapy session. The following answers support the realism demonstrated by the Alice chatbot:

> *The answers it gave were very human, including paraphrases and reflections. I found it hard to distinguish its responses from human.*
>
> *The bot reminded me of some challenging clients I have worked with who engage in rigid thinking and are still developing insight.*

However, there is still room for improvement, as indicated by the results for question 3, where 73% (11/15) of therapists felt the chatbot seemed too robotic, as illustrated by the following feedback:

> *Some of the responses were robotic. For example, repeating key words too often, which, as mentioned at 4, brought me (the clinician) back to the focal topic in a way that a real client would not.*

Luke Chatbot

Analysis of depression-related LIWC features revealed statistically significant differences in health and illness features between synthetic and organic transcripts. This discrepancy can be attributed to specific elements within the clinical vignette used to construct Luke's persona. The vignette's inclusion of an ankle injury reference influenced the chatbot's responses, particularly when addressing questions about preferred discussion topics for the therapy session. As a result, the Luke chatbot consistently and repeatedly mentioned the injury when responding to inquiries about setting the session agenda, leading to elevated scores in both health and illness categories. This openness and specificity in discussing health issues is further supported by survey results for questions 10 and 12, where 86% (12/14) of psychologists agree or strongly agree that Luke can clearly articulate issues. The following answers from participants support this point:

> *It felt quite repetitive. This isn't necessarily atypical of someone with depression/anxiety though so may not be an issue.*
>
> *Luke tends to be repetitive with the reason for consultation but doesn't elaborate beyond that. Typically, people aren't as repetitive with their symptoms; humans describe their symptoms in various ways, drawing on their biographical memory and recounting specific situations. Luke doesn't do this.*

Despite the 4 depression features that showed statistically significant differences between synthetic and organic transcripts, mental health professionals still found that the chatbots provided a coherent and convincing narrative typical of someone enduring depression. This is evident from survey results for questions 1 and 6, where over two-thirds of therapists agree or strongly agree that the chatbot conducted a realistic therapy session. The following answers support the realism demonstrated by the Luke chatbot:

> *Reminded me of significantly depressed clients that I've previously worked with.*
>
> *The client was realistic in that he was resistant to intervention in a similar way to a real depressed client. It was hard work.*

However, there is still room for improvement, as indicated by the results of question 3, where 64% (9/14) of therapists felt the chatbot appeared too robotic. This sentiment is reflected in the following feedback:

> *The bot struggled to understand some of my questions/responses in ways that very much seemed robotic. One example was when trying to provide validation (ie, not asking a question) it responded with "I don't understand your question.*"

Client 101

Overview

The clinicians' feedback on the Client101 platform reveals a promising tool for training psychologists, while also highlighting areas for enhancement to increase its efficacy and realism. The platform's strengths and potential improvements can be summarized as follows:

Strengths and Training Potential

Of skill development, multiple participants emphasized the platform's value in developing crucial skills. One participant noted:

> *I see it as a valuable instrument capable of honing skills in posing precise questions and adhering to protocols during psychological consultations.*

Of diagnostic practice, participants highlighted its utility in differential diagnosis and criteria assessment. As 1 participant stated:

> *[it serves as a] useful tool for conducting differential diagnoses and developing proficiency in assessing diagnostic criteria, akin to using a checklist.*

Of protocol adherence, the ability to practice following established protocols was highlighted, with 1 participant commenting:

> *I think it's a valuable tool that potentially enables the development of skills for asking the right questions or learning to follow protocols in a psychological consultation.*

Areas for Improvement

Despite its strengths, the participants' feedback indicates significant room for improvement in enhancing the chatbot's human-like qualities. Two key areas for refinement emerged from the responses: response timing and proactive engagement.

Of response timing, therapists noted that the chatbot's near-instantaneous response generation created a perceptible sense of artificiality. As 1 participant observed:

> *Responses were very quick! Could some delay be added to feel more "human"?*

Of proactive engagement, therapists also emphasized the need for the chatbot to initiate conversations or offer insights without requiring user prompts. As 1 clinician observed:

> *Not having an in-person session always makes it less human-like. Also, having to first ask something before*

getting a response makes it feel more like a chatbot than an actual real person.

Discussion

Principal Findings

Our key findings for each research question are:

1. When analyzing the statistical differences in LIWC features between organic and synthetic transcripts, we found that more features associated with thematic content exhibited statistical significance differences than features related to writing style.
2. Mental health professionals highlighted the platform training value, particularly for developing critical clinical skills in formulating precise questions, practicing differential diagnosis, assessing diagnostic criteria, and following established therapeutic protocols during psychological consultation.
3. Mental health professionals highlighted areas for improvement in the chatbot's human-like qualities, specifically in response timing, proactive engagement, and the chatbot's responses, which were perceived as robotic.

Implications of LIWC Findings

Interestingly, LIWC features associated with writing style, such as the use of personal pronouns and present-focused language, did not show a statistically significant difference between the organic and synthetic data. Additionally, psychological process features, including mental and social dimensions, also did not reveal significant differences. These results provide a foundation for future work that explores an equivalence or similarity test for these features, as the lack of significant differences may suggest that GPT-4 powered chatbots not only captured surface-level linguistic patterns but also effectively modeled deeper psychological constructs typically associated with depressive and anxious states.

However, when inspecting the 2 writing style features that did show significant differences, negation and negative emotions, the findings illustrate important implications for using Client101 as a training tool. The greater use of negation in the organic data may indicate a limitation in the types of clients the chatbots could model. For instance, in the organic transcripts, patients sometimes refused to follow advice or suggestions from the therapist, whereas the chatbot consistently complied with the suggestions. This difference suggests that while chatbots can simulate certain aspects of human communication, they may not fully replicate the more complex, resistance-based interactions seen with real clients, thus impacting their effectiveness as a training tool in some therapeutic scenarios.

Whereas the greater use of negative emotions in the synthetic data may indicate a limitation in how well the chatbots can represent the full emotional range experienced by clients. This could suggest that the chatbot models may lean toward portraying more extreme emotional states more constantly, potentially limiting their ability to simulate the nuanced emotional dynamics that occur in real-life therapeutic interactions.

In general, all the LIWC features tend to have higher values for the synthetic data. This finding implies that GPT-4 may be amplifying or intensifying certain linguistic characteristics associated with depression and anxiety. This amplification could be attributed to a pattern of over-generalization by the model, in which it has identified key linguistic patterns associated with depression and anxiety and applied them more consistently or intensely than typically observed in organic data, where individual variation is more prominent. Yet, this variation is not achieved due to the prompt influence, which constantly instructs the model to follow the persona of a depressed or anxious patient.

In the case of the LIWC features associated with thematic content that presented a significant difference, such as illness and family, we attribute these differences to the specific prompts provided to the LLMs. These prompts inherently contained elements associated with family dynamics and health concerns, thus influencing the thematic content of the generated text. While the prompts used to instruct the LLMs may reflect the diversity of topics encountered in 1 real therapeutic session, this could become a limitation if the platform were used to simulate multiple sessions with the chatbot portraying a patient. Over time, the topics could become stale and repetitive, as the chatbot would continually focus on the same themes, whereas real clients typically bring up a broader and more varied range of issues based on their individual experiences. This potential lack of diversity in simulated sessions could limit the platform's effectiveness in training mental health professionals to handle the evolving nature of a client's concerns and the wide array of therapeutic situations encountered in real-world practice.

Implications of Survey Findings

Therapist feedback revealed a consensus that both chatbots exhibited robotic interactions. When chatbots fail to replicate authentic human communication, they limit trainees' opportunities to practice essential therapeutic competencies, such as building rapport, responding to emotional cues, or managing the unpredictability of real client interactions. This rigidity risks creating a distorted representation of therapeutic dialogue, potentially conditioning trainees to approach client interactions with a structured, algorithmic mindset rather than the fluid, empathetic engagement required in mental health practice.

Responses to the open-ended survey questions highlighted key factors contributing to this robotic perception, including response timing, proactive engagement, and repetitiveness. These insights provide valuable guidance for improving the platform's human-like qualities. For instance, implementing a variable delay mechanism, where response times fluctuate within a natural human range, could significantly enhance the authenticity of interactions by eliminating the unnatural immediacy of automated replies. Similarly, programming the chatbot to occasionally initiate meaningful follow-up questions or offer unsolicited insights could create a more dynamic and human-like interaction.

The repetitiveness partly arises from the use of static prompts to configure message-role parameters, which rigidly instruct the LLM in the same manner for every interaction, constraining

natural variability in responses. To address this while preserving the chatbot's core therapeutic persona, a dynamic prompting approach could be implemented. This method would retain fixed persona elements that uphold the chatbot's essential identity while integrating session-specific details into the prompt.

Another option to reduce the robotic perception of the chatbot responses is exploring different prompt engineering techniques that aim to enhance the emotional generation aspect of LLMs. One such prompt engineering technique is Emotional Chain-of-Thought [33], which aligns LLMs with human emotional intelligence guidelines to enhance emotional generation capabilities. Emotional Chain-of-Thought has been shown to improve the quality of emotionally charged responses, making interactions with AI more relatable and human-like.

Strengths, Limitations, and Future Work

To strengthen the claims and results obtained in our analysis, this research could benefit from a larger sample size of synthetic therapy sessions. Due to practicalities, we limited the number of participants to 16, with the aim that each conduct 2 virtual sessions, 1 with each of the 2 chatbots. Future studies could increase the number of mental health professionals involved or the number of sessions each psychologist performs, thereby enhancing the robustness and generalizability of the findings.

The next step for Client101 is to evaluate its effectiveness as an educational tool for training and assessing psychologists. We are currently running a study in which a sample of psychology students is testing out Client101. Via their questionnaire responses and thematic analysis of their follow-up interviews, we are gathering preliminary feedback and perspectives from such student end users.

Client101 will subsequently be, as a trial, embedded into the curricula of 2 psychology subjects at the University of Melbourne in 2025. In these subjects, students are required to report on the delivery of psychological intervention to a client. However, this assignment poses challenges related to the equivalency of client presentations, the severity of client issues, and the number of client sessions each student can conduct. The incorporation of Client101 aims to address these issues by providing a standardized and equitable platform for students to demonstrate their intervention skills. By using Client101, students will engage in a prescribed number of sessions with the chatbot, ensuring a controlled and comparable environment for skill demonstration. This approach will enhance the ability to assess student competency more effectively. Students will be required to download the transcripts of their sessions with Client101 and critically appraise and evaluate their performance. This process will facilitate a more consistent and objective assessment of their intervention skills, ultimately improving the training and evaluation of future psychologists.

Future research could explore adapting the Client101 platform to other languages and using the LIWC-22 dictionaries in those languages to evaluate the psycholinguistic features of the generated transcripts. If therapy transcript databases in these languages are available, it would be valuable to measure the similarities between synthetic and organic therapy transcripts across different languages. Furthermore, comparing and contrasting the psycholinguistic features of therapy transcripts in various languages could provide valuable insights into how LLMs capture and reflect language-specific nuances, cultural contexts, and psychological dynamics. Beyond measuring LIWC-22 features, it is crucial to involve mental health professionals who are native speakers of the corresponding languages to evaluate the quality of the sessions. Assessing the quality of non-English synthetic text is particularly important, as multiple studies have shown that the performance of LLMs tends to be worse in non-English tasks [34].

In this research, we used clinical vignettes to construct prompts for simulating patients with depression or anxiety. Future research could develop new clinical vignettes that represent a broader range of backgrounds and demographics than those used in our study. Additionally, future studies could explore the simulation of other types of mental health conditions, such as obsessive-compulsive disorder, schizophrenia, or comorbid conditions such as anxiety and depression. Other types of therapies, such as dialectical behavior therapy and motivational interviewing, could also be tested to evaluate how well an LLM can simulate a patient in those therapeutic contexts. Group therapies could also be explored, with one or multiple LLMs simulating different patients. This approach could provide valuable training environments by reducing the challenges and costs associated with hiring actors to portray mental health patients.

Further development of the Client101 platform remains an open task. The minor improvement of adding organic response delays, as mentioned earlier, is 1 simple example. More generally, there are opportunities to incorporate more advanced mechanisms into the chatbot architecture. For example, using expanded prompt constructions or more advanced LLM-related information storage techniques, such as retrieval-augmented generation, could enable the construction of a more detailed set of client details and the accumulation of facts revealed during chat sessions. Ultimately, the goal is to have chatbots that can sustain a succession of therapy sessions and demonstrate a therapeutic evolution as their sessions progress.

Finally, exploring the use of open LLMs could offer significant benefits for the Client 101 platform, particularly in overcoming the limitations of third-party services such as OpenAI's models. One key drawback of proprietary models is the presence of built-in guardrails that may restrict certain responses, which poses a challenge when simulating mental health patients. For example, outputs related to sensitive topics such as suicide or self-harm may be blocked, limiting the realism of the simulation. Additionally, proprietary LLMs require paid access, which could constrain the number of simulated sessions due to cost limitations. In contrast, open-source models can be deployed without these restrictions, provided users have the necessary computational resources to run them locally. Another significant advantage of open-source LLMs is enhanced data security, as no information would be transmitted to third parties, further strengthening the platform's privacy and safety measures.

Other Ethical Considerations

While using conversational agents powered by LLMs offers significant potential as a tool for training psychologists, they also raise notable ethical considerations.

In our experimental approach, Client101 was designed to closely mimic patients with mental health problems. However, further research is needed to assess potential biases that the model could be exhibiting when simulating mental health patients. LLMs can manifest various types of biases in their outputs, including gender, racial, and religious biases [35-37]. Studies have shown that these stereotypes and biases exert adverse effects on mental health treatment outcomes [38,39]. Therefore, it is essential to examine these models to prevent the inadvertent propagation of such biases.

Additionally, a primary concern in using Client101 is the potential for boundary transgressions, traditionally observed in human therapist-client interactions. In conventional therapy, therapists may inadvertently cross boundaries through behaviors such as excessive self-disclosure, forming dual relationships, or displaying undue affection toward clients [40]. The introduction of chatbot clients raises questions about whether trainee clinicians might exhibit similar behaviors when interacting with AI entities. For instance, the "ELIZA effect"—the tendency to unconsciously attribute human-like qualities to computer programs—could lead trainees to engage in inappropriate self-disclosure or develop misplaced trust in the chatbot's responses [41].

Furthermore, the use of AI-driven chatbots in psychotherapy training necessitates a thorough understanding of their limitations and ethical implications. Counselors must receive adequate training to comprehend these limitations and ensure that AI serves as a supportive tool rather than a replacement for human judgment. This approach aligns with ethical guidelines emphasizing the importance of professional competence and the responsible integration of technology in clinical settings [42].

Moreover, while chatbots can simulate certain aspects of client interactions, they lack the genuine emotional depth and autonomy of human clients. Relying heavily on chatbot interactions during training may impede the development of essential relational skills, such as empathy and the ability to navigate complex human emotions, which are crucial for establishing effective therapeutic relationships. Therefore, it is imperative to assess whether trainees can effectively use chatbots as an initial training tool without experiencing adverse effects on their ability to engage authentically with human clients in real-world scenarios.

Conclusions

We developed Client101, a web conversational platform featuring LLM-driven chatbots designed to simulate mental health clients. To evaluate the chatbots' performance, participants engaged in single sessions with the chatbots and provided questionnaire responses. Comparative analysis was undertaken to examine the psycholinguistic features of the sessions conducted with Client101 and single webchat therapy sessions obtained from an actual online counseling service. This comparison aimed to evaluate the resemblance between the AI-generated and human-generated transcripts, focusing on linguistic and psychosocial indicators associated with depression and GAD.

Notably, LIWC features related to thematic content showed a significant difference between the organic and the synthetic data, likely due to the explicit inclusion of these themes in the prompts. Interestingly, no significant differences were detected in the means of psychosocial process features, such as mental and social dimensions, within the limits of our sample size and data variability. The absence of significant differences suggests potential for future work that explores equivalence or similarity testing for these features, offering further insights into the capacity of GPT-4, and LLMs more generally, to model deeper psychological constructs.

These findings, along with feedback from therapists, have important implications for the utility of Client101 as a simulation tool, its potential as a training resource for mental health professionals, and its applications in psycholinguistic and computational psychiatry research. The platform's value is enhanced by its availability and accessibility compared to established training methods, such as using actors to simulate mental health patients for training psychologists. Moreover, Client101 offers flexibility in creating a wide variety of mental health personas, capable of simulating different types of mental health disorders. This versatility, combined with its ability to resemble actual therapy sessions, makes Client101 a promising tool for mental health education, training, and research.

Abstract

Background: Concept maps are a suitable method for teaching clinical reasoning (CR). For example, in a concept map, findings, tests, differential diagnoses, and treatment options can be documented and connected to each other. When combined with virtual patients, automated feedback can be provided to the students' concept maps. However, as CR is a nonlinear process, feedback concept maps that are created together by several individuals might address this issue and cover perspectives from different health professionals.

Objective: In this study, we aimed to develop a collaborative process for creating feedback concept maps in virtual patient–based CR education.

Methods: Health professionals of different specialties, nationalities, and levels of experience in education individually created concept maps and afterward reached a consensus on them in structured workshops. Then, medical students discussed the health professionals' concept maps in focus groups. We performed a qualitative content analysis of the transcribed audio records and field notes and a descriptive comparison of the produced concept maps.

Results: A total of 14 health professionals participated in 4 workshops, each with 3 - 4 participants. In each workshop, they reached a consensus on 1 concept map, after discussing content and presentation, as well as rationales, and next steps. Overall, the structure of the workshops was well-received. The comparison of the produced concept maps showed that they varied widely in their scope and content. Consensus concept maps tended to contain more nodes and connections than individual ones. A total of 9 medical students participated in 2 focus groups of 4 and 5 participants. Their opinions on the concept maps' features varied widely, balancing between the wish for an in-depth explanation and the flexibility of CR.

Conclusions: Although the number of participating health professionals and students was relatively low, we were able to show that consensus workshops are a constructive method to create feedback concept maps that include different perspectives of health professionals with content that is useful to and accepted by students. Further research is needed to determine which features of feedback concept maps are most likely to improve learner outcomes and how to facilitate their construction in collaborative consensus workshops.

Introduction

Background

"Clinical reasoning encompasses health professionals thinking and acting in assessment, diagnostic, and management processes in clinical situations taking into account the patient's specific circumstances and preferences" [1]. It is evident that health professionals in different disciplines (eg, physicians and nurses) differ in their reasoning approaches [2], and there are differences between novices and experts [3]. Even experienced health professionals of the same discipline do not follow the same

diagnostic process, even when they are confronted with the same medical case, and ultimately arrive at the same diagnosis [4,5]. A study by Charlin et al [6] showed that experts' case solutions also varied depending on the situation, for example, whether they were asked to give answers as an examinee or as a panel member.

The variety and nonlinearity of possible clinical reasoning (CR) approaches make CR training and assessment a highly complex matter [4,7]. Therefore, concept maps have been suggested as a useful method for training the CR skills of medical students [4,8], especially in terms of problem representation [9].

Concept mapping is a method used to represent concepts and their relationships in a visual diagram, using explanatory terms to relate concepts to each other [10]. A typical use in health education is to present students with a case scenario and have them create a concept map to represent their thought process as the case unfolds [9,11]. They can record relevant findings, tests, differential diagnoses, and treatment options and connect concepts to each other to visualize their CR process [8]. Torre et al [12] show that concept maps promote the connection between theory and practice and facilitate knowledge integration and critical thinking.

Teachers can ask students to create concept maps in different forms, depending on the purpose, such as freely from scratch or in a preconstructed form [10,11]. Because creating a comprehensive and accurate concept map is time-consuming and students need some time to learn how to do it, Daley and Torre [8] suggest the use of semistructured concept maps.

Concept maps have also been found to be suitable for measuring learning outcomes [13], and various ways of assessing and scoring concept maps, both qualitatively and quantitatively, have been described in the literature [14-17]. A study by Morse and Jutras [18] showed that working with concept maps had an effect on the students' problem-solving performance only when feedback was provided. However, in order to provide students with feedback on their concept map, some form of "expert concept map" is needed to compare students' results with [19], which can then be provided in real time in digital environments. Such "expert concept maps" can be created by a single teacher or by a panel of professionals or experts [19-21]. In their systematic review of different methods for assessing CR skills, Daniel et al [9] concluded that "using written cases, expert consensus is the most prevalent method" used to create concept maps as feedback for students. However, little is known about the process and challenges involved when health professionals are asked to reach a consensus on a concept map for teaching CR.

Recent studies suggest that virtual patients (VPs) are an appropriate method for training CR [22-24], especially for some components of this process, such as collecting data, generating differential diagnoses, or developing a treatment plan [25,26]. VPs are computer-based patient case scenarios that students can interact with [27]. Often, such scenarios are designed so that the cases gradually lead the student to the final diagnosis by providing more and more information over time [28,29]. VPs provide a safe environment, in which mistakes can be made without harming real patients [30]. It has been suggested that combining concept map activities with VPs can reinforce the educational effect of VPs in CR outcomes [31]. The importance of VPs has increased over the years [32], especially since the beginning of the COVID-19 pandemic, when direct patient contact and opportunities for CR training were limited [33].

Objectives

In this study, we aimed to develop a collaborative process for creating feedback concept maps in VP-based CR education. From this, we derive the following research questions: (1) What are the similarities and differences of concept maps for teaching CR that have been created by individual health professionals and groups? (2) What themes emerge when health professionals are asked to jointly create a concept map in a consensus workshop? (3) What are the challenges and benefits of such consensus workshops? (4) What aspects of the consensus concept maps do medical students find helpful in learning CR?

Methods

Study Design

This study followed a convergent mixed methods approach. First, we asked health professionals from different disciplines to individually create concept maps for 2 VPs that would serve as feedback for medical students. We then conducted structured digital workshops for those health professionals in which they reached a consensus on the concept maps. After the workshops were finished, we conducted focus groups with medical students to discuss which aspects of the professionals' concept maps they found helpful for learning CR.

Ethical Considerations

The study was approved by the institutional review board of the Ludwig-Maximilians-University, Munich, Germany (21 - 0941), and adhered to ethical guidelines. Informed consent was obtained from all participants prior to their participation in the study, with assurances of anonymity and confidentiality. Participants were informed of the objectives of the study and how the data collected would be used. In addition, strict measures were taken to protect the privacy and confidentiality of the study data. Students who participated in the focus groups received a US $16 voucher as compensation for their time.

Data Collection

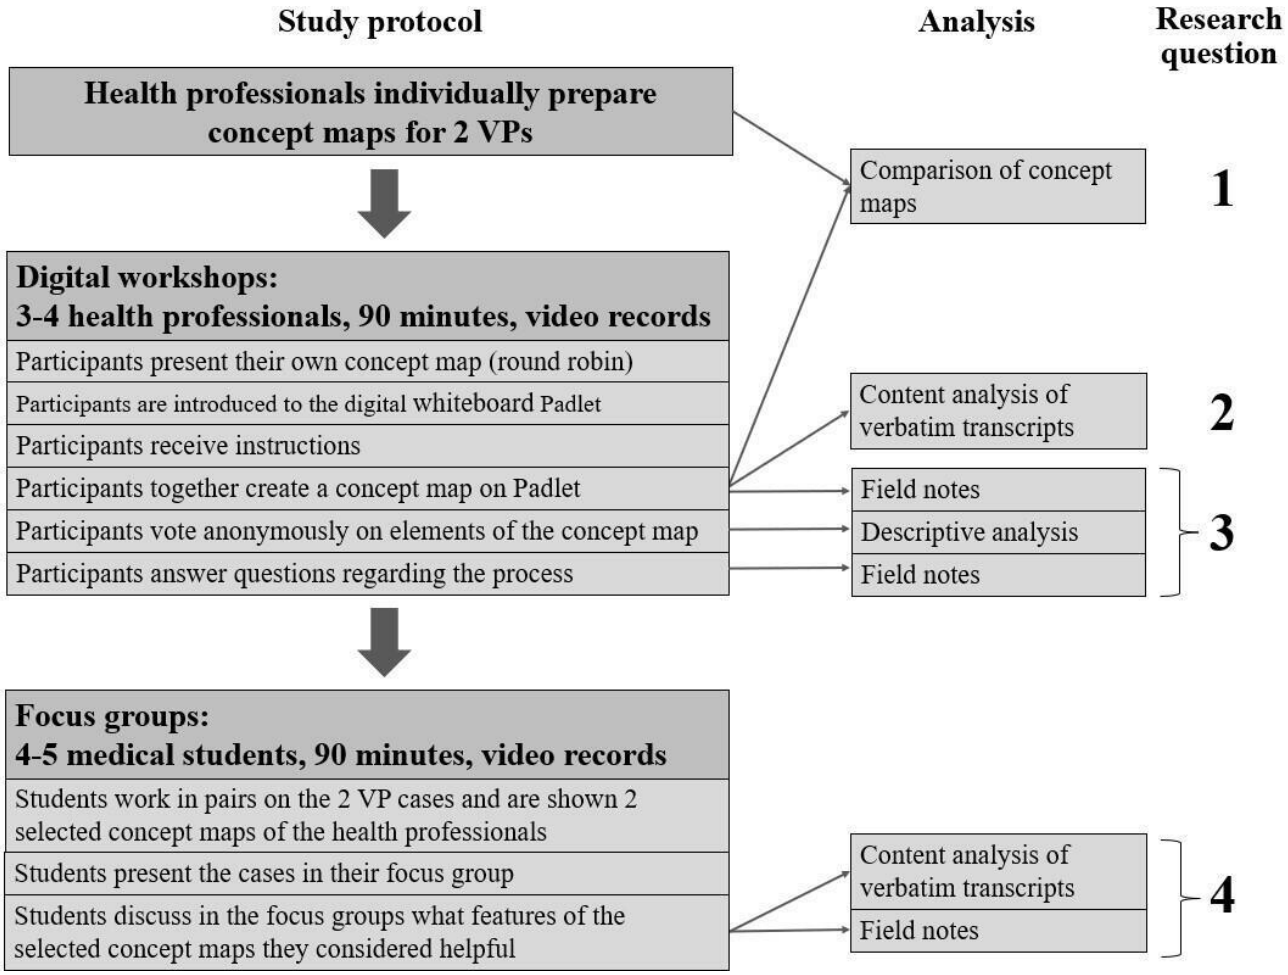
Between November 2021 and January 2022, we sent out emails to invite health professionals of different specialties, nationalities, and levels of experience in medical education to participate in our study. The email included study information and a written informed consent form. After returning the signed written consent by email, participants were asked to create concept maps for 2 VP cases. We used the software platform CASUS (Instruct gGmbH), which is a VP player and authoring environment with integrated concept map functionality [31]. The study participants were told that these concept maps would serve as feedback for medical students. We carefully chose the VPs with regard to their sociodemographic features, key symptoms, and difficulty levels. They were a 19-year-old female student with mononucleosis and a 58-year-old male nurse with hepatitis E. We chose them for providing patients of different

sex, age, and profession. Both were heterosexual and of Caucasian origin. We deliberately chose these VPs because they provided different levels of difficulty for the students but had key symptoms that are common in daily practice and easily recognizable by health professionals of different specialties. The 2 VPs can be found on the CASUS platform and are part of a collection of over 200 freely available VPs in 6 languages [34]. These VPs include a semistructured concept map that students fill out while solving the case, covering 4 categories: findings, differential diagnoses, tests or examinations, and treatments [31].

Participants were also asked to complete a web-based questionnaire that included personal data and level of experience in concept mapping and teaching CR. We used a convenience sampling strategy, inviting partners from 2 recent Erasmus+ projects, iCoViP (International Collection of Virtual Patients) and DID-ACT (Developing, Implementing, and Disseminating an Adaptive Clinical Reasoning Curriculum for Healthcare Students and Educators) [35,36], who were interested in teaching CR with concept maps. As the VPs are available in multiple languages, we valued the international composition of the study group that would reduce local bias in clinical practice. Participants were given 10 days to create the individual concept maps and were reminded of the task 3 days before the workshop. After that, we held structured digital workshops of 90 minutes, where they met in groups of 3 - 4 to reach a consensus on a common concept map. The workshops took place on the Zoom platform (Zoom Video Communications) and were video recorded. A Mayer and MS facilitated the workshops, following a predefined structure according to the nominal group technique [37,38] (Figure 1): first, all participants explained their own concept maps to the others in a round robin and described their reasoning. Then, A Mayer and MS introduced them to the digital whiteboard Padlet (Wallwisher Inc), and the participants had the opportunity to try it out. Once they felt comfortable with the tool, A Mayer and MS gave them instructions on how to create a concept map together. They then created a new concept map on Padlet based on their individual concept maps. A Mayer and MS answered participants' questions, kept track of the timeline, and reminded participants of the original assignment if they strayed from the topic. When the concept map was complete, A Mayer and MS provided the opportunity to anonymously rate the concepts and connections with a thumbs up or down mechanism on Padlet. Afterward, they asked the participants about their experience of creating the concept map together. IH and AAK attended the workshops as neutral observers and, together with A Mayer and MS, took field notes, which they all discussed immediately after the workshop. The study was piloted as a face-to-face workshop in October 2021. Afterward, we decided that web-based meetings would be equally feasible and made minor changes to the study protocol, such as adding an anonymous voting round.

After all workshops were completed, IH and MS selected 4 individual and 4 consensus concept maps to be discussed by medical students in focus groups. For this purpose, 9 international medical students were recruited to participate in 90-minute focus groups during a transnational meeting of the iCoViP project. Written informed consent was obtained prior to participation. In the beginning, the students were asked to work in small teams (2 - 3 students) and solve 1 of the 2 VP cases together. Afterward, the teams were shown 2 of the selected concept maps from the workshops to compare and decide which one they would prefer to have as feedback for their case and why. Then, 2 teams of students who had worked on different cases were brought together as a focus group. They presented their cases to the others and then started a group discussion, facilitated by A Mayer and MS, about which of the presented concept maps they found most helpful and how different features of the concept maps could improve their CR process.

Figure 1. Flowchart of study protocol and analysis plan with regard to the research questions. VP: virtual patient.



Data Analysis

This study used a convergent mixed methods design. In the quantitative part, a descriptive statistical analysis of the questionnaire, concept maps, and votes was performed using Microsoft Excel. The individual and consensus concept maps were analyzed for scope (number of nodes and connections), agreement (number of "likes" of nodes or connections in the consensus phases of the group concept map authors), and content (number of times a particular concept, eg, "fever," appeared in the individual and consensus concept maps). We extracted information from the concept maps and compared them separately for each of the 2 cases.

The qualitative part of the study involved the thematic analysis of the transcripts and field notes from the workshops and focus groups. It was conducted in several steps. The recordings of the workshops were transcribed verbatim and anonymized. Two authors (A Mayer and A Müller) performed a thematic analysis of the transcripts, following the 6 steps for qualitative content analysis proposed by Kuckartz [39]. Using an inductive approach, they independently created codes for the first 2 workshops and reached a consensus on an initial coding framework. They then coded 1 workshop at a time, applying and refining the coding framework in an iterative process. They used MAXQDA software (version Analytics Pro 2022; VERBI GmbH) for coding and discussed discrepancies until a consensus was reached. A Mayer, A Müller, and IH then grouped similar codes into themes. Throughout the process, AAK and MS reviewed the coding framework and emerging themes and provided feedback; discrepancies were discussed until a consensus was reached.

We analyzed field notes taken during the workshops and participants' responses during the round of questions for challenges and benefits. Student focus group recordings were transcribed verbatim and anonymized. Two authors (A Mayer and A Müller) independently extracted statements from the transcripts about what students found helpful in the selected concept maps, grouped them into themes, and discussed discrepancies until a consensus was reached. Finally, we looked for confirmation or discrepancies of the results obtained from the mixed methods.

Results

Participants

A total of 14 health professionals from 6 European countries participated in our study, of whom 9 were female and 5 were male. On average, participants were 37 (SD 10) years of age and had 10 (SD 9) years of professional experience. Participants worked in different disciplines (Table 1) and had an average of 6 (SD 5) years of experience in health education. Participants differed only slightly in their teaching experience with concept maps or CR.

Table . Characteristics of participating health professionals (N=14).

Characteristics	Values

Participants created 13 individual concept maps prior to the workshops. We held 4 digital workshops with 3‐4 participants each, resulting in 4 consensus concept maps (2 hepatitis E and 2 mononucleosis). We also conducted 2 focus groups with 4 and 5 medical students, respectively. The students were in their final year of study (sixth year), with an average age of 24 (SD 0.5) years. In total, 8 students were female, and 1 was male. We chose students from Portugal (n=5) and Poland (n=4) because these countries represent educational systems from different parts of Europe.

Research Question 1: Comparison of Individual and Consensus Concept Maps

The individual concept maps varied widely from each other regarding scope and content. We found most similarities in the final diagnoses and treatment options and only a few similarities regarding findings, differential diagnoses, and tests. The same was true when comparing the consensus concept maps.

When we compared the consensus concept maps to the individual versions, we found that they all had a bigger scope than the individual concept maps, as can be seen in Table 2 and

in the examples given in Figure 2 (original images are provided in Multimedia Appendix 1). We also found that most of the nodes from the individual concept maps were present in the consensus versions, and only in a few cases were nodes left out or new nodes added during the workshops. Altogether, the consensus versions showed higher similarities to the underlying individual versions than to each other. All consensus concept maps included connections, while these were missing in 5 of the individual versions.

Table . Comparison of number of elements in consensus and individual concept maps.

	Hepatitis E				Mononucleosis			
	Workshop 1		Workshop 2		Workshop 3		Workshop 4	
	n (GRP)[a] (%)	Rn (IND)[b]	n (GRP) (%)	Rn (IND)	n (GRP) (%)	Rn (IND)	n (GRP) (%)	Rn (IND)
Total	56 (100)	10-29	33 (100)	11-25	39 (100)	13-22	43 (100)	9-11
Nodes								
Findings	9 (16)	6-8	9 (27)	1-8	10 (26)	3-6	12 (28)	3-4
Examinations or tests	11 (20)	2-8	5 (15)	2-5	7 (18)	2-4	7 (16)	0-3

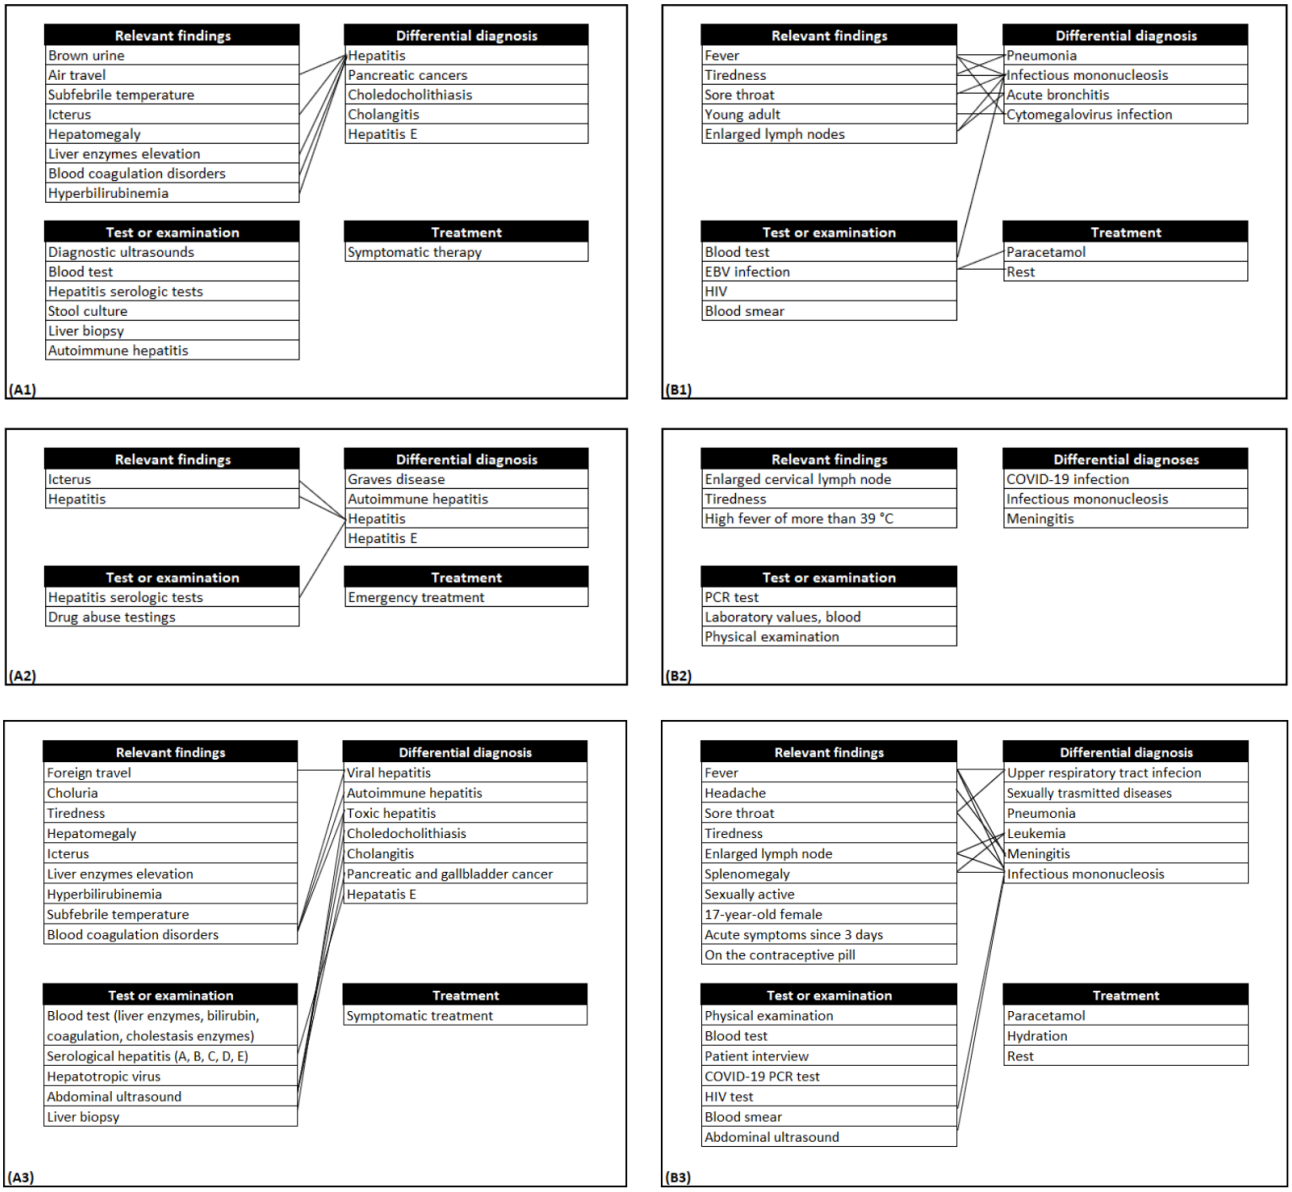
Treatments	1 (2)	1-1	1 (3)	1-1	3 (8)	0-2	2 (5)	0-0
Connections	24 (43)	0-13	11 (33)	3-5	12 (31)	0-13	16 (37)	0-0

[a]n (GRP): number of elements in the group consensus concept map.

[b]Rn (IND): range of element number in the individual concept maps.

Figure 2. Examples of individual concept maps and consensus versions. (A1 and A2) Individual concept map (hepatitis E), (A3) consensus concept map (hepatitis E), (B1 and B2) individual concept map (mononucleosis), and (B3) consensus concept map (mononucleosis). EBV: Epstein-Barr virus; PCR: polymerase chain reaction



Research Question 2: Themes Emerging During the Consensus Process

From the qualitative content analysis of the creation phase, we identified 4 themes: the first theme covered the content of the consensus concept maps, that is, participants discussed which findings, examinations or tests, differential diagnoses, treatments, and connections should be included. Related to this, the second theme was the rationales they gave during their discussion, that is, why they thought something should (not) be part of the consensus concept map. The third theme covered the presentation of the consensus concept map, that is, participants discussed how to present the content. In the fourth theme, participants discussed their next steps, that is, how to approach the creation of the consensus concept map. Table 3 shows the 4 themes and associated subthemes, including sample quotes, and their frequency in the verbatim transcripts of the workshops.

Table . Themes and associated subthemes derived from the qualitative content analysis.

Themes and subthemes	Description	Sample quotes	Values, n (%)
Content of the consensus concept maps (n=677)			
Relevant findings	Which findings (not) to include in the concept map	“Sore throat” [Workshop 4]	227 (41)
Differential diagnoses	Which differentials (not) to include in the concept map	“Should we add EBV and CMV as a differential?” [Workshop 1]	200 (30)
Tests or examinations	Which tests or examinations (not) to include in the concept map	“Liver biopsy could be relevant” [Workshop 2]	170 (25)
Treatment	Which treatments (not) to include in the concept map	“Paracetamol I think is perfect in this case” [Workshop 3]	25 (4)
Connections	Which connections (not) to include in the concept map	“Maybe this splenomegaly should be also connected?“ [Workshop 3]	55 (8)
Presentation of the content (n=89)			
Layout	Visual aspects of the concept map or possible actions such as highlighting, crossing out, rearranging, merging, splitting, enlarging, or reducing nodes	“I’m just putting this in a nice order” [Workshop 3], “Can I change the color of the connections?” [Workshop 1]	40 (45)
Categorization	Which heading a node should be assigned to	“Could we add other headings, for example ‘recommendations’?” [Workshop 4]	6 (7)
Phrasing	Use of synonyms or abbreviations	“Is writing ‘STDs’ appropriate or should I use ‘sexually transmitted disease’?” [Workshop 3]	32 (36)
Level of granularity	Detail level of the concepts	“Viral hepatitis, autoimmune hepatitis or [just] hepatitis?” [Workshop 2]	11 (12)
Rationales (n=318)			
Medical relations	Medical relations between the concepts, including the probability of differential diagnoses	“I think about it because it’s a young female on the pill” [Workshop 3], “We think about it because it’s quite common” [Workshop 1]	96 (30)
Relevance	Highlighting the medical urgency or indicating that most participants are of the same opinion	“It’s a potentially dangerous situation for our patient” [Workshop 3], “And also COVID-19, I think we all agree” [Workshop 4]	42 (13)
Individual concept maps	Referring to individual concept maps or clinical reasoning process when creating them	“In the individual mapping, we have PCR-test, someone wrote that” [Workshop 4], “Was this something you came up with now during this process or [when creating your concept map]?” [Workshop 1]	62 (19)
Referring to the case	Referring to the case by quoting or repeating facts	“He’s not saying that he takes any drugs” [Workshop 2], “The case has provided us a biopsy” [Workshop 1]	65 (20)
Professional experience	What participants have experienced in daily practice or what they are accustomed to doing	“This is usually the first serology I order” [Workshop 1]	19 (6)
Common knowledge	General phenomena in society or “universal truths”	“People lie – he might be an alcoholic” [Workshop 2] “One would expect that this nurse is already immunized” [Workshop 1]	5 (2)

Themes and subthemes	Description	Sample quotes	Values, n (%)
Encounter setting	Regional standards or differences between facilities (hospital, general practice, etc)	"How [do] you have it in Spain or Germany?" [Workshop 4], "I was wondering whether I would have done urine analysis in the [general] practice" [Workshop 1]	9 (3)
Hindsight	Assumption that the consensus process might be unconsciously guided by already knowing the final diagnosis	"[We think so because] we already know that it's mononucleosis" [Workshop 3]	6 (2)
Didactical aspects	What could be helpful for the students or is the content appropriate for their level of knowledge, etc	"It could be a good training for students, to think what can cause hepatitis" [Workshop 1], "I think it's too specialistic" [Workshop 3]	8 (3)
Functionality of the VP[a] platform	Features, navigation, or structure of the CASUS platform	"I don't know if this is possible on CASUS" [Workshop 2]	6 (2)
Next steps (n=107)			
Developing a strategy	How to approach the creation of the concept map	"[Let's] do differentials first before adding anything to tests" [Workshop 3]	78 (73)
Referring to facilitators	Referring to instructions given by facilitators or directly asking them for advice	"[It depends on] what is wanted or what is expected" [Workshop 1]	29 (27)

[a]VP: virtual patient.

Research Question 3: Challenges and Benefits of the Workshops

The results presented here are a summary of the field notes from the creation phase and the final round of questions, expanded by a descriptive analysis of the voting round. From a technical point of view, there were some problems due to the digital format, for example, weak network signal, low audio quality, or some participants feeling uncomfortable using Padlet for the first time. Since none of the participants were native English speakers, some struggled to find the right terms or misunderstood what others were saying due to a lack of vocabulary or the speaker's accent.

Regarding the different disciplines, it seemed that participants who had worked in their specialty for many years were somewhat biased by their daily experiences and had difficulty seeing the cases from a student's point of view. Some of the participants who were not physicians by training struggled to find the right diagnosis and expressed their uncertainty about certain medical terms or conditions. It was noticeable that topics such as didactic purpose, uncertainty (probability of differential diagnoses), or logical arrangement of nodes were hardly discussed.

All participants were cooperative and reached a consensus on the concept maps in an amicable manner. For about 10% (n=10) of the nodes, half (or more) of the participants abstained from voting or gave a thumbs down. We compared these nodes with the verbatim transcripts and found that for 6 nodes, there was no evidence in the discussion that any of the participants disagreed.

In the final round of questions, participants reported that creating a concept map with others was a complex task. On the other hand, participants found the group work helpful in stimulating their reflection and that it was constructive to create concept maps that included perspectives of different health professionals. In general, the structure of the workshops and the given timeline for the different parts were well-received. The round robin was seen as a useful introduction that helped them to understand the reasoning of other participants. Some participants mentioned that it was difficult to create a concept map for a case that they had not developed themselves or that they struggled with the fact that the case evolved over time, which made it more difficult to agree on a final version. Participants had mixed feelings regarding the usefulness of the consensus concept maps. While some were satisfied with the final concept maps and expected them to be helpful for students, others found the concept maps too messy or crowded in the end.

Research Question 4: What Students Considered as Helpful

When the medical students were asked whether they preferred the individual or consensus concept maps, there was a slight tendency toward the consensus versions as they contained more findings, which the students found helpful for their own CR process.

Regarding the content and scope of the concept maps, there was agreement that there should not be too many connections between nodes, as this was seen as more confusing than helpful. However, the students expressed contradictory opinions regarding the nodes. While some preferred the concept maps with only the most relevant nodes, others preferred those with a wider scope, as these would contain "the most details that we also agreed on while we were solving the case."

The same was true for the presentation of the content. Some students suggested having more layout features, such as "some type of colors" or dropdown functions, while others preferred a clear design and simple structure. Regarding the granularity of the nodes, some suggested that "the feedback map should be more [general.] To give us freedom" and should use broad terms such as "blood test." Others said that in their medical school, they "can't just say 'do blood test,' [but] must be very specific"; therefore, more specific terms would be helpful in the concept maps.

Discussion

Main Findings

In this study, we described the process of collaborative authoring of concept maps to serve as feedback in CR education using VPs. The participants regarded the collective process stimulating for reflection and helpful to understand the perspectives of the other health professional groups. We were able to find confirmation for this qualitative finding quantitatively by showing that the consensus concept maps contained more nodes and connections than the individual ones. This can also have negative aspects, as in the consensus workshops, participants tended to collect all nodes from the individual concept maps into the consensus version instead of selecting only the most relevant ones, paying little attention to didactic aspects. The structure of the workshops was well-received, participants appreciated working in interprofessional groups and easily reached a consensus, supporting their additions to the concept maps by high scoring of the concept map elements. However, there were some challenges, such as technical problems or participants being biased by their daily practice as specialists.

The final-year medical students in our focus groups preferred a variety of features of the concept maps, most of which were contradictory. As a result, it remains unclear which features can improve learners' outcomes and whether consensus concept maps are more suitable for teaching CR than individual ones.

Implications of the Findings

Our research suggests that there are a few approaches to help health professionals reach a consensus on a concept map. The procedure we used for the workshops served its purpose and was well-received by the participants. Thus, the results of this study can be seen as an important step toward establishing a sound consensus concept map protocol, informing about the benefits and challenges, and leading to the following recommendations for improving the process in the future:

1. Regarding the technical aspects of the workshops, we recommend that participants be given access to the digital whiteboard prior to the workshop so that those who wish to can familiarize themselves with the tool in advance.
2. Since didactic aspects played a minor role in the creation of the consensus concept maps, we recommend that an independent person with experience in didactics and concept mapping participates at the workshop. An alternative would be to prepare a pedagogical guide or checklist to be considered when developing concept maps for teaching CR. If such an opportunity arises, addressing the pedagogical aspects of concept map development would be a helpful element of faculty development courses on VP authoring.
3. When considering concept maps for VPs that address general CR skills in medicine, such as the one in the iCoViP project repository, workshops should preferably involve only internal medicine or family medicine physicians to avoid specialty bias. This would be different if the goal of the VPs was to achieve learning objectives for specialty or interprofessional education from the outset.

In terms of real-world implementation, we consider this study an important step in providing more diverse feedback to students working on CR concept maps in the context of VPs. This study contributed to this by showing that the concept maps created by consensus groups were more elaborate, both in terms of representing many viewpoints and in terms of the number of concepts and connections. However, this study also showed that the consensus groups should be more effectively encouraged to discuss the pedagogical aspects of the concept maps, such as how to adjust the complexity to the level of knowledge or cognitive load of the students.

Limitations

Our study has several limitations. First, the number of concept maps underlying the quantitative analysis was limited, so that the corresponding results should be interpreted with caution.

Second, it is possible that the results of the workshop are not applicable to "real-world" situations, in which colleagues work together on a concept map without being observed. The participants in our workshops were very polite to each other and tended to avoid disagreements, probably because most of them did not know each other. On the other hand, we were able to include the perspectives of professionals from different disciplines.

Third, we had a limited number of students in the focus groups. Our data suggest that the effect of different features of concept maps on individual learning and preferences may vary considerably from student to student. Future research is needed to explore this in more depth.

Fourth, the sample size of VPs and workshop participants was limited, which might make our findings less generalizable. However, we did not see any new themes emerging in the subsequent workshops and focus groups, suggesting that the qualitative analysis had reached its saturation point.

Comparison With Prior Work

There is a large body of literature on the so-called "group concept mapping" [14,40], including approaches to optimizing group compositions [41] or to identifying different cognitive styles [42]. However, to the best of our knowledge, most of these studies only include undergraduate students. Therefore, our study can be considered unique in proposing a novel approach to consensus concept mapping for health professionals.

The structure of the workshops, derived from the nominal group technique and adjusted to the needs of digital education, can be seen as a major strength. First, the round robin allows participants to gain insight into one another's CR approach.

Second, participants found the consensus creation of the concept maps useful and inspiring. Third, anonymous voting at the end facilitates the interpretation of the final concept map, as it gives the participants' view on each individual element without the need to openly criticize someone else's ideas.

When we compared the individual concept maps, we found a common tendency but also a great deal of variation, with most having only the final diagnosis and treatment in common. This is supported by the work of McGaghie et al [43,44], which shows the wide variety of approaches to a concept map of pulmonary physiology, even among experts in the same field. Therefore, the consensus process in our approach increased the universality of the feedback concept maps. Another positive aspect is that the process contributed to a rational increase in the number of connections in the concept maps. As previous research has shown, well-chosen connections are an important element of this form of knowledge representation, which is helpful in CR education [45].

We did not exclude from the study professionals without teaching experience, as we did not see clear evidence that this might be a limiting factor in creating meaningful concept maps. This is supported by a study by Charlin et al [46], who found that teaching and nonteaching physicians were similarly well suited to be part of the reference panel for concordance tests used to assess complexity and ambiguity in CR.

While some authors suggest the use of concept maps for CR assessment [47], most researchers in the field are ambivalent on this issue [8,9]. This is consistent with our findings, which suggest that the complexity and variety of the CR process make it very challenging to generate "expert concept maps" that can be used as a gold standard against which student versions can be compared.

Participants reported that they found the consensus workshops useful for reflecting on their individual concept maps and CR approach. Therefore, such workshops could also be a suitable tool for improving the concept map development of the individual participants. Further research is needed to determine the impact of the workshops on participants' ability to develop concept maps.

Our study focused on the creation of concept maps for medical students. Future research should investigate how this can be applied to other professions, as a recent meta-analysis suggests that concept maps are also an appropriate method for improving critical thinking skills in nursing students [48].

Conclusions

By providing feedback concept maps that illustrate the complexity and diversity of the CR process, we aim to support students in reflecting on their own thinking. The collaborative creation of concept maps for teaching CR is an opportunity to integrate different perspectives of health professionals and to account for individual differences in the reasoning process. In our study, we described a process for developing such collaborative concept maps and identified themes that emerged in workshops using this process. The resulting consensus concept maps tended to contain more nodes and connections than those created by individual health professionals and were well-received by students. We consider this study an important step in establishing a robust method for collaboratively creating effective concept maps in CR education. Future studies will focus on streamlining the process and identifying the most effective pedagogical features of feedback concept maps.

Acknowledgments

The creation of these resources has been partially funded by the Erasmus+ grant program of the European Union (grant 2020-1-DE01-KA226-005754). Neither the European Commission nor the project's national funding agency DAAD (German Academic Exchange Service) are responsible for the content or liable for any losses or damage resulting from the use of these resources. The authors would like to thank all the participants who took part in the workshops and student focus groups. In addition, the authors would like to thank Harriet Bergman for the language and grammar review.

Authors' Contributions

A Mayer, AAK, MS, and IH conceptualized the study. A Mayer and MS facilitated the workshops, which AAK and IH attended as observers, taking field notes. A Mayer and A Müller conducted the qualitative content analysis of the workshop transcripts, developing the coding framework and deriving themes from the data. AAK, MS, and IH reviewed the coding framework and the themes. MS and A Mayer facilitated the student focus groups. A Mayer and A Müller extracted themes from the focus group transcripts. A Mayer and AAK conducted the descriptive analysis of the questionnaire and the concept maps. A Mayer prepared all figures and the first draft of the paper. All authors reviewed and edited the draft and agreed on the final version.

Abstract

Background: Nowadays, generative artificial intelligence (GAI) drives medical education toward enhanced intelligence, personalization, and interactivity. With its vast generative abilities and diverse applications, GAI redefines how educational resources are accessed, teaching methods are implemented, and assessments are conducted.

Objective: This study aimed to review the current applications of GAI in medical education; analyze its opportunities and challenges; identify its strengths and potential issues in educational methods, assessments, and resources; and capture GAI's rapid evolution and multidimensional applications in medical education, thereby providing a theoretical foundation for future practice.

Methods: This scoping review used PubMed, Web of Science, and Scopus to analyze literature from January 2023 to October 2024, focusing on GAI applications in medical education. Following PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses Extension for Scoping Reviews) guidelines, 5991 articles were retrieved, with 1304 duplicates removed. The 2-stage screening (title or abstract and full-text review) excluded 4564 articles and a supplementary search included 8 articles, yielding 131 studies for final synthesis. We included (1) studies addressing GAI's applications, challenges, or future directions in medical education, (2) empirical research, systematic reviews, and meta-analyses, and (3) English-language articles. We excluded commentaries, editorials, viewpoints, perspectives, short reports, or communications with low levels of evidence, non-GAI technologies, and studies centered on other fields of medical education (eg, nursing). We integrated quantitative analysis of publication trends and Human Development Index (HDI) with thematic analysis of applications, technical limitations, and ethical implications.

Results: Analysis of 131 articles revealed that 74.0% (n=97) originated from countries or regions with very high HDI, with the United States contributing the most (n=33); 14.5% (n=19) were from high HDI countries, 5.3% (n=7) from medium HDI countries, and 2.2% (n=3) from low HDI countries, with 3.8% (n=5) involving cross-HDI collaborations. ChatGPT was the most studied GAI model (n=119), followed by Gemini (n=22), Copilot (n=11), Claude (n=6), and LLaMA (n=4). Thematic analysis indicated that GAI applications in medical education mainly embody the diversification of educational methods, scientific evaluation of educational assessments, and dynamic optimization of educational resources. However, it also highlighted current limitations and potential future challenges, including insufficient scene adaptability, data quality and information bias, overreliance, and ethical controversies.

Conclusion: GAI application in medical education exhibits significant regional disparities in development, and model research statistics reflect researchers' certain usage preferences. GAI holds potential for empowering medical education, but widespread adoption requires overcoming complex technical and ethical challenges. Grounded in symbiotic agency theory, we advocate establishing the resource-method-assessment tripartite model, developing specialized models and constructing an integrated system of general large language models incorporating specialized ones, promoting resource sharing, refining ethical governance, and building an educational ecosystem fostering human-machine symbiosis, enabling deep tech-humanism integration and advancing medical education toward greater efficiency and human-centeredness.

KEYWORDS

generative artificial intelligence; GAI; large language model; ChatGPT; medical education; human-machine symbiosis

Introduction

Background

The 21st century has seen accelerated advancement in information technology and artificial intelligence (AI), significantly altering lifestyles and work paradigms. With progress in deep learning and large-scale data processing, generative artificial intelligence (GAI) has emerged as an influential innovation. GAI rapidly expands into diverse applications, enabling content generation across text, images, and audio through the analysis of extensive datasets [1]. Its market demonstrates notable growth, with a 2024 global valuation of ~US $16.8 billion and a projected 37.6% compound annual growth rate (CAGR) from 2025 to 2030 [2], reflecting its significance in commercial and academic domains.

GAI's development is driven by advances in natural language processing (NLP), particularly the Transformer architecture, which enables the generation of complex content. Large language models (LLMs) serve as core technical implementations of GAI. Models like GPT-3, GPT-4, Copilot, and LLaMA 3 have expanded GAI applications from basic automation to sophisticated tasks including content creation, data analysis, and intelligent question-answering systems [3]. These transformer-based LLMs exemplify how conceptual GAI frameworks are operationalized via model architectures and engineering practices.

With technological advancements, GAI has gradually infiltrated more specialized fields, with medical education a prime example. This domain faces challenges due to its knowledge-intensive and highly practical characteristics: traditional teaching methods struggle to replicate clinical scenarios efficiently, and increasingly scarce clinical teaching specimens and patient resources limit the clinical practice training of medical students, all of which are not conducive to the cultivation of medical talents with both clinical thinking and practical ability [4]. In this content, GAI may empower medical education through its enhancement effects on 3 core educational elements: improving resource generation efficiency, optimizing the interactivity of pedagogical approaches, and enhancing the automation level of assessment processes [5,6]. Nevertheless, the accompanying integration risks include potential biases and inaccuracies in generated content [7] and possible inhibition of critical thinking through over-reliance [8]. Thus, optimal implementation strategies warrant further investigation.

Current GAI integration in medical education involves rapid technological iteration and shifting research paradigms [1,9,10]. Prior reviews exhibit three limitations: (L1) Overreliance on single-model analyses (predominantly ChatGPT) [9,10], (L2) insufficient examination of geographical disparities in adoption patterns, and (L3) fragmented assessment of GAI's impact across 3 core dimensions of medical education. These dimensions include resources (teaching support materials like GAI-generated clinical cases and pathological images), methods (instructional strategies like adaptive learning pathways and simulated decision-making), and assessment (automated evaluation of learner performance, such as automated short-answer scoring). Crucially, studies before 2023 were constrained by the technology's maturity, missing the recent shift from theoretical exploration to operational implementation [1]. Therefore, a new round of scoping review is urgently needed to focus on the critical evolution period between January 2023 and October, 2024 (before the completion of this scoping review), construct a multidimensional analytical framework (encompassing resources, methods, and assessment), and clarify the complex picture of the deep interaction between GAI and medical education. To guide this investigation, this study discusses the multifaceted landscape of GAI adoption in medical education through 3 interconnected lines of inquiry. First, it aims to examine whether regional disparities exist in GAI implementation and how researchers exhibit preferences for specific LLMs (eg, ChatGPT). We posit that adoption patterns will demonstrate significant stratification aligned with national development levels and reflect preferential usage of widely accessible general-purpose models. Second, it seeks to map the current state of GAI applications across educational resources, methods, and assessment dimensions. We hypothesize that effectiveness will vary substantially across these domains due to differences in technical implementation requirements and inherent task complexities. Third, it intends to identify current limitations and future challenges, positing that technical deficiencies, including ethical risks such as compromised academic integrity and data hallucinations, will constitute the most significant barriers to sustainable integration.

Theoretical Framework

Theoretical Model: The Theory of Symbiotic Agency

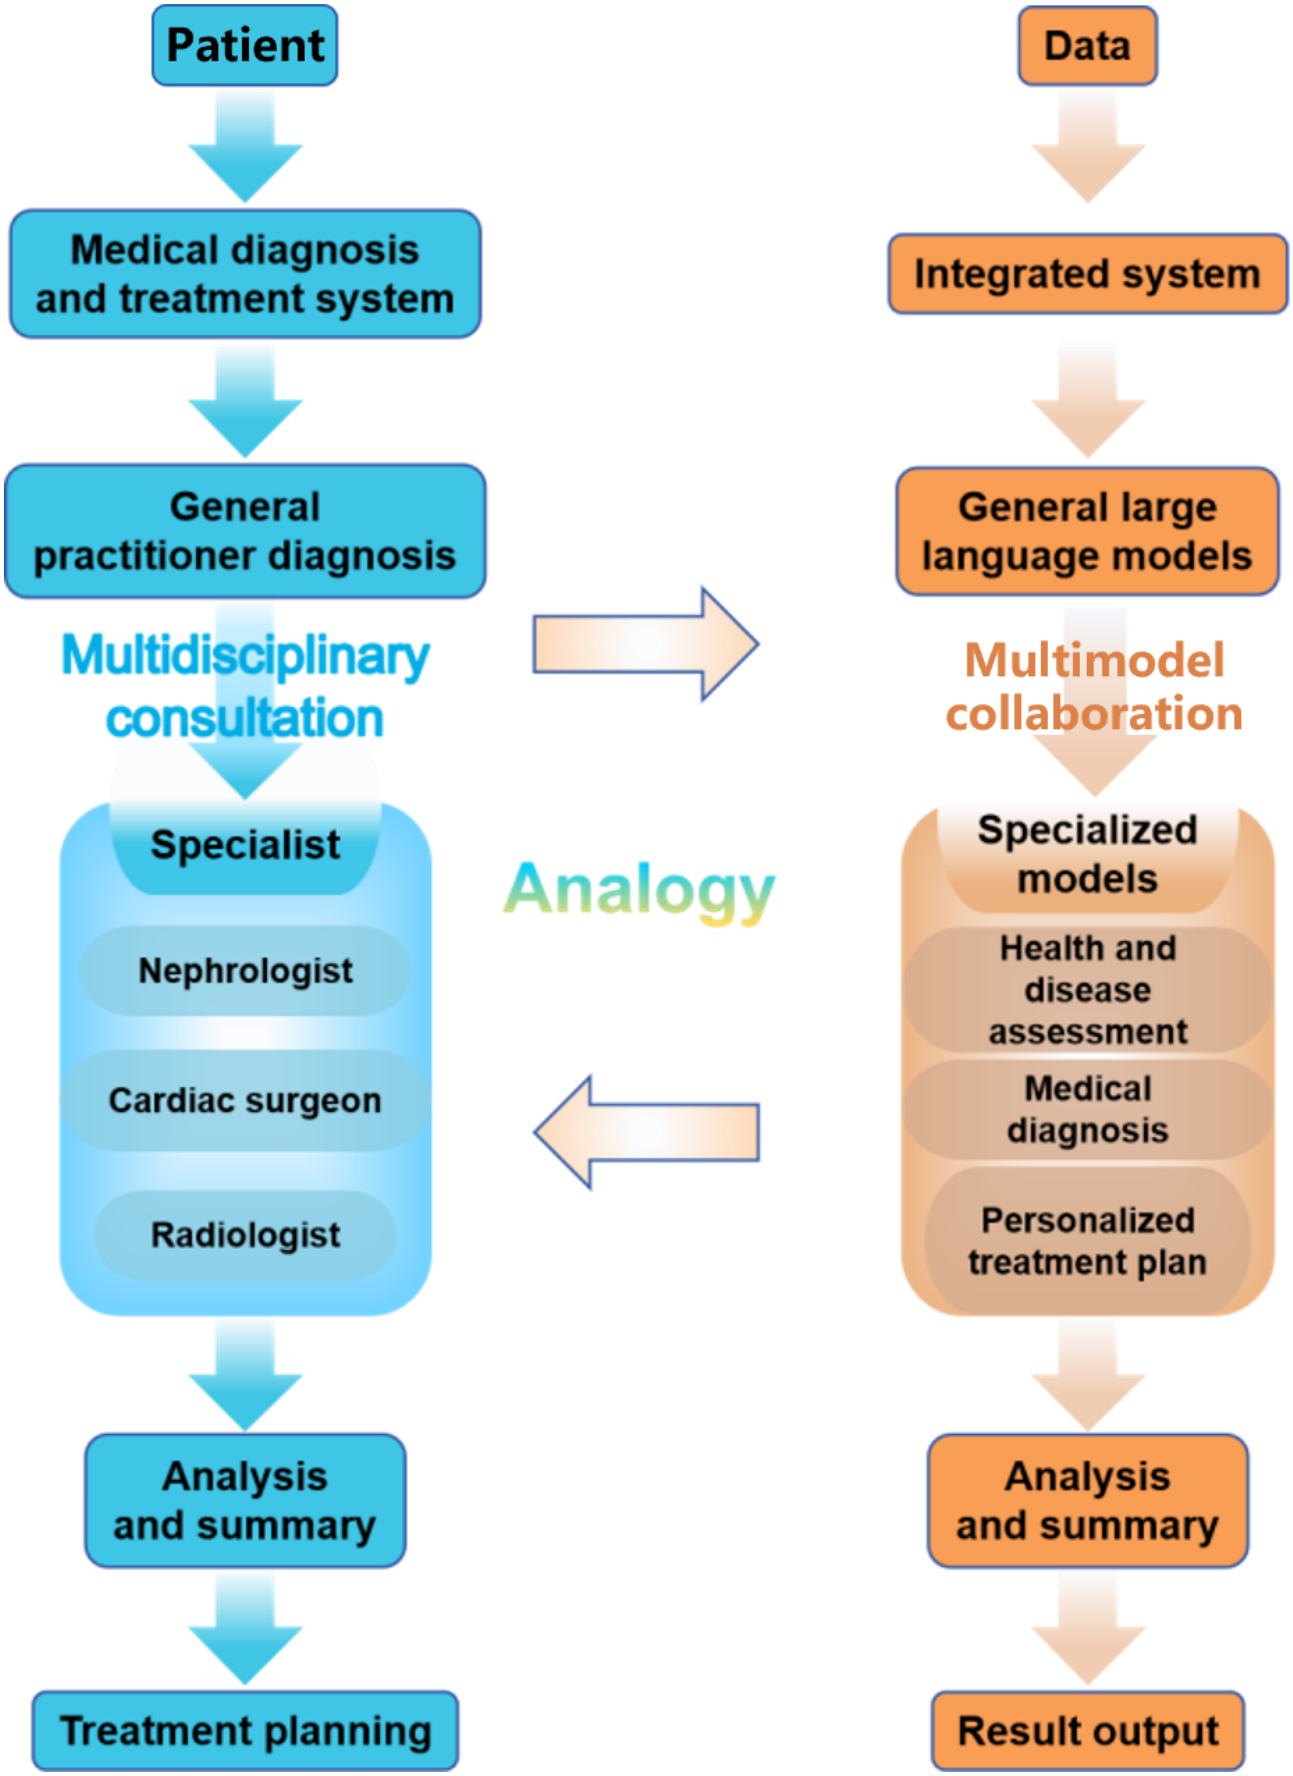
Based on the theoretical framework of symbiotic agency [11], a theory emphasizing interdependent and collaborative relationships between humans and technology, this study conceptualizes human-technology relations as a process of mutual constitution. Technology functions neither as a passive instrument dominated by humans nor as an autonomous replacement for human agency. Instead, it develops in tandem with humans through interdependent interactions: technology enhances human efficacy by expanding cognitive boundaries and enabling novel multimodal interactions, while humans legitimize technological practice by embedding ethical norms and conducting context-specific interpretations such as weighting clinical decisions. This symbiosis transcends traditional master-servant dichotomies by establishing a responsibility-sharing network. Within this network, technology acts as a co-agent in human activity systems, collectively enhancing capabilities rather than substituting human roles. This perspective provides the foundational understanding needed to maintain a dynamic balance in human-technology interdependence within medical education, forming the basis of our conceptual model.

Conceptual Model 1: Specialized Models Integrated System Based on General Large Language Models

Building upon the analytical framework established in Table S1 in Multimedia Appendix 1, which systematically compares general-purpose and domain-specialized GAI models across 3 critical dimensions (knowledge representation fidelity, task compatibility, and ethical constraint mechanisms), this study deconstructs technological heterogeneity to avoid conflating "GAI" as a homogeneous entity. The models in Multimedia Appendix 1 (see Table S1) were selected via multisource evidence synthesis, including peer-reviewed studies, industry reports (eg, Global Large Language Model (LLM) Market Research Report 2024) [12-20], and empirical validation in educational contexts, based on four criteria: (1) technological representativeness of core advancements (multimodality, reasoning, and domain adaptation); (2) broad academic and practical relevance in medical education; (3) functional diversity covering text, image, video, and domain-specific tasks; and (4) market prevalence, wide recognition, technical maturity, and development by prominent AI companies. Notably, models like Perplexity, DeepSeek, Notebook LM, and Midjourney, though used by clinicians and students in specific scenarios, were not included due to limited evaluative data and insufficient supporting information in the referenced reports.

Within this ecosystem, general LLMs serve as multitasking hubs, leveraging cross-domain adaptability and natural language interaction, while specialized models achieve context-specific efficacy through the embedding of deep medical knowledge. To resolve their complementary yet fragmented coexistence, we propose a specialized model integration system anchored to general LLMs, inspired by symbiotic agency theory and hospital diagnostic workflows [21] (see Figure 1). This architecture establishes a 3-tiered clinical analog: general LLMs serve as primary coordinators, managing task orchestration; specialized models act as domain experts, executing depth-specific processing; and protocol-based collaboration enables online consultation through knowledge distillation and output validation. This hierarchical integration embodies symbiotic agency principles: general models extend the applicability of specialized techniques by transcending domain boundaries, while specialized models enhance system depth by reinforcing medical logical rigor. Through functional complementarity and role differentiation, they form a synergistic symbiont exceeding individual capability limits, establishing an intelligent foundation for medical education characterized by adaptability, expertise, and reliability.

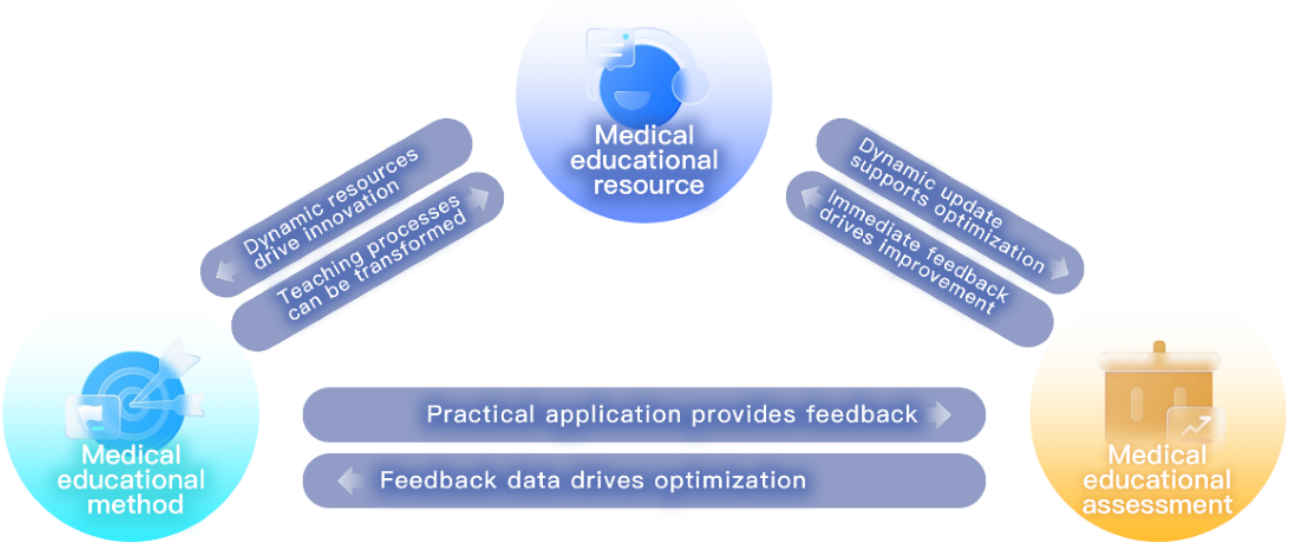
Figure 1. Specialized model integration system based on general large language models.



Conceptual Model 2: Tripartite Synergistic Integration Model for Medical Education Resources, Methods, and Assessment

The tripartite synergy paradigm, rooted in complex systems management theory and evidenced across domains from political governance to integrated health care systems (eg, the mission alignment model by Peek et al [22]), establishes our resource-method-assessment (RMA) framework (see Figure 2) as the core analytical structure [22,23]. This framework defines three interdependent dimensions: (1) resources encompassing dynamic content provisioning mechanisms, (2) methods designing knowledge-to-practice training pathways, and (3) assessment managing outcome monitoring and feedback generation. Their cyclical optimization forms an integrated whole, as resource renewal enables pedagogical innovation, method implementation yields evaluative data, and assessment outputs drive resource refinement and method calibration. Within this architecture, GAI operates as a collaborative instrument executing content generation, interaction support, and data analysis under educator-directed goal design, ethical governance, and critical intervention. The established framework provides essential categorization criteria for subsequent empirical analysis: it defines 3 dimensions—resources, methods, and assessment—directly corresponding to 3 primary research domains in GAI applications for medical education. By consolidating fragmented literature within a unified analytical structure, this framework systematically addresses cognitive limitations arising from isolated examinations of technological functions, thereby elucidating the intrinsic operational logic of technology-enabled educational transformation.

Figure 2. The model of integrated and collaborative development of medical education methods, resources, and assessment.



Methods

Review

With the rapid development of GAI, its applications in medical education have garnered considerable attention and have become a significant research focus. We conducted a preliminary search using the keyword combination of “generative artificial intelligence” and “medical education” across PubMed, Web of Science, and Scopus. Our goal was to analyze the publication trend regarding the applications and challenges of GAI in medical education over the past 5 years (from January 2020 to October 2024). The literature search was limited to sources published between January 2023 and October 2024 for the following reasons: (1) Technological progression: The 2023‐2024 period coincides with a shift from theoretical proposals (pre-2023) to empirical studies on GAI implementation in medical education. (2) Scope alignment: The review prioritizes analysis of current applications, identified limitations (eg, output inaccuracies and integrity concerns), and near-future developments rather than historical trends. (3) Avoiding redundancy: Pre-2023 literature is excluded to prevent overlap with existing syntheses and focus on emergent applications (eg, automated assessment and adaptive resources) evidenced in the sampled literature (n=131). (4) Practical relevance: This timeframe reflects consolidated evidence on operational challenges and benefits relevant to contemporary pedagogical decision-making.

Search Strategy

We used Boolean operators to combine GAI and medical education keywords, creating the final search strategy (see Multimedia Appendix 2). A thorough search was conducted across 3 major databases: PubMed, Web of Science, and Scopus, focusing only on English-language articles published from January 2023 to October 2024.

Inclusion and Exclusion Criteria

This study included research articles focusing on the applications, challenges, and future development of GAI in medical education applications. Articles were excluded if they were commentaries, editorials, viewpoint, perspective, and short reports or communications with low level of evidence or did not discuss GAI within medical education. Studies focusing on non-GAI forms such as predictive analytics and natural language processing or those centered on other fields of medical education (eg, nursing) were also excluded. We excluded nursing based on fundamental educational differences. Clinical and dental

education follow structured undergraduate curricula focused on acute care, diagnostics, and technical skills within hospital settings. Nursing emphasizes community practice, longitudinal relationships, and chronic disease management [24]. Including nursing would introduce significant heterogeneity in learning outcomes, GAI applications, and educational contexts. This methodological exclusion preserves thematic coherence and internal validity for analyzing GAI's role in comparable, technology-driven medical education environments.

Initially, YL and ZL conducted a preliminary screening of titles and abstracts from 3 databases. With the help of Zotero 7.0.13 (64-bit), a document management software (it is a project of Digital Scholar and developed by a global community), ZL detected duplicates of the initially screened articles according to title, author, abstract, and other information and removed duplicates. Following this initial phase, YL and ZL independently reviewed the full texts for a second round of evaluation. In cases of disagreement, ZY and NZ were consulted to mediate and make the final determination regarding inclusion.

Data Extraction Protocol

To ensure the systematicity, transparency, and reproducibility of this scoping review, a detailed data extraction protocol was developed and rigorously followed.

Data Point Definition and Protocol Development

Before comprehensive data extraction, a structured data extraction form was collaboratively developed by all authors. This iterative process was guided by our research questions and the predefined thematic framework outlined in Table 1, which focused on the applications, challenges, and prospects of GAI in medical education applications. The form was designed to systematically capture key information from each included article, encompassing: bibliographic details (eg, authors, publication year, journal, and country or region), study characteristics (eg, research design, objectives, and population), specific GAI models used (eg, ChatGPT [OpenAI] and Gemini [Google]), application scope (single-model vs multimodel), analysis type (performance comparison across models or examination of synergistic enhancement through model integration), detailed descriptions of identified applications, challenges, and future directions of GAI application in medical education categorized exclusively through our tripartite Trinity Framework and quantitative performance metrics (reported accuracy rates, percentages, mean scores, standard deviations, and *P* values related to GAI model performance in various tasks). This granular definition of data points ensured that all relevant information pertinent to our broad research inquiry was systematically collected.

Table . A systematic thematic analysis of applications and challenges of generative artificial intelligence (GAI) in medical education.

Category and theme		Subtheme
Medical educational assessment		
	Scoring short answers automatically.	—[a]
	Evaluating articles.	—
Medical educational resources		
	Providing standard answers.	• The performance of different question types. • The performance of different difficulty questions. • The performance of questions at different cognitive levels.
	Generating diverse clinical cases.	—
	Digital interaction and communication training.	—
	Sharing educational resources.	—
	Generating clinical images.	—
Medical educational methods		
	Curriculum design.	—
	Generating customized teaching aids.	—
	Generating explanations for MCQ[b].	—
	Personalized learning support.	—
	Medical decision aid.	—
	Multidisciplinary knowledge acquisition.	—
	Academic writing optimization.	—
Existing defects at this stage		
	Insufficient scene adaptability.	• Poor ability to handle complex clinical scenarios. • Lack of local background in specific regions. • Language adaptability issues. • Lack of nontextual information analysis skills.
	Data quality and information bias	• Hallucination phenomena. • Lack of details on output content. • Lack of personalization. • Dataset dependency.
Potential issues in the future		
	Overreliance	• Impaired critical thinking. • Decreased creativity. • Decreased teamwork ability. • Decreased practical problem-solving ability.
	Ethical controversy	• Authenticity of the test results. • Academic misconduct. • Lack of clinical interaction and emotional resonance. • Resource inequality. • Ownership of intellectual property rights. • “Black box” problem and attribution of responsibility.

[a]Not available.

[b]MCQ: multiple choice question.

To better understand the global research landscape in this field, we analyzed the countries or regions of origin for the 131 selected articles. For those without a precise location, we assigned them according to the country or region of the corresponding author's institution. To analyze the distribution of research based on the countries or region's development level, we used the Human Development Index (HDI) classification. The latest HDI data categorizes countries or regions into 4 tiers: very high, high, medium, and low human development with higher HDI scores correlating with greater national development. We also investigated cross-level HDI collaborations, which refer to partnerships between countries from different HDI categories [25].

Protocol Testing and Quality Control

To validate the comprehensiveness and clarity of the data extraction form, a pilot test was independently conducted by 2 reviewers, YL and ZL, on a randomly selected subset of 10 included articles. During this pilot phase, any discrepancies in data extraction or ambiguities within the form were identified and discussed. Based on these discussions, the data extraction form underwent iterative revisions to refine categories, clarify definitions, and ensure consistent interpretation of data points among reviewers. Following this refinement, YL and ZL independently extracted data from all 131 included articles. In cases of disagreement between the 2 independent extractors, consensus was initially sought through discussion. If a consensus could not be reached, a third and fourth reviewer, ZY and NZ, were consulted to mediate and make final determinations regarding the applicability and extraction of the data.

Synthesis of Results

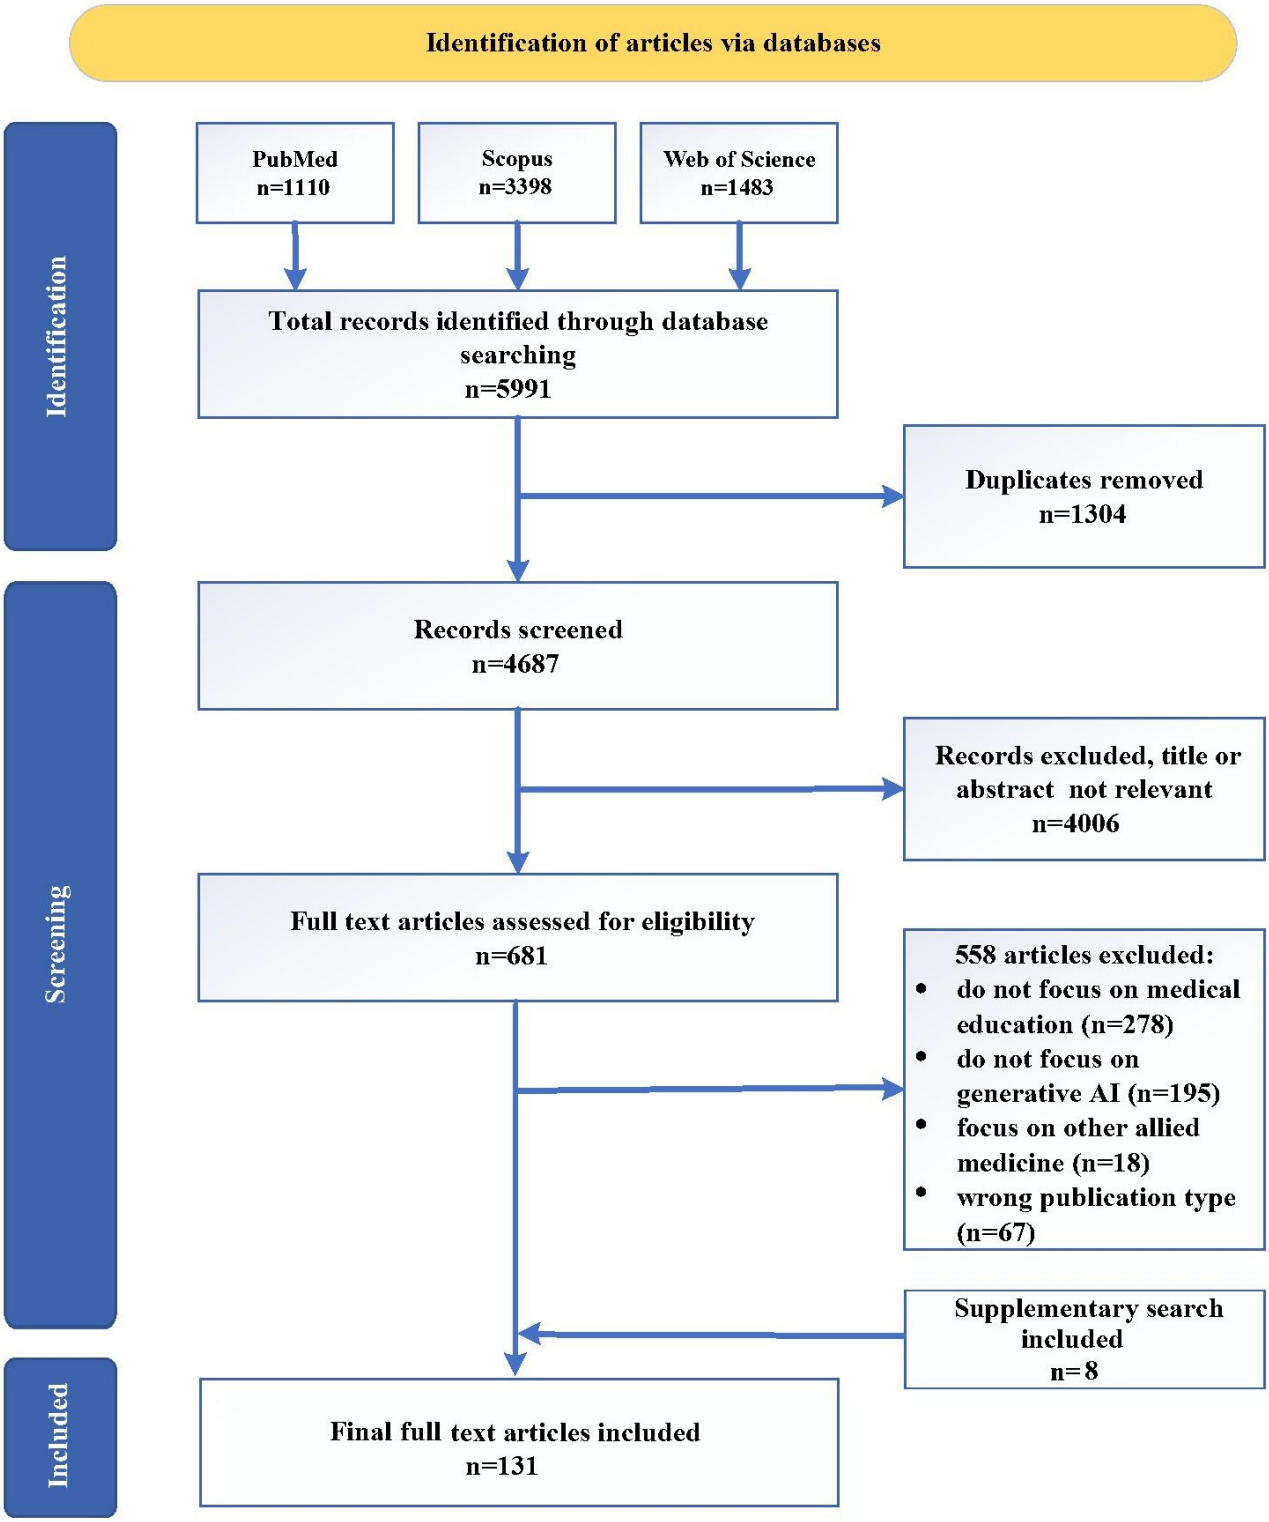
ZY subsequently compiled and reorganized the extracted data, assigning new identifiers for easier reference. This organized dataset was then categorized according to the predefined themes and subthemes (see Table 1), forming the basis for the subsequent descriptive summary and analysis. Our analysis employed a theory-driven, top-down approach anchored in a tripartite conceptual model of medical education: resource generation, method innovation, and assessment upgrade. The following sections will present a descriptive summary of the extracted data.

Results

Overview

Following our search strategy, we retrieved 5991 articles, of which 1304 were duplicates, leaving 4687 articles. In the first round of screening, 4006 irrelevant articles were excluded based on titles and abstracts, leaving 681 articles. In the second round, we excluded 558 articles after full-text review, including 278 nonmedical education articles, 195 non-GAI articles, 18 focused on other medical fields (eg, nursing), and 67 of different types (eg, commentaries). During the paper preparation, we conducted a supplementary search for 8 systematic reviews and meta-analyses. Ultimately, 131 articles were included in the final review (see Figure 3). Among the 131 included studies, the distribution of research designs was as follows: 83 cross-sectional studies, 5 randomized controlled trials (RCTs), 2 quasi-experimental studies, 1 cohort study, 1 quasi-randomized controlled trial, 8 systematic reviews and meta-analyses, 5 mixed-methods studies, and 1 case study. The remaining 25 studies were categorized as "other" with nonstandardized research designs, which were not fitting typical epidemiological or evidence-based medicine classifications. Collectively, cross-sectional studies (descriptive research designs) constituted the majority (n=83), reflecting the emerging state of GAI in medical education, where most research focuses on initial application explorations, feasibility assessments, and user experience descriptions rather than hypothesis-driven experimental designs. Other study types, including RCTs, cohort studies, and systematic reviews, provided supplementary evidence on intervention effects, longitudinal trends, and synthesized findings, respectively.

Figure 3. Article screening flow chart. AI: artificial intelligence.



Analysis of Literature Source and Human Development Levels

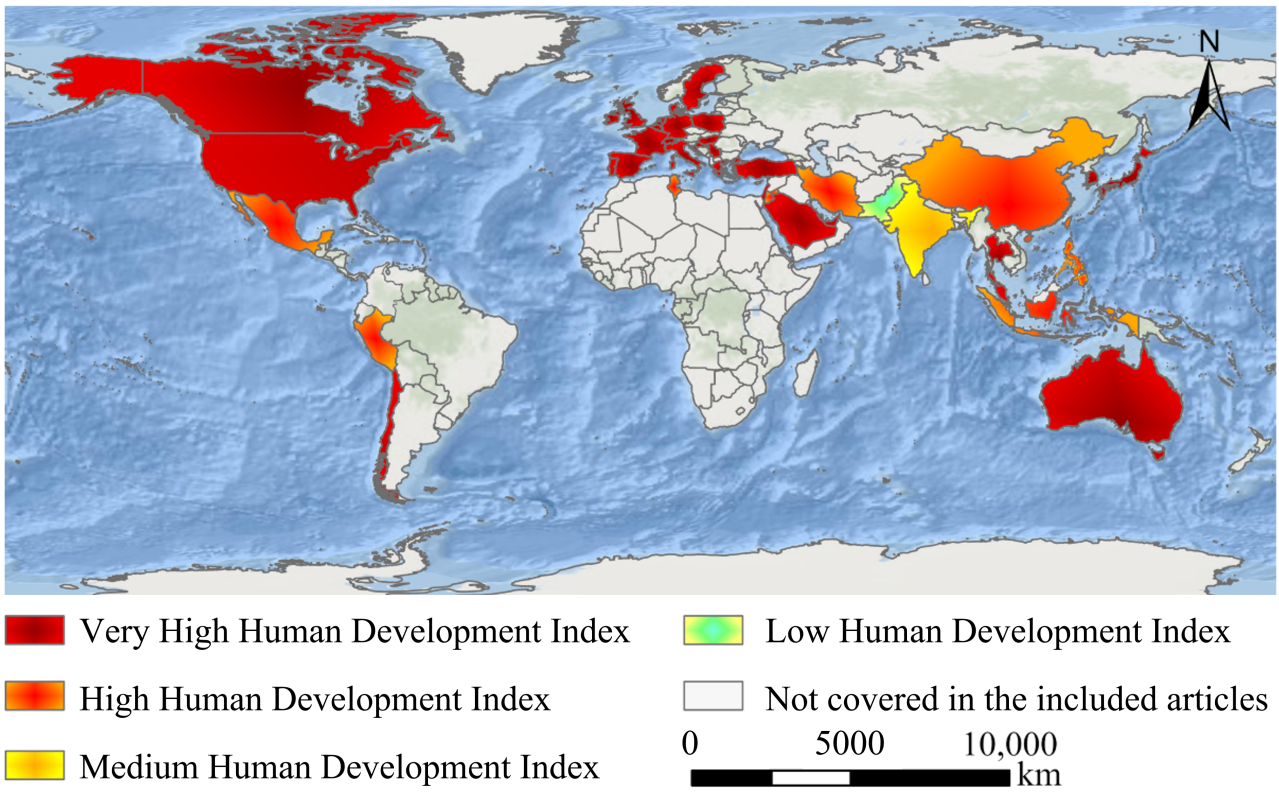
Based on the countries or regions of origin for the included articles and HDI classification, we analyzed the distribution of related studies. The results are illustrated in Table 2 and Figure 4. A significant portion (74%, n=97 articles) of the research came from countries or regions with very high human development, with the United States contributing 33 studies. High human development countries or regions produced 15% (n=19 articles), with China contributing 13 studies. Medium human development countries or regions contributed 5% (n=7 articles), mainly from India, while low human development countries or regions accounted for only 2% (n=3 articles). Furthermore, 4% of the studies (n=5 articles) involved cross-level collaborations, primarily between very high and medium or low HDI countries or regions.

Table . Distribution of countries or regions of origin for generative artificial intelligence (GAI) research in medical education (categorized by the HDI[a]).

HDI classification	Portion, n (%)
Very high human development	97 (74.0)
High human development	19 (14.5)
Medium human development	7 (5.3)
Low human development	3 (2.2)
Cross-level HDI collaboration	5 (3.8)

[a]HDI: Human Development Index.

Figure 4. Geographical distribution of countries or regions of origin for generative artificial intelligence (GAI) research in medical education.



Applications of GAI in Medical Education

Medical Educational Assessment

Scoring Short Answers Automatically

A recent study examined GPT-4 (OpenAI) and Gemini 1.0 Pro in automated short answer grading using 2288 student responses from 12 undergraduate medical courses across 3 languages, with instructor-provided rubrics or sample solutions as reference standards. GPT-4 showed high precision (0.91) in identifying fully correct answers, though its scores were significantly lower than human graders, while Gemini 1.0 Pro had no significant difference from human evaluations, with a mean normalized score of 0.68 (SD 0.32) and median of 0.75, similar to humans. Both models demonstrated high consistency across repeated evaluations, especially with high-quality standard responses, and these findings are specific to undergraduate medical education contexts [26].

Evaluating Articles

Liu et al [27] reported that in their study of 50 rehabilitation-related original articles, 50 sections (introductions, discussions, and conclusions) were generated by ChatGPT-3.5 and 50 were corresponding AI-rephrased versions using Wordtune Originality.ai, achieved 100% accuracy in detecting both AI-generated and AI-rephrased content. ZeroGPT correctly identified 96% of AI-generated texts and 88% of rephrased ones. The study focused specifically on rehabilitation medicine with analyzed content limited to partial article sections rather than full texts. It is notable that such high detection rates have not been widely observed across other disciplines or with newer large language model versions. The specialized nature of medical writing, including technical terminology use, may also influence these outcomes in ways not seen in broader academic contexts, which should be considered when evaluating the generalizability of these findings. Another study comparing automatic scoring systems (ChatGPT-3.5 and ChatGPT-4) with manual scoring for article quality assessment found no

significant difference between GPT-4-based scoring and human grading. This demonstrates the considerable potential of GAI to enhance the quality evaluation of articles [28].

Medical Educational Resources

Providing Standard Answers

The performance of different question types: The studies encompassed a range of question types, including multiple-choice questions (MCQs), single-choice questions, short-answer questions (SAQs), true or false questions, open-ended short-answer questions (SOAQs), long-answer questions, clinical case analysis questions (CAQs), and image-text integrated questions [29-37]. An exploratory study conducted by a research team from Qatar University evaluated ChatGPT's performance across various assessment formats relevant to undergraduate dental education. The study included 50 assessment items covering 50 different learning outcomes, with 10 items for each of the 5 formats: MCQs, SAQs, short essay questions (SEQs), single true or false questions, and fill-in-the-blank items. These items were based on core clinical topics in dental education, such as restorative dentistry, periodontics, endodontics, and oral surgery, aligned with the learning outcomes expected of undergraduate dental students. In this study, ChatGPT demonstrated 90% accuracy for SAQs, SEQs, and fill-in-the-blank items and notably achieved 100% accuracy in single true or false questions [31]. However, other studies have revealed a significant decline in accuracy for CAQs, as low as 17%, which require strong logical reasoning and lack predefined options [34].

Regarding MCQs, a study reported that GPT-4 and Microsoft Bing achieved top scores (76%) on the University of Antwerp medical licensing MCQ exam, outperforming medical students. However, ChatGPT's accuracy fell considerably when tackling Chinese-language medical MCQs with an accuracy of 37%. In addition, another study reported that in the Chinese Master's Degree Entrance Examination, ChatGPT's accuracy for single-choice questions (A1 type) was 56%, whereas for MCQs, it dropped to 33% [15]. These findings suggest that GAI's performance is not uniformly robust across all MCQ types and is influenced by factors such as question structure, subject domain, difficulty, language, and the presence of clinical vignettes or images.

The performance of different difficulty questions: In terms of difficulty, questions were generally classified as "easy," "medium," or "difficult." For example, the difficulty levels are defined based on the performance indicators of the historical question bank: "Difficult" (P<.30; less than 30% of the students answered correctly), "Medium" (P=.30 to .80), and "Easy" (P>.80) [35]. ChatGPT-4 demonstrated strong performance on easy questions, with accuracy rates reaching 97.4%. Yet, even in this category, ChatGPT-4's performance lagged behind that of residents [35,38-42]. In contrast, ChatGPT-4 excelled on medium and difficult questions, outperforming residents by 25.4 and 24.4 percentage points, respectively [38]. Across all models, performance tended to decline with increased difficulty, especially for higher-level questions that required multistep reasoning, where accuracy dropped markedly [39-45].

The performance of questions at different cognitive levels: 2 studies investigated the performance of ChatGPT-4 on questions categorized by Bloom's taxonomy, which includes 6 cognitive levels: remembering, understanding, applying, analyzing, evaluating, and creating [46]. These studies found that ChatGPT-4 consistently performed well across all cognitive levels, with an average correct answer rate of 71.96% for each cognitive level [47,48].

Generating Diverse Clinical Cases

By collaborating with instructors, GAI can quickly generate comprehensive clinical cases, including patient history, physical examination results, lab data, and differential diagnoses tailored to predefined learning objectives (eg, chest pain and joint pain). This reduces the time instructors spend developing such cases [49,50]. Furthermore, GAI-generated cases can integrate various contextual factors such as race, occupation, and lifestyle, significantly enriching the diversity of teaching materials [51]. For example, when creating a case based on a disease profile specific to a region, the ethnicity of the generated patient can be adjusted accordingly. In the context of type 2 diabetes, modifications can be made to the age range and weight distribution. In addition, randomized prompts for urine analysis may be included in urinary tract infection cases. Both patient presentations and examination findings can be randomized, and symptom expression can be customized to meet specific learning needs [51].

In Smith and colleagues' [52] study, GAI was assigned the task of creating a case of an immigrant with mental health concerns, as this group may require specialized social psychiatry interventions. The results indicated that GAI was able to produce a case that met fundamental educational objectives. However, it included several signs of emotional disorders, highlighting a need for further refinement.

Digital Interaction and Communication Training

Studies have shown that GAI is effective in promoting interactive learning and providing practice in communication skills. GAI-powered simulation tools simulate changes in clinical conditions in scenarios such as advanced cardiac life support (ACLS) and intensive care unit (ICU) sepsis, prompting students to critically analyze whether their decisions are correct [53]. In addition, conversational GAI-created digital patients provide anesthetists with valuable training for patient interactions, reducing reliance on human actors while enhancing the flexibility and consistency of the training process [54]. These digital interactions create a safe space for repeated practice, providing dynamic learning experiences that traditional textbooks cannot match [52,55]. Furthermore, conversational GAI models, such as chatbots, can simulate the role of a professor, offering critical evaluations of literature and distilling complex research into easily understandable key findings, thus fostering simulated discussions between students and experts in the field [56]. However, besides experiences and qualitative observations, formal evaluations of the reliability and validity of such GAI-generated information in a professor-like capacity are still needed.

Sharing Educational Resources

By generating accessible public health information, GAI enhances the public's understanding of essential health issues, such as infectious disease prevention and vaccination, ultimately leading to improved health literacy [30]. Furthermore, GAI-generated clinical cases can be disseminated as Open Educational Resources (OERs), providing medical educators with globally adaptable teaching materials that are customized to local contexts [51].

Generating Clinical Images

GAI tools such as Adobe Firefly, DALL·E 2 (OpenAI), Bing Image Creator, and generative adversarial networks (GANs) can create clinical images displaying various pathological features based on textual descriptions, potentially addressing the shortage of authentic pathological images in traditional medical education due to medical confidentiality and patient privacy restrictions [51,57-59]. For instance, images of retinal disease generated by the stable diffusion model enhance students' learning opportunities in ophthalmic pathology, greatly enhancing the availability of visual teaching resources [57]. However, their reliability and accuracy vary significantly across models and tasks. For example, DALL·E 2 demonstrated an overall clinical accuracy rate of 22.2% in aligning generated images with textual prompts across 15 semantic relations (eg, spatial and action-based relationships), with only 3 relationships (touching, helping, and kicking) achieving moderate consistency above 25%. In a medical education context, DALL·E 2 achieved 78% accuracy for soft-tissue tumor images but produced inconsistent results for wound images, with 65% of generated wound images containing anatomical inaccuracies or irrelevant elements [58]. A comparative study of DALL·E 2, Midjourney, and Blue Willow for generating skin ulcer images showed DALL·E 2 performed best with an average score of 3.2/5 (scale 1 - 5) but still produced irrelevant content (eg, X-rays instead of pressure ulcers) in 20% of cases. Midjourney generated stylized, exaggerated features in 40% of images, while Blue Willow produced images with little relevance to prompts in 70% of attempts [59].

Medical Educational Methods

Curriculum Design

GAI shows potential in the early stages of curriculum development, aiding in quickly creating course objectives, learning strategies, and frameworks. For instance, in a study on integrated pharmacotherapy of infectious disease education modules, ChatGPT helped design curriculum goals (eg, "describe mechanisms of antibiotic resistance") with an average expert rating of 92% for appropriateness and accuracy, supporting educators—especially in designing foundational courses [60].

Generating Customized Teaching Aids

Researchers have developed derivative applications based on classical models, such as Glass AI (a powerful AI-driven knowledge management system developed by Glass Health, focusing on organizing and retrieving health-related information efficiently). It integrates GPT-4 with evidence-based, peer-reviewed clinical guidelines to generate differential diagnoses and clinical plans based on textual input of clinical cases, enabling students to interact with it and experience the GAI-driven diagnostic process for cases [61]. Similarly, an MCQ generator based on ChatGPT-generated cases offers a dynamic platform for personalized learning assessments [62].

Generating Explanations for Multiple-Choice Questions

Research shows that when GAI is used to answer MCQs, the explanations generated by GAI can better convey key knowledge points and achieve good accuracy and degree of matching with teachers' explanations. Of the 81 questions explained by the teacher and correctly answered by ChatGPT, 92.6% of the explanations were accurate and included at least part of the teacher's explanation. However, the research also highlights that if an initial response is incorrect, the likelihood of subsequent errors increases significantly (P<.001), indicating that an early mistake may lead to systematic inaccuracies in later explanations [63]. Complementing this, in a systematic review, the broader literature reviewed showed that the majority of studies (5/8, 62.5%) indicate the effectiveness of AI in generating valid MCQs, with a preference for the latest GPT-4 models (6/8, 75%) [64].

Personalized Learning Support

Studies demonstrate that GAI boosts students' learning efficiency across multiple stages by offering personalized feedback and customized content. This includes support for exam preparation [55,65-68], optimizing learning paths and review strategies [52,69-71], clarifying medical concepts [68,72-76], and assisting in the development of tailored career plans [77]. For instance, in physiological case analysis, GAI offers precise responses and contextually relevant feedback. A cross-sectional study tested 77 physiology case vignettes (covering diverse physiological and pathophysiological scenarios, designed for undergraduates) on ChatGPT 3.5, Google Bard, and Microsoft Bing. Rated by two physiologists on a 0 - 4 scale, ChatGPT scored highest at 3.19 (SD 0.3), outperforming Bard (2.91, SD 0.5) and Bing (2.15, SD 0.6) with P<.001. ChatGPT's precision accelerates task completion, helping students grasp medical knowledge in practical scenarios more effectively [78]. Furthermore, a study found that in cases of initial incorrect responses, GPT-4 was able to self-correct and provide accurate answers after simple follow-up questions or hints, mimicking pedagogical interactions observed in residency programs. This dynamic learning approach, coupled with rapid information processing, positions GPT-4 as an important asset for personalized learning [79].

Medical Decision Aid

GAI uses its ability to analyze complex, domain-specific knowledge to support the diagnosis of rare and intricate diseases. In addition to diagnosis, it can generate differential diagnoses tailored to the unique characteristics of each disease, providing health care professionals with precise decision-making support [80-83]. For common pathological issues and basic data analysis, GAI tools are efficient and accurate, helping pathologists organize their thought processes and expedite the initial diagnostic phases [84]. The impact of domain-specific training is profound. For instance, refined datasets in the surgical and

anesthesiology fields enhance GAI's clinical decision-making capabilities. In scenarios such as a "30-year-old pregnant woman requiring an emergency appendectomy," GAI suggests not only tailored surgical strategies but also factors in critical anesthesia protocols [85]. Furthermore, in the field of traditional Chinese medicine, when combined with such tools, GAI can effectively create knowledge maps that organize entities, attributes, and their relationships to traditional Chinese medicine through graphical structures. GAI provides unique support for teaching traditional Chinese medicine and disease diagnosis and treatment decisions [86].

Multidisciplinary Knowledge Acquisition

GAI demonstrates potential in multidisciplinary knowledge acquisition within medical education by providing high-quality knowledge across various medical subfields [87-94]. GAI demonstrates adaptability across disciplines, including shoulder and elbow surgery, sports medicine, and oncology [91]. Research further indicates that GAI models such as ChatGPT-4 excel in internal medicine, pediatrics, obstetrics and gynecology, surgery, emergency care, and public health [88-90,92-94]. Notably, a study assessing ChatGPT-4's performance in the American Board of Family Medicine (ABFM) certification examination demonstrated its significant proficiency, with both the custom robot version (embedded in a specialized subenvironment designed to mimic examination conditions and given extensive preparation resources) and the regular version (standard ChatGPT-4) achieving high correct response rates of 88.67% and 87.33% respectively, well above the passing threshold. This further highlights GAI's value in enhancing medical education within a multidisciplinary framework, making it a powerful learning support tool across a wide range of fields, including family medicine [95]. A meta-analysis of ChatGPT-3.5/4 across medical, pharmacy, dentistry, and nursing licensing exams revealed an overall accuracy of 70.1% (95% CI 65% - 74.8%; $P<.001$). Performance varied significantly by field (Q=15.334; $P=.002$), with pharmacy having the highest rate (71.5%, 95% CI 66.3% - 76.2%) and nursing having the lowest rate (61.8%, 95% CI 58.7% - 64.9%). These results demonstrate GAI's potential to provide multidisciplinary learning support in health professions [96]. It is crucial to note that the evidence presented in this section highlights the individual learner's ability to access and comprehend information across disciplines. This review's existing evidence has not yet extensively covered GAI's direct support for complex interdisciplinary teamwork, closed-loop communication, or the cultivation of specific professional behaviors within collaborative learning environments.

Academic Writing Optimization

A study shows that GAI excels in creating article outlines and editing formatting, which alleviates common writing challenges related to poor organization and grammatical mistakes [28]. In addition, GAI can significantly improve the quality and standardization of academic writing, allowing medical educators and students to express their ideas more accurately and clearly [28,55,97]. Furthermore, GAI assists students in organizing and generating literature content while writing their thesis [98]. The content produced by GAI maintains consistency in language and includes appropriate academic terminology and logical structure, helping students present themselves more professionally in their academic writing [55]. Furthermore, GAI supports many non-native English speakers in overcoming language barriers during the academic writing process, which enables them to engage more confidently in academic communication [71].

Statistical Analysis of the Application of GAI Models

The models discussed in 131 articles include ChatGPT, Gemini (formerly known as Bard), Copilot (formerly known as Bing), Claude, and LLaMA, as well as other types of models such as StyleGAN2-ADA, Stable Diffusion, and customized chatbots.

Among the various models studied, ChatGPT stands out due to its advanced natural language processing capabilities. Of the 131 articles, 119 (89.5%) focused on ChatGPT, which was applied in diverse educational contexts, including simulating doctor-patient conversations, generating exam questions, and providing personalized learning support. These applications highlight their flexibility and adaptability in medical education. Notably, research had shown that as versions have iterated, ChatGPT-4 has significantly improved in both performance and scope compared to ChatGPT-3.5 [26,94,99-101].

Gemini was mentioned in 22 articles, accounting for 16.5% of the total. Copilot was mentioned in 11 articles, primarily due to its integration with the Microsoft ecosystem, making it ideal for educational management and resource development. Claude was cited in 6 articles. LLaMA, referenced in 4 articles, stands out for its ability to run locally, making it suitable for environments with limited resources. In addition, StyleGAN2-ADA, Stable Diffusion, and Convai were discussed in individual studies, mainly for their use in image generation and visualizing doctor-patient interactions.

The performance assessment of two or more models was compared in 26 articles. In comparative studies within the articles, numerous models have undergone head-to-head research, including ChatGPT-4 with Gemini 1.0 Pro [26], ChatGPT-4 with ChatGPT-3.5 [96], ChatGPT 3.5 with Google Bard and Microsoft Bing [78], DALL-E 2 with Midjourney and Blue Willow [59], and Originality.ai with ZeroGPT [27]. Based on these head-to-head investigations, different models demonstrate proficiency in specific tasks: ChatGPT-4 performs better in handling complex tasks, providing accurate medical knowledge, generating exam questions, and offering personalized learning support, especially in English-language medical licensing examinations; Gemini 1.0 Pro is noted for its strong contextual understanding and multimodal capabilities; ChatGPT-3.5 excels in simulating doctor-patient conversations, generating exam questions, and providing personalized learning support; Microsoft Bing achieved top scores alongside GPT-4 in medical licensing MCQ exams; DALL-E 2 shows potential in creating clinical images with specific pathological features from textual descriptions; and Originality.ai achieves high accuracy in detecting both AI-generated and AI-rephrased medical writing.

Challenges of GAI in Medical Education

Existing Defects at This Stage

Insufficient Scene Adaptability

Insufficient scene adaptability is due to the following factors.

First is the poor ability to handle complex clinical scenarios. GAI faces substantial limitations when handling complex clinical scenarios, particularly in cases requiring multistep reasoning, intricate calculations, and recognition of atypical clinical symptoms [45,87,102,103]. For instance, studies have shown that GAI struggles with MCQs, X-type problems, and tasks demanding deep reasoning. This underscores its limited ability to perform the nuanced decision-making required in medical judgments [29,30,39,41,44,47,48,66,67,84,89-92,104-107]. Furthermore, GAI-generated clinical scenarios often lack flexibility and fail to replicate the diversity and complexity of real-life clinical environments, thereby limiting learners' exposure to the spectrum of challenging cases [108,109]. GAI also faces technical limitations in generating simulated images for complex diseases, resulting in images that fail to depict atypical manifestations accurately [57]. Furthermore, GAI models demonstrate uneven knowledge depth, exemplified by an ophthalmology meta-analysis: accuracy was 78% in "Pathology" but significantly lower in foundational or clinical areas, such as "Ophthalmology fundamentals" (52%), "Clinical ophthalmology" (57%), and "Refractive surgery" (59%) [110].

Second is the lack of local background in specific regions. Numerous studies have shown that GAI often struggles to adapt effectively to a specific region's unique background and needs when dealing with medical content related to that region, thereby undermining its universal applicability in multicultural settings [33,38,102,111]. For example, ChatGPT often responds to public health issues in India with a Western-centric perspective, overlooking local situations and cultural differences [33]. Similarly, ChatGPT struggles to accurately comprehend and adapt to the local regulatory environment when addressing medical policies specific to China, largely due to the limited representation of Chinese data in its training set [102,112].

Third is language adaptability issues. Currently, GAI exhibits significant limitations in processing languages, particularly in non-English medical education environments. The accuracy of GAI models like ChatGPT often varies greatly when handling languages such as Chinese, Korean, and Polish, resulting in incorrect outcomes in these contexts [29,30,34,38,106,113-115]. A meta-analysis quantified disparity: GPT-3.5 achieved 57% accuracy (95% CI 52% - 62%; P<.01) in English-speaking countries and 58% (95% CI 52% - 64%; P<.01) in non-English-speaking countries (P=.72). GPT-4 scored 86% (95% CI 82% - 89%; P<0.01) in English-speaking countries versus 80% (95% CI 76% - 83%; P<.01) in non-English-speaking countries (P=.02), demonstrating the adaptability issues of GAI models across different linguistic and regional contexts [116].

Fourth is a lack of nontextual information analysis skills. Current GAI tools like ChatGPT and Bard struggle to handle image-based queries, limiting their application in fields such as dentistry, neurosurgery, and nuclear medicine, where visual analysis of images and tissue samples is crucial for clinical decision-making [31,36,42,67,73-75,117].

Data Quality and Information Bias

Data quality issues and information bias occur due to the following factors.

First is the hallucination phenomenon. In GAI applications, hallucinations occur when the content generated by GAI diverges from factual accuracy or contradicts itself, remaining a prevalent issue. In total, 3 primary types of hallucinations have been identified: input-conflicting hallucination, context-conflicting hallucination, and fact-conflicting hallucination. Input-conflicting hallucination occurs when the GAI-generated content contradicts the initial information provided by the user. This can mislead learners and hinder their understanding of specific concepts [51,65,118]. Context-conflicting hallucination arises when the GAI offers contradictory responses to the same or similar questions. This inconsistency is particularly evident in complex case analyses [71,90,119,120]. Fact-conflicting hallucination occurs when the GAI reports facts that contradict established information, often with a high confidence level, which can easily mislead learners [54,121-137].

Second is the lack of details on output content. Numerous studies have highlighted that GAI often generates overly simplified or vague responses, lacking essential details and knowledge necessary for a comprehensive understanding [31,53,56,60,63,73,114,118,120,135,136,138,139]. For instance, evaluations of GAI in cardiology have revealed that it fails to specify the types of heart murmurs associated with valve diseases. In addition, GAI-generated descriptions of pathophysiology and epidemiology tend to be overly general, often including vague statements such as "certain age groups are at higher risk" without specifying the specific conditions. Furthermore, GAI often produces incomplete or inaccurate information when generating case study materials, which can lead to misleading students. For example, GAI-generated learning materials on melanoma have been known to omit crucial tumor markers like S-100 or the latest treatment for BRAF (B-Raf proto-oncogene, serine, or threonine kinase) mutations [63,138]. The same problems are evident in academic writing assistance, where GAI may create basic article structures but often lacks the depth, detail, and critical citations found in human-generated content [120].

Third is the lack of personalization. The content generated by GAI lacks personalization tailored to individual needs. This limitation mainly manifests in the generated text, which often adopts similar writing patterns and standardized language, struggling to incorporate personalized perspectives or creative expressions [28]. In a medical environment, GAI-generated treatment plans, although generally reasonable, often fail to consider individual patient characteristics, such as the severity of the disease, lifestyle, and personal preferences [105].

Fourth is dataset dependency. The performance of GAI is significantly influenced by the quality and diversity of its training data. If the data is insufficient or skewed, it may lead

to potential biases and limitations in practical applications, causing underperformance in less-represented areas [33,59,73,82,85,86,111,117,122,126,140-143]. In addition, the cutoff date for the training data means that GAI may lack knowledge of the latest research, leading to outdated or inaccurate recommendations [26,32,41,66,67,74,80,89,92,94,109,129,136,141,144]. For example, when advising on treatment for bipolar disorder in pregnant women, ChatGPT-4 failed to incorporate the latest studies and instead suggested outdated methods [89]. Furthermore, the data bias present in GAI during the training process cannot be overlooked [51-53,58,61,71,72,78,107,108,132,139,145]. Such biases often arise from the intrinsic imbalances within the dataset, which subsequently permeate the generated content. These biases manifest as stereotypes, mainly depicting certain professions or physical attributes. For instance, some occupations may be associated with higher BMIs, while the French ethnicity is stereotypically linked to the profession of "wine connoisseur" [51].

Potential Issues in the Future

Overreliance

Overreliance can be caused due to the following factors.

First is impaired critical thinking. The rapid feedback provided by GAI may reduce students' time for deep thinking, weakening their ability to analyze problems and independently engage in critical learning. This phenomenon is particularly evident in medical education, where students often rely on the answers provided by GAI when solving complex problems rather than relying on their logical reasoning and knowledge accumulation for analysis and resolution [35,39,40,50,55,69,70,72,74,75,77,98,99,124,136,146-152].

Second is decreased creativity. When students use GAI tools like ChatGPT, they often receive writing suggestions that lack the creativity and depth of human-generated content. Thus, prolonged reliance on such tools may weaken their independent writing skills and hinder their ability to engage with complex topics that require critical thinking and practical expertise [28]. Similarly, educators who overly depend on GAI for content creation may stifle their curricular innovation, limit diversity and depth in teaching materials, and ultimately diminish the overall quality of education [60].

Third is decreased teamwork ability. Overreliance on GAI tools such as ChatGPT can weaken students' communication skills and ability to engage actively in collaborative teamwork [72,152]. Furthermore, the frequent use of these tools limits opportunities for meaningful interpersonal interaction with peers and mentors, hindering the development of essential teamwork and communication skills [152].

Fourth is decreased practical problem-solving ability. Practical problem-solving is essential for clinical decision-making and patient management. However, the convenience of GAI tools may lead students to rely on preexisting solutions, neglecting the deeper analysis and logical reasoning necessary to develop personalized answers [52,55,74,75,77,87,151-153]. Furthermore, using these tools may reduce interaction with mentors and peers, limiting students' opportunities to gain diverse perspectives through collaborative discussions and approach problems from multiple angles [147].

Ethical Controversy

Ethical controversies can occur due to the following factors.

First is the authenticity of the test results, as the integration of GAI in testing and assessment may compromise the accuracy and effectiveness of traditional methods used to evaluate students' actual capabilities. GAI-generated responses or GAI-assisted evaluations risk reflecting the performance of GAI itself rather than students' authentic abilities. This issue is evident in various exams, such as medical licensing and specialty exams, presenting new ethical challenges in medical education [27,50,78,99,144,146,154].

Second is academic misconduct, since GAI-generated content often evades traditional plagiarism detection tools, making it easier for students to exploit GAI tools to complete assignments or write papers without being detected, thus jeopardizing academic integrity [31,154]. In addition, the ease of using GAI to generate answers cultivates students' mindset of overreliance on such tools for academic tasks, which may increase their future likelihood of academic misconduct [70-72,124,155]. This issue extends beyond individual students and poses a broader threat to academic ethics, as GAI-generated content can be misinterpreted as original work, distorting academic evaluations [125,150].

Third is a lack of clinical interaction and emotional resonance. When addressing complex ethical or emotional medical issues, GAI lacks the empathy and emotional responsiveness inherent in human physicians, potentially undermining trust in the doctor-patient relationship [98,131]. This limitation is supported by a General Medicine In-Training Examination (GM-ITE) study comparing GPT-4 and Japanese residents. In the GM-ITE, "medical interview and professionalism" category assesses patient communication, ethics, and professionalism. It uses scenario-based questions (eg, addressing a terminally ill patient's anxiety or resolving treatment ethics). Responses are scored 0‐10 based on communication appropriateness, empathy depth, and ethical application, with top marks for nuanced, human-centric judgment. Notably, GPT-4 scored 8.6 points lower here than residents [38]. Furthermore, because GAI tools do not provide an authentic, interactive experience or situational awareness, they may struggle to simulate the behavior and reactions of real patients accurately. This limitation makes it challenging for students to fully appreciate the importance of empathy and its application in doctor-patient interactions, which affects their development of communication and empathy skills development [38,54,76,77,101,107,147,152].

Fourth is resource inequality, which is most evident in the unequal access to technology and data. Datasets used for training GAI often exhibit biases, particularly involving data from different racial or socioeconomic backgrounds. This can worsen existing health care disparities. Furthermore, developing high-quality LLMs requires substantial computational resources, creating significant access barriers, especially for educational institutions or students with limited financial means. Hence,

subscription fees and hardware limitations restrict their access to these GAI tools [67,74,85,134].

Fifth is the ownership of intellectual property rights. The widespread use of GAI in medical education raises numerous intellectual property concerns, particularly regarding copyright disputes related to the medical data used during AI training [113]. In addition, the legal status of GAI-generated content remains unclear, as current copyright laws do not adequately address the ownership of GAI-generated images and texts. This leaves the ownership of such content unclear, complicating the determination of whether the rights belong to the user, the developer, or other stakeholders [27,50,58,59,124].

Sixth is the "black box" problem and the attribution of responsibility. The application of GAI in medical education faces a significant challenge known as the "black box" problem. This issue arises from the lack of transparency and interpretability of GAI models, which directly affects the safety and reliability of these applications in medical settings. This lack of transparency makes it hard to understand how GAI reaches specific conclusions, especially when results are erroneous or biased, complicating efforts to trace and correct mistakes [86,88,148]. Furthermore, when GAI is used for diagnostic or clinical decision support, any errors or biases in its generated results can make it difficult to establish accountability. Trust in the doctor-patient relationship is built on clear responsibility. However, the lack of transparency in GAI models undermines this trust, leaving patients and physicians uncertain about the safety and reliability of GAI-driven decisions [36,114].

Discussion

Principal Findings

This scoping review systematically identifies 3 core characteristics of GAI in medical education through an analysis of 131 included studies: pronounced regional disparities, empowerment potential via RMA synergy, and unresolved technical and ethical challenges. These findings must be contextualized within the field's evolving landscape: Our initial screening retrieved 5991 articles, a striking number reflecting both the opportunities and challenges of this emerging domain. This vast volume can be attributed to GAI's rapid evolution as a nascent technology, where relevant concepts remain loosely defined and inconsistent. Consequently, keyword usage lacks standardization, often resulting in the inclusion of tangentially related cross-disciplinary studies. Furthermore, GAI's inherently interdisciplinary nature broadens the scope of relevant literature. While this abundance highlights widespread interest and diverse applications, it also emphasizes the lack of conceptual clarity and consistency in frameworks. Therefore, although research is progressing, the field remains in a transitional stage, moving from "conceptual standardization" to "unified frameworks." To propel the field forward, the academic community needs to reach a consensus on GAI-related definitions and application structures. Achieving this standardization will enable better tracking of emerging trends and facilitate the effective use of new insights.

Against this backdrop, regional distribution analysis reveals marked concentration of GAI research in very high HDI regions (74%), with minimal contributions from low-HDI regions (2%) and scarce cross-regional collaborations (4%), highlighting structural inequities in global technology diffusion. Model use patterns further demonstrate ChatGPT's dominant adoption (89.5%), driven by its superior performance in multifaceted educational tasks: (1) iterative version advancements (eg, GPT-4's significant improvements in reasoning accuracy and error reduction over GPT-3.5); (2) proven efficacy across diverse applications including clinical simulation, exam question generation, and personalized tutoring; and (3) robust multilingual support despite variability in non-English contexts. This technical versatility explains its preferential adoption by researchers. The disproportionately high usage rate of general LLMs over specialized models, coupled with a predominant focus on cross-model comparisons rather than synergistic integration, reflects insufficient exploration of technical adaptability and system interoperability within current research.

Within the RMA tripartite framework established in this study, GAI reshapes medical education through coordinated optimization across 3 dimensions. In resource provisioning, it effectively mitigates traditional constraints of specimen scarcity and privacy limitations through the efficient generation of diverse clinical cases and pathological images. Methodologically, it facilitates the transition from standardized instruction to personalized education through interdisciplinary knowledge integration and targeted learning support. For assessment, high concordance in automated scoring and academic integrity monitoring provides scalable solutions for educational quality assurance. This closed-loop optimization mechanism, which encompasses resource allocation, pedagogical implementation, and evaluative feedback, validates the framework's explanatory power for technology-enabled educational transformation.

Nevertheless, profound barriers impede deeper GAI integration. Current technical deficiencies manifest as: inadequate contextual adaptation (eg, limitations in complex clinical reasoning and MCQ processing), data quality flaws (including hallucinatory outputs and deficient nontextual information analysis), and linguistic or regional biases (particularly performance degradation in non-English contexts). Long-term risks include erosion of critical thinking and creativity due to overreliance, alongside ethical governance dilemmas that encompass ambiguous accountability, inequitable resource distribution, and deficient clinician-patient emotional engagement. These dual challenges constitute fundamental barriers to implementing human-AI collaboration paradigms.

Comparison With Existing Literature

This scoping review specifically focuses on the period between January 2023 and October 2024, a critical transitional phase where GAI in medical education shifted from theoretical exploration to practical implementation. By capturing this transformative era, it addresses the gap in previous reviews [1,9] that lacked coverage of the latest advancements. While building on the foundational insights of earlier studies, this review extends their scope by identifying emerging trends and practical

applications that have emerged with GAI's maturation in educational contexts.

Our observation of pronounced regional disparities starkly aligns with and quantifies the well-documented "digital divide" prevalent in global health technology diffusion [156]. However, this study provides concrete, GAI-specific evidence within medical education, highlighting the extreme concentration and the critical scarcity of cross-tier collaboration, thereby reinforcing concerns about equity in accessing transformative educational technologies and potentially exacerbating global health workforce inequities.

Regarding model use, the overwhelming dominance of ChatGPT mirrors its widespread popularity in GAI application studies [157]. Yet, our analysis delves deeper than mere prevalence reports or bibliometric study [158-160], specifically attributing this dominance to its rapid iteration (eg, GPT-4's improvements), proven versatility across key educational tasks (clinical sim, QG, and tutoring), and relatively robust (though imperfect) multilingual support, which are crucial for adoption in the diverse contexts of medical education research.

Our development of the RMA tripartite framework represents a key theoretical departure. While existing research acknowledges GAI's impact on discrete educational facets (resource provision, teaching methodologies, and evaluative processes), a unifying framework that binds these elements into a synergistic, closed-loop optimization mechanism is conspicuously absent from the current discourse [1,9,10]. Such a framework uniquely conceptualizes these three dimensions as an interdependent, dynamic closed-loop system essential for understanding GAI's holistic transformative potential. Crucially, the empirical identification of significant RMA imbalance (robust exploration of educational methods and resources vs sparse focus on learner assessment) does not imply that assessment is under-prioritized in education broadly, but rather reflects a current skew in GAI-medical education integration—with research disproportionately focusing on resource enrichment and methodological optimization, while lagging in the development of learner assessment applications [161]. This imbalance, viewed through our novel integrative lens, offers a structured diagnostic for the systemic gap in aligning GAI capabilities with the specific needs of learner assessment within medical education.

The unresolved technical-ethical challenges documented (eg, contextual limitations, hallucinations, biases, erosion of critical thinking, and concerns about empathy) resonate strongly with growing critiques of LLMs in healthcare [162,163]. Our review explicitly maps these well-recognized limitations onto the sensitive context of medical education, highlighting their manifestation and potential impact in shaping future clinicians. This reinforces concerns raised elsewhere but grounds them firmly in the educational domain.

Another distinctive contribution of this review lies in revealing a critical technological imbalance: the overwhelming focus on general-purpose LLMs like ChatGPT contrasts sharply with the lack of systematic development of specialized medical models and the near absence of research on multimodel collaborative mechanisms within medical education [10,164]. This finding highlights a gap in the current technological approach, which hinders depth and clinical authenticity. While previous studies used available tools, our synthesis highlights this specific limitation as a barrier to deeper integration.

Implications of the Findings

Implications for Educational Practice

This study makes a key contribution to pedagogical practice by establishing the RMA tripartite framework and revealing its developmental imbalances, thereby providing a practical paradigm for the integration of GAI into medical education. The core value of this framework lies in elucidating the dynamic closed-loop nature of technology-enhanced education, wherein resource provision establishes the pedagogical foundation, methodological innovation activates knowledge transformation, and assessment feedback drives systemic evolution; these 3 components constitute an interlocking educational mechanism [165].

As evidenced in the results section, the current imbalance, characterized by rich exploration in GAI-supported educational resources and teaching methods yet relatively limited progress in GAI-driven automated evaluation of learner performance, stems from an overemphasis on short-term efficiency in early technology adoption. This has led to systemic neglect of assessment's role as an optimization tool. For example, GAI is widely used to generate diverse clinical cases and pathological images to enrich educational resources and design adaptive learning pathways to innovate teaching methods. However, in learner assessment, most GAI tools still rely on simple automated scoring of knowledge-based quizzes, with few leveraging GAI to evaluate higher-order competencies such as clinical reasoning or diagnostic accuracy [26]. Another instance is that many researchers use GAI to create interactive simulation scenarios as a methodological advancement but fail to integrate automated assessment features that track learners' decision-making processes in these scenarios [53]. This misses opportunities to use assessment data to refine the scenarios themselves. Overreliance on GAI for resource and method innovation without matching progress in automated learner assessment risks disconnecting what is taught or provided from what learners need to master, ultimately limiting GAI's ability to drive meaningful change in medical education.

Achieving optimal integration requires establishing a bidirectional enhancement cycle centered on assessment. Automated assessment data capturing learning bottlenecks should guide the real-time expansion of clinical case libraries' pathological spectra and difficulty calibration [166], shifting resource provision from one-size-fits-all to demand responsiveness. Simultaneously, the focus on core competencies (such as clinical reasoning and problem-solving) emphasized in teaching methods must be integrated into new assessment dimensions [167], driving teaching methods to evolve from mere knowledge transmission to competency development. Within this cycle, assessment functions not merely as a quality monitoring tool, but as the central nexus for the co-evolution of resources and methods.

Realizing this vision necessitates educators reconceptualizing operational logic [165]. This involves using assessment data to inform the development of educational resources, specifically leveraging insights into learners' knowledge gaps and skill deficiencies to dynamically adjust the complexity of clinical cases [168], embedding real-time, practical, and contextual feedback mechanisms within high-order teaching activities like simulated diagnostics to optimize pedagogical strategies [169], and establishing adaptive rules enabling cross-dimensional interaction to facilitate systemic iteration [170,171]. Collectively, this structural transformation elevates the tripartite framework into an organic educational operating system.

However, technological integration inherently presents dual challenges, highlighting the importance of upholding core principles of human-AI collaboration. Generating educational resources without clinical context review risks reinforcing data biases [172]; methodological innovation overly reliant on algorithmic decisions may erode critical thinking [9]; and automated assessment replacing human judgment may overlook students' psychological needs, reducing course engagement and well-being scores [173]. These manifestations of technological alienation arise from the partial ceding of human agency. Resolution lies in upholding a human-AI symbiotic vision: recognizing GAI as a collaborator, not a replacement, in educational evolution. Specifically at the resource layer, clinicians and educators must oversee the development of educational resources (eg, clinical cases) to balance efficiency, ethics, and clinical authenticity [174,175]. At the method layer, educators should direct learning path design to integrate technological augmentation with pedagogical wisdom [176]. At the assessment layer, institutions should implement verification systems that combine human evaluation with machine automation, ensuring assessments balance efficiency with humanistic dimensions [173,177]. This reconfiguration of responsibilities positions technology as a tool and reaffirms human stewardship of education.

Implications for Technological Development

This study identifies a technological imbalance in the application of GAI within medical education. This imbalance is characterized by the dominance of large general language models, while the development of specialized models for specific medical disciplines has lacked systematic progress. This limitation restricts the depth of technology-enabled education and indicates a neglect of multimodel collaborative mechanisms within current research paradigms.

The study proposes an integrated system using general LLMs alongside specialized medical models, employing a hierarchical collaborative architecture to reshape the technological ecosystem of medical education. The core operational logic establishes a 3-tiered functional division: general models act as the central hub for teaching interactions, handling basic task parsing and process orchestration; medical specialized models, drawing on vertical domain knowledge bases, execute high-complexity core teaching tasks such as clinical reasoning and medical image generation; and a cross-model validation mechanism forms a closed-loop quality control system. This architecture adapts the hospital's multidisciplinary team approach to AI in education, aligning technological capabilities with the requirements of medical education for expertise, reliability, and contextual authenticity.

Within medical education, this integrated system can facilitate 3 key changes. First, it addresses limitations in specialized knowledge depth inherent in traditional general models, improving training efficacy for advanced clinical reasoning. Second, it leverages GAI's multimodal capabilities, which integrate text and image data, to address key issues in medical imaging education including shortages of teaching resources like rare pathological images and the limits of static materials in showing dynamic anatomical relationships. This support helps evolve pathology visualization from static atlases to interactive 3D simulations, letting students explore spatial structures and pathological changes more intuitively [178]. Third, it establishes a cross-model knowledge validation chain to automatically identify and correct typical logical inconsistencies and factual errors in general models, ensuring the academic rigor of teaching content. These changes collectively represent a paradigm shift from tool-assisted learning to intelligent teaching partnership systems [179].

Supporting the effective operation of this system requires targeted solutions to key technical challenges. The primary task involves developing specialized models with medical context adaptive capabilities, specifically enhancing their semantic parsing of unstructured clinical texts to address performance variability in complex case analysis [180,181]. Concurrently, it is necessary to construct dynamically evolving medical education datasets that incorporate cross-regional case spectra and multilingual clinical literature to systematically mitigate cultural biases and time-lag effects in training data [182]. Integrating privacy-preserving computation techniques like federated learning can enable secure data collaboration among institutions, continuously optimizing model localization and adaptation while safeguarding patient information security [183,184].

Implications for Policies and Governance

This study reveals a pronounced regional disparity in the application of GAI within the field of medical education. Specifically, regions with a very high HDI dominate research output in this domain, while contributions from the low-HDI areas account for only 2%. The scarcity of cross-tier collaboration between very high- and low-HDI areas further exacerbates this structural inequity in resource distribution. This imbalance epitomizes systemic inequalities within global knowledge production systems, rooted in 3 compounding barriers: inadequate computational infrastructure in resource-constrained settings impedes technological localization, proprietary restrictions on core models under patent regimes limit feasible technology transfer, and excessive reliance on clinical data from high-income countries compromises model adaptability to regional health care priorities. Without deliberate intervention, this self-reinforcing Matthew Effect cycle risks intensifying the global fragmentation of medical educational resources [185].

Addressing this complex challenge necessitates a multitiered governance framework. At the international level, binding

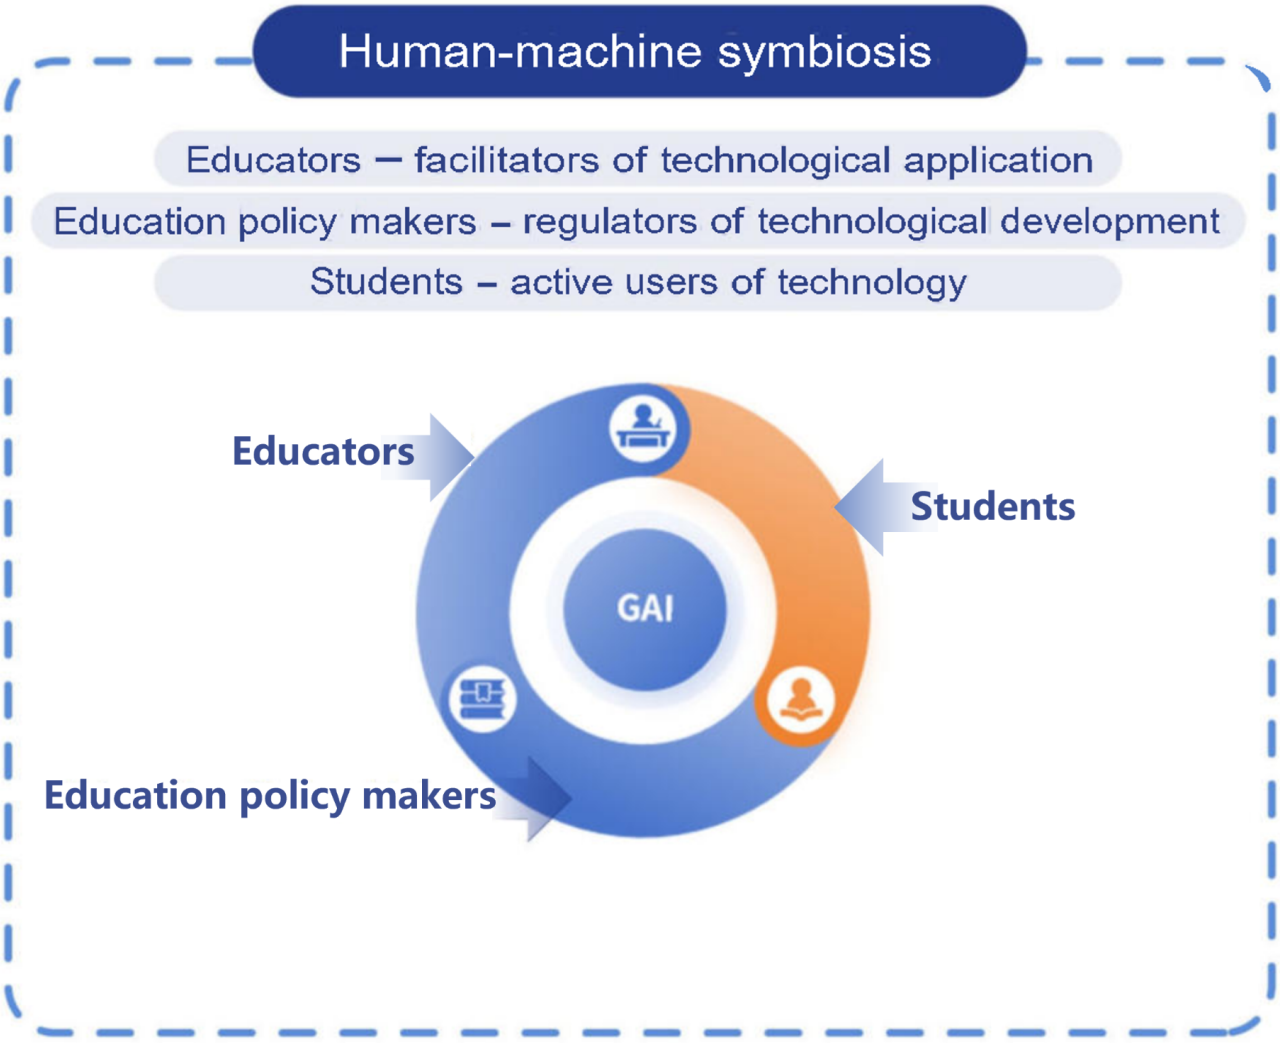
technology-sharing agreements should request that holders of advanced models provide architectural access under fair-use principles, emphasizing the need to balance innovation with equitable access, while emulating open-source paradigms as a reference model [186]. Concurrently, the World Health Organization could coordinate multinational efforts to develop nonprofit medical corpora incorporating disease spectra prevalent in low-HDI regions, such as tropical and endemic diseases [187]. Nationally, ministries of education should integrate computational infrastructure into public medical education budgets [188] and similar to the Medical Education Partnership Initiative (MEPI) [189], establish dedicated funds for cross-border institutional partnerships to co-develop localized pedagogical tools that address specific regional educational needs. Institutionally, medical schools should adopt algorithmic transparency protocols, requiring deployed GAI tools to provide auditable model documentation that details the demographics and geographical coverage of training data. Fairness assessments of these tools should be carried out by multidisciplinary committees, which include clinicians, ethicists, and community representatives [190].

Simultaneously, institutional responses must address secondary risks through integrated technical, educational, and regulatory safeguards. To counter academic misconduct, educational institutions should implement dual-track verification systems that require GAI-assisted submissions to be accompanied by generation logs and validated through detection tools [191]. Academic journals must establish clear authorship standards declaring proportional human-GAI contributions [192]. Mitigating critical thinking erosion requires curriculum committees to incorporate GAI-free clinical reasoning assessments, such as on-site case analyses evaluating independent diagnostic and management planning capabilities as prerequisites for professional certification [193].

Technical deficiencies demand targeted interventions. Reducing model hallucinations requires dynamic fact-checking systems linking GAI outputs to authoritative medical knowledge bases, with confidence levels displayed during teaching platform usage [194]. To address the opacity of algorithms, where the process by which GAI models derive conclusions remains unclear, it is necessary to document the diagnostic reasoning processes of these models. Such documentation allows instructors to review the reasoning, helps determine accountability when inconsistencies occur, and can be integrated into resident training evaluations to strengthen oversight of GAI-assisted decision-making [195].

Fundamentally, governance paradigms must transition from a technocentric approach to symbiotic development. Compared to the commonly used “human in the loop” [196], which mainly emphasizes humans overseeing or making final decisions in AI systems, symbiotic agency theory goes further: it highlights mutual shaping between humans and AI. Humans guide AI development through ethical norms and clinical experience, while AI enhances human capabilities by expanding cognitive boundaries, forming a dynamic, mutually reinforcing relationship [11]. Policies should affirm human primacy in medical education, exemplified by reserving clinical empathy training exclusively for human instructors while limiting GAI to standardized case supplementation. An effective return to the essence of symbiotic agency means building collaborative mechanisms as shown in Figure 5: educators lead in setting teaching goals and ensuring ethical alignment (eg, reviewing GAI-generated cases to match real clinical logic); GAI supports personalized learning; students provide feedback to refine GAI tools; and policies clarify rights and responsibilities in this interaction. This human-centered approach ensures technological advancement aligns with pedagogical integrity and global equity imperatives.

Figure 5. Vision of human-machine symbiosis: a schematic diagram. GAI: generative artificial intelligence.



Limitations and Future Direction

This scoping review has several limitations that should be acknowledged. First, the rapidly evolving nature of GAI means our findings primarily reflect the landscape captured up to the search date; newer models and applications emerging subsequently may shift current patterns. Second, the inherent conceptual breadth and interdisciplinary nature of GAI pose challenges for exhaustive literature capture, potentially leading to omissions despite broad search parameters. Third, and most critically, while this study proposes 3 key conceptual frameworks (the RMA tripartite model, the hierarchical collaborative architecture, and the symbiotic agency principle) and argues for their feasibility based on synthesized evidence, it has not empirically tested their implementation or efficacy in authentic educational settings. Finally, reliance on published literature may underrepresent real-world implementation challenges and grassroots innovations.

Future research must bridge this critical gap by translating these frameworks into practice. Priority should be given to: (1) implementing and evaluating the RMA balancing strategies and the integrated system combining general and specialized medical GAI models in specific medical education contexts to assess their impact on learning outcomes and operational feasibility; (2) conducting longitudinal studies to track the dynamic evolution of GAI integration over time, observing its long-term empowerment effects on educational processes and outcomes; and (3) operationalizing the symbiotic agency framework to guide the design, deployment, and assessment of these interventions. This framework is essential for ensuring that human-AI collaboration in practice genuinely augments educator and learner agency, fosters critical competencies, and upholds pedagogical integrity, thereby realizing the envisioned synergistic educational ecosystem.

Conclusion

The application of GAI in medical education exhibits significant regional inequities, reflecting structural disparities in technological diffusion. Statistical findings from the model research reflect that researchers have certain preferences in its usage. The emergence of GAI has revitalized medical education, which is manifested in its promotion of the diversification of educational methods, the scientific evaluation of education assessment, and the dynamic optimization of education resources. However, these innovations are accompanied by current limitations and potential future challenges. By establishing the RMA tripartite model as a dynamic closed-loop system for educational optimization, proposing an integrated multimodel architecture to reconcile general and specialized

GAI capabilities, and advancing the symbiotic agency principle to safeguard human primacy, this study provides foundational frameworks for navigating GAI integration. These contributions collectively address critical gaps in conceptual standardization and collaborative design, while delineating actionable pathways for pedagogical innovation, equitable technology development, and governance reform, which ultimately steer the field toward responsible human-AI collaboration that enhances clinical education without compromising pedagogical integrity or global equity.

Abstract

Background: Learning style is a biologically and developmentally imposed configuration of personal characteristics that makes the same teaching method effective for some and ineffective for others. Studies support a relationship between learning style and career choice, resulting in learning style patterns observed in distinct types of residency programs, which can also be applied to general surgery, from medical school to the latest stages of training. The methodologies, populations, and contexts of the few studies pertinent to the matter are very different from one another, and a scoping review on this theme will unequivocally enhance and organize what is already known.

Objective: The goal of this study is to identify and map out data from studies that report on learning styles in medical students, surgical residents, medical staff, and surgical teachers.

Methods: The search strategy was performed on September 25, 2023, by a librarian and digital search strategy expert, through the descriptors “learning, style” and “surgery.” The databases consulted were Embase, SCOPUS, Web of Science, and PubMed through descriptors and their synonyms, according to MeSH (Medical Subject Headings). Of the 213 articles found, 135 articles remained after the exclusion of duplicates. The remaining 78 articles were analyzed by 3 of the researchers independently. A total of 27 articles were selected, and 2 articles were excluded because the full article was not found.

Results: A total of 25 articles were included in the review. A total of 96% (n=24) of the articles used cognitive theories as their theoretical basis. Regarding learning style instruments, 36% (n=9) articles used the visual, aural, read, and kinesthetic learning method instrument, and 40% (n=10) articles chose Kolb’s learning style inventory. The papers concentrate especially on the 2010s, and most of them are from North America (16/25, 64%) or Europe (6/25, 24%). The smallest study had 15 participants and the biggest had 1549 participants. The included studies primarily focused on surgical residents (21/25, 84%), with fewer targeting faculty and staff (9/25, 36%). The primary objectives of the studies were to investigate the relationship between learning styles and performance (15/25, 60%), gender differences (7/25, 28%), changes over time (4/25, 16%), and motivation (3/25, 12%).

Conclusions: This scoping review reveals a limited and geographically concentrated body of research on learning styles in surgery education, primarily focusing on surgical residents and using Kolb’s learning style inventory and visual, aural, read, and kinesthetic learning method instruments. Considerable gaps exist regarding geographical diversity and the study of medical staff and faculty. These findings underscore the need for future research with a broader scope to better inform educational strategies in surgery.

Introduction

The concept of learning styles was first developed as a result of the interest in individual differences through the learning process, at the beginning of the 1960s [1]. According to Dunn, everyone has a peculiar learning style, like a signature. In this regard, tailoring teaching to different learning styles may help and improve results in education.

Several theories and inventories were created to assess and determine one's learning style, including the following: Kolb's model, Felder and Silverman's model, and Gregorc's model, especially in health care education. A debate about whether learning styles are fixed or flexible exists to this day, and to what extent the context can influence and determine them [2].

However, it is important to acknowledge the growing body of evidence that challenges the effectiveness and validity of learning styles theories. While these theories suggest that tailoring instruction to individual learning preferences can enhance learning outcomes, empirical studies have shown limited support for this approach [3]. Specifically, research indicates that many students do not study in ways that align with their self-reported learning styles, and that matching instruction to these styles does not necessarily improve performance [4].

For example, David Kolb describes learning as a process where knowledge is transformed through experience, and that acknowledgment is the combination of appropriation and transformation of experience. His theory is a holistic model called "experiential learning" and emphasizes experience in its core, differing from other theories [5]. Kolb's scheme hypothesizes that the learner has a concrete experience, upon which he reflects. Through reflection, it is possible to formulate abstract concepts and make appropriate generalizations, then consolidate the understanding by testing the implications of the knowledge in new situations. This then provides a concrete experience, and the cycle continues. Learners with different learning preferences will have different strengths and weaknesses in the quadrants of the (Kolb) cycle [6]. Based on that, he created the learning style inventory (LSI) to determine and assess individually the different learning styles, divided into converging, diverging, assimilating, and accommodating [7].

In medical education, it is particularly important to remember the heterogeneity of students. Some programs count on learners who have already completed a university degree; in others, the students come straight from secondary school, and many face a mixture of both. The broader concept of medical education includes postgraduate students and continuing professional development, too. Each of them will have variable individual constraints, experiences, and preferences [8].

The diversity in educational backgrounds, cultural influences, ethnic origins, and gender identities among contemporary surgical trainees presents unique challenges and opportunities for educators. While it is often assumed that these diverse backgrounds necessitate a personalized approach to learning, it is crucial to recognize that individual learning preferences may not always align with optimal learning strategies [9].

Instead, effective surgical education should focus on evidence-based instructional methods that cater to a wide range of learners, while also promoting critical thinking, adaptability, and lifelong learning skills.

Perry [10] noted that students change their learning approach as they progress through their college years. Students often begin with a "duality" approach, with a clear view between right and wrong, towards "multiplicity," where they recognize that context is important, and that there are various valuable sources of knowledge and experience.

Knowledge is the main domain of medical education, but the outcome depends strongly on other domains such as attitude, lifelong learning, empathy, communication, ethics, and professionalism. The clinical environment is challenging for both the student and the teacher, without mentioning the patient, who is at the center of the action. In this bigger context, it is vital to use different learning theories to promote effective learning [8].

Contemporary surgical trainees come from diverse educational, cultural, ethnic, and gender backgrounds [11], and are pressured to develop skills not only in the role as a medical expert, but also as a professional, scholar, health advocate, manager, collaborator, and communicator [12].

Educating surgeons is an ancient tradition that has existed since the development of surgery [13], and for centuries, surgical residency curricula have been guided primarily by tradition. The apprenticeship model has been one of the essential components of surgical training. It generally involves 3 steps: assisting at operations, performing operations with expert assistance, and operating without assistance.

Modern surgical education has been revolutionized by exponents such as Halsted: the historical model of apprenticeship was transformed into the current organized system that we call Residency [11].

The present day, however, requires the realization of more complex procedures, performed more regularly and in safer manners, demanding even more prepared professionals [14].

Studies report on a relationship between learning style and medical career choice, resulting in learning style patterns observed in distinct types of residency programs, which can also be applied to general surgery. Based on Kolb's LSI, students classified as accommodating and diverging frequently chose surgery as their career choice, whereas converging chose internal medicine, and assimilating chose academic medicine [15].

However, despite the theme's relevance, a preliminary search in the MEDLINE, Cochrane Database of Systematic Reviews, and Joanna Briggs Institute's evidence synthesis revealed no scoping review. Moreover, the methodologies, populations, and contexts of the few studies pertinent to the matter are very different from one another, and a scoping review on this theme would unequivocally enhance and organize what is already known.

Therefore, the aim of this scoping review is to identify, map, and synthesize the existing literature on learning styles in medical students, surgical residents, medical staff, and surgical teachers within the field of surgery. This review seeks to provide a comprehensive overview of the current state of knowledge, identify gaps in the literature, and inform future research and educational practices in surgical training.

Methods

Overview

The scoping review proposed here was carried out according to Arksey and O'Malley's [16] structure, using the first five stages: (1) identify the research question; (2) identify relevant studies; (3) select studies; (4) map out the data; and (5) collate, summarize, and report the results. Since this is preliminary research, it is likely that more studies on the theme will be finalized. Although the sixth stage of Arksey and O'Malley's [16] structure (consulting) will not be completed in this review, its results can inform this stage in a future study. The structure is congruent with The Joanna Briggs Institute's scoping review methodology. The protocol for this scoping review was duly developed in accordance with relevant reporting guidelines and has been publicly registered [17].

Inclusion Criteria

After a discussion involving the researchers, the eligibility criteria were defined.

Participants

Studies were made with medical students, surgical residents, medical staff in general surgery, and the general surgery's medical faculty. It was not obligatory to contain all the population's extracts. Studies were included if they involved at least one of these population groups; it was not required for a study to include all listed groups.

Concept

The included studies approached "learning styles" of the target population, regardless of the chosen instrument to define them.

Context

The eligible studies were those related to teaching surgery to the population in question, in any country.

Types of Sources

The following types of sources were included in the review: studies with qualitative and quantitative approaches, primary studies, systematic reviews, meta-analyses and meta-synthesis, books, and guidelines, published in indexed sources.

Research Strategy

The search strategy was performed on September 25, 2023, by a librarian and digital search strategy expert, through the descriptors "learning, style" and "surgery." There was no time frame restriction in the search. For the combination of descriptors, the Boolean operators "AND" and "OR" were considered. Words were reduced to their root to embrace variations in writing and broaden the search scope.

Databases consulted were Embase, SCOPUS, Web of Science, and PubMed through descriptors and their synonyms—according to the Medical Subject Headings—to every strategy item. These databases were selected because they are comprehensive and have a broad coverage of health publications. The databases' search resulted in a table made using a Microsoft Excel spreadsheet. In accordance with PRISMA-P (Preferred Reporting Items for Systematic Reviews and Meta-Analyses Protocols) guidelines, the detailed search strategy used for one database (eg, PubMed) is provided in Multimedia Appendices 1 and 2 including specific search terms, Boolean operators, and any applied limits, to ensure reproducibility.

Data Selection and Extraction

The articles were evaluated by 3 independent researchers after discussions about inclusion and exclusion criteria. To align the eligibility criteria among the researchers, the titles and abstracts of 25 random articles were analyzed by 3 of the researchers. Disagreements regarding the inclusion or exclusion of the articles were discussed until a consensus was reached. There was a 100% agreement concerning the inclusion and exclusion of the articles. After the articles' selection, a form was used to extract data from the articles' full analysis, both quantitatively and qualitatively.

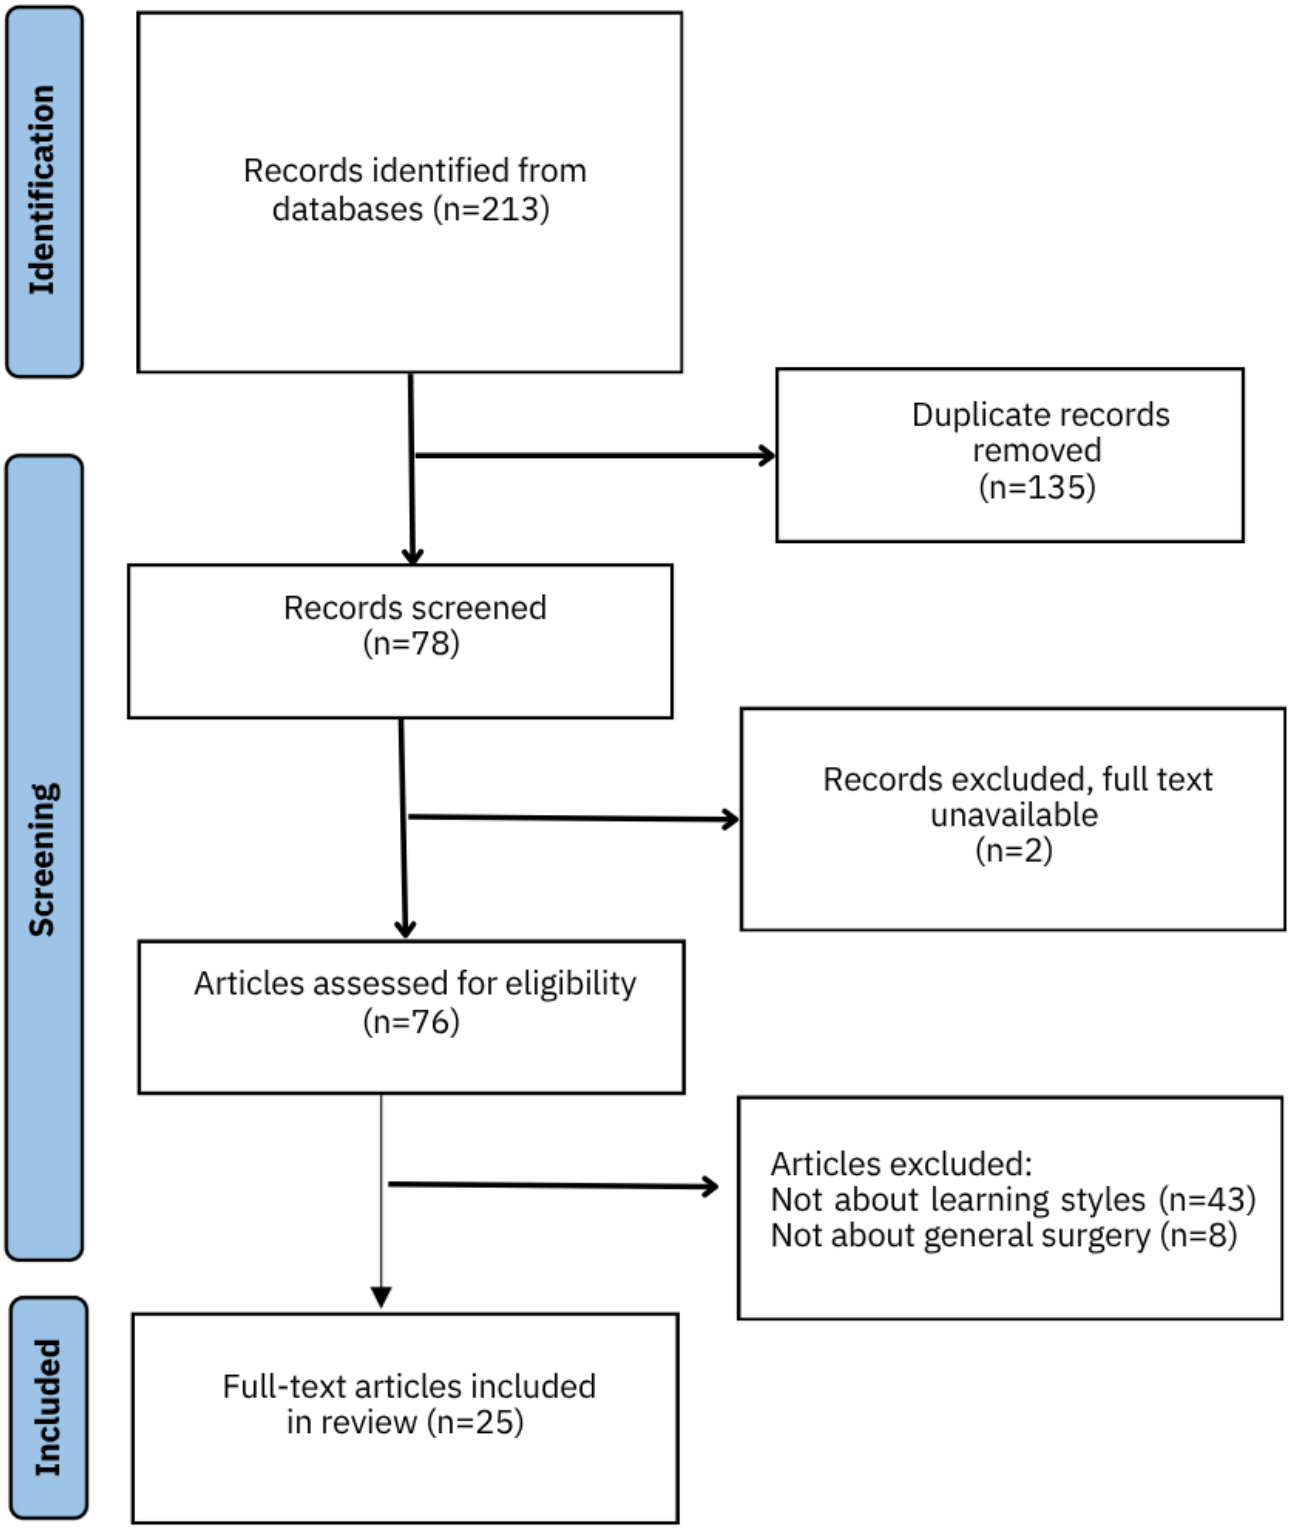
After the articles' selection, a form was used to extract data from the articles' full analysis, both quantitatively and qualitatively.

Results

Overview

Of the 213 articles found, 135 remained after the exclusion of duplicates. The remaining 78 articles were analyzed by 3 of the researchers independently, from which 27 articles were selected, and 2 articles were excluded because the full article was not found. A PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses extension for Scoping Reviews; Checklist 1) flow diagram was produced (Figure 1). Thus, the analysis included a total of 25 articles.

Figure 1. PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses extension for Scoping Reviews) flow diagram of learning styles in general surgery.



Learning Theory and Learning Style Instrument

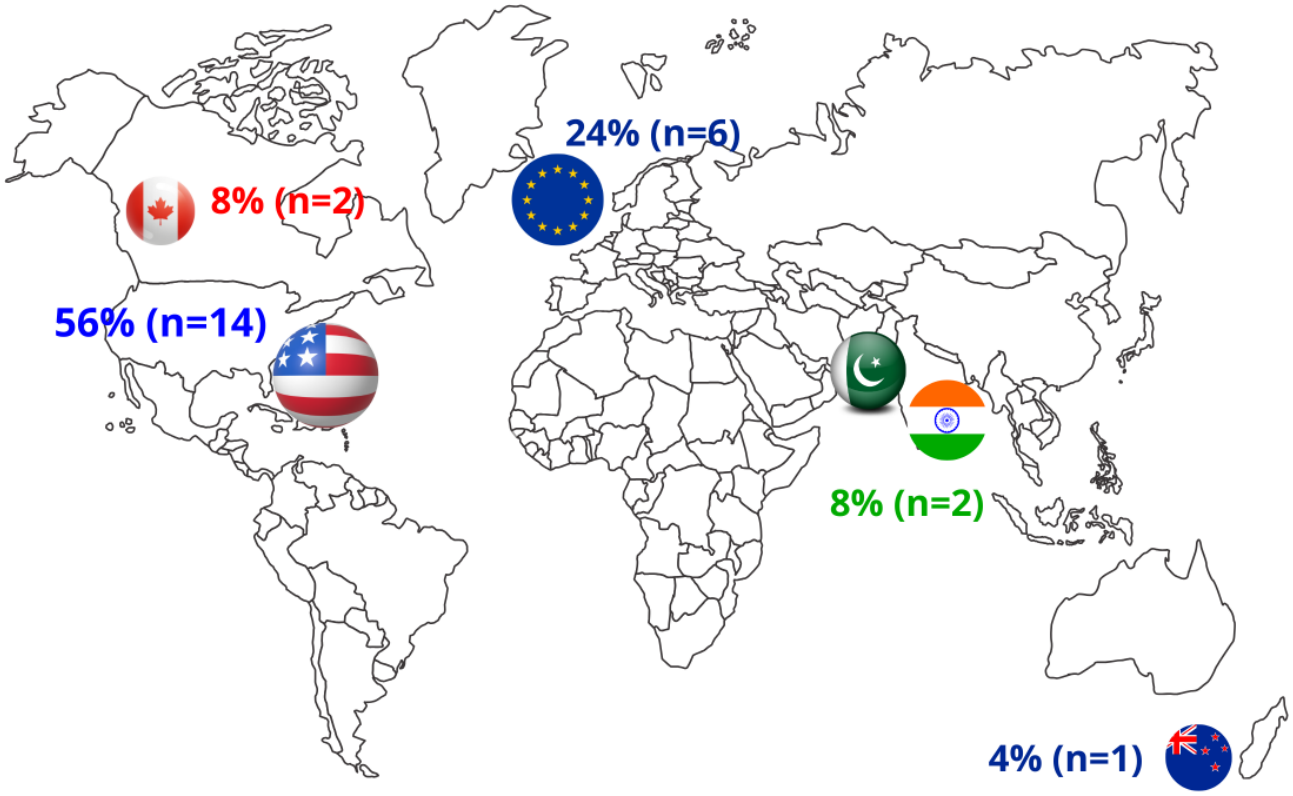
Regarding the theoretical basis, 96% (n=24) of the included articles used cognitive theories as a theoretical basis. Regarding the choice of learning style instrument: 36% (n=9) used the visual, aural, read, and kinesthetic learning method (VARK) instrument, and 40% (n=10) chose Kolb's LSI. One study opted for the Multiple Intelligences Developmental Assessment Scales [18] instrument; another used the Meyer-Briggs type indicator [19]. One study used the students' learning preferences questionnaire [20], and 2 others chose the 24 self-reported LSI questionnaire [21,22]. One study was conducted as a review, so it explained various learning styles approaches [23].

Mapping Studies Around the World

A majority of the studies were conducted in North America or Europe. Specifically, 14 studies were developed in the United States and 2 studies were from Canada, accounting for 64%

(n=16) of the studies with a northern American population. A total of 24% (n=6) of the studies took place in Europe, 4 studies in the United Kingdom, one study in Spain [24], and one study in the Netherlands [23]. Only one study was conducted in Oceania (New Zealand) [18], and the other 2 studies were from Asia (2/25, 8%), one from Pakistan [20] and the other from India [21]. No studies (0/25, 0%) were found regarding learning styles and surgery in Latin America or Africa. Figure 2 summarizes these findings.

Figure 2. Map of previous studies conducted around the globe regarding learning styles and surgery.



Interest in Learning Styles Across Time

Learning styles were not a common subject until the 1960s. Table 1 shows the number of articles on the theme in each decade. The year 2010 was the most interesting in the subject, with 15 published papers.

Table . Number of articles about learning styles in surgery through the decades.

Year	Articles, n
1970	1
2000	4
2010	15
2020	4

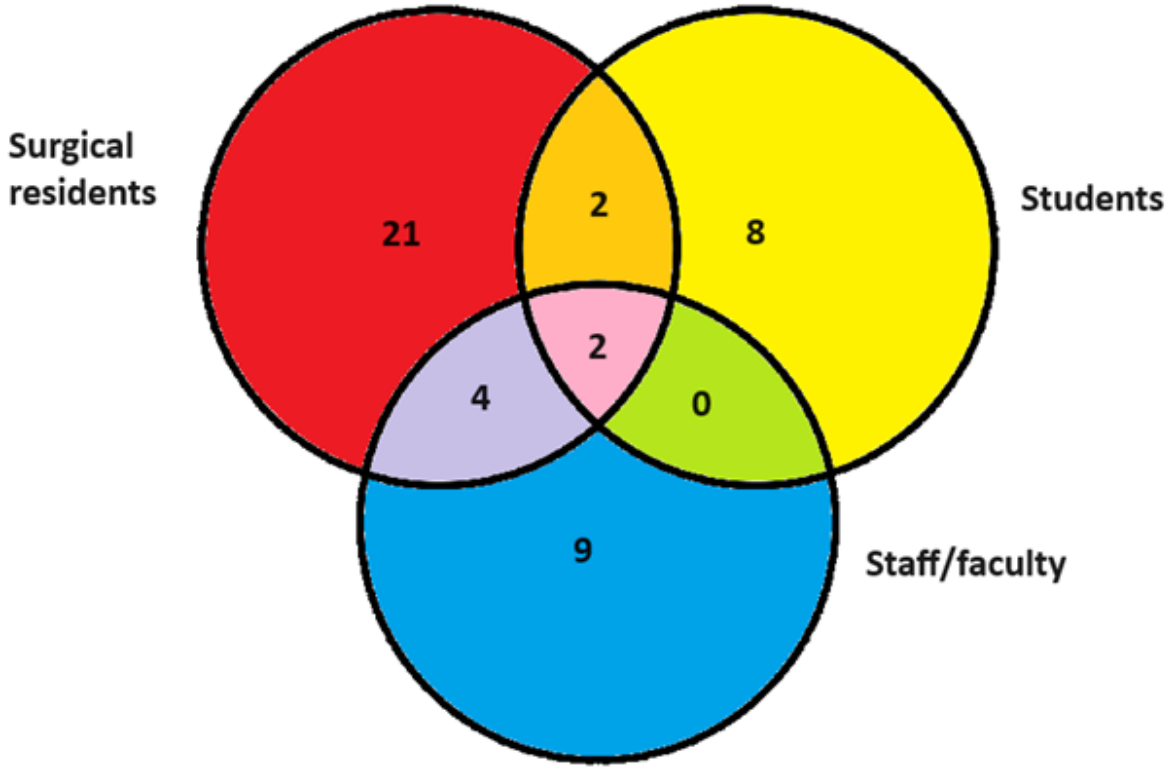
Characteristics

Most articles had a transversal design, accounting for 88% (n=22) of the total. One study (1/25, 4%) was a review, and 3 others (3/25, 12%) were cohorts. The number of participants was, on average, 114. The smallest study had 15 participants [25] and the biggest, 1549 participants [19].

The articles included students, surgical residents, and surgical staff/faculty. Figure 3 shows the number of articles with each of these populations. Specifically, 84% (n=21) of the papers included general surgery residents, while 36% (n=9) targeted faculty and staff.

The goals of these studies differed a bit. A total of 60% (n=15) of participants were interested in the relation between learning styles and performance, such as laparoscopic or robotic skills, academic achievement, and so on. Another 28% (n=7) of participants also looked over gender gaps and differences among female and male participants. Four studies (4/25, 16%) took an interest in changes in learning styles over time. Three studies (3/25, 12%) also evaluated motivation.

Figure 3. Number of articles with each population.



Discussion

Principal Findings

This scoping review identified 25 studies published between the 1960s and 2023 that explored learning styles in the context of surgery education. The majority of these studies were published in the 2010s and were predominantly conducted in North America and Europe. The most frequently used instruments to assess learning styles were Kolb's LSI and the VARK questionnaire. The included studies primarily focused on surgical residents, investigating the relationship between learning styles and various outcomes such as performance, gender differences, changes over time, and motivation.

There are several ways to face adult education. For example, there are multiple theories that can be superposed along with multiple ways of evaluating them according to the chosen theory. In health care, there are several specificities that make the educational process more complex, since there are a lot of abilities and competencies to be developed in a short period of time. On top of it, medical science evolution becomes faster every day, adding challenges to education and the preparation of professionals.

Surgery is commonly known as a delicate place for developing skills and training in high-risk procedures. When teaching surgery, it is important to account for medical students, residents, and continuous improvement for teachers and medical staff. These pieces of surgical educational chess are very different from each other, each one with special needs and goals. To understand how these population extracts capture and keep knowledge is vital to effective learning [26].

As highlighted in the results, Kolb's LSI and the VARK instrument were the most commonly used tools in the reviewed literature. Kolb's LSI, based on experiential learning theory, categorizes learners into 4 styles (diverging, assimilating, converging, and accommodating) based on their preferences for concrete experience, reflective observation, abstract conceptualization, and active experimentation [4,5]. The VARK questionnaire, on the other hand, focuses on sensory preferences for information intake and output, classifying learners as visual, auditory, read/write, or kinesthetic [16]. While both instruments aim to identify individual learning preferences, they stem from different theoretical frameworks and assess distinct aspects of the learning process. Kolb's model is more focused on how individuals process information through a cycle of experience and reflection, whereas VARK is centered on the modality through which information is best received and conveyed. The prevalence of these instruments in the literature may be attributed to their relative ease of administration and interpretation. However, it is important to note that the psychometric properties and theoretical underpinnings of some learning style instruments, including Kolb's LSI, have faced criticism in the broader educational psychology literature, raising questions about their validity and the implications of findings based solely on these tools [27-29]. Future research should consider these limitations and potentially explore alternative or complementary approaches to understanding individual differences in surgical learning.

The study field of learning styles and surgery is wide and still poorly explored. It is only possible to imagine the benefits that would emerge with the amplification of this understanding in teaching and learning surgery in the next decades.

Principal Results

Historically, there are not many studies on learning style in surgery, as pointed out by this scoping review. The papers concentrate especially on the year 2010, and most of them are in North America or Europe. Thanks to important cultural, financial, and political contexts, it is evident that more information on the participants from the rest of the world is needed.

The main instruments used in the papers were Kolb's LSI and the VARK instrument, both derived from cognitive theories. The ease of handling the instruments was probably an impact factor in their choice, on top of their proven effectiveness and reproducibility.

A total of 84% (n=21) of papers had general surgery residents as the target, while only 36% (n=9) targeted faculty and staff. The improvement of teaching goes by deep knowledge of teachers and their methods [30]. So, prospective surgeons should not be the only goal of surgical educational research. The ratio is to disarticulate the former master-learner vision, understanding that everyone involved in the learning process is a potential and continuous learner [16,24].

The main purpose of the papers was to relate learning styles and performance, motivation, gender, and changes over time.

The articles aiming for performance did it in a lot of diverse ways. One way to assess performance is to evaluate the scoring in admission tests, and research has concluded, many times, that a nonspecific learning style is being favored in those types of admissions [25-29]. Others took interest in psychomotor skills, measured by specific metrics [14,19,20,30]. There were also the ones that focused on academic achievement throughout college [31] or residency program [11,21], by overlooking the number of procedures [32], for example.

In surgery, gender is a substantial subject because the surgical environment is, in general, very masculine. There is still today a discrepancy between women in the early career (residents) and late career (teachers) [33-38], and differences in payment, rates of sexual harassment, rates of sexual abuse, rates of psychological abuse, and so on. The proportion of women in surgery, although it has been increasing in the past few decades [17,20,28,31,32,39]

Motivation is key to good learning, and many learning theories rely on it [40,41]. Without motivation, the learner lacks stimuli and fatally decreases their learning. There is no robust evidence in the literature to support the relationship between learning styles and degree of motivation [16,42-44].

Limitations

The main limitation of this scoping review is the fact that only English articles were searched, which diminishes the cultural range due to the language barrier, especially if we consider that surgical residency has very different types of models and resources around the world.

Comparison With Prior Work

No scoping review on learning styles in surgery was ever done.

Conclusions

This scoping review identified a limited number of studies exploring learning styles in surgery education, with the majority concentrated in the 2010s and predominantly conducted in North America and Europe. The review found that Kolb's LSI and the VARK instrument were the most frequently used tools, and that research has primarily focused on surgical residents, investigating relationships between learning styles and performance, gender, changes over time, and motivation. The scarcity of studies from other regions, particularly Latin America and Africa, and the limited focus on medical staff and faculty highlight considerable gaps in the current literature. Based on these findings, understanding the characteristics of the existing research landscape is key to informing future studies. Further research is needed to broaden the geographical scope, explore diverse populations within surgical education, and investigate the practical implications of learning style research for enhancing teaching and learning strategies in surgery.

Acknowledgments

The authors wish to thank Luiz Vianney Saldanha Cidrão Nunes, who, even through hard times, was ready to collaborate deeply in the success of the search strategy.

Authors' Contributions

GGS and JCA contributed to the conceptualization of the study. Data curation was performed by GGS, MARF, CDSC, and BCG. FSF was responsible for formal analysis. GGS, LVCN, and JCA conducted the investigation and developed the methodology. Project administration was carried out by DVO, FF, PSF, ARAL, VMSB, HCC, and JCA. Validation and visualization were undertaken by SRPVTC, JDSM, MQS, WDM, NAASRC, ERS, HLGC, ALL, ABQ, and SMML. The manuscript was written, reviewed, and edited by GGS and JCA.

Abstract

Background: With the growing use of technology in medical education, a framework is needed to evaluate learners' and educators' acceptance of these technologies. In this context, the Technology Acceptance Model (TAM) offers a valuable theoretical framework, providing insights into the determinants influencing users' acceptance and adoption of technology.

Objective: This review aims to systematically synthesize the body of research in medical education that uses the TAM.

Methods: An electronic literature search was conducted using the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) approach in February 2024 on the Embase, MEDLINE, PsycINFO, PubMed, and Web of Science databases, yielding 680 articles. Upon elimination of duplicates and applying the exclusion criteria, a total of 39 articles were retained. To evaluate the quality of the study, the Medical Education Research Study Quality Instrument score was calculated for each analysis with a qualitative component.

Results: Studies using TAM in medical education began in 2010, with the model's application relatively rare up to 2016. Most of the studies were quantitative, operationalizing the TAM as a survey instrument, but it was also used as a research framework in qualitative data analysis. Structural equation modeling, descriptive analysis, and correlation analysis were the most common data analysis approaches in the studies. E-learning and mobile learning were the predominant learning interventions explored, but there were indications that novel learning technologies such as augmented reality, virtual reality, and 3D printing were being investigated.

Conclusions: The study's findings reveal an expanding scholarly engagement with using TAM in medical education. Although the TAM has been mostly used as a survey instrument, it can also be adapted as a qualitative research framework to analyze data. This systematic review provides a foundation for future research to understand the factors influencing users' acceptance of technology, especially in medical education.

Introduction

Technology has changed how we learn and access knowledge, particularly with the introduction of digital devices and the internet. No longer are we constrained by time or space, and information is available anytime and anywhere. Today, learning can happen through massive open online courses such as Khan Academy [1], edX [2], and Coursera [3], or simply by viewing one of countless video tutorials online. Books can be supplemented or even replaced with multimedia resources that can provide learners with a richer learning experience. The way that knowledge is accessed has changed dramatically over the past 2 decades with the development of new technologies.

Medical education has traditionally relied on time-honored teaching methodologies. Cadaveric dissection has always been considered the gold standard for anatomy instruction [4], providing students with hands-on experience with human tissues and structures. However, as educational resources face constraints and medical knowledge expands, these traditional approaches have begun to be transformed through the use of technology. Teaching modalities such as virtual [5] and augmented reality [6] provide students with an immersive 3D learning experience. Three-dimensional printing technology [7]

has enabled the creation of anatomical models on demand that can be customized for specific learning outcomes [8], and e-learning resources [9] have democratized access to high-quality learning materials. In a study on rural posting clerkships, iPads equipped with mobile health information resources have positively influenced medical students' information-seeking behavior [10]. With the increasing use of technology in medical education, it is essential to understand how it is accepted for use in learning.

The Technology Acceptance Model (TAM) provides a framework to understand the factors influencing the decision to use new technologies in medical education [10-12]. The perceived ease of use is the extent to which a person believes the system will be free of effort. In contrast, perceived usefulness is the extent to which a person believes using the system would improve their productivity or job performance. However, one shortcoming of the TAM when applied to complex medical teaching environments is that it does not consider broader contextual factors, such as organizational culture, social influence, and other affective factors like attitudes and beliefs that may significantly impact the acceptance of educational technology.

To address this issue, the Technology Acceptance Model 2 (TAM2) was proposed by Venkatesh and Davis [13] as an improvement to the original model to include social influence and cognitive processes that may influence an individual's acceptance of technology. The purpose of developing the TAM2 was to include additional crucial factors influencing perceived usefulness and usage intention constructs to explain user behavior and acceptance. These factors include subjective norms, output quality, result demonstrability, and social factors, among others, that explain user behavior and acceptance. By integrating these factors, the TAM2 offers a more comprehensive framework for analyzing how individual and social variables influence beliefs, attitudes, and intentions to use the technology in medical education.

Despite the growing use of technology in medical education, understanding the factors that influence its adoption remains challenging for educators and institutions. Previous research has identified barriers to technology implementation such as technical difficulties [14], resistance to change, and varying acceptance by faculty and students [15]. The TAM has emerged as a valuable theoretical framework for examining these adoption challenges [10,16,17], yet its application within medical education contexts remains fragmented and inconsistently synthesized [16,18]. This knowledge gap may hinder evidence-based decision-making on the use of education technology that could enhance teaching and learning outcomes in medical education.

To address this limitation, this systematic review aims to synthesize the current research on the application of the TAM in medical education to provide insights into the factors influencing technology acceptance among medical professionals and students. The guiding questions that we aim to answer with this systematic review are as follows:

1. What is the state of TAM in medical education?
2. How has TAM been operationalized?
3. What education interventions are used in such studies?

Methods

This review was designed and is reported using the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) guidelines [19].

Search Strategy

A systematic search was conducted in February 2024 to identify original published articles on TAM and medical education from January 2003 to December 2023. We set the search criteria to focus on the last 20 years to capture only the most recent advancements in the field. An author (JYT) then systematically searched 5 databases accessible through the university library. A search of "all fields" with the keywords "TAM" or "Technology Acceptance Model" and "Medical Education" was used for the Embase, MEDLINE, PubMed, PsycINFO, and Web of Science databases.

Inclusion and Exclusion Criteria

Peer-reviewed articles were included if they used the TAM as a survey instrument in the study methodology or as a theoretical framework in medical education. This includes using the original TAM model proposed by Davis [20] or the TAM2 model proposed by Venkatesh and Davis [13]. We define medical education–related studies as training medical professionals, residents, and students pursuing their undergraduate, clerkship, postgraduate, or continuing medical education. If the study comprised a mix of medical students and students from other health care science professions (eg, nursing, pharmacy, emergency response), they were also included as part of the review.

Studies were excluded from our research if they were not related to medical education, such as research focused solely on nursing and allied health professions like pharmacy and physiotherapy, articles not written in English, articles published before 2003, and non–peer-reviewed documents, including theses or conference abstracts lacking comprehensive methodological details. When the cohort under study comprised a mixture of health professionals, including those who met the inclusion criteria, the entire cohort was included in the research analysis.

Final Study Selection

After retrieving the search results from the identified database, JYT removed the duplicates and uploaded the articles into a shared Microsoft Teams [21] folder. The shortlisted articles were entered into an Excel spreadsheet for screening by the authors. The final screening process involved JYT noting articles for inclusion or exclusion based on the title or abstract, which was verified independently by the primary author (JWYL). JYT also assigned a reason for exclusion for each excluded article. In cases of uncertainty, the articles in question were retained and screened together by both authors (JWYL and JYT). JYT extracted the full text of the retained articles and this was verified by JWYL for consistency.

Data Extraction and Analysis

After the shortlisted studies were identified, details of the studies were entered into the spreadsheet, including (1) general study information (eg, authors, title, and publication year), (2) participant-related information, (3) sample size, (4) application of the TAM framework, (5) study design, (6) statistical analysis used, (7) education intervention investigated, and (8) study quality (Medical Education Research Study Quality Instrument [MERSQI] score). Please see Table 1 for information gathered from the shortlisted studies.

Table . Articles included in the study.

[a]TAM: Technology Acceptance Model.

[b]MERSQI: Medical Education Research Study Quality Instrument.

[c]N/A: not applicable.

[d]SEM (CB): covariance-based structural equation modeling.

[e]SEM (PLS): partial least squares structural equation modeling.

To assess the study quality of quantitative studies, the MERSQI was used to measure the methodological quality of the selected studies [56]. The MERSQI is an instrument that measures the quality of experimental, quasi-experimental, and observational studies. The MERSQI contains 6 domains (study design, sampling, type of data, validity evidence for the evaluation instrument, data analysis, and outcomes), with a study scoring a possible total of 18. The MERSQI was not designed for use in qualitative studies. Therefore, these studies will not be assessed using the MERSQI.

Results

Overview

A systematic literature retrieval and analysis was methodically executed across 5 authoritative databases (Embase, MEDLINE, PsycINFO, PubMed, and Web of Science), yielding 580 records. The PRISMA checklist informed the review protocol and is depicted in the flow diagram in Figure 1. Using automation tools to narrow the search criteria, 30 studies were removed, and 266 duplicate records were excluded. This resulted in 384 studies that were eligible for screening. Based on the abstract or title, 329 studies that did not meet the study inclusion criteria were eliminated. This left 55 studies for full-text retrieval. Both authors read through all shortlisted papers and excluded a further 18 papers, where 1 was a duplicate, 8 did not use the TAM in the study, and 9 were unrelated to medical education. Therefore, the total number of studies included was 37.

Table 2 presents the source database, publisher, and number of studies found in the search results.

Figure 1. PRISMA flowchart. PRISMA: Preferred Reporting Items for Systematic Reviews and Meta-Analyses.

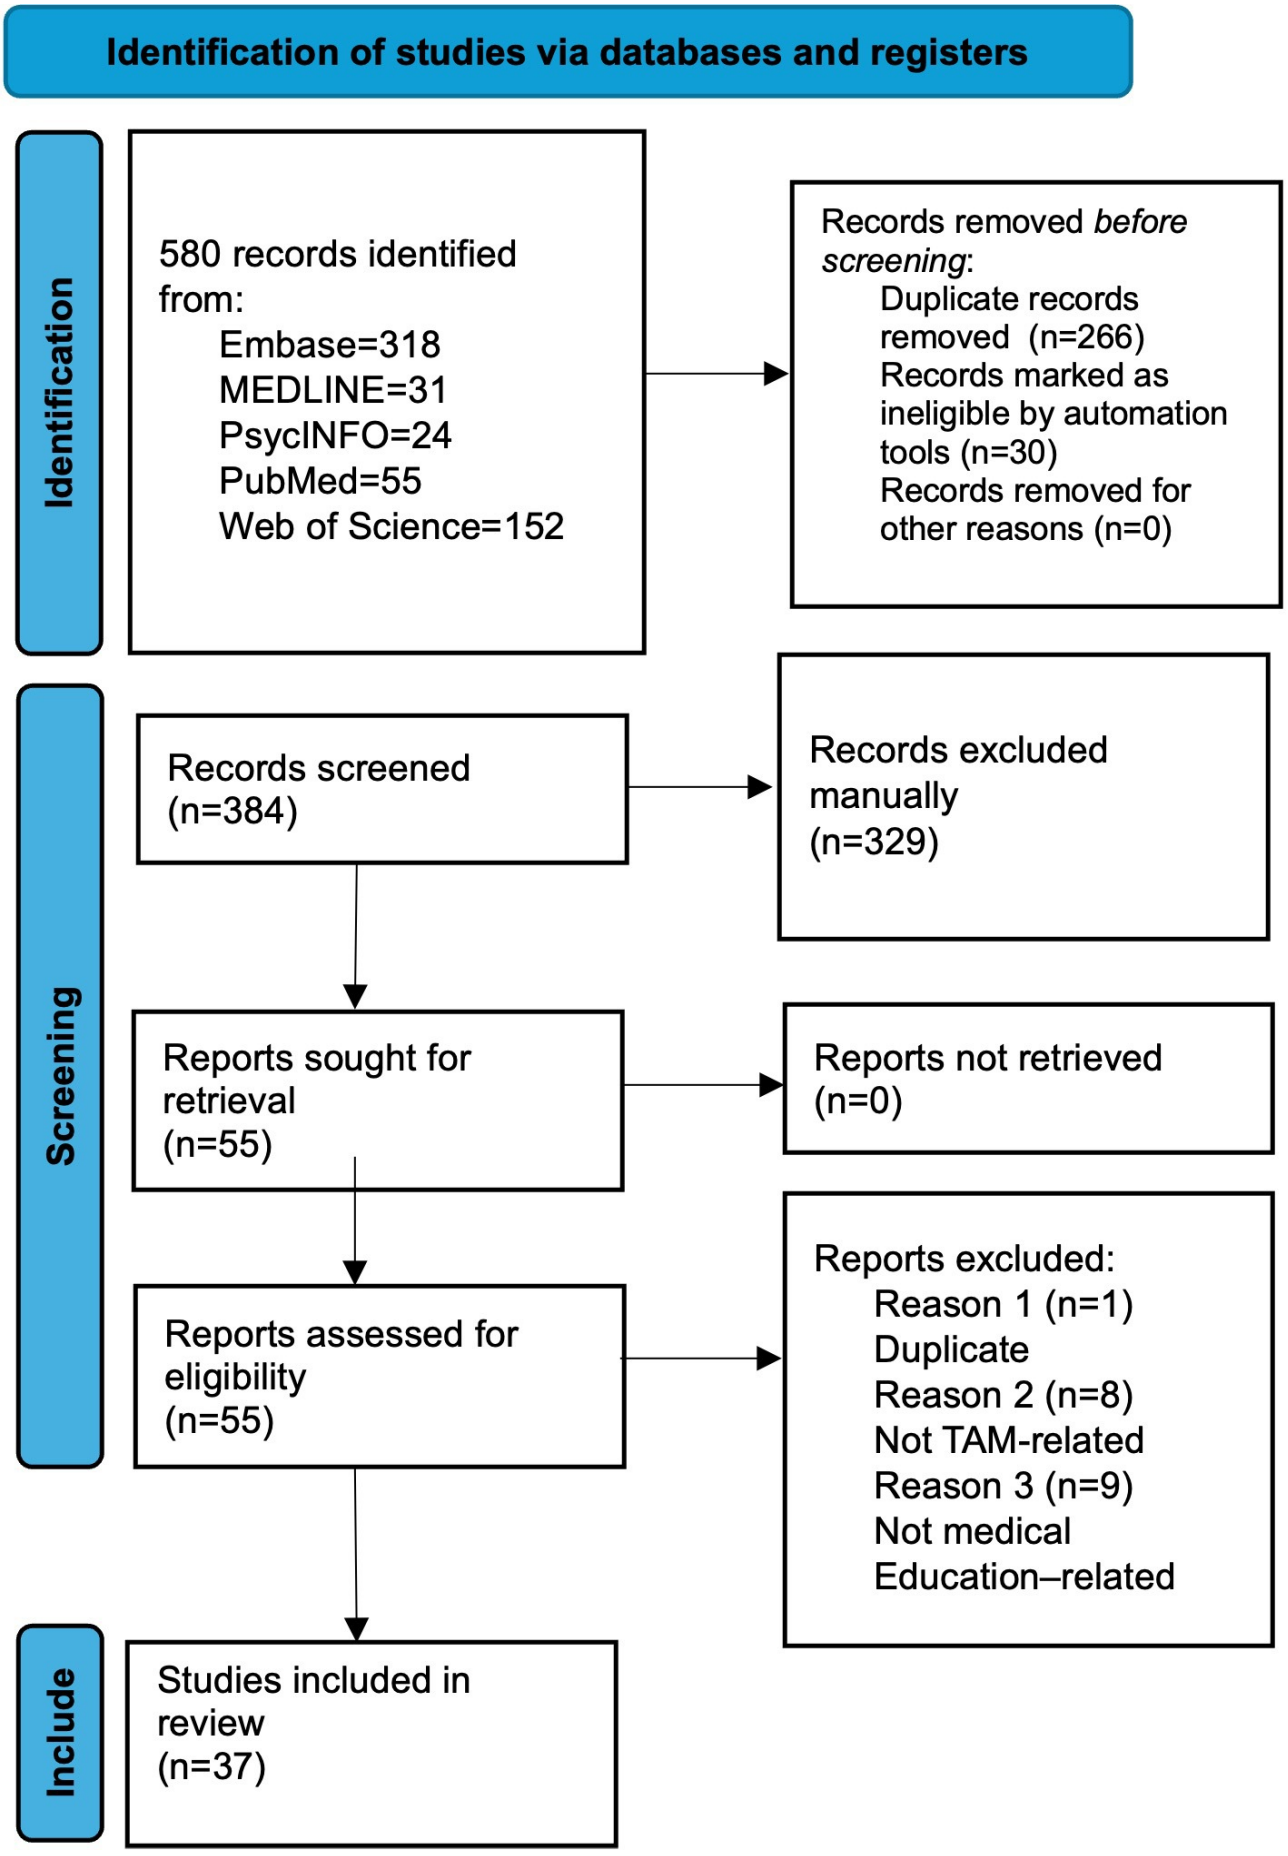

Table . Databases and search results (N=680).

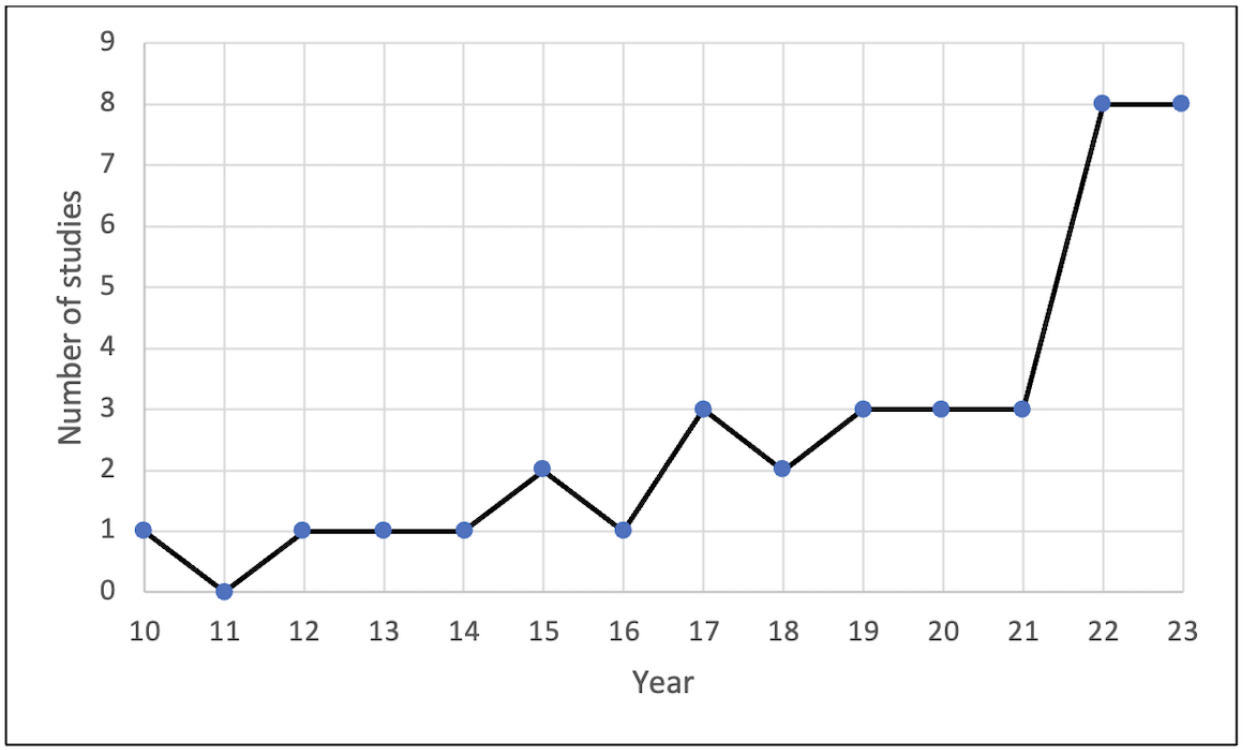
Database	Vendor/publisher	Search results, n (%)
Embase	Elsevier	318 (46.3)
MEDLINE	OvidSP	31 (4.6)
PsycINFO	APA	24 (3.5)
PubMed	PubMed	155 (22.8)
Web of Science	Clarivate	152 (22.4)

Year of Publication

Despite the TAM being developed in the 1990s and our search spanning from 2003 to 2023, we only found a single study from 2010, which marked the earliest TAM usage in this review. The adoption of TAM in medical education remained relatively rare up to 2016. It was not until 2017 that a consistent uptick in the number of peer-reviewed publications using this model could be observed, with an average of 3 studies each year until 2022, when there was an almost 3-fold increase to 8 studies, which remained constant in 2023 (Figure 2). This surge in numbers was likely driven by the rapid integration of technologies from 2021 onward, which will be covered in the Discussion section.

Figure 2. Number of publications by year from 2010 to 2023.



Country of Study

The included studies were conducted in 21 countries, with no single region dominating the publications. Six of the studies were conducted in the United States [23,26,34,45,47,48], 4 in Taiwan [25,27,53], 3 in Spain [12,28,51]; 2 each in Canada [10,38], Denmark [24,32], Iran [29,35], Turkey [31,36], United Arab Emirates [33,41], and the United Kingdom [22,49]; and 1 each in Australia [30], Belgium [55], Botswana [52], Brazil [43], Egypt [40], Hong Kong [44], India [42], Indonesia [54], Jordan [50], Singapore [39], Uganda [46], and Zambia [17]. This diverse set of countries suggests that TAM has been applied globally across low-income and high-income nations, reflecting its adaptability to various education and technological contexts. Table 3 is a description of the countries by location.

Table . Location of study by country.

Country	Number of studies

Zambia	1

Study Participants

The array of participants in the studies analyzed is quite diverse, reflecting the multifaceted nature of medical education. The review included 2 studies on general undergraduates of various disciplines [50], 1 on general undergraduate and postgraduate students of various disciplines [41], 3 on health care educators [38,44,53], and 9 on health care professionals [23,24,32,39,40,48,52,5537]. Three studies centered around health science undergraduates [46,51,54], 12 studies focused on undergraduate medical students [10,26-29,34-36,42,43,45,49], and 4 investigated undergraduate medical students and health care professionals [12,17,25,31]. Notably, 3 studies were systematic or scoping reviews [22,33,47], which, by their nature, did not involve direct study participants. Table 4 presents a summary of publications by study participants.

Table . Summary of publications by study participants.

Study participants	Publication count
General undergraduates	2
General undergraduate and postgraduate students	1
Health care educators	3
Health care professionals (doctors, nurses, pharmacists, residents)	9
Health science undergraduate students	3
Medical undergraduates	12
Medical undergraduates and health care professionals	4
Review articles (scoping or systematic review)	3

Application of TAM

The TAM served dual purposes in the surveyed studies. In 26 (70%) of the studies, it functioned as a survey instrument, quantitatively measuring the variables influencing user acceptance of and interaction with educational technology. The remaining 11 (30%) studies incorporated TAM as a foundational research framework, which involved thematic analysis of the

collected data or shaping the methodology for data collection. This 2-pronged application of the TAM highlights its adaptability and role in the empirical and theoretical examination of technology adoption in medical education. Table 5 is a summary of the application of TAM.

Table . Summary of the applications of the Technology Acceptance Model.

Application	Count
Research framework	11
Survey instrument	26

Study Design

The studies reviewed encompass quantitative, qualitative, and mixed methods research methodologies, each engaging the TAM differently. The quantitative studies operationalize the TAM through survey instruments, measuring variables such as perceived ease of use and perceived usefulness to explain the users' behavioral intentions and actual technology use. In contrast, qualitative studies contextualize the TAM within the broader theoretical landscape, using it to guide the thematic analysis of focus group discourse or to underpin systematic reviews that explore the factors influencing technology adoption. The mixed methods approach combines both, where survey data are analyzed quantitatively while concurrently using qualitative techniques such as semistructured interviews or textual analysis to capture the subtleties of user experience and perception. Most of the included studies (25/37) were quantitative, 7 were qualitative, and 5 adopted a mixed methods approach, as described in Table 6.

Table . Summary of study methodology.

Methodology	Count
Quantitative	25
Qualitative	7
Mixed method	5

Statistical Analysis

Correlation analysis was the predominant quantitative technique used in 10 studies to delineate the degree and direction of the linear relationship between the variables of interest. The next most used approach was structural equation modeling (SEM), with an equal number of studies (n=4) that used the covariance-based structural equation model and partial least squares structural equation model. Descriptive analysis was the third most frequently used method, implemented in 7 studies to succinctly summarize and describe the collected survey data. Three studies used regression analysis to predict the effect of the dependent variable based on the independent variable, and 2 other studies leveraged hypothesis testing, specifically the *t* test and *U* test, to conduct a comparative analysis of survey outcomes across different intervention groups. Seven studies were qualitative and therefore did not include statistical analysis. Table 7 summarizes the statistical approach taken by the reviewed studies, sorted by the complexity of the analysis.

Table . Statistical analysis approach of reviewed studies.

Statistical analysis approach	Count
Correlation analysis	10
SEM-CB	4
SEM-PLS	4
Descriptive analysis	7
Regression analysis	3
Hypothesis testing	2
Not applicable	7

Types of Education Intervention

The studies reviewed can be classified broadly into 2 categories of education interventions: education technologies and education methodologies. Under education technologies, 1 study examined 3D printing [26], 2 studies examined artificial intelligence [33,50], 3 studies focused on virtual reality [27,48,51], and 1 on augmented reality smart glasses [31], indicating an interest in integrating cutting-edge approaches into medical education. E-learning emerged as the most prevalent intervention, with 15 studies emphasizing digital learning [12,17,22,23,37,38,40-42,44,46,47,53-55]. In comparison, using mobile devices for learning was explored in 8 studies [10,28,29,34,36,39,45,52]. Two studies each investigated the use of serious games [24,43] and haptic devices [25,30]. One study evaluated the use of a website to improve transitions

between clinical placements [49]. Lastly, under the category of education methodologies, 1 study explored remote simulation training [34] and another explored flipped learning [45] in medical education. Table 8 summarizes the types of interventions investigated in the reviewed studies.

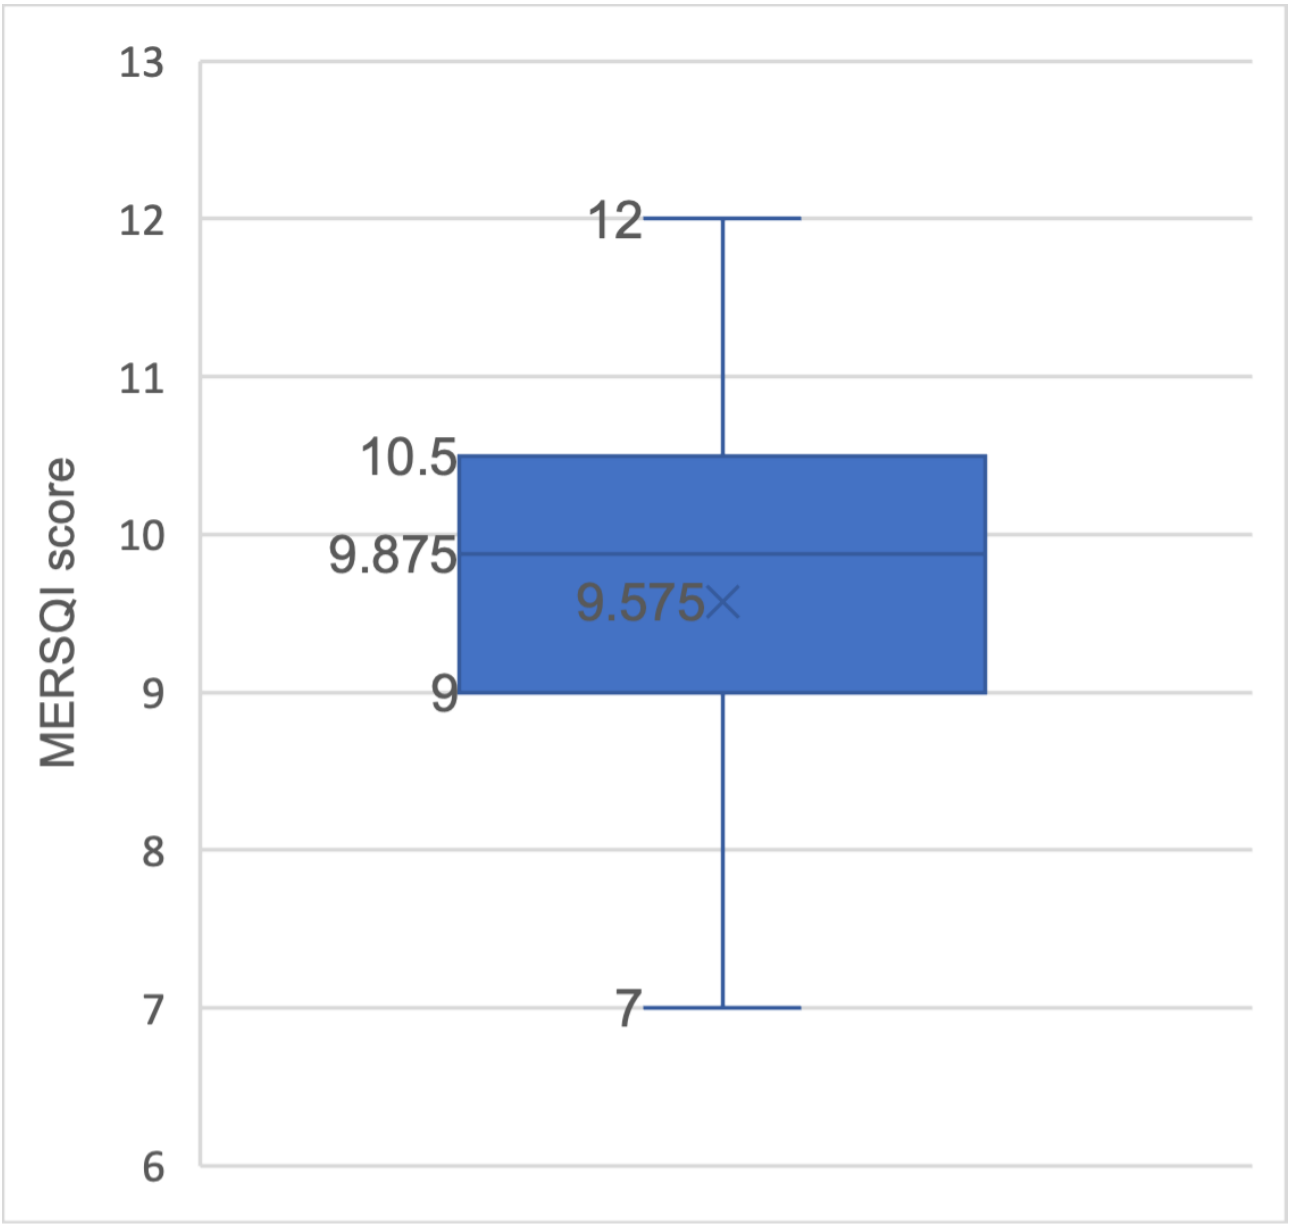
Table . Breakdown of the types of interventions investigated.

Intervention	Count
Education technologies	
3D printing	1
Artificial intelligence	2
Augmented/virtual reality	4
E-learning	15
Haptic device	2
Mobile device	8
Serious games	2
Website	1
Education methodologies	
Remote simulation training	1
Flipped learning	1

Study Quality

The MERSQI can be used to evaluate study quality in medical education research as it provides a validated, comprehensive framework for assessing methodological rigor across multiple dimensions. The MERSQI is a validated tool [57] consisting of 10 items across 6 domains: study design, sampling, data type, instrument validity, data analysis, and outcomes. Each domain can be scored up to 3, bringing the maximum score to 18. Thirty studies (25 quantitative and 5 mixed methods studies) were scored by the researchers using the MERSQI. The minimum score for the reviewed papers was 7, while the maximum was 12. The mean score was 9.58 (SD 1.31), with the mixed methods studies scoring generally below the mean score. Figure 3 is a boxplot diagram of the reviewed studies. Qualitative studies were not measured using the MERSQI. Table 1 displays a detailed summary of the MERSQI scores of the studies reviewed.

Figure 3. Boxplot diagram of the MERSQI score of reviewed studies. MERSQI: Medical Education Research Study Quality Instrument.



Discussion

Opportunities for TAM in Medical Education

Over the past two decades, technological progress has significantly shaped the education landscape. Traditional teaching approaches are enhanced with technology, making learning no longer bound by space or time. Yet, this systematic review found that the number of studies in medical education that use the TAM is notably infrequent when contrasted with other fields such as health informatics (134 studies) [16], higher education (104 studies) [58], mobile learning (87 studies) [59], and health profession education (142 studies) [18]. The review found a modest output of 1 study per year from 2010 to 2016. There was an uptick of 3 publications per year through 2021, followed by a large increase to 8 studies in 2022 and 2023, suggesting a growing interest in and recognition of TAM's relevance in medical education research.

This could be because the health care education field takes a conservative approach when adopting new digital initiatives. The curricula in medical education are highly structured and content-heavy, thus leaving little room for incorporating digital technologies. However, more recently, there have been calls for reforms within the curriculum [60], especially to integrate technology to enhance students' learning experience [61,62], which has been shown to affect student learning outcomes positively [63]. This can explain the steady increase in the number of studies that use TAM to understand user acceptance of learning interventions.

The low adoption rate of the TAM within medical education may be due to the focus on prioritizing satisfaction and basic usage statistics [64-66] when evaluating new technologies for learning. This approach overlooks the more nuanced dimensions that TAM examines, such as perceived usefulness and perceived ease of use. This emphasis on program-level satisfaction metrics fails to capture the complex psychological and organizational factors influencing technology acceptance in health care

educational environments. Such reliance on superficial evaluation matrices creates a significant gap between measuring program satisfaction and truly understanding the complex factors driving technology acceptance and sustained use in medical education.

The COVID-19 pandemic caused a global shift to digital platforms for learning. This created an urgent need to understand technology adoption in education and health care. The TAM became a framework for evaluating user acceptance of rapidly implemented technologies like e-learning platforms [26,34,56] and mobile learning [19-21]. The forced accelerated adoption of mobile and web-based learning highlighted the importance of TAM in assessing factors such as perceived usefulness and ease of use for remote teaching tools. The pandemic served as a global natural experiment in technology adoption, driving researchers to apply TAM across diverse contexts to address barriers to digital transitions. This surge in TAM applications demonstrated its adaptability in analyzing critical acceptance factors [32,36,42,46] during systemic disruptions, offering insights into user behavior that were essential for navigating the rapid technological transformations brought on by the crisis.

In this systematic review, each study with a quantitative element was appraised using the MERSQI, which is designed to assess the quality of published medical education research. Typically, a higher score is often associated with greater methodological rigor and would result in higher acceptance to quality journals [67,68]. With a mean MERSQI score of 9.6 (SD 1.17), the average score found within this review was higher than that found in a paper by Smith and Learman [57], yet it did not reach the benchmark of the high-quality score of 10.5 (SD 2.5) described by Reed et al [67]. Our analysis indicates that the substantial scores in this review are partly due to the inclusion of the TAM. Given that the TAM is a validated survey tool, its use—whether in its original or modified version—immediately contributes to a base score of five: 3 points for the tool's validity and 2 points for measuring behavioral outcomes. A study can accrue 4-5 points by using a methodologically robust and sound approach in the study design and reporting. Therefore, incorporating the TAM may potentially contribute to a higher quality of publication output.

Operationalizing the TAM

The TAM was originally developed as a theoretical framework based on the Theory of Planned Behavior [69], which can be operationalized as a survey based on the constructs within the model. This review found that the prevalent application of TAM in studies is through survey instruments, aligning with findings from other reviews [59]. Apart from the survey instrument, the TAM can be used qualitatively, such as adapting the constructs to guide the discourse in focus group discussions [32] or semistructured interviews [39].

Several different statistical analysis approaches were used to analyze the qualitative data. SEM stands out as one of the most comprehensive methods, adept at testing hypotheses concerning both observed and latent variables [70]; these studies generally had higher MERSQI scores [10,12,29,36,41,45]. Despite its robustness, SEM demands a thorough grasp of complex statistical concepts and a sufficiently large sample size to ensure the stability and accuracy of its estimates [71]. Correlation analysis offers a more straightforward approach to measuring the strength and direction of relationships between variables. Regression analysis further extends the analytical capability by providing predictive insights and facilitating the exploration of potential causal links between factors. Additionally, the TAM is frequently used in a descriptive capacity, offering an interpretive lens to dissect and articulate the intricacies of user interactions with technology, their attitudes, and the behavioral intentions that these factors precipitate.

This systematic review found that a large number of learning interventions were investigated for e-learning. This could be explained by the shift in higher education over the past 2 decades to web-based learning [72], accelerated by the COVID-19 pandemic, which necessitated and expedited the transition to web-based learning across various disciplines [73], including medical education. The integration of mobile technology into our everyday lives has naturally extended into the realm of education. This has prompted research on mobile devices for information access [15,23,32,47] and mobile apps for learning [12,45].

Additionally, this systematic review found studies delving into more innovative educational technologies beyond e-learning, such as virtual reality, augmented reality, serious games, and 3D printing. Virtual reality allows for students to practice their technical skills repeatedly in a risk-free setting, thus increasing their confidence and proficiency without jeopardizing patient safety [25,74]. Augmented reality overlays digital information onto physical or live environments, allowing students to understand complex anatomical structures [6] and to gain spatial awareness [75]. Another emerging tool that combines interactive gameplay with educational outcomes is serious games, which simulate real-world medical scenarios in a controlled and engaging environment [24,43]. 3D printing allows for the rapid development of customized models that can be used for teaching and learning [26]. Together, these technologies are changing the way learning is happening in medical education by providing immersive, interactive, and accessible tools to complement traditional teaching approaches. The TAM can serve as a valuable framework for understanding how these new and existing technologies are adopted and used for learning in medical education. By having a framework, educators and institutions can use the TAM to evaluate the integration of these technologies into their curricula and their potential for improving educational outcomes.

Limitations and Future Research

One limitation of this review is that it only encompasses data published up until 2023. Given the observed publication trend, it is plausible that subsequent studies using TAM in 2024 and beyond fall outside the scope of this review. Consequently, the conclusions drawn here are pertinent to the specified research period. Future studies should consider extending the review to include these additional years, thereby capturing a more comprehensive dataset, potentially offering a more current evaluation of TAM's application in the field.

Although this review contributes valuable insights into the use and application of TAM in education, the findings are primarily

within the context of medical education and exclude other health professions, including nursing and allied health professionals. Medical education is a highly specialized domain with unique challenges and practices that may not directly translate to the broader educational context outside of medicine. Furthermore, the complexity and heterogeneity within medical education, such as the variation in curricula and culture, may pose an additional challenge to generalizing findings even within the discipline.

Despite these limitations, the framework used in this review offers significant potential for broader application across other health care disciplines. Researchers could adapt this approach to explore TAM's adoption and effectiveness in nursing education, allied health training, or interdisciplinary health care programs. Expanding research beyond medical education would enhance the generalizability of findings and provide comparative insights into how TAM influences technology adoption across diverse health care professions. Additionally, extending TAM-based research to non–health care fields could further enrich our understanding of its applicability and utility in varied educational contexts.

Future researchers should consider adopting the additional constructs in TAM2 to better understand how social and cognitive factors influence technology acceptance beyond the perceived ease of use and perceived usefulness. For example, researchers can investigate how subjective norms or job relevance may influence the students' willingness to adopt new technologies and professional identities in an educational context.

Conclusions

This systematic review aimed to understand the use of the TAM in medical education over the past two decades, highlighting its utility as both a theoretical framework and survey instrument. This study reported on TAM's increasing popularity and versatility for measuring and understanding the learners' acceptance of the intervention. With the increasing integration of e-learning, digital learning, and other new learning modalities, it is critical that researchers can leverage technologies that learners will adopt. Such curriculum innovations are critical for maintaining educational continuity in the face of global health challenges by facilitating remote learning and continuous professional development. Consequently, these curricular reforms are expected to catalyze a significant surge in the adoption of digital technologies within medical education.

The growing importance of the TAM in understanding technology acceptance cannot be overstated, especially in medical education, where the use of artificial intelligence, virtual reality, and other adaptive learning platforms is increasingly popular. Educators and developers can use TAM as a theoretical framework to design curricula or interventions considering barriers to adoption, such as organizational support or the intervention's technical complexity. The TAM is relevant as an evaluation tool and can guide future innovations in medical education. Policymakers should consider using the insights gained using the TAM to develop strategies for the education system while meeting the challenges of cost, accessibility, and infrastructure development.

This review provides a comprehensive understanding of how the TAM has been applied within the field of medical education over the past 20 years. As the field continues to innovate, TAM will continue to play an important role in helping educators, policymakers, and researchers understand the dynamics of technology integration and the impact on teaching and student learning outcomes.

Abstract

Background: Quality clinical care is supported by effective patient-centered communication. Health care professionals can improve their communication skills through simulation-based training, but our knowledge about virtual simulation and its effectiveness and use in training health professionals and students is still growing rapidly.

Objective: The objective of this study was to review the current academic literature to identify and evaluate the virtual simulation tools used to train communication skills in health care students and professionals.

Methods: This review was carried out in June 2023 by collecting data from the MEDLINE/PubMed and Web of Science electronic databases. Once applicable studies were identified, we recorded data related to type of technology used, learning objectives, degree of learning autonomy, outcomes, and other details.

Results: We found 35 articles that had developed and/or applied a virtual environment for training communication skills aimed at patients, in which 24 different learning tools were identified. Most had been developed to independently train communication skills in English, either generally or in the specific context of medical history (anamnesis) interviews. Many of these tools used a virtual patient that looked like a person and had the ability to vocally respond. Almost half of the tools analyzed allowed the person being trained to respond orally using natural language. Of note, not all these studies described the technology they had used in detail.

Conclusions: Many different learning tools with very heterogeneous characteristics are being used for the purposes of communication skills training. Continued research will still be required to develop virtual tools that include the most advanced features to achieve high-fidelity simulation training.

Introduction

Effective patient-centered communication is one of the key components of quality clinical care [1]. Thus, it is vital that health care professionals adequately manage their communication skills. This involves mastering the transmission of information; listening and comprehensively understanding all the issues related to the health of each patient [2]; and responding appropriately to the physical and emotional needs of patients [3]. Better communication when supporting decision-making means that patients are better able to understand their situation, feel better informed, and are more active in the decision-making process [4]. Hence, acquiring good communication skills has been related to improved health outcomes, general patient satisfaction [5], better adherence to treatment plans [6], and positive effects on health care costs and length of hospital stay [7].

However, despite recognizing the importance of communication, health professionals are not always sufficiently skilled in this area [8]. Therefore, it is advisable that both health and educational institutions introduce different means of supporting the development of communication skills into their training plans as a priority objective. Furthermore, this training must also be implemented through effective educational strategies [9]. It has previously been shown that simulation-based learning is an effective means of acquiring communication skills [9]. Specifically, simulation with a standardized or simulated patient, which consists of using trained people to realistically portray a patient within learning contexts [10], is widely used to train communication skills [1].

Nonetheless, although the use of simulation methodologies has greatly advanced training in communication skills, its implementation also has limitations. For example, in terms of the human resources used in this type of training, it is particularly difficult to recruit actors able to simulate patients precisely and consistently in a completely standardized way [11,12]. Other difficulties include temporal–spatial issues because the availability of simulations with standardized patients is limited to a specific physical space and time [13]. A training alternative that could overcome these limitations is the use of standardized virtual patient programs that use computerized characters rather than real actors [14].

Indeed, compared to standardized patients, there are significant advantages to the use of virtual patients, including the need for fewer staff and resources once developed [15], unlimited availability, and the fact that they are highly customizable [14]. Additionally, these tools provide highly interactive, engaging, and more standardized experiences because educators can control their design, programming, delivery, and use [14]. It is also worth noting that these solutions can be personalized according to specific individual needs, given that they are not limited by time or space, so students can repeatedly engage in training in more clinical scenarios than is possible through traditional methods [15]. In addition, this technology also allows students to learn in a safe environment with low levels of risk and anxiety, which encourages them to gain greater personal awareness of their learning processes [16].

Virtual simulation has gained attention in recent years as a promising tool for training both undergraduate and graduate students, as well as health care professionals, in various competencies, including nontechnical skills. This growing interest is evident in an increasing number of studies focused on its potential applications in health care education [17]. However, despite this expanding body of research, it is advisable to continue researching with the aim of fully exploring and understanding which technological and technical skills are more suitable to train in virtual simulation [17]. Some reviews on virtual simulation and the learning of nontechnical skills such as communication are available [17-19]. For example, in their integrative review, Peddle et al [19] examined how interactions with virtual patients impacted nontechnical skills in general, without exclusively focusing on communication skills or technical and instructional design characteristics. Subsequently, both the systematic review by Lee et al [18] and the literature review by Battegazzorre et al [17] examined the technical characteristics of virtual learning applications aimed at improving communication skills. However, it is noteworthy that these reviews include studies published only up to December 2018 and May 2020, respectively, which highlights a gap in the literature regarding recent advancements in virtual simulation technologies.

The development of communication skills is fundamental for the effective clinical practice of health care professionals. However, the increasing diversity of virtual simulation tools and the rapid pace of technological innovation pose significant challenges to understanding which tools are most effective for training these skills. This raises the following key questions: what are the characteristics of the current virtual simulation tools used for training communication skills, and how effective are they in fostering realistic and immersive learning experiences? To address these questions, we conducted a systematic review of the virtual simulation tools available to train communication skills in health care professionals, analyzing their design, degree of immersion, and autonomy to identify their strengths and limitations.

Therefore, the objective of this study was to review the current academic literature to identify and evaluate the virtual simulation tools used to train communication skills in health care students and professionals and to assess their effectiveness and limitations in training health care personnel.

Methods

Design

We completed a literature review to identify virtual simulation tools designed to train communication skills in health care professionals, including students in training and practicing professionals. The inclusion criteria were studies that examined (1) virtual simulation tools and/or those based on artificial intelligence (AI), (2) tools used to train communication skills in health professionals, and (3) tools targeting training in communication skills and/or therapeutic relationships with patients. Studies were excluded if (1) the tools were designed to train interprofessional communication, (2) the objective was noneducational, and (3) the tool was designed to train patients in social and/or communication skills. This systematic review was conducted in accordance with the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) 2020 [20] guidelines to ensure comprehensive and transparent reporting of the methodology and findings.

Search Strategy

The search for studies was conducted in June 2023 in the MEDLINE/PubMed and Web of Science electronic databases. As part of the search strategy, we consulted the PubMed thesaurus using the following Medical Subject Headings (MeSH) terms: “Artificial Intelligence,” “Machine learning,” “virtual reality,” and “social skills.” The natural language search terms included in the title and/or abstract fields were “artificial intelligence,” “machine learning,” “virtual reality,” “e-simulation,” “web-based simulation,” “virtual simulation,” “virtual patient,” “social skills,” “interpersonal skills,” “social ability,” “social competences,” and “communication skills.”

The complete search strategy was as follows: (((“Artificial Intelligence”[MeSH Terms] OR “Machine Learning”[MeSH Terms] OR “Artificial Intelligence”[Title/Abstract] OR “Machine Learning”[Title/Abstract])) OR ((“Virtual Reality”[MeSH Terms] OR “Virtual Reality”[Title/Abstract] OR “e-simulation”[Title/Abstract] OR “web-based simulation”[Title/Abstract] OR “virtual simulation”[Title/Abstract]) OR (“virtual patient”[Title/Abstract]))) AND ((“Social Skills”[MeSH Terms] OR “Social Skills”[Title/Abstract] OR “interpersonal skills”[Title/Abstract] OR (“social ability”[Title/Abstract] OR “social abilities”[Title/Abstract]) OR (“social competence”[Title/Abstract] OR “social competences”[Title/Abstract]) OR “communication skills”[Title/Abstract])).

No temporal restrictions were applied in any of these cases. Despite previous reviews focusing on similar topics [17-19], it was decided not to base the current review on them. This decision was due to differences in the search strategy used, which did not account for the wide range of synonyms associated with each term established for this review. Furthermore, it is important to note that Lee et al [18] focused their strategy exclusively on communication among medical students, while Peddle et al [19] directed their attention to all nontechnical skills, not just communication skills.

The eligibility of the studies was independently assessed by 2 of the authors (MJCM and RJS) and any discrepancies were resolved by another author (SE).

Data Extraction

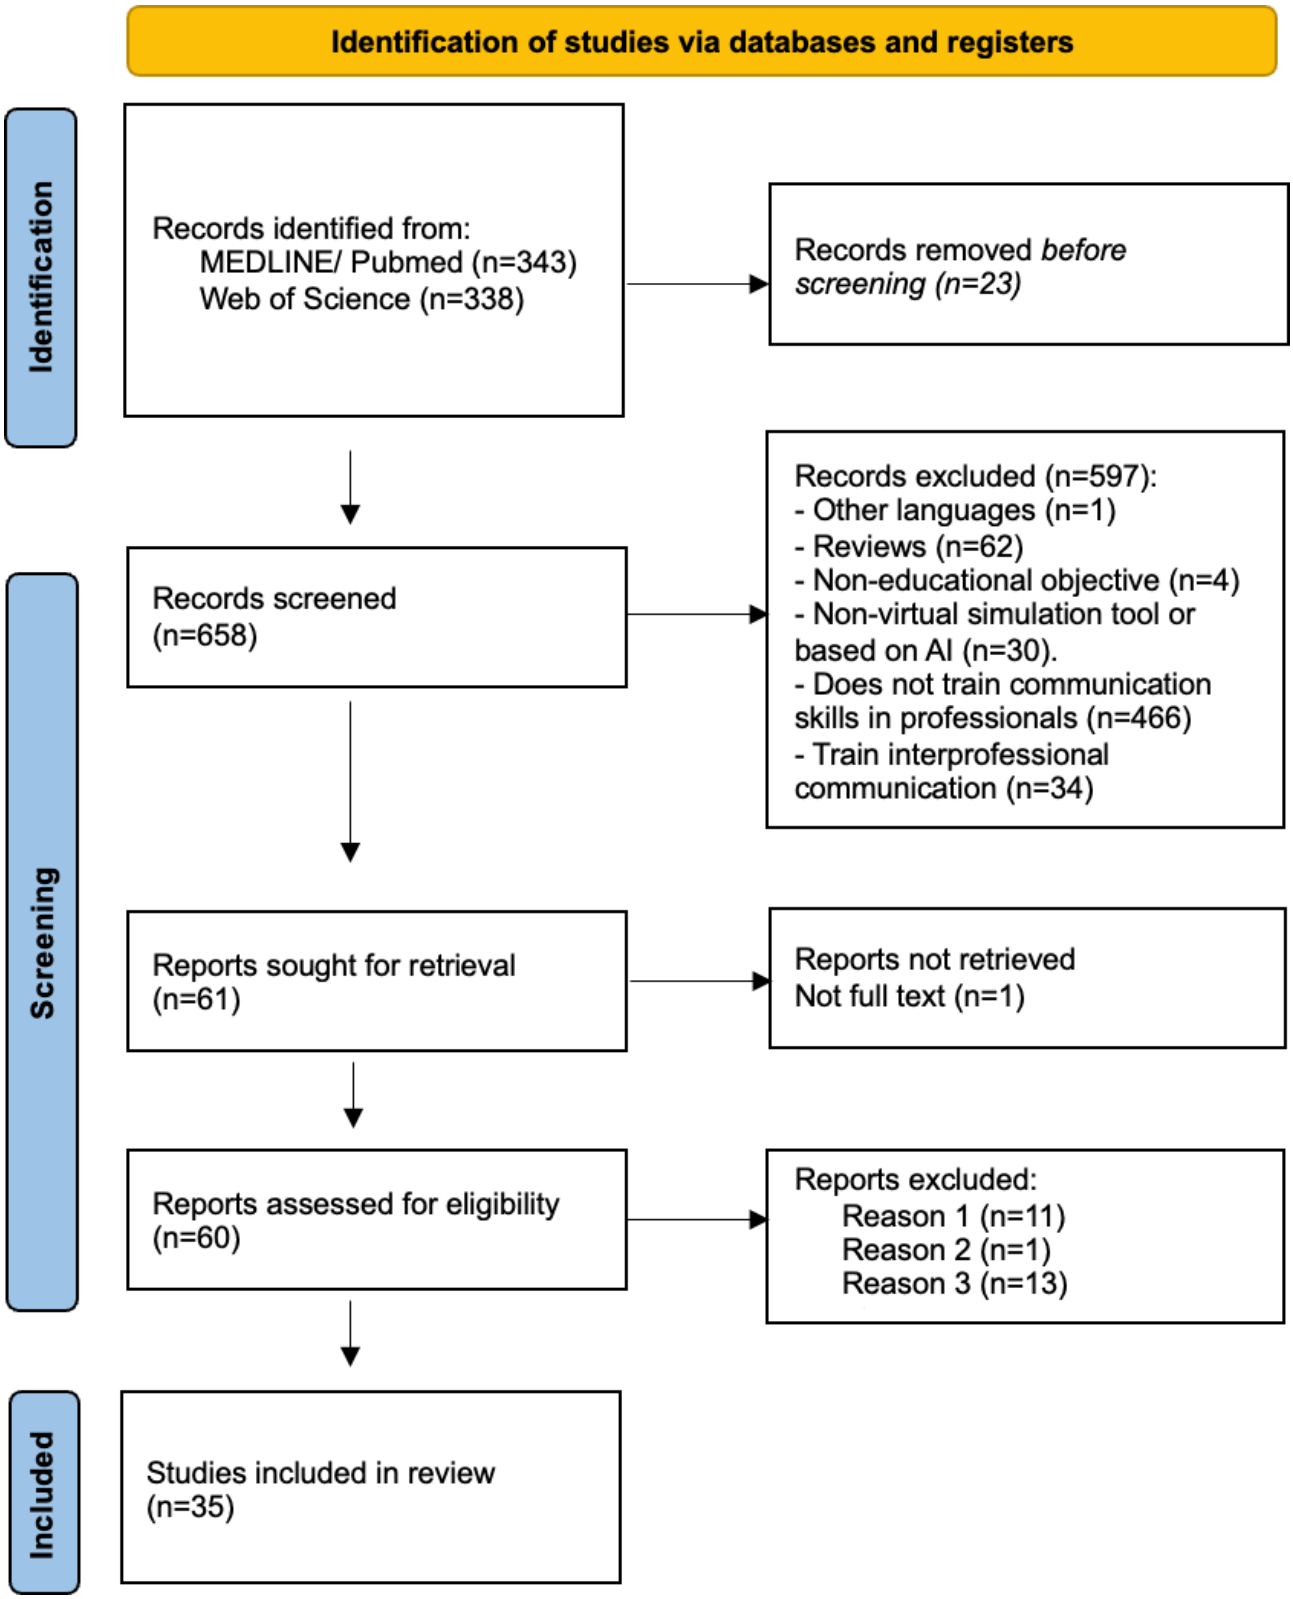
Data related to the characteristics of the studies (publication year, country, language, objective, and type) as well as data related to the outcome of the use of the digital/virtual training tool for improving communication skills in health care professionals were recorded. Specifically, we noted the tool name, training language, learning objective, degree of learning autonomy (fully autonomous vs instructor-mediated training), patient type (avatar/doll, virtual patient with a human-like appearance, real person, etc), type of answers given by the trainee (written or oral conversation), and type of technology used.

Results

Overview

The studies were manually screened and coded. Our search of PubMed and the Web of Science produced 681 records, of which 23 duplicates were eliminated. During the screening process, 2 of the authors independently analyzed 658 studies based on their titles and abstracts (Figure 1). After this initial screening, the full texts of 61 records were obtained for analysis. We requested the full texts of a further 2 articles from the corresponding authors by email and through ResearchGate; of these, we included 1 in this review. Of these 60 studies, 25 were excluded because they did not meet the inclusion criteria. Specifically, 11 articles had not directly trained clinical communication skills with patients (criterion 1), 1 had not studied virtual training (criterion 2), and 13 had not used a tool designed for training purposes (criterion 3). Therefore, a total of 35 articles were included in the review. Finally, one of the authors extracted the relevant data from these 35 studies and entered them into a database following the coding manual we had prepared for this purpose.

Figure 1. PRISMA flowchart. Reason 1: articles not directly related to training clinical communication skills with patients; reason 2: did not study virtual training; reason 3: did not use a tool designed for training purposes. AI: artificial intelligence; PRISMA: Preferred Reporting Items for Systematic Reviews and Meta-Analyses.



Characteristics of the Studies Included

A total of 35 articles were obtained that had developed and/or applied a virtual environment for training communication skills that would be directed toward patients; overall, 43% (n=15) were articles published in the United States and 17% (n=6) were from Australia, with the remaining articles having been published in Europe and Asia (Table 1). All the articles had been published in English and their objectives are shown in Table 1.

Table . Description of the studies (N=35).

Articles	Country	Language	Objective
Ali et al [21], 2020	United States	English	Describe the iterative participatory design of SOPHIE, an online virtual patient for "practice" based on feedback from sensitive conversations between patients and clinicians and discuss an initial qualitative evaluation of the system by professional end users.
Bánszki et al [22], 2018	Australia	English	Explore a novice clinical educator's experience in training essential communication and interpersonal skills using a virtual patient.
Bearman and Cesnik [23], 2001	Australia	English	Assess students' attitudes toward learning communication skills through a virtual patient; compare the acceptability of the 2 distinct types of virtual patient designs.
Bearman et al [24], 2001	Australia	English	Compare 2 types of virtual patients to understand how different virtual patient designs affect the student learning experience.
Bearman [25], 2003	Australia	English	Explore the students' experience with the virtual patient.
Borja-Hart et al [26], 2019	United States	English	Assess students' confidence and impressions when using their communication skills with a virtual patient and evaluate their competencies in the use of this technology.
Chae et al [27], 2023	Korea	English	The purpose of this study was to describe the development of SimCARE and evaluate the feasibility of its use in nursing education.
Courteille et al [28], 2014	Sweden	English	To investigate the dynamics and congruence of interpersonal behaviors and socioemotional interaction exhibited during the learning experience in a virtual patient, and to evaluate which interaction design features contribute most to behavioral and affective engagement in the medical student.
Deladisma et al [29], 2008	United States	English	Develop a virtual training environment system that can be accessed independently.
Dickerson et al [30], 2006	United States	English	Provide information about the advantages and disadvantages of using synthesized speech and evaluate the fidelity necessary for the training of communication skills.
Du et al [31], 2022	China	English	To evaluate the history-taking skills of nursing undergraduates using a virtual standardized patient, and to explore its independent influencing factors.
Guetterman et al [32], 2019	United States	English	To investigate the differential effects of a virtual patient–based simulation developed to train health care professionals in empathetic patient-provider and interprofessional communication.

Articles	Country	Language	Objective
Hwang et al [33], 2022	Taiwan, Japan	English	A virtual patient–based social learning approach is proposed to enhance nursing students' performance and clinical judgment in education programs.
Jacklin et al [34], 2018	United Kingdom	English	Create a virtual patient that simulates a primary care consultation, offering the opportunity to practice decision-making. A second objective was to involve patients in the design of a virtual patient simulation and inform the design process.
Jacklin et al [35], 2021	United Kingdom	English	This study aims to evaluate a virtual patient workshop for medical students aimed at developing the communication skills required for shared decision-making.
Kleinsmith et al [2], 2015	United States	English	Develop an understanding of whether students can respond empathically to expressions of concern from a virtual patient.
Lok [36], 2006	United States	English	Teach communication skills using virtual humans.
Maicher et al [37], 2019	United States	English	Describe a virtual standardized patient system that allows students to practice their history-taking skills and receive immediate feedback.
Mayor Silva et al [38], 2023	Spain	English	The objective was to develop a virtual reality simulator to improve communication skills and compare its results with a traditional workshop based on cases and theoretical content explained through video.
Nakagawa et al [39], 2022	Japan	English	The objective structured clinical examination is among validated approaches used to assess clinical competence through structured and practical evaluation.
Ochs et al [40], 2019	France	English	Evaluate the virtual reality training platform in which the user experience is analyzed based on the virtual environment.
Perez et al [41], 2022	United States	English	The purpose of this study was to explore the use of virtual simulation to experience difficult conversations and to evaluate differences in perceptions between nurse educator, family nurse practitioner, and nurse anesthesia students.
Plass et al [42], 2022	Germany	English	The purpose of this study is to evaluate the effectiveness of a brief virtual role-play motivational interviewing training program on motivational interviewing knowledge and skills in first-year undergraduate medical students, making use of both a pretest and a then-test (retrospective pre-test) to check for response shift in evaluating the educational intervention.

Articles	Country	Language	Objective
Quail et al [12], 2016	Australia	English	Investigate students' communication skills, knowledge, confidence, and empathy in simulated and traditional learning environments.
Real et al [43], 2017	United States	English	Develop an immersive virtual reality curriculum on addressing flu vaccine hesitancy using Kern's 6-step approach to curriculum design. The goal of the program was to teach best communication practices in cases of questions about the flu vaccine.
Real et al [44], 2017	United States	English	Create an immersive virtual reality curriculum to teach pediatric residents communication skills when discussing flu vaccination. Compare effectiveness with a control group.
Real et al [45], 2022	United States	English	Examined the acceptability and tolerability of the approach and the impact of deliberate practice using virtual reality simulations on clinicians' confidence related to shared decision-making communication skills.
Rouleau et al [46], 2022	Canada	English	This study aimed to assess the acceptability of a virtual patient simulation to improve nurses' relational skills in a continuing education context.
Sapkaroski et al [47], 2022	Australia	English	The aim of this study was to establish whether the mode of delivery, virtual reality simulated learning environments versus clinical role-play, could have a measurable effect on clinical empathic communication skills for magnetic resonance imaging scenarios.
Sezer and Sezer [48], 2019	Turkey	English	Design, develop, and evaluate a 3D virtual patient application that can move, has voice and lip synchronization, allows written communication, and is supported by a solid scenario to improve students' communication skills.
Şimşek Çetinkaya et al [49], 2022	Turkey	English	This study aimed to determine the effectiveness of 2 simulation types used for family planning consultation of midwifery students and to compare these methods.
Shorey et al [50], 2019	Singapore	English	Develop and evaluate the use of virtual patients to better prepare undergraduate nursing students to communicate with real-life patients, their families, and other health care professionals during their clinical stays.
Shorey et al [51], 2020	Singapore	English	To examine user attitudes and experiences and clinical facilitators' perspectives on student performance in the clinical environment following virtual patient training.

Articles	Country	Language	Objective
Shorey et al [52], 2023	United States	English	This study aimed to evaluate the effectiveness of this theory-based virtual intervention on nursing students' learning attitudes, communication self-efficacy, and clinical performance.
Stevens et al [53], 2006	United States	English	Create an interactive virtual clinical scenario of a patient with acute abdominal pain to teach medical students history-taking and communication techniques.

Features of the Virtual Tools

After reading the full text of the 35 articles, we identified 24 different learning tools that had been developed to train communication skills in students or health professionals (Table 2). Most of them (n=15; 62%) had provided training in English [2,21,22,24,26,28,29,32,34,37,41,43,46,47,52]. Regarding the learning objective of the virtual environment, 42% (n=10) aimed to train communication skills in the specific contexts of a clinical history and/or anamnesis interview [2,29,31,33,35,37,42,46,48,52], 42% (n=10) taught general communication skills [22,24,26-28,38,39,41,47,49], and 8% (n=2) covered giving bad news [21,40]. There was also a tool that had been specifically developed to train communication skills to address flu vaccination hesitancy [43-45]. Another tool that had been used to train communication skills focused on empathy is also worth highlighting [32].

Table . Virtual tools and their characteristics (n=24 tools).

Articles	Tool name	Language	Study purpose	Degree of learning autonomy	Patient type	Type of student responses during training	Type of technology used
Ali et al [21], 2020	SOPHIE	English	Train communication skills for the delivery of bad news. Aimed at health professionals.	Autonomous	Virtual patient with the appearance of a person. Responded with a voice. The entire transcript can be seen.	Oral conversation	Artificial intelligence
Bánszki et al [22], 2018; Quail et al [12], 2016	Not specified	English	Training communication skills. Aimed at health care students.	An instructor mediated the training.	Virtual patient with the appearance of a person. Responded with a voice.	Oral conversation	The instructor was in another room where they controlled everything and responded in the simulated interaction.
Bearman and Cesnik [23], 2001; Bearman et al [24], 2001; Bearman [25], 2003	Not specified	English	Training in communication skills. Aimed at medical students.	Autonomous	Real person speaking. Viewing of recorded videos.	Written. Choice of 3 or 4 written response options available after each video. The authors developed 2 types of responses to compare which was more effective: narrative (detailed communicative structures) or problem-solving (labels with possible actions).	A total of 154 recorded videos. The next video shown was adjusted depending on the response given. Therefore, the virtual patient became satisfied according to responses chosen by the student.
Borja-Hart et al [26], 2019	Used *Shadow Health* from Elsevier	English	Training in communications skills. Aimed at pharmacy students.	Autonomous	Virtual patient with the appearance of a person. Responded with a voice.	Natural language (written and spoken). Students could choose the interaction they would carry out: ask, empathize, or educate.	*Shadow Health* is simulation software that generates different scenarios. The article did not explain any more about the technology used.
Chae et al [27], 2023	SimCARE	Korean	Training in intercultural communication skills. Aimed at nursing students.	Autonomous	Virtual patient with the appearance of a person. Responded with a voice.	They selected a written response from among those on offer.	A virtual reality headset. The authors described the technology used to generate the 3D graphics (Unity 2019.4.0f1 game engine), avatars (DAZ 3D software), and avatar animation (iClone 7).

Articles	Tool name	Language	Study purpose	Degree of learning autonomy	Patient type	Type of student responses during training	Type of technology used
Courteille et al [28], 2014	Not specified	English and Swedish	Training in communication skills. Aimed at medical students.	Autonomous	Real person speaking. Viewing of recorded videos.	Written. Students replied in text written in natural language.	Interactive Simulation of Patients. A database with 200 videos for each case, allowing the simulator to respond according to the question posed by the student.
Deladisma et al [29], 2008; Dickerson et al [30], 2006; Lok [36], 2006; Stevens et al [53], 2006	Not specified	English	Training in communication skills and anamnesis techniques. Aimed at medical students.	Autonomous but with availability of additional resources. The technology that drives this interaction largely consisted of commodity hardware and software: 2 desktop computers, 2 cameras, a data projector, and a wireless microphone.	Virtual patient with the appearance of a person (an avatar called Diana) who spoke and produced natural gestures. The authors developed 2 types of communication for the avatar to study which one was more effective: real recorded communication or virtual communication.	Oral conversation. The students could speak using natural language. The software also detected various gestures.	The speech recognition worked using *Dragon Naturally Speaking* by Scansoft, which is a database developed with content organized in semantic categories to detect the communicative structures used by the students.
Du et al [31], 2022	University A Virtual Patient (UA-VP, 2021)	Chinese	Training in communication skills to carry out a nursing evaluation by following Gordon's Functional Patterns.	Autonomous	A virtual patient with the appearance of a person. Responded with text based on a predefined chat.	Written and oral conversation	Recognizes structures and offers feedback based on the uploaded chat scripts (as bullet points and not reflecting the most important part of the interaction). Used WeChat, a social media app.
Guetterman et al [32], 2019	Used MPathic-VR	English	Trained empathic communication skills. Aimed at medical students.	Autonomous	Virtual patient with the appearance of a person. Responded with a voice.	Oral conversation. It also detected gestures and movements.	Artificial intelligence.
Hwang et al [33], 2022	Not specified	Chinese	Trained students in diagnosis and treatment and has a specific medical history module which trains communication skills.	Autonomous	Virtual patient with the appearance of a person. Responded with voice and text.	Did not specify	Learning system designed as a decision tree.

Articles	Tool name	Language	Study purpose	Degree of learning autonomy	Patient type	Type of student responses during training	Type of technology used
Jacklin et al [34], 2018; Jacklin et al [35], 2021	Not specified	English	Training in communication skills for shared decision-making during clinical interviews. Aimed at medical and/or pharmacy students.	Autonomous	Virtual patient with the appearance of a person. Responded through a voice and with gestures.	Written text. Choice of 3 answer options.	A web-based virtual patient simulator.
Kleinsmith et al [2], 2015	Neurological Examination Rehearsal Virtual Environment	English	Trained communication skills for use during clinical interviews. Aimed at nursing students.	Autonomous	Virtual patient with the appearance of a person. A virtual patient responded with a voice and through text.	Written. The student inserted text written in natural language.	Virtual People Factory. A database used by the simulator to respond based on the student's question.
Maicher et al [37], 2019	Not specified	English	Trained skills for performing an anamnesis (to collect medical information). It does not address communicative listening strategies such as empathy. Aimed at medical students.	Autonomous	Virtual patient with the appearance of a person. Responded with voice and text.	Oral conversation. Text could also be written.	Artificial intelligence. The open-source natural language processing engine ChatScript is used for the conversion element. Unity gaming platform.
Mayor Silva et al [38], 2023	Not specified	Spanish	Training in communication skills. Aimed at nursing students.	An instructor mediated the evaluation.	Not specified	Not specified	A virtual reality headset.
Nakagawa et al [39], 2022	Not specified	Japanese	Trained communication skills such as desire suppression, expectation acceptance, facial expression, emotional communication, dominance, maintaining relationships, and dealing with disagreements. Aimed at pharmacy students.	Autonomous	A chatbot. Written and oral.	Oral conversation in natural language	Artificial intelligence. If the artificial intelligence did not detect the keywords, the conversation did not continue. There was no direct feedback.
Ochs et al [40], 2019	ACORFORMed	French	Training in the delivery of bad news. Aimed at medical practitioners (students and professionals).	Autonomous in some functions (eg, dialogue generator). In others (eg, categorizing the response and sending it to the simulator), the instructor mediated the learning.	Virtual patient with the appearance of a person. Responded with a voice.	Oral conversation	A virtual reality headset. The instructor categorized the response using a previously coded database and sent that information to the simulator.

Articles	Tool name	Language	Study purpose	Degree of learning autonomy	Patient type	Type of student responses during training	Type of technology used
Perez et al [41], 2022	Used the Mursion tool	English	Trained communication skills for use in difficult conversations. Aimed at nursing students.	Autonomous	Virtual patient with the appearance of a person. Responded with a voice.	Oral conversation in natural language.	Artificial intelligence (using the Mursion tool).
Plass et al [42], 2022	Used the Kognito Conversarion Platform	German	Training in person-centered communication skills for motivational interviewing. Aimed at medical students.	Autonomous	Virtual patient with the appearance of a person. Responded with a voice.	Select between different answer options.	Artificial intelligence (using the Kognito Conversation Platform).
Real et al [43], 2017; Real et al [45], 2022; Real et al [44], 2017	Not specified	English	Training in communication skills to inform patients about vaccination. Aimed at medical residents.	An instructor mediated the training.	Virtual patient with the appearance of a person. Responded through a voice and with gestures.	Oral conversation and natural language.	Unity gaming platform. A virtual reality headset.
Rouleau et al [46], 2022	Not specified	French, English	Training in nursing relational skills for use in motivational interviews.	Autonomous	Virtual patient with the appearance of a person. Responded with a voice.	Select between different answer options	Used the MedicActiV platform
Sapkaroski et al [47], 2022	Not specified	English	Training in communication skills. Aimed at medical students.	Autonomous	Virtual patient with the appearance of a person. Responded with voice and text.	Select from among answer options. This part of the case simulation was mandatory. It was also capable of natural language oral conversation and the ability to ask alternative questions was optional.	Clinical Education Training Solution virtual reality clinic software using the Oculus Rift CV1 virtual reality headset.
Sezer and Sezer [48], 2019	Not specified	Turkish	Training in basic communication skills for use in a medical interview. Aimed at training health care students.	Autonomous	Virtual patient with the appearance of a person. Responded with a voice and in writing.	Natural written text	Virtual People Factory for avatar and simulation generation. The scenario was created in Unity 3DTM. Different variations of the simulation interventions the students could apply at each stage were included and these answer combinations were compared to the closest preprogrammed scenario to give an answer.

Articles	Tool name	Language	Study purpose	Degree of learning autonomy	Patient type	Type of student responses during training	Type of technology used
Şimşek Çetinkaya et al [49], 2022	Not specified	Turkish	Training in communication skills for use in a family planning consultation. Aimed at midwifery students.	The instructor offered feedback after watching the simulation.	The patient type was not specified. Responded with a voice.	Oral conversation	Not specified
Shorey et al [50], 2019; Shorey et al [51], 2020; Shorey et al [52], 2023	Virtual Counselling Application using Artificial Intelligence	English	Trained basic communication skills for use in an interview. Aimed at nursing students.	Autonomous	Virtual patient with the appearance of a person. Responded with a voice and in writing.	Oral conversation in natural language	Artificial intelligence. Used the Dialogflow chatbot from Google Cloud to store and process natural language. The scenario was created in Unity 3D.

Several major virtual tools were identified in this review for training communication skills in health care professionals. SOPHIE [21] is a tool designed to train the delivery of bad news using a virtual patient that interacts through oral conversations, leveraging AI. Shadow Health [26] focuses on communication skills for pharmacy students, allowing both written and spoken interactions with a virtual patient. SimCARE [27] is a virtual reality–based tool aimed at nursing students, training intercultural communication skills through animated avatars. MPathic-VR [32] trains medical students in empathic communication, featuring virtual patients that respond with voice and detect nonverbal cues like gestures. ACORFORMed [40] trains medical practitioners in delivering bad news through virtual reality interactions with a virtual patient. Mursion [41] is designed for nursing students to practice difficult conversations using natural language processing for realistic interactions, while the Kognito Conversation Platform [42] supports motivational interviewing through person-centered communication training with virtual patients. VCAAI [50-52] trains basic communication skills in nursing interviews. These tools highlight the diversity of approaches in the use of virtual patients for communication training. Finally, 14 virtual tools did not specify their name.

Some (n=19, 79%) of the tools allowed students to train completely autonomously, whereas 21% (n=5) required an online instructor to mediate the training and respond during the interactions [22,39,40,44,49]. One of the tools could be defined as partially autonomous because a trained instructor had to perform some of the functions [40]. Regarding the patient type used for the training, the vast majority of the tools used virtual patients (n=19; 79%) with the appearance of a real person [2,21,22,26,29,31-33,35,37,40-42,44,46-48,51]. Of these, 95% (18/19) responded with a voice (18/24, 75%), except for the tool published by Du et al [46]. Two tools (8%) used videos recorded with real people [24,28].

Regarding the types of responses the user could give during the training, almost half of the tools analyzed (n=11, 45%) allowed the user to respond orally using natural language [21,22,26,29,31,32,37,39,41,44,49,51]. Shadow Health [26], for example, offers both written and spoken interactions, while SOPHIE [21] focuses solely on oral communication.

Discussion

This study reviews and analyzes the 24 virtual simulation tools available for training communication skills in health care professionals, assessing their characteristics, levels of immersion, and the autonomy they provide in learning processes. Although virtual simulation tools have shown significant growth in recent years, driven by technological advances, the review identified a high degree of heterogeneity in the approaches, technologies, and interaction methods used. This variety has made it challenging to standardize and effectively integrate these tools into consistent training plans. Most tools rely on virtual patients with a limited range of interaction capabilities, and very few offer fully immersive experiences that mimic real-world clinical communication. Furthermore, limited accessibility to tools in languages other than English, as well as a lack of high-fidelity technologies for simulating realistic, natural language–based conversations, continue to pose significant challenges. Considering these challenges, this review highlights several key findings regarding the applications of virtual environments to enhance communication skills training that will be detailed in the following paragraphs.

First, it is important to highlight the large number of different applications we identified that have been used to improve communication skills (either in basic or more specific situations) through virtual environments. Similarly, other reviews have also concluded that the use of virtual patients for clinical communication training has grown exponentially over the last decade [17,18], which has been driven by rapid technological advances [54], also providing further evidence of the benefits associated with this type of resource [18]. In fact, this work has included 13 new virtual simulation environments developed based on the published review by Battegazzorre et al [17].

Most of the applications we considered in this review used English, which could represent an obstacle for professionals and students who do not know this language. Indeed, only one of the tools identified used Spanish and in this case, it was also mediated by an instructor, thereby making it difficult for students to use it autonomously and independently [38] Therefore, there is still a long way to go to make these tools highly accessible at an international level. Regarding the more technical characteristics, we observed visible heterogeneity in the types of technologies used, including in the different types of patients used for training—for example, the use of chatbots, images, and/or recordings of real people and virtual patients. However, our results showed that almost all the applications we identified had designed virtual environments using virtual patients that looked like a person and could vocally respond to and receive oral responses to simulate a real conversation [21,22,26,29,32,37,39,41,44,49,51]. A key implementation across the tools was the use of natural language processing to simulate realistic conversations.

Training in simulation environments that assume an appropriate level of fidelity (a 3D term that includes physical/environmental, psychological, and conceptual elements) increases realism [55] and influences learning engagement [56]. For example, in their systematic review, Kaplonyi et al [1] reflected how simulations with the use of standardized patients are considered realistic environments and an effective means for learning communication skills. Indeed, the academic literature proposes that virtual patients can be used as a complementary alternative to working with standardized patients [57] and can represent patients in a realistic clinical environment [17] to effectively help students to acquire or improve their communication skills [18]. Nonetheless, it will be important for future lines of research to use standardized tests to evaluate the beneficial effects of training with this type of virtual tool before fully integrating them into training plans [18,54].

In terms of the fidelity of these tools, increasing the immersion of virtual simulations—defined as the psychological state of the perception of being inside or surrounded by something [58]—by using virtual patients with natural language processing and auditory and visual behavior [17,59] is positively related to better communication skills performance [17,19]. However, we must not forget that realism and authenticity, which are both relevant factors in design, are not only achieved through physical resemblance (physical fidelity) but also require other fidelity factors [19]. Hence, future research in this field should be designed to also consider conceptual fidelity (scenarios and cases consistent with reality) and psychological fidelity (the ability to provoke emotional responses like reality) in the design of virtual simulations [19], factors that were not considered in this review.

Nevertheless, we identified 2 tools that had specifically used recordings of real people in the clinical situations being trained, which could have generated a greater feeling of immersion among students because of the increased physical, auditory, and visual fidelity of these tools. However, in the interactions with the simulation developed by Bearman et al [23], users had to respond from a pool of pre-established options, limiting the immersion experience because the participant was unable to develop their own communication skills in the way they would have to when facing real situations. In a tool developed by Courteille et al [28], although the user had been allowed to issue a natural language response, this had to be done in writing, which also reduced the degree of reality and spontaneity one would expect from a real conversation. Therefore, highly immersive technologies must be designed to overcome these ongoing technological challenges, such as how to integrate effective natural language processing systems and natural conversation flows into these tools [60] and how to best capture nonverbal communication [17,18]. For example, in this review, we only identified 2 applications that could detect gestures and/or emotions [29,32].

Of note, most of the tools we identified were based on autonomous learning and therefore represented promising applications with potential great benefits such as high accessibility levels, the possibility of repeating the experience multiple times, and cost reduction once running [16,17]. In this sense, technological advances that can integrate systems that provide feedback to participants—such as AI and machine learning (ML)—without the need for an instructor/teacher to mediate the learning stand out in particular [60]. For example, compared to a previous literature review [18], we found more tools in which the feedback was provided by the virtual system itself. However, as discussed, despite cataloging the existence of various patient simulation tools with interesting characteristics, we did not identify any that simultaneously integrated the use of a real person (a standardized patient) with the objective of increasing the environmental fidelity to allow the user to train through an oral conversation using natural language and using complex technology, such as AI and ML, with the ability to detect, encode, and respond to complex communication structures [60].

Finally, it is important to note that there were several limitations to this review. First, we only consulted 2 medical databases—MEDLINE/PubMed and the Web of Science. Despite being a health science–specific database and a multidisciplinary database, respectively, having replicated the search in more technological databases may have provided some additional studies for consideration. Therefore, it is possible we did not recover all the relevant records on virtual simulation tools to train communication skills in health care professionals registered in the academic literature. Second, there is still inadequate standardization in academic and scientific fields regarding the term “virtual simulation” [16,55,61]. Thus, different terms in the academic literature are all used to refer to the concept of virtual simulation including “serious games,” “virtual worlds,” “virtual patients,” and “virtual reality,” [55] which may have also caused us to miss certain relevant records.

In conclusion, this review identified and analyzed the 24 main virtual tools described in the academic literature that have been used to date to train communication skills in the context of health sciences. The high heterogeneity in terms of their characteristics means that tools based on AI and ML that contribute to training both students and practicing health professionals with as high a fidelity as possible to real life remain to be developed. Although many tools offer a degree of realism, few incorporate advanced features like AI-driven

conversational flows or nonverbal cue detection, limiting the immersive experience. This highlights a need for further development to create more effective training environments. Addressing these gaps requires future innovations that integrate natural language processing and other advanced capabilities to enhance both the realism and educational value of virtual simulations.

Abstract

Background: A virtual simulated placement (VSP) is a computer-based version of a practice placement. COVID-19 drove increased adoption of web-based technology in clinical education. Accordingly, the number of VSP publications increased from 2020. This review determines the scope of this literature to inform future research questions.

Objective: This study aimed to assess the range and types of evidence related to VSPs across the health care professions.

Methods: Studies that focussed on health care students participating in VSPs. Hybrid, augmented reality, and mixed reality placements were excluded. In total, 14 databases were searched, limited to English, and dated from January 1, 2020. Supplementary searches were employed, and an updated search was conducted on July 9, 2023. Themes were synthesized using the PAGER (patterns, advances, gaps, evidence for practice, and research recommendations) framework to highlight patterns, advances, gaps, evidence for practice, and research recommendations.

Results: In total, 28 papers were reviewed. All VSPs were designed in response to pandemic restrictions. Students were primarily from medicine and nursing. Few publications were from low and middle-income countries. There was limited stakeholder involvement in the VSP designs and a lack of robust research designs, consistent outcome measures, conceptual underpinnings, and immersive technologies. Despite this, promising trends for student experience, knowledge, communication, and critical thinking skills using VSPs have emerged.

Conclusions: This review maps the VSP evidence across health care education. Allied health and midwifery research require greater representation, and based on the highlighted gaps, other areas for future research are suggested.

KEYWORDS

technology; students; learning; scoping review; simulation; healthcare education; virtual simulated placement; practice placement; clinical placement

Introduction

Background

Practice placements are important activities in the training of health care students. They promote the application of knowledge to a practical setting for developing the skills, attitudes, and behaviors expected of a health care professional [1-3]. Placements allow active involvement in care delivery under supervision, and the opportunity to receive feedback on student performance [4]. In other words, student learning on placement is contextualized to future practice.

Simulation-based placements present an alternative to traditional practice placements. In traditional placements, students enter a workplace and learn through observation and participation in actual clinical events. In contrast, health care simulation is a technique that produces a scenario designed to represent a real-life practice situation for experiential learning [5,6]. Compared with traditional placements, simulation can ensure that low-frequency and high-risk cases or situations receive sufficient practice in a safer space, without mistakes causing harm to real persons [7]. Thus, the advantage of simulation is the ability to control and direct case-based learning.

With advances in technology, simulation-based education is expanding into web-based environments, a trend accelerated during the pandemic. The increasing complexity of health care also requires an agile workforce of lifelong learners, capable of substituting skills across professions [8,9]. Consequently, health care training must keep pace with technology developments, and virtual simulations could support the training of these skills [10-12]. Furthermore, virtual simulations offer greater flexibility

and scalability compared with using standardized patients (people play acting the role of a service user) [13].

Problem Statement

As virtual simulated placements (VSPs) are an emerging field, mapping the literature across health care and analyzing gaps is recommended before more specific research questions are defined [14,15]. Therefore, our research team chose a scoping review method to conduct a broader search across medicine, nursing, midwifery, and allied health, for undergraduate and postgraduate students who undertook VSPs. Considering the importance of practice placement, the advantages of simulation-based learning, and recent advances in technology, this topic was relevant for the review. We define virtual simulations as computer-based activities according to the Healthcare Simulation Dictionary [16], and our aim was to determine the scope of the VSP literature to inform future research questions. Our objective was to assess the range and types of evidence related to VSPs, across the health care professions.

Review Questions

First, what is the scope of the literature relating to VSPs for health care students? Second, what outcomes are reported in relation to the students undertaking VSPs? Third, what are the patterns and gaps in the literature and the reported outcomes? Finally, what are the implications of the review findings for future directions in VSP research?

Methods

Overview

This study followed the stages detailed in a framework for scoping reviews [14]: (1) identify the research question; (2) identify relevant studies; (3) study selection; (4) charting the data; and (5) collating, summarizing, and reporting the results.

A preliminary search of MEDLINE, the Cochrane Database of Systematic Reviews, and Joanna Briggs Institute Evidence Synthesis was conducted on June 17, 2022 to locate any existing or underway reviews on the topic. One systematic review [13] was identified and focused on digital placements for undergraduate nursing and medical students. The review also included experiences such as telemedicine and on-screen role-play. While their search located 16 studies in April 2021, the increased trend toward implementing VSPs within undergraduate and postgraduate programs across the wider health professions justified this review.

An a priori protocol used the Joanna Briggs Institute template for scoping reviews [15] and was registered with the Open Science Framework (DOI 10.17605/OSF.IO/AY5GH) [17]. The PRISMA-ScR (Preferred Reporting Items for Systematic reviews and Meta-Analyses extension for Scoping Reviews) checklist (Checklist 1) ensured methodological rigor when reporting this review [18].

Relevant Studies

The eligibility criteria are listed in Table 1 using the SPIDER (sample, phenomenon of interest, design, evaluation, research type) [19] and PCC (population, concept, and context) [15] formats:

Table . Eligibility criteria in population, concept, and context and sample, phenomenon of interest, design, evaluation, research type formats.

Item	Inclusion	Exclusion
S (sample) or population	Papers reporting on undergraduate and postgraduate health care students, from medicine, nursing, midwifery, and allied health	• Papers reporting on professions outside of the target group
PI (phenomenon of interest) or concept and context	Virtual simulation learning in a practice placement. Articles should stipulate that it is a placement, clerkship, elective, selective, practical, or practicum in the curriculum	• Onsite simulation • Augmented reality and mixed reality interventions • Contact with real or standardized patients, even if telecast to students or delivered in a virtual simulation suite • Hybrid or blended approaches (part online, part onsite) • Tutorials training isolated clinical skills and case studies • Theory-based education • Assessment of learning
D (design)	Studies with quantitative, qualitative, or mixed methods.	• Papers where no research methods were described
E (evaluation)	At least 1 student-centered outcome is included (eg, student satisfaction, confidence, self-efficacy, engagement, learning, knowledge, attitude, skills, or clinical performance)	• No student-centered outcomes recorded
R (research type)	Any primary research, including gray literature. In English language and published since January 1, 2020	• Reviews—although primary studies will be extracted from relevant reviews to determine their eligibility • Study protocols, expert opinion, discussion papers, letters, comments, editorials, and book chapters • Survey research (without a virtual simulated placement case)

The selection criteria were piloted by screening 50 randomly selected titles and abstracts, independently by 2 reviewers (JS and MG). This process generated 94% agreement (Cohen κ=0.6) and served to clarify the selection criteria. In discussion with a third reviewer (NT), the Health and Care Professions Council definition for allied health [20] was adopted in place of the National Health Service (NHS) criteria [21], since this definition includes practitioner psychologists—a population potentially well-suited to VSPs, with the emphasis on talking therapies.

Search Strategy

An initial limited search of MEDLINE and CINAHL was undertaken on June 28, 2022 to identify articles on the topic. The text words contained in the titles and abstracts of relevant articles and index terms were used to develop a full search strategy. This was checked by a health care research librarian and run on MEDLINE on August 3, 2022 (Multimedia Appendix 1). The search strategy was then adapted for each database. The databases searched included MEDLINE, CINAHL, Allied and Complementary Medicine Database, Cochrane Database, PsychINFO, Education Resources Information Center, SCOPUS, ScienceDirect, and Biomed Central. Gray literature sources include PubMed, Electronic Theses Online Service, ProQuest (dissertations), Google Scholar, and Institute of Electrical and Electronics Engineers Xplore. Searches were limited to English language and dated from January 1, 2020. The date limitation was justified given that VSP research has essentially emerged postpandemic.

Supplementary search strategies were employed using existing knowledge and networks, contacting relevant organizations, hand-searching journals, and checking the reference list of all included sources and relevant reviews. Advances in Simulation, British Medical Journal: Simulation and Technology Enhanced Learning (BMJ STEL) and Clinical Simulation in Nursing were hand-searched. These supplementary searches were conducted by one reviewer (JS) and checked by another (NT).

An updated database search was conducted on July 9, 2023. A second reviewer (MG) checked the title, abstract, and full-text selection decisions. Registries (Clinical Trials.gov, World Health Organization International Clinical Trials Registry Platform, and the Cochrane Database) were searched for additional papers [22]. Updated hand searches were performed in Advances in Simulation and Clinical Simulation in Nursing (BMJ STEL had since discontinued). A second reviewer (NT) checked these supplementary searches.

Source Selection

Following the database searches, all identified citations were uploaded into EndNote (Clarivate) [23], and duplicates were removed. Each potential duplicate was confirmed separately, rather than using batch automation to prevent the removal of

false positives [24]. Citations were exported to Rayyan and rechecked for any missed duplicates [25].

Once pilot screening was complete, the remaining titles and abstracts were screened independently by 2 reviewers (JS and MG) against the revised criteria, and potentially relevant sources were retrieved in full text. These were assessed in detail against the inclusion criteria by 2 independent reviewers (JS and MG), blinded in Rayyan. There was 83% agreement (Cohen κ=0.5) between reviewers. A 100% agreement was reached through discussion. Further details of the source selection, including a list of references excluded at full text screening are detailed in Multimedia Appendix 2.

Data Charting

A Microsoft Excel spreadsheet was used as a data charting tool to standardize obtaining information from the papers. Furthermore, 2 independent reviewers (JS and MG) conducted a pilot of 5 included papers to assess the utility of the information charted and generate emerging themes. Consensus was reached between reviewers (JS and MG) on the charting method, and modifications were made to the spreadsheet, to improve the quality of charted data (Multimedia Appendix 3). Following this, one reviewer (JS) charted the remaining data, which was checked by another (NT).

A table of included study characteristics was collated, and numerical analysis in Microsoft Excel was undertaken to provide descriptive statistics. The size of the dataset was manageable enough to organize findings across the PAGER (patterns, advances, gaps, evidence for practice, and research recommendations) domains [26], for synthesis, without the use of NVivo software (Lumivero; as was planned in the protocol).

Ethical Considerations

The Coventry University Ethical Approval process has been completed and the project has been confirmed and approved as low risk (project reference P139783). Date of approval is August 12, 2022.

Results

Overview

The search results and selection process are reported in the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) flow diagram (Figure 1).

The characteristics of the 28 included papers are summarized in Multimedia Appendix 4. Overall, VSPs were a combination of videoconferencing sessions with educators and peers, as well a variety of web-based material, including videos, reading, modules, and assignments. Most VSPs included some form of case-based learning that required problem-based activities to complete. Teaching methods ranged from didactic lecture-style sessions to peer learning and flipped classrooms. Session delivery featured more formal case conference-style sessions, as well as small group learning, and the use of online chat, polls, and quizzes.

The PAGER themes across the papers are summarized in Table 2. Key patterns and gaps are mapped across all included studies in Tables 3 and 4. The global distribution of publications is illustrated in Figure 2.

Patterns are mapped across all included studies in Table 3 and gaps are mapped in Table 4.

Figure 1. PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) flowchart (modified from) [27].

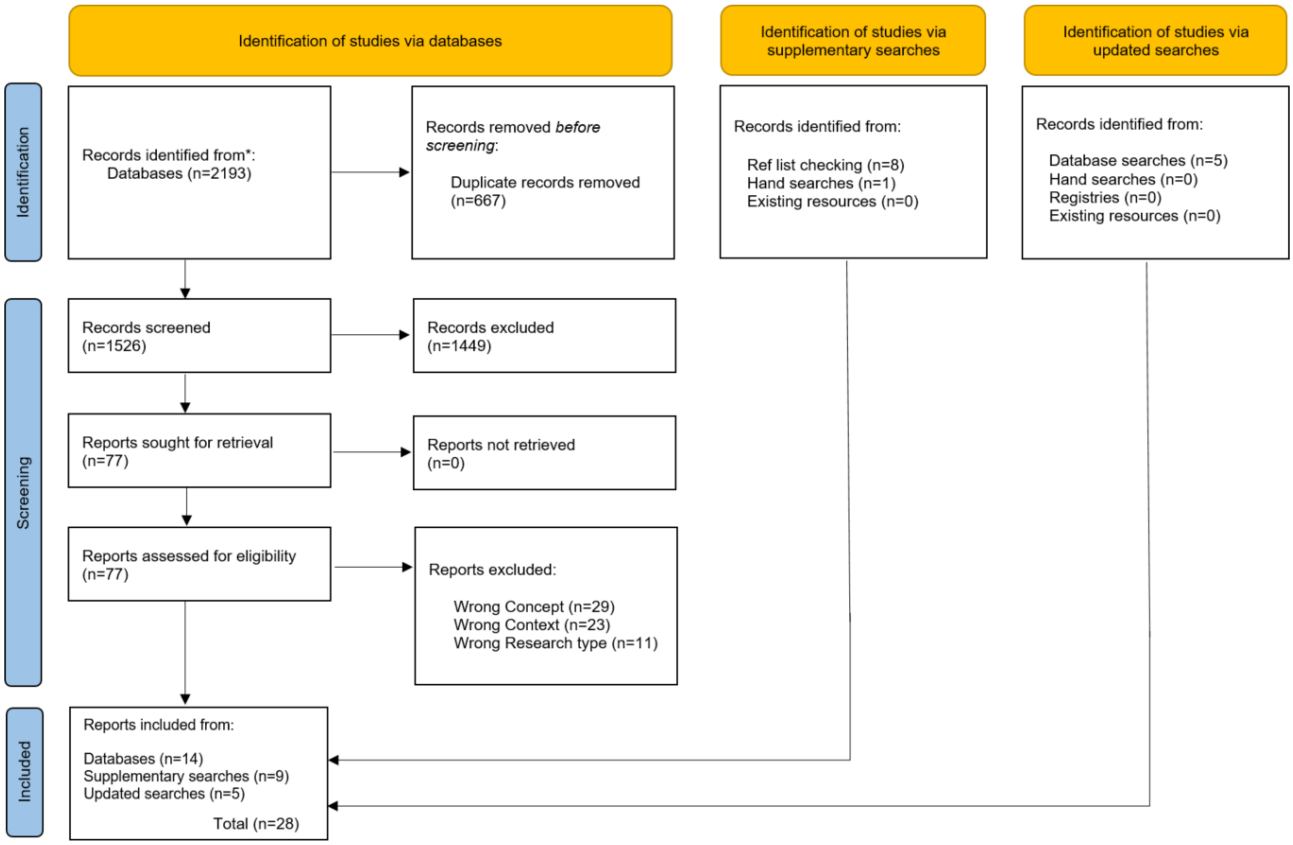

Table . PAGER (patterns, advances, gaps, evidence for practice, and research recommendations) framework themes summary.

Patterns	Advances	Gaps	Evidence for practice	Research recommendations
Publications from high-income countries (Figure 2)	Innovations occurred mostly in countries with resources to support VSP[a] development	Few publications from the LMICs[b]	VSPs can be delivered remotely and are scalable (useful for supporting training in the LMICs)	Sharing resources across countries and overcoming barriers such as internet connectivity or access to devices
Narrow profession focus	VSPs occurred within single profession silos. Populations were mostly medical or nursing	No IPE[c] and minimal allied health representation	Support for VSPs delivering on improved discipline specific skills	The development of IPE VSPs to train skills informed by allied health collaborations
Pandemic response	Rapid innovation to shift from in-person placement to VSPs in response to COVID-19 restrictions	Research planned under time pressure may explain the lack of robust experimental design and conceptual frameworks	Positive outcomes suggest that VSPs could be utilized beyond the pandemic response	With less time pressure, future research could consider conceptual frameworks, with more robust experimental designs
Stakeholder involvement in the VSP design	Most studies involved university faculty. Others also included clinicians	Few incorporated student input and consultation. No evidence of cocreation with service users	Design that involves student participation throughout the process better serves the end user needs	Participatory research designs should include all stakeholders, including students and service users (who ultimately benefit)
Use of generic platforms and screen-based delivery	Platforms such as Microsoft Teams, Zoom, and existing learning management systems were used to facilitate delivery	Limited use of bespoke software or VR[d]. No headsets, haptics, or conversational artificial intelligence systems	Student feedback frequently rated the live interaction with facilitators positively	Bespoke VR software, headsets, and haptic research may emerge as devices become more ubiquitous
A focus on case-based learning	VSPs were oriented toward clinical cases and knowledge, clinical reasoning, decision making, and communication	Practical skills training was rare. Few featured social determinants of health or community interventions	Evidence for improved knowledge, clinical thinking, and communication skills from VSP interventions	Hybrid is currently more suitable for practical skills but haptics may feature as technology improves. Community VSPs link well to IPE
Survey-based outcome measures	Most VSPs were evaluated through custom-designed surveys and student marks	Few validated outcome measure scales or standardized examinations	Evaluations were overall positive and test score improvements were equivalent to in-person cohorts	Validated outcome measures and standardized tests in future trials would provide more robust data for comparison

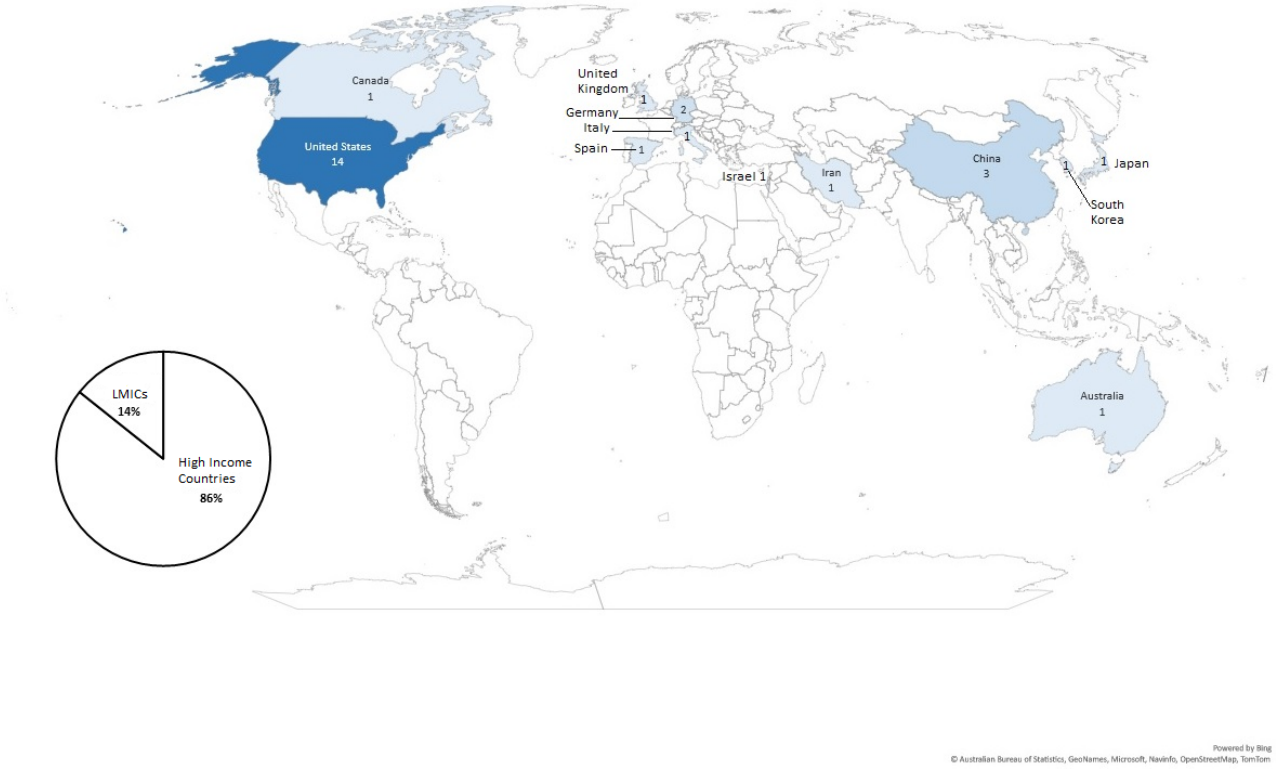
[a]IPE: interprofessional education.

[b]VR: virtual reality.

Figure 2. Country of origin of included papers. LMIC: low or middle-income country.



Countries of Origin

In total, 86% (24/28) of the included papers were published in high-income countries, as defined by the Organisation for Economic Co-operation and Development [56]. The VSP research was located primarily in the United States and the Northern Hemisphere.

Range of Professions

The literature was predominantly medical and nursing research, constituting 93% (26/28) of the included papers. The distribution by profession and breakdowns by specialty are illustrated in Multimedia Appendix 5. Diagnostic radiology rotations were the most prevalent VSPs in medicine and pediatrics in nursing. Where stated, learners were often in their latter stages of training, or undertaking these VSPs as postgraduates.

Pandemic Response

All the VSPs in the included papers were developed in response to COVID-19 restrictions, which aligns with the time span of the scoping search. The context at the time was that the pandemic necessitated that face-to-face (FTF) practice placements were often discontinued. VSPs were implemented to provide alternative placement hours, enabling students to progress toward professional registration and graduation.

Experimental Designs

The most basic study design was a single group, with a postintervention measure, featuring in 16 papers. In total, 7 papers compared measures pre- and postintervention [34,37,39,41,48,50,54]. Furthermore, 5 papers compared VSP outcomes with a previous cohort of students who completed FTF placements prepandemic [28,33,45,51,55].

Stakeholder Involvement

Practice partners (clinicians working in practice) were involved in the VSP course development with faculty in 8 studies [29,32,37,41,44,48,50,55] and students were involved in 4. Furthermore, 3 studies developed a needs assessment from student surveys [34,43,52]. None involved service users.

Conceptual Frameworks

Conceptual underpinnings include pedagogy, theoretical frameworks, and professional standards. Although no single paper covered all elements, underpinning concepts are evident across the literature, summarized in Multimedia Appendix 6. Pedagogies employed, focused on adult student learners, case-based activities, and experiential and web-based learning. The frameworks structured the VSP development, and the professional standards guided curriculum, simulation, and placement.

Software

All studies used generic software such as Zoom (Zoom Communications) or Microsoft Teams for screen-based communication, and many used existing learning management systems to host files and activities. Others adopted commercial software applications, allowing students to conduct a history by selecting from a menu of interview questions. None used conversational artificial intelligence (AI) systems (computer-generated conversation, assisted by AI). Some applications presented virtual reality (VR) patient avatars with which the student could direct a physical examination, although this was delivered via a screen [31,38,40,41,51] and 1 study provided an interactive community setting in screen-based VR [53]. All software resources are outlined in Multimedia Appendix 7.

Intended Learning Outcomes

The focus of most VSPs was clinical cases, through which knowledge, reasoning, decision-making, and communication skills (both verbal and written) were developed. Practical skills training was rarely practiced, with 1 study including home practice surgical kits as the exception [1]. Instead, skill learning was visualized through virtual patient encounters and instructional or walk-through procedure videos. The social determinants of health were the focus in 2 studies [50,53] and another facilitated students in teaching roles [42].

Outcomes

The most common outcome measures were custom-developed student evaluation questionnaires, followed by exam marks. Custom questionnaires provided positive feedback for student experience, satisfaction, and usability, although some technical issues and Zoom fatigue were cited [31,50]. In total, 3 papers reported a 100% pass rate on their VSPs [35,49,52], and 4 used a standardized exam to demonstrate comparable outcomes with FTF cohorts [45,51], or the national average [30,32].

Table 5 summarizes the outcomes of research that employed a repeated measures design or group comparisons.

Table . Outcomes from intra- and intergroup comparisons.

Study feature and outcomes	Papers
Measures compared pre- and post-VSP[a]	
Increase in self-rated competencies	Holmberg et al [37], Kasai et al [39], and Williams et al [54]
Increase in knowledge scores	Ganji et al [34], Steehler et al [48], and Villa et al [50]
Improvement in interview skills	Ganji et al [34]
Improvement in critical thinking ability	Luo et al [41]
Comparison between a VSP group and a previous cohort that attended a FTF[b] placement	
No significant difference in exam scores between groups (P>.05)	Redinger et al [45], Weston and Zauche [51], and Zhou et al [55]
Mixed outcomes from survey responses	Fehl et al [33] and Alpert et al [28]

[a]VSP: virtual simulated placement.

[b]FTF: face-to-face.

When measures were compared pre- and post-VSP, there was a trend of improvement in self-rated competencies, knowledge scores, and critical thinking skills. However, when the comparison is made with traditional FTF placements, the pattern is less clear. There were no differences in grades when post-VSP exam scores were compared with previous cohorts' who attended an FTF placement prepandemic. Student satisfaction was comparable in a study conducted in medical general practice, but professional exchange and learning scored higher in the VSP, while the attainment of new skills and attitudes scored higher in the FTF placement [33]. Furthermore, 1 paper compared students who participated in web-based readouts (the radiology equivalent of patient rounds) with students who attended workplace readouts prepandemic [28]. The educational value was comparable in survey results, although students on the VSP rated slightly higher for perceived interaction. That FTF students that were mostly observing on their placement might explain this finding. Conversely, FTF students had greater confidence in using the workstations, considered the case because the VSP students were unable to operate Picture Archiving Communication System workstations remotely.

Discussion

Principal Findings

This study mapped the literature describing VSPs across health care. All 28 papers were pandemic responses, primarily from medicine and nursing in high income countries . Selecting studies that conducted a web-based simulation, rather than employing a hybrid or blended approach may explain why all papers in this review were pandemic responses, and why the student populations were in their latter stages of training or postgraduates. COVID-19 necessitated a rapid shift to provide VSPs as a replacement for lost clinical hours to allow students to progress toward graduation [57]. However, these VSPs were often produced in a short time frame, under emergency situations, and may explain why few papers featured robust experimental designs and conceptual frameworks.

Replacing FTF placement hours with simulation is a contentious issue. Accordingly, a Delphi study considered the benefits and limitations of this approach [58]. Expert consensus across multiple professions agreed that between 11% - 30% of hours replaced with simulation would be acceptable, and this aligns with the current allocation set by the Nursing and Midwifery Medical Council [59]. VSPs in the curriculum may offset some pressure on workplace settings as they attempt to fulfill the NHS long-term plan to recruit and train more health care learners [11]. However, this does not diminish the importance of building further workplace placement capacity [58]. VSPs can be considered an additional pedagogy that offers a different, yet complimentary experience to traditional FTF placements.

Content and Technologies

In general, VSPs had a teleconferencing and a web-based learning component. The teleconferencing was commonly conducted with educators and peers over Zoom or Microsoft Teams, and the web-based learning activities included, but were not limited to videos, reading, modules, and assignments. There were a few examples of immersive learning with VR patient avatars, and these were delivered via a screen [31,38,40,41,51,53].

Disciplines that rely on image-based diagnoses may be more easily adapted to screen-based delivery, and consistent with this, diagnostic radiology, and pathology VSPs together constituted over 30% (6/19) of the medical papers in this review. In the development of this scoping review, we anticipated that psychology might be suited to VSPs due to the nature of talking-based therapies over physical skills, although it is possible that psychological presentations were considered too complex to portray accurately in computer-based simulations. With future developments in conversational AI systems and the growing acceptance of this technology, this situation may change. Similarly, professions that rely heavily on hands-on assessment, such as physiotherapy, may feature more in extended reality spaces with haptics, as further research and development into these technologies emerge. In the meantime, VSPs that require complex conversations are likely to include telecast or telemedicine simulations. Likewise, VSPs that teach advanced handling skills might adopt a hybrid or blended approach, thus combining the strengths of both web-based and FTF approaches.

Interprofessional Education

VSPs have the potential to break down silos between professions, by delivering interprofessional education (IPE) over a web-based platform. IPE is defined as 2 or more professions, "*learning with from and about one another to improve collaborative practice and quality of care*" [P4] [60]. The intended outcome is to improve mutual understanding, teamwork, and leadership among different professionals [61]. VSPs have advantages over FTF training in building asynchronous activities for flexibility in timetabling and hosting synchronous activities without geographical constraints [62]. Given the relevance of IPE to quality care and the fit with web-based technologies, IPE-VSPs may be an important area for future research.

VSP Design and Stakeholder Involvement

Elements of thoughtful VSP design are evident across several papers. Frameworks, such as ADDIE (analysis, design, development, implementation, and evaluation), ensure that there is structure to the process and stakeholder needs are met [30]. Existing curricula [54,55], or processes such as Kern's 6-step model for curricular development could be used [43,45,46,50,52]. If framed within existing standards [40,49], VSPs can align with specified learning outcomes. Principles in pedagogy, such as andragogy [29,30] and web-based learning [33,50], ensure that VSPs build features that engage students with experiential learning [30] and promote problem-solving [29,30,39] and active reflection [49]. The conceptual underpinnings documented across this body of literature could provide a blueprint for best practice in VSP design.

Stakeholder involvement is a key process to inform the design of a VSP. Service users could inform the content, which is especially important in computer-based simulations, yet no service user involvement was documented. Students are the end users of a VSP, yet they were involved in a minority of studies. When students were involved, surveys informed a needs assessment, or they were consulted early in the process. This is a tokenistic approach compared with cocreation, the preferred method of engaging with stakeholders. Cocreation involves a collective effort with all stakeholders to collaborate across the entire design, development, implementation, and testing phases [63]. One noteworthy research report provided an overview of VSP development within a nursing program, which included input from students, service users, and other universities throughout [64]. Their working group comprised of academics, clinicians, a service user, a carer involvement lead, and an education technology lead. Therefore, in addition to underpinning VSP design with the relevant conceptual frameworks (pedagogical principles, theoretical frameworks, and published standards), broad stakeholder cocreation is optimal.

Research Designs

The pattern of positive student evaluation, improvement from baseline measures post VSP, and equivalence in exam scores, compared with in-person cohorts, appears promising, although,

it should be remembered that the objective of a scoping review is to map the literature for patterns and gaps, rather than in-depth appraisal of the quality of the papers.

The findings compare with a systematic review that examined digital clinical education more broadly [13]. Stand-alone digital education was reported to be as effective as conventional learning for knowledge and practice, in nursing and medicine. However, there are some methodological concerns with this systematic review [13]. There was no a priori protocol, and the study lacked a pilot to test the methods. A librarian's involvement in verifying the search strategy was not reported, gray literature was not searched, and duplicate processes were absent for the study selection and data extraction stages.

There are several barriers to conducting a systematic review of VSPs across health care. First, there is insufficient research across midwifery and allied health [34,49]. Another consideration is that all student evaluations in this scoping review were custom-designed. Therefore, the inconsistency of outcome measures might prevent meaningful comparisons across papers. One study used previously researched scales for clinical thinking ability, academic self-efficacy, and student engagement, which demonstrated good reliability [41]. Some of the exams were standardized [30,32,45,51], but none compared the baseline marks of each group to determine whether there were differences at the outset. In all cases, VSP exam scores were compared with a previous cohort that attended placement FTF prepandemic, or the national average, rather than adopting a prospective design.

It is clear from the paucity of research outside nursing and medicine, the lack of prospective research designs and inconsistent, nonvalidated outcome measures, that research into VSPs is in its infancy. It is tempting to recommend greater consistency of outcome measures and more robust experimental designs to improve the evidence base. However, such approaches may not fit the study of complex educational interventions such as VSPs. More suitable approaches include quasi-experimental, qualitative, and evaluative designs to examine conceptual underpinnings, VSP cocreation, the mechanisms mediating learning responses, and individual case trends over time.

Strengths and Weaknesses

The strengths of this study relate to the methodology. A structured process for defining search terms was undertaken, and a librarian was consulted for the search strategy. A range of databases were searched across medical and technology specialties. Gray literature sources were searched, and an updated search included trial registries. An a priori protocol was registered, and a subset of data was piloted to determine the declared changes. Duplicate processes in study selection and data charting were employed, and existing guidelines were used to design the protocol, synthesize the findings, and report the paper.

One weakness is that many health care educators may have implemented VSPs without documenting their practices. As such, a scoping review of the literature will always underestimate the scale and depth of innovation in practice. Limiting the search to English language increased the risk of language bias. While the limited number of publications from low or middle income countries could reflect the language limitation, it is also likely that countries with greater resources were better positioned to make the rapid shift to web-based education and publish their research during a global health emergency. Web-based platforms are suited to sharing resources and overcoming geographical constraints to access expertise, and VSPs present an opportunity to address inequality in health care education moving forward.

Conclusion

This scoping review mapped the VSP evidence across health care, highlighting patterns and gaps in the evidence base. All papers documented pandemic responses, primarily in medicine and nursing in high income countries. There are notable gaps in the midwifery and allied health research. Although emerging trends for VSPs in this review demonstrate some positive outcomes, this review highlights the need for improvements in VSP design. These include cocreation with a wider range of stakeholders and underpinning by pedagogical principles, theoretical frameworks, and published standards. Research into student engagement using VR headsets, haptics, and conversational AI systems in VSPs, are areas for future research, as immersive technologies and their use cases develop. The pandemic has revealed an opportunity to augment placement capacity through VSPs. There is the potential for future VSPs to feature IPE, thus promoting joined-up care in health care graduates. There is also the opportunity for VSPs to improve local and global access to quality clinical education experiences.

Acknowledgments

We acknowledge our health librarian, Carlo Avillo, for assisting with the search strategy.

This review will contribute towards a PhD award for JS.

Abstract

Background: Understanding the roles and patient management approaches of the entire oncology team is imperative for effective communication and optimal cancer treatment. Currently, there is no standard residency or fellowship curriculum to ensure the delivery of fundamental knowledge and skills associated with oncology specialties with which trainees often collaborate.

Objective: This study is a systematic review that aims to evaluate the multidisciplinary oncology education in postgraduate medical training.

Methods: A systematic literature search was performed using MEDLINE, Embase, Cochrane Database of Systematic Reviews, Cochrane CENTRAL, APA PsycINFO, and Education Resources Information Center in July 2021. Updates were performed in February 2023 and October 2024. Original studies reporting the effectiveness of multidisciplinary oncology training among residents and fellows were included.

Results: A total of 6991 studies were screened and 24 were included. Fifteen studies analyzed gaps in existing multidisciplinary training of residents and fellows from numerous fields, including surgical, medical, and radiation oncology; geriatrics; palliative medicine; radiology; and pathology programs. Trainees reported limited teaching and knowledge of oncology outside of their respective fields and endorsed the need for further multidisciplinary oncology training. The remaining 9 studies assessed the effectiveness of educational interventions, including tumor boards, didactic sessions, clinical rotations, and case-based learning. Trainees reported significant improvements in multidisciplinary oncology knowledge and skills following the interventions.

Conclusions: These data suggest postgraduate medical trainees have limited formal multidisciplinary oncology training. Existing educational interventions show promising results in improving trainees' oncology knowledge and skills. There is a need for further research and the development of multidisciplinary oncology curricula for postgraduate medical training programs.

KEYWORDS

multidisciplinary; oncology; postgraduate medical education; resident; fellow; surgery; hematology; radiation oncology; geriatrics; palliative

Introduction

Cancer was the second leading cause of death in the United States in 2023 [1]. Cancer care often requires a team of physicians including surgical, medical, and radiation oncologists, as well as specialists in radiology and pathology [2]. Knowledge of collaborating oncologists' roles and appropriate multidisciplinary referrals may impact cancer treatment. There is evidence of improved adherence to standard treatment guidelines with multidisciplinary referrals for patients with prostate [3], lung cancer [4], and bladder cancer [5].

There is considerable potential to improve interdisciplinary communication between various oncologic specialists and to optimize psychosocial support for patient care. Therapies with different oncologists must be well coordinated and specifically selected based on the medical and social needs of each patient.

To achieve this, knowledge of other disciplines' roles, responsibilities, and treatment options is necessary for effective communication and optimal cancer care.

There is currently no standard curriculum for delivering multidisciplinary oncology education in residency and fellowship programs in the United States [6-10]. Mattes et al [11] identified that while many of the program requirements for oncology subspecialties emphasize the importance of providing multidisciplinary cancer care, how this occurs varies widely between subspecialties. Not all programs mandate multidisciplinary oncology rotations or experiential specialty training, and only a select few require attendance at multidisciplinary tumor board meetings (MTBM) [6-12]. Such a training gap may impact trainee education and, as a result, influence referral patterns and the timely access of patients to multimodal cancer therapies.

The objective of this study was to perform a systematic review of the literature to evaluate the multidisciplinary oncology education in postgraduate medical training (ie, interns, residents, and fellows). This study provides a review of literature analyzing the education of learners about the role of any collaborating physician specialty involved in oncology care, including but not limited to, medical oncology, radiation oncology, surgical oncology, and palliative care. These data summarize gaps in training programs identified across studies, the suggested educational interventions to bridge these gaps, and limitations in the literature within the field.

Methods

Research Design and Methodology

This systematic review was reported based on PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) guidelines [13]. The protocol was registered and published by PROSPERO (ID: CRD42022271308).

Search Strategy

A search strategy was developed with the assistance of an information specialist using these and other related terms: "Residents or Fellows or Trainees or Medical Training" AND "Education or Training Programs" AND "Multidisciplinary" AND "Oncology." The following databases were searched from inception: MEDLINE, MEDLINE In-Process, Embase Classic + Embase, Cochrane Central Register of Controlled Trials, Cochrane Database of Systematic Reviews, and APA PsycINFO (all via the Ovid platform); and Education Resources Information Center via the EbscoHost platform. The search was initially performed on July 21, 2021, and updated twice (ie, on February 26, 2023, and October 9, 2024). Table S1 in Multimedia Appendix 1 shows the number of citations identified from each database. The search strategy and the number of citations identified via MEDLINE are included in Table S2 in Multimedia Appendix 1.

Eligibility Criteria

Eligibility criteria were developed prior to the search strategy. The scope of this study was to evaluate the multidisciplinary oncology education offered by residency and fellowship programs to postgraduate medical trainees. Thus, the first eligibility criterion was the inclusion of studies investigating postgraduate medical training (ie, interns, residents, and fellows). Studies about nonphysician specialties (eg, nursing, pharmacy, or dentistry), attending or staff physicians, or those involving solely Masters, PhD, or medical students were excluded. Studies were included if their focus was specific to oncology care. Selected studies focused on multidisciplinary aspects of medical education, which included knowledge of collaborating medical specialties and their roles in cancer care (eg, surgical trainees' knowledge of radiation or medical treatments). Trainees from all specialties were included, as long as the study was assessing the multidisciplinary oncology education of trainees, and therefore, these were not necessarily restricted to oncology residency or fellowship programs (eg, medical oncology, radiation oncology, surgical oncology). Only primary research papers and studies available in English (ie, both original and translations to English) were included. Thus, all reviews, case studies, opinion papers, abstract-only papers, conference literature, and short reports were excluded.

Study Selection

There were 2 stages of review: title and abstract screening, followed by full-text screening. A total of 6 reviewers (HT, GK, CML, IB, ZF, and RV) were involved, and studies were screened by a minimum of 2 independent reviewers at each stage. Discrepancies were resolved by a third reviewer. Both screening stages were performed on Covidence [14], a web-based systematic review organization software.

Data Extraction and Synthesis

Data extraction was performed on the selected studies. Studies were divided between 3 reviewers (HT, CML, and RV) who performed data extraction. Study design, study population, outcome measures, and main results were extracted from each study.

Quality Assessment

Selected studies were independently assessed for quality by 2 independent reviewers (CL, IB, and RV) using the Mixed Methods Appraisal Tool (MMAT) version 2018 [15]. Discrepancies were resolved through discussion with a third author (HT). The MMAT was chosen due to its ability to concomitantly assess multiple study types (ie, qualitative, quantitative randomized controlled trial, quantitative nonrandomized, quantitative descriptive, or mixed methods). Each study was evaluated on a set of 5 criteria depending on the study type. For survey studies, the risk of nonresponse bias was deemed to be high if the response rate was below 70%. Studies were assigned an overall quality score ranging from 0 to 5 stars based on the number of criteria that were met.

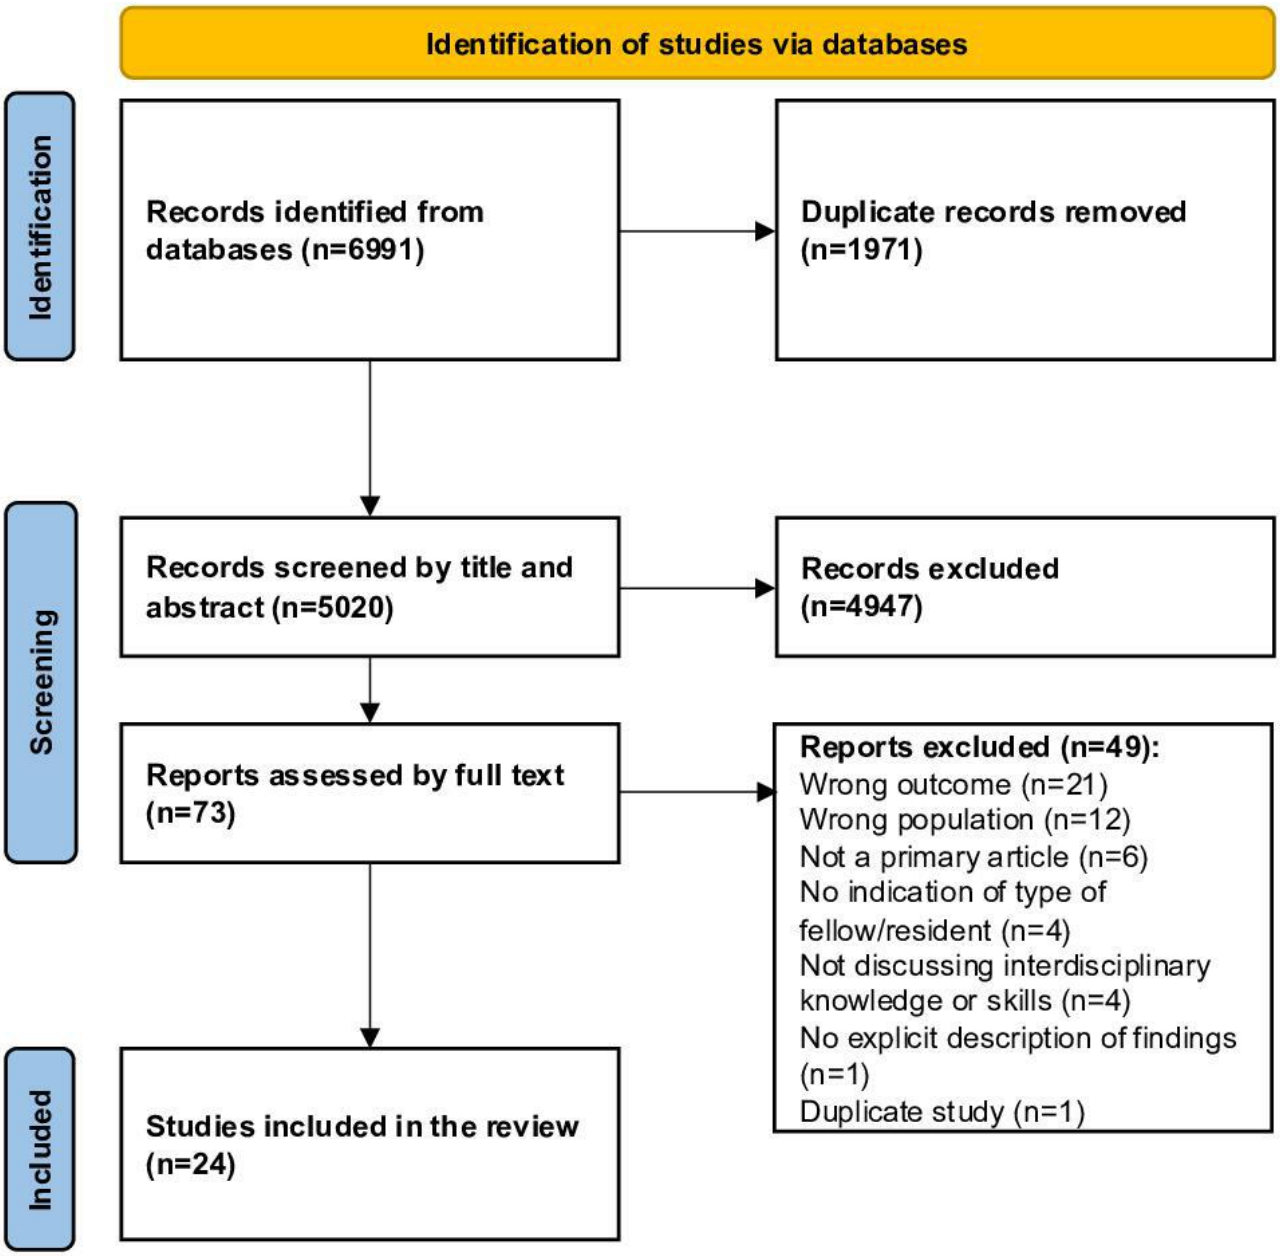
Results

Study Characteristics

The search strategy resulted in a total of 6991 studies. After removing duplicates between databases, 5020 unique studies were identified. A total of 73 studies remained after title and abstract screening. Full-text screening excluded 49 studies, and

24 studies were therefore included in the final analysis. The PRISMA flow diagram is demonstrated in Figure 1.

Figure 1. PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) diagram of the systematic review. Adapted from Page et al [13].



The remaining 24 studies were divided into 2 categories. Fifteen studies assessed the quality of existing postgraduate oncology training based on trainees' multidisciplinary knowledge. The remaining 9 assessed trainees' multidisciplinary knowledge following an educational intervention. For the latter category, all studies with educational interventions directed toward improving multidisciplinary oncology knowledge and skills among interns, residents, and fellows were included. These included studies that are part of the formal postgraduate medical training (eg, residency or fellowship program), as well as external initiatives for improving multidisciplinary oncology training. Studies involving educational interventions for medical students and staff or attending physicians were not included.

Existing Multidisciplinary Training

A summary of the 15 studies evaluating the impact of existing multidisciplinary oncology training is included in Table 1. These studies included surgical or surgical oncology fields [16-23], hematology or medical or hematology oncology [16,20-22,24,25], geriatrics or geriatric oncology [20,22,26], radiation oncology [16,20,21,23,27], palliative medicine [16,20], radiology [21], pathology [21], genetics [23], dermatology [23], pediatric specialties [28], and other medical fields (eg, internal medicine, nephrology, neurology) [22,23].

Table . Summary of studies evaluating the existing multidisciplinary education across postgraduate medical training programs.

Reference	Study design	Sample	Outcome measure	Main findings and conclusions
Akthar et al [16]	Electronic surveys completed by oncology trainees and program directors across the United States in 2013	• 557 hematology or medical oncology, surgical oncology, radiation oncology, and palliative medicine residents and fellows • 141 hematology or medical oncology, surgical oncology, radiation oncology, and palliative medicine program directors	Proportion of trainees who received formal education in oncology fields outside of their specialty	• Generally limited interdisciplinary oncology education: ≤70% of trainees reported receiving formal interdisciplinary education; highest rate of training in radiation oncology (70% of trainees) and lowest rate of training in geriatric oncology (19% of trainees) • Consistently lower rates of interdisciplinary oncology training reported by trainees compared to program directors (P<.01)
Brenner and De Donno [17]	Survey of postgraduate year 1 - 5 residents from 3 general surgery programs: Florida Atlantic University, The University of Iowa, and The University of Connecticut	• 135 general surgery residents	Proportion of residents who indicated receiving training in a specific multidisciplinary field	• Limited proportion of residents indicated receiving multidisciplinary training: radiation oncology (23%), chemotherapy (31%), and palliative medicine (53%) • Majority (82%) of residents endorsed further multidisciplinary training
David et al [25]	Survey of hematology residents (ie, postgraduate years 4 - 5) or fellows (ie, postgraduate year 6 - 7) across Canada as part of a cross-sectional study	• 29 hematology residents and 3 hematology fellows	Geriatric oncology curriculum needs assessment	• 56.3% did not receive geriatric oncology teaching • 96.9% endorsed the inclusion of geriatric training in hematology residency
Delaye et al [22]	Surveys completed by French residents and senior physicians regarding the field of onco-nephrology	• Residents (n=130) and senior physicians (n=98) from nephrology, oncology, hematology, surgery and geriatrics	Current practices in onco-nephrology, information resources, existing cooperation networks, and expectations about onco-nephrology	• Oncology residents rated their confidence in facing renal events as 5.5/10 • Nephrology residents rated their confidence in facing cancer events as 6.0/10 • 21% of residents had received onco-nephrology teaching, which was judged as insufficient
Eid et al [24]	Review of literature, expert consultation, review of fellows' rotation evaluations, and interviews with current and recently graduated fellows, as a means of needs assessment for the development of a geriatric oncology program at MD Anderson Cancer Center	• 9 current hematology-oncology fellows (years 1 - 3) at MD Anderson Cancer Center • 2 MD Anderson faculty members who recently graduated from a hematology-oncology fellowship	Geriatric oncology training program needs assessment	Top 3 identified needs for geriatric oncology programs, based on current educational gaps: • Geriatric assessment • Pharmacology knowledge • Psychosocial knowledge

Reference	Study design	Sample	Outcome measure	Main findings and conclusions
Givi et al [29]	Semistructured interviews with program directors and faculty in head and neck surgery across the United States and Canada over a 7-month period	• 58 participants including head and neck surgery program directors and faculty	Head and neck surgical oncology training needs assessment	• 38% endorsed increasing the number of head and neck surgery fellows' interactions with medical oncology, radiation oncology, and speech and language pathology • 85% view exposure to multidisciplinary teams as essential in training curricula
Le Nail and Samargandi [30]	Web-based questionnaire on various aspects of MTBMs[a] completed by French orthopedic oncology residents	• 27 orthopedic oncology residents	Residents' opinions on educational impact and areas of improvement for MTBMs	• 54% agreed that MTBM is an appropriate venue for teaching • 75% endorsed that MTBMs improved their knowledge of other specialties involved • 71% indicated opportunities to improve teaching during MTBM, the most popular suggestion being active participation of residents (voted by 46% of all residents)
Maggiore et al [26]	Web-based survey completed by program directors of geriatrics fellowship programs in the United States	• 67 geriatrics program directors	Proportion of program directors offering or endorsing future learning opportunities in the field of geriatric oncology	• Majority (81%) of program directors offered didactic teaching in the form of formal geriatric oncology lectures/seminars • Limited number of program directors offered clinical experience: 39% offered mandatory oncology clinical experience and 46% offered clinical electives • Majority (77%) endorsed oncology training as part of the geriatrics fellowship
Mäurer et al [23]	Web-based survey distributed to all junior oncology groups represented in Young Oncologists United in Germany regarding interdisciplinarity in oncology	• 294 participants including 268 physicians (staff and trainees) from internal medicine, gynecology, radiotherapy and radiation oncology, general surgery, genetics, neurosurgery, urology, neurology, and dermatology	Opinions on interdisciplinarity at clinic, educational, and research levels	• 63.1% assigned a high priority to interdisciplinary residency training • Only 18.3% had the opportunity to participate in rotations in other specialties beyond their curriculum • 71.4% were interested in participating in rotations in other specialties • 73.1% of those who completed interdisciplinary rotations benefited from them

Reference	Study design	Sample	Outcome measure	Main findings and conclusions
Morris et al [27]	Web-based survey completed by radiation oncology residents in Australia, New Zealand, and Singapore	• 61 radiation oncology residents	Proportion of residents who indicated receiving or endorsing future geriatric oncology training	• Majority (91.8%) did not receive any geriatric training • Limited number of residents (39.3%) comfortable managing complex geriatric issues • Majority (85.3%) endorsed additional geriatric training
Morris et al [20]	2-stage Delphi consensus with input from a panel of internationally recognized oncology experts, staff physicians, radiation oncology and clinical oncology trainees, allied health professionals, patients, and caregivers. Experts were from geriatrics, geriatric oncology, and radiation oncology. Staff physicians were from clinical/medical oncology, palliative care, and surgical oncology.	• A total of 103 and 54 individuals participated in rounds 1 and 2 of the modified Delphi consensus process, respectively • Majority were radiation oncologists (43%)	Establishing learning outcomes for a geriatric radiation oncology curriculum	• 33 learning outcomes identified in the areas of fundamental geriatric medicine concepts, epidemiology, geriatric screening, planning and delivery of radiation therapy, geriatric palliative care, surgery, systematic treatment, research, communication skills, and health advocacy
Park et al [18]	30 item self-efficacy survey completed by residents at Ohio State University Wexner Medical Center, in order to measure knowledge and skills in 6 breast cancer care aspects: genetics, surgery, medical oncology, radiation oncology, pathology, and radiology	• 31 general surgery residents	Residents' perceived capability (ie, self-efficacy score) in various domains of breast cancer care	• Highest self-efficacy in surgery (3.56/5) vs lowest in genetics (2.67/5), radiation oncology (2.67/5), and pathology (2.67/5) • Significant improvement of self-efficacy in surgery only (P=.002) with additional years in residency
Picca and Reed [28]	Semistructured interviews with faculty and trainees across pediatric oncology, radiology, pathology, surgical oncology, and palliative care	• 4 pediatric oncology fellows • 11 pediatric oncology, pathology, radiology, palliative care, and surgical oncology faculty physicians	Exploration of learning in tumor boards	• Trainees found tumor board presentation to be educational • Barriers to learning: competing clinical/administrative responsibilities • Facilitators to learning: learning-focused goals, faculty mentorship during presentation preparation, collaborative discussion, content tailored to learners and board exams, and supportive environment • Web-based tumor boards promoted accessibility and convenience but decreased learning due to limited engagement, discussion, and professional relationship development

Reference	Study design	Sample	Outcome measure	Main findings and conclusions
Walraven et al [21]	Semistructured interviews with Dutch residents and specialists in medical/surgical/radiation oncology, radiology, nuclear radiology, and pathology participating in MDTMs[b]	• 19 residents • 16 specialists	Residents' barriers and facilitators to participate in MDTMs	• 100% agreed that MDTMs play an important role in both education and patient care • Barriers: insufficient supervisor guidance, time constraints, meeting atmosphere and hierarchy, strict regulations, unfamiliarity, and resident's personal characteristics • Solutions: MDTM simulation training, and training courses on communication and meeting skills
Wilson et al [19]	Survey of applicants to Roswell Park Cancer Institute surgical oncology fellowship program	• 29 general surgery residents or recent general surgery graduates applying to surgical oncology fellowship	Proportion of applicants with breast surgery exposure and their comfort with medical and surgical management of breast cancer	• Majority (65%) had exposure to multidisciplinary breast cancer clinics, involving medical and surgical oncologists • Lower level of comfort (7.07/10) with breast cancer medical management compared to surgical management (7.34 - 9.10/10 depending on the type of surgery)

[a]MTBM: multidisciplinary tumor board meeting.

[b]MDTM: multidisciplinary team meetings.

Thirteen studies obtained opinions of trainees with respect to multidisciplinary oncology education within their training programs [16-25,27,28,30]. Morris et al [20] used a Delphi consensus process, and 4 studies directly interviewed trainees and faculty [21,24,28,29]. The remainder of the studies used surveys. Maggiore et al [26] surveyed geriatrics program directors, Givi et al [29] surveyed head and neck surgery program directors, and Akthar et al [16] surveyed program directors of pediatric and adult hematology oncology, surgical oncology, radiation oncology, and palliative medicine. Eid et al [24] used a combination of expert consultation, trainee interviews, review of trainee rotation evaluations, and literature review to assess their multidisciplinary educational needs.

While all studies analyzed the quality of existing multidisciplinary education, there were differences in the disciplines investigated across studies. Akthar et al [16], Delaye et al [22], Mäurer et al [23], Walraven et al [21], Picca and Reed [28], and Brenner and De Donno [17] focused on identifying broad gaps in multidisciplinary education including knowledge and skills of trainees in numerous fields, such as radiation, surgical, and medical oncology, radiology, pathology, geriatrics, palliative medicine, and other pediatric and medical fields. The remaining 8 studies focused on a more specific set of trainee skills. David et al [25], Eid et al [24], and Maggiore et al [26] assessed gaps in geriatric oncology education among hematology residents and fellows, hematology oncology fellows, and geriatrics fellows, respectively. Morris et al [20,27] assessed gaps in the radiation oncology training curriculum. Park et al [18] and Wilson et al [19] assessed the quality of general surgery residency training in breast cancer care. Le Nail and Samargandi [30] evaluated the quality of tumor boards for orthopedic oncology trainees. Finally, Givi et al [29] performed a needs assessment analysis of the head and neck surgery training curriculum.

13 studies assessed the strengths and weaknesses of oncology training programs [16-19,21-23,25-30]. Of these, 11 found that trainees had limited exposure to multidisciplinary oncology disciplines, barriers to attending multidisciplinary oncology meetings, and a low level of trainee comfort in multidisciplinary oncology knowledge [16-19,21-23,25-28]. Givi et al [29] found that 27% of interviewees indicated exposure to multidisciplinary care as a strength of the head and neck surgery training program, although 38% endorsed the need to improve fellows' multidisciplinary participation. In general, Akthar et al [16] found the least amount of multidisciplinary training in geriatric oncology, compared to palliative medicine, medical, radiation, and surgical oncology. Similarly, Morris et al [27] found that less than 10% of radiation oncology trainees received geriatrics training. Furthermore, less than half of geriatrics fellows were offered geriatric oncology rotations [26]. For multidisciplinary

breast cancer management, Park et al [18] found limited training in genetics, radiation oncology, and pathology among surgical residents, compared to rotations within surgery, radiology, and medical oncology. Brenner and De Donno [17] found that a small proportion of general surgery residents received training in the fields of radiation (23%) and medical oncology (31%), but over half (53%) received exposure to palliative care.

Additionally, 11 studies researched areas of improvement for multidisciplinary oncology education among the postgraduate programs via surveys, interviews, Delphi consensus, and literature search [17,20,21,23-30]. Maggiore et al [26] and Morris et al [27] found that 77% of geriatrics fellows and 85.3% of radiation oncology residents advocated for further geriatric oncology training. David et al [25] found that over 95% of hematology trainees endorsed geriatric training during residency. 82% of general surgery residents surveyed by Brenner and De Donno [17] agreed that additional multidisciplinary training is needed to optimize cancer care. Additionally, based on an educational needs assessment, Eid et al [24] found that the top 3 priorities for a geriatric oncology program included geriatric assessment, pharmacology, and psychosocial skills. MTBMs were found to enhance trainee experience and multidisciplinary oncology education [21,28,30]. However, some barriers to attending meetings included time constraints, clinical duties, and lack of active resident participation [21,28,30]. Residents and specialists interviewed by Walraven et al [21] suggested that the educational value of multidisciplinary team meetings could be improved through additional training such as multidisciplinary team meeting simulations and courses on effective communication and meeting skills.

Impact of Educational Interventions

A summary of the 9 studies analyzing the impact of educational interventions is included in Table 2. The majority included general surgery trainees [31-35]. Faculty and trainees from radiation oncology [32,35], medical oncology [12,35], respirology [12,36], thoracic surgery [12], gynecology [35], urology [37], and palliative medicine [38] were also included. All 9 studies demonstrated improvements in multidisciplinary oncology knowledge and skills postintervention.

Table . Summary of studies evaluating the impact of multidisciplinary educational interventions.[a]

Reference	Study design	Sample	Outcome measure	Main findings and conclusions
Cook et al [31]	Electronic surveys were sent to general surgery residents at the completion of 4-week rotations in MDB[b], USOS[c], and community-based TSR[d] at Oregon Health and Science University in 2010 - 2013. MDB included operative time, as well as half-days in pathology, radiology, medical oncology, and surgery clinic.	• Total sample size: 32 in MDB, 73 in USOS, and 51 in TSR • Operative logs of 29 residents in MDB, 11 in TSR, and 12 in USOS were obtained	• Trainee satisfaction based on surveys • Operative volume based on operative logs	• MDB rotation residents rated the opportunity to perform and learn procedures higher than those in USOS (P=.02) and TSR (P=.01) • 83% of MDB residents' operative experience included breast cancer operations, compared to 71% of USOS and 12% of TSR groups • MDB rotation residents rated higher on the quality of faculty teaching and educational materials than those on TSR (P=.03 and P=.04, respectively)
Khoshgoftar et al [37]	Short interviews were held with urology residents and faculty members regarding needs for holding web-based tumor boards prior to implementation of 20 monthly web-based tumor boards. Tumor boards were assessed through questionnaires postintervention, resident pretest and posttest scores for 5 consecutive tumor boards, and external evaluators from the faculty of urology.	• 35 urology residents • 25 urology faculty members • Panelists from pathology, radiation oncology, medical oncology, radiology, and nuclear medicine	• Needs assessment, satisfaction levels, pretest and posttest scores, recommendations from external evaluators	• Resident needs assessment was divided by level of importance and postgraduate years (ie, years 1 - 2 vs 3 - 4). An important limitation to participate was significant clinical responsibilities, particularly for lower year residents • High resident satisfaction rate (71% - 88%) based on various aspects of web-based tumor boards. The most important technical issue was the low bandwidth speed. • There was significant improvement in resident posttest scores in the majority of sessions
Mackay et al [36]	Respiratory and oncology trainees completed a 3-hour MDTM[e] simulation session and completed pre- and postsimulation questionnaires	• 19 oncology and respiratory trainees (specialty training years 3 - 7)	• Perceptions of current training programs, confidence presenting in MDTMs, use of the simulation, and impact on future clinical practice	• Trainees rated 4/10 for how well their program prepared them to present at MDTM • Trainee confidence in presenting in MDTMs increased from 5/10 to 7/10 postintervention (P<.01) • Trainees rated 9/10 for usefulness and 9/10 for likelihood the session will lead to changes in their practice

Reference	Study design	Sample	Outcome measure	Main findings and conclusions
Martin et al [38]	Fellows completed three 1-hour lectures in palliative radiotherapy, as well as pre- and postcourse questionnaires and objective knowledge assessment multiple-choice questions.	• 5 hospice and palliative medicine fellows at the University of California, San Diego	• Knowledge and confidence in palliative radiotherapy	• Postintervention improvement in trainee-reported confidence in discussion with patients about radiotherapy (0.009), managing its common side effects (*P*=.021), and identifying oncologic emergencies related to radiotherapy (*P*=.012) • Significant improvement in radiotherapy knowledge based on objective knowledge assessment questions (22% vs 86% pre- vs postintervention; *P*=.010) • Increased trainee-reported likelihood of collaboration with radiation oncologists postintervention (*P*=.014)
Mattes et al [12]	Faculty, fellows, and residents attended a didactic lecture on radiation therapy in lung cancer care. Knowledge was tested using multiple choice questions pre- and postintervention.	• A total of 121 faculty and trainees from pulmonology, thoracic surgery, and medical oncology • Pretest: 54 residents/fellows and 9 faculty participated • Posttest: 23 residents/fellows and 2 faculty participated	• Knowledge of radiation therapy in lung cancer treatment and comfort in appropriate referral to radiation oncology	• The majority had no didactic training (75%) or rotations (85.5%) in radiation oncology preintervention • Significant improvements in mean objective test scores postintervention (*P*<.001) • Postintervention, 100% of participants felt more knowledgeable in radiation therapy and 96% felt more comfortable making appropriate radiation oncology referrals
Meani et al [35]	Faculty and trainees completed a postintervention questionnaire following a multidisciplinary breast cancer course.	• A total of 42 participants in medical oncology, radiation oncology, gynecology, and general surgery • 11 heads of department/professors • 17 consultants/attending Physicians • 14 trainees: residents, medical fellows, PhD students, and postdoctoral fellows	• Opinions on the impact of the course	• Postintervention, 64% made changes in their clinical practice and 33% made institutional changes in breast cancer management • 95% reported increased knowledge of MDB cancer care
Sloan et al [32]		• 22 general surgery residents • 3 radiation oncology residents • 15 faculty at stations • 12 patients with breast cancer at stations	• Self-reported trainee improvement in breast cancer care–specific skills • Perception of faculty, patients, and residents of the overall quality of intervention	

Reference	Study design	Sample	Outcome measure	Main findings and conclusions
	Residents at the University of Kentucky received multidisciplinary instruction and completed 15 case-based stations about various domains of breast cancer care (ie, surgical oncology, medical oncology, radiology, radiation oncology, plastic surgery, and pathology). Surveys about the overall quality of intervention were completed by patients, faculty, and residents. Residents also completed pre- and postintervention surveys regarding specific breast cancer care-specific skills.			• Statistically significant trainee-reported improvement for all measured skills, including fine-needle aspiration, mammography interpretation, and treatment discussion with patients • Overall, intervention rated favorably by trainees, faculty, and patients
Sloan et al [33]	Residents at the University of Kentucky completed 12 case-based stations during a head and neck oncology workshop, designed by faculty from general surgery, speech pathology, dentistry, radiation therapy, otolaryngology, plastic and reconstructive surgery, pathology, anesthesiology, and cardiothoracic surgery. Surveys about the overall quality of intervention were completed by patients, faculty, and residents. Residents also completed pre- and postintervention surveys regarding head and neck-specific skills.	• 21 general surgery residents • 11 faculty at stations • 8 standardized patients at stations (including 6 patients with cancer)	• Self-reported trainee improvement in skills relevant to head and neck cancer care • Perception of faculty, patients, and residents of the overall quality of intervention	• Statistically significant trainee-reported improvement for most skills postintervention (P<.001) • Overall, intervention rated favorably by trainees, faculty, and patients • Residents generally endorsed having intervention minimum twice during residency
Sloan et al [34]	2 groups received multidisciplinary teaching in breast cancer care, including radiation oncology, radiology, surgery, and medical oncology, in the form of a 15-station workshop. The other 2 groups served as controls. 1 intervention and 1 control group were administered an 11-problem OSCE[f] assessment immediately postintervention and the remaining 2 groups were administered the same OSCE assessment 8 months later. Residents were assessed by faculty and standardized patients during OSCE assessments.	• 48 general surgery residents from the University of Kentucky, divided evenly into 4 groups • 15 faculty at stations • 12 standardized patients at stations (including 5 patients with cancer)	• Skills in diagnosis and management of breast cancer postintervention, assessed by faculty and standardized patients during OSCE assessments	• Improvement in skills of residents who attended the workshop, compared to the control group, both immediately and 8 months postintervention (P<.01) • Residents' skills diminished after 8 months, as evidence by the difference in skill set between the group tested immediately versus the one tested 8 months postintervention (P<.004)

[a]Patients who performed assessments included actual and simulated patients.

[b]MDB: multidisciplinary breast.

[c]USOS: university surgical oncology service.

[d]TSR: traditional surgical rotation.

[e]MDTM: multidisciplinary team meeting.

[f]OSCE: Objective Structured Clinical Examination.

The study by Cook et al [31] compared the impact of a multidisciplinary breast rotation to traditional oncology or community rotations using trainee self-evaluations. Martin et al [38] and Mattes et al [12] analyzed the effectiveness of didactic learning for palliative radiotherapy and lung cancer radiotherapy, respectively, using pre- and postcourse trainee evaluations. Meani et al [35] studied the impact of a multidisciplinary breast cancer course on the knowledge and practice of faculty and trainees using a questionnaire. Three studies by Sloan et al tested the quality of case-based instruction, involving workshops or Objective Structured Clinical Examination (OSCE) stations, where evaluations were completed by trainees, standardized patients, and faculty [32-34]. In the 2004 study by Sloan et al [34], faculty and standardized patient completed evaluations following the observation of trainees in OSCE stations. Patient ratings mainly included interpersonal skills, while faculty ratings included both the clinical and interpersonal skills of trainees. In the other 2 Sloan et al studies, faculty and standardized patients provided feedback on the overall quality of workshops, rather than a specific focus on trainee skills [32,33]. Many of the standardized patients were actual patients with cancer [32-34]. Two of the Sloan et al studies with breast cancer-specific stations focused on knowledge and skills in the following fields: surgical, medical, and radiation oncology; pathology; plastic surgery; and radiology [32,34]. A pilot study by the same group included a head and neck workshop in which stations were designed by faculty from general surgery, radiation oncology, cardiothoracic surgery, otolaryngology, plastic surgery, pathology, anesthesiology, speech pathology, and dentistry [33].

In 8 of these 9 studies, the benefit of educational interventions was noted by the trainees through self-assessment of knowledge or skills [12,31-33,35-38], while Sloan et al [34] demonstrated improvements in knowledge or skills, as assessed by faculty and patients following the observation of trainees in OSCE stations. In addition to reporting subjective benefits, Khoshgoftar et al [37], Mattes et al [12], and Martin et al [38] used objective assessments to demonstrate improvements in trainee knowledge postintervention. Interestingly, Sloan et al [34] showed that while the intervention benefited residents' knowledge and skill set in breast cancer management both immediately after and 8 months postintervention, it declined after 8 months. In the other 2 studies by this group [32,33], trainees, faculty, and patients rated the interventions highly.

Quality Assessment

A summary of the MMAT quality assessment is included in Table S3 in Multimedia Appendix 1. Five studies were categorized as nonrandomized, 4 as qualitative, 13 as quantitative descriptive, 1 as mixed methods, and 1 as randomized controlled. Studies were given a score out of 5, based on the number of MMAT criteria met. Two studies were given an overall MMAT quality rating of 3 stars, 14 studies were rated as 4 stars, and the remaining 8 were rated as 5 stars. Overall, all studies were deemed to be satisfactory by authors, based on MMAT quality assessment criteria.

Discussion

Principal Results

To our knowledge, this is the first systematic review of multidisciplinary oncology education in postgraduate medical training. These data summarize educational gaps and potential solutions to improve multidisciplinary education for future trainees. Of the 24 studies included in the final analysis, 15 obtained faculties' and trainees' opinions on deficiencies and areas of improvement for existing multidisciplinary oncology education [16-19,24,26,27]. They generally reported limited multidisciplinary oncology training or knowledge, barriers to multidisciplinary training, and advocated for further instruction in different areas. The remaining 9 studies studied the impact of educational interventions on trainees' oncology expertise [31-34,38]. Multidisciplinary rotations, tumor board meetings, didactic teaching, and case-based learning were found to be beneficial based on trainee self-assessments, written exams, and evaluations from faculty and patients following the observation of trainees in OSCE stations.

Filling the current gaps in multidisciplinary oncology education using the aforementioned educational interventions has the potential to improve multidisciplinary communication, appropriate referrals, and oncologic outcomes [3-5]. Studies by Mattes et al [12] and Martin et al [38] found that trainees were more likely to collaborate and make appropriate referrals to radiation oncologists after didactic teachings in lung cancer treatment and palliative radiotherapy, respectively. Several studies also found MTBMs to enhance trainee education [30,36,37]. In fact, the study by Mackay et al [36] found that tumor board simulation sessions significantly improved trainee's confidence in presenting in tumor board sessions. After all, improved communication and referral patterns are central to effective multidisciplinary collaboration among oncology specialists and ultimately improve the access of patients to evidence-based oncologic treatments.

Comparison With Prior Work

Geriatric oncology was consistently found to be an area in which trainees received limited training [16,26,27,39]. As cancer incidence increases in older adults, a population with a higher burden of comorbidities, trainees must gain sufficient knowledge and experience in geriatric oncology to optimize treatment [40]. These findings are echoed in a review by Morris et al [39] highlighting insufficient training and education in geriatric oncology among radiation oncology trainees across several different countries. This training should identify the specific needs of older patients and thereby result in a more informed and nuanced approach to this population's medical and psychosocial issues [24]. Development of these skills may be achieved through dedicated rotations or training in geriatric oncology.

Based on findings from this study, it is evident that the quality of multidisciplinary oncology education and training needs to be assessed and addressed. Implementation of benchmarks to ensure sufficient training across residency and fellowship programs commonly involved in cancer care would provide an educational quality metric [6-10]. This would encourage training

programs to develop and establish multidisciplinary oncology curricula. One approach to achieve this would be to ensure trainee participation in a variety of educational activities such as multidisciplinary case conferences, research, rotations, didactic teaching, and case-based learning led by faculty from other disciplines [11,31-34,38]. Furthermore, a review of each residency or fellowship program's curriculum by a multidisciplinary faculty committee may ensure sufficient trainee exposure to collaborating oncology areas.

Competency-based medical education is an outcome-based approach to evaluate medical trainees and ensure a high degree of graduate skill set [41]. This is often done via objective measures, such as entrustable professional activities (EPAs) and milestones. The development of standardized and program-specific EPAs, specifically for multidisciplinary oncology education, would provide training programs with a specific measure of their trainees' knowledge, skills, and progress in this area. Using EPAs would also identify areas of improvement for trainees early on in their training and would allow for additional support to improve multidisciplinary oncology competencies. Ultimately, these EPAs should mirror curriculum changes to ensure effective multidisciplinary oncology education. The benefits of using EPAs for geriatric oncology training are echoed by Eid et al [24]. They provide an example of an EPA to assess the appropriateness of chemotherapy for a geriatric patient, which includes the ability to perform a comprehensive geriatric assessment, having sufficient knowledge of chemotherapy toxicities and interactions, and assessment of suitability based on patients' comorbidities. This represents a geriatric oncology-specific EPA for medical or hematology oncology trainees. Oncology training programs may adopt similar EPAs to ensure a high quality of multidisciplinary oncology training within their residency and fellowship programs.

Despite its merits, there are potential barriers to the implementation of oncology training curricula. Several factors may prevent trainee participation in multidisciplinary education activities, including limited elective time, educational options, or available personnel. For instance, those training in the community or rural hospitals may not have access to many electives in other oncology fields. For the same reason, there may be limited available multidisciplinary faculty to either design effective oncology curricula or mentor trainees. Furthermore, many residency or fellowship programs may have strict curricula and elective requirements, and thus limit elective options for trainees. To overcome some of these challenges, studies have suggested the importance of web-based courses or teaching sessions to supplement their curriculum. As a result of the COVID-19 pandemic, web-based education has become an integral part of medical training that will likely remain used to various degrees in the future [42,43]. Data supports the effectiveness of web-based training, including web-based rotations or clinical training [44-46], tumor board meetings [28,37], surgical skills training [47], and didactic and case-based teaching [48-52].

Furthermore, local, state-wide or provincial, and national resources and programs could also be offered to trainees interested in further advancing their multidisciplinary oncology knowledge and skills outside their residency and fellowship programs. Certainly, didactic teaching [12,35,38], as well as workshops and OSCE-style evaluation sessions [32-34] are valuable in advancing trainee education in multidisciplinary oncology care. Depending on the topic, these teaching sessions could be offered in person, remotely via web-based applications, or as a prerecording to enhance trainee participation. As indicated by Mackay et al [36], tumor board simulation sessions contribute to significant improvements in trainee confidence and skills in participating in tumor boards. This is a novel educational intervention not traditionally offered by residency or fellowship programs. The addition of such resources and programs outside of the mainstream postgraduate training programs has the potential to supplement trainee education toward multidisciplinary oncology care.

Given the time constraint of residency and fellowship, it is not feasible for trainees to gain all relevant multidisciplinary knowledge and skills while also excelling in all core competencies relevant to their program. Every proposed intervention will have its own challenges to implement and needs to be balanced against other rotations within the curriculum. Yet, it is preferred that trainees obtain sufficient multidisciplinary knowledge during training rather than through experience during practice. It is crucial that training programs conduct an evaluation of any new educational intervention and prioritize selected interventions in their curricula based on outcomes and feedback.

Limitations

This study has limitations. Only 24 studies have analyzed the quality of multidisciplinary oncology education among postgraduate medical trainees. Furthermore, we limited our study to English-only and primary papers. It is possible that additional studies analyzing multidisciplinary oncology education in other languages or papers (eg, grey literature) exist that are missing from our results. Over a third of these studies were also published more than 5 years ago. Particularly, 3 of the intervention studies are by Sloan et al [32-34], published in 1997, 1999, and 2004, which could have had overlapping participants. This could limit the generalizability of the findings from these studies. There is a need for additional and more contemporary research assessing the needs of postgraduate medical trainees and the impact of newer educational interventions. It is particularly important to evaluate the use of technologies currently used in medical education such as web-based live teaching [43-47], clinical teaching tools such as case-based modules with built-in radiology software [53,54], and virtual reality surgical training [55-57]. Additionally, none of the studies on educational interventions were conducted with trainees in geriatric oncology. As previously discussed, this is an important aspect of oncology, though generally missing from oncology training curriculums. Thus, additional studies are needed within these fields. Furthermore, while a large proportion of studies solely focus on gaps in geriatric oncology education, this may not be generalizable to all multidisciplinary oncology education needs. Future research will be important in developing multidisciplinary oncology curricula for postgraduate trainees.

Conclusions

This systematic review demonstrated several gaps in the existing multidisciplinary oncology training of postgraduate medical trainees and the promising results of various educational interventions in bridging these gaps. Further studies investigating the needs of trainees at both local and national levels are needed to develop specific educational curricula and program requirements that focus on multidisciplinary oncology collaboration. Future research should also assess contemporary educational interventions to determine the most effective methods of attaining multidisciplinary oncology expertise among postgraduate medical trainees.

Authors' Contributions

The authors met all International Committee of Medical Journal Editors criteria for authorship. HT, GK, ER, ME, and TDC contributed to the study design. HT, GK, CML, IB, ZF, RV, and ME contributed to the processes of screening or data acquisition. HT, GK, CML, IB, ZF, ER, TDC, and RV participated in data analysis. All authors contributed to manuscript drafting and revision.

Conflicts of Interest

None declared.

Abstract

Background: Telemedicine is a key element of modern health care, providing remote medical consultations and bridging the gap between patients and health care providers. Despite legislative advancements and pilot programs, the integration of telemedicine education in Romania remains limited. Addressing these educational gaps is essential for preparing current and future medical professionals to effectively use telemedicine technologies.

Objective: This study aimed to evaluate the current state of telemedicine education for medical professionals in Romania, focusing on the integration of diagnostic and therapeutic capabilities into medical curricula, identifying the challenges and opportunities, and providing recommendations for improving telemedicine education.

Methods: A scoping review was conducted following Arksey and O'Malley's framework. Peer-reviewed articles from 2019 to 2023 were identified using databases such as PubMed and Scopus. Additional gray literature was reviewed to provide a comprehensive understanding of telemedicine education in Romania. Data were thematically analyzed to extract key findings and recommendations.

Results: The review identified significant progress in the legislative and infrastructural aspects of telemedicine in Romania, but highlighted gaps in integrating telemedicine education into curricula for medical professionals and other health care practitioners directly involved in telemedicine practices. While some universities have included telemedicine components, dedicated telemedicine courses and hands-on training remain insufficient. Barriers include a lack of infrastructure, digital literacy, and practical exposure to telemedicine technologies.

Conclusions: For telemedicine to be effectively integrated into Romania's health care system, medical education must be adapted to include comprehensive telemedicine training. Recommendations include enhancing digital literacy, fostering public-private partnerships, and incorporating telemedicine into undergraduate and continuous professional education programs. These efforts are essential for improving healthcare access and quality through telemedicine.

telemedicine; digital health; healthcare education; micro-credentials; scoping review; health education; Romania; future healthcare; telehealth; healthcare providers; technologies; digital literacy; healthcare system; quality care

Introduction

Telemedicine in Romania has undergone significant development over the years, marked by early pilot projects, legislative advancements, and a growing recognition of its potential to transform health care delivery. Given the rapid advancements in digital health globally, understanding and improving telemedicine education in Romania will not only enhance national health care delivery but also offer insights for similar health care systems transitioning to more digital practices.

For the purposes of this study and in accordance with Romanian legislation, telemedicine is defined as the use of digital technologies to deliver medical acts such as diagnosis, treatment, and therapy performed exclusively by licensed medical professionals. This differs from telehealth, which encompasses broader health-related services, including health education, prevention, and administrative activities.

While telemedicine inherently involves medical acts performed by licensed clinicians, it relies on a collaborative team, including nonclinical professionals, to ensure efficient and comprehensive care delivery.

Several interdependent factors, including educational competencies, regulatory policies, technological infrastructure, and institutional readiness shape telemedicine education. This study adopts a theoretical framework that integrates competency-based medical education, digital health policies, and workforce development strategies to evaluate the current state of telemedicine training in Romania. The framework is informed by internationally recognized guidelines, such as the World Health Organization (WHO) Digital Health Competency Framework (DHCF), the International Society for Telemedicine & eHealth (ISfTeH) guidelines, and the European Health Telematics Association (EHTEL) recommendations, which outline essential skills and knowledge areas for telemedicine practitioners.

Within this framework, telemedicine competencies are influenced by both regulatory structures and digital readiness, which shape how educational programs can be effectively implemented. While Romania has made legislative progress in supporting telemedicine, educational curricula remain inconsistent, lacking standardized competencies and hands-on training opportunities. Furthermore, limited technological infrastructure and digital literacy among both professionals and patients present additional challenges. By assessing these dimensions, this study identifies the current gaps in telemedicine education and proposes targeted recommendations to improve training programs, ensuring alignment with international best practices.

The journey began in 2001 when the Romanian Space Agency (ROSA) launched the Demonstrative Pilot of Telemedicine. This project, a significant milestone in the country's health care history, focused on diagnostic, clinical, and educational applications, serving as a pioneering effort to explore the capabilities of telemedicine in the country. In 2003, further progress was made in establishing the Romanian Association for Telemedicine and Space Applications for Health (ATASS), which aimed to promote and develop telemedicine technologies [1].

A significant legislative milestone came in 2018 when telemedicine was formally incorporated into Romanian law through Government Emergency Ordinance number 8/2018, which amended Health Reform Law 95/2006. This legislative change aimed to address the chronic shortage of medical personnel, particularly in remote areas, and ensure more equitable access to healthcare services.

The COVID-19 pandemic in 2020 acted as a catalyst for telemedicine's rapid adoption. In response to the crisis, the Romanian government took swift and decisive action to establish a regulatory framework for telemedicine services. Government Decision 252/2020 and subsequent ordinances laid the groundwork for telemedicine during states of emergency and beyond. These regulations facilitated various telemedicine services, including teleconsultation, tele-expertise, teleradiology, and telemonitoring. By 2022, the regulatory framework had further evolved with Government Decision 1133/2022 [2], which approved comprehensive implementation norms for telemedicine. This decision standardized procedures for scheduling remote appointments, protecting data privacy, and setting up payment mechanisms through the National Health care Insurance House. These measures ensured that telemedicine services could be provided seamlessly and securely, enhancing their integration into the healthcare system.

In the last 2 years, significant financial investments have supported the expansion of telemedicine in Romania. The recovery and resilience plan allocated substantial funds, including approximately €100 million for telemedicine support and €300-€400 million for hospital digitalization. These investments underscored the government's commitment to advancing telemedicine as a critical component of health care delivery.

Despite these significant financial investments, the low levels of health and digital literacy among Romanian citizens present substantial barriers to the successful adoption and utilization of these technologies. Digital literacy for the public refers to the ability to access, understand, and use digital technologies for obtaining health information and services. For health care professionals, digital literacy extends to proficiency in using digital tools for clinical care, such as eHealth records, telemedicine platforms, and data privacy protocols.

Eurostat statistics [3] indicate that only 40% of Romanians use the internet to search for health information, significantly below the European Union average of 55%. This discrepancy highlights the role of education in digital engagement, with just 17% of individuals with low educational attainment using the internet for health purposes, compared with 41% of those with medium education and 66.5% of highly educated individuals.

The first cross-sectional study on health literacy in Romania [4] underscores the challenges faced by the population in processing health information. Approximately 21.6% of respondents found it difficult to protect themselves from illness based on health information provided by the media. Moreover, 7.5% of participants demonstrated inadequate health literacy, and 33.2% had problematic health literacy, leaving a majority (59.2%) with sufficient health literacy. Key determinants of health literacy included age, gender, education, and self-reported health status, while the residential area did not appear to influence health literacy levels. These findings underscore the considerable gaps in both health and digital literacy among the Romanian population.

Moreover, significant gaps still need to be addressed in integrating telemedicine education effectively within medical curricula, particularly in ensuring that current and future medical professionals are adequately prepared to leverage these technologies in practice. Most medical universities and medical schools have started incorporating telemedicine into their curricula, mainly as part of the medical informatics discipline, aiming to familiarize future health care professionals with digital health tools and focusing on both telemedicine's technical and ethical aspects. Professional development opportunities have also expanded, with continuous education programs incorporating modules on telemedicine. Online training

platforms and workshops have become vital resources for health care providers, helping them stay updated with the latest advancements and best practices in telemedicine. Beyond serving as a means of continuing education, these platforms often provide essential initial training for health care professionals new to telehealth, equipping them with foundational knowledge and skills.

Telehealth competency, encompassing knowledge, skills, and attitudes essential for effectively delivering care via telemedicine, is increasingly recognized as a critical aspect of modern health care practice. However, in Romania, health care professionals often lack structured and standardized training in telemedicine, resulting in gaps in areas such as conducting teleconsultations, ensuring data security, and communicating effectively with patients in virtual settings. These gaps highlight the need for targeted educational interventions to prepare health care professionals for the demands of telemedicine.

The scope of this study is confined to telemedicine, which involves clinical activities performed by physicians and other licensed medical professionals, ensuring a clear distinction from the broader concept of telehealth.

The aim of this scoping review is to evaluate the current state of telemedicine education in Romania, identify the challenges and opportunities associated with its integration into medical curricula, and provide recommendations for improving telemedicine education. Specifically, this study maps existing telemedicine education initiatives, assesses barriers to implementation, and proposes strategies to enhance training programs for health care professionals.

Methods

Study Design

This study used a scoping review methodology to comprehensively explore the current landscape of telemedicine education in Romania. The study specifically evaluates educational approaches for medical professionals performing telemedicine, addressing clinical activities such as diagnosis, therapy, and patient management. Telemedicine education evaluated in this study encompasses competencies applicable to multiple specialties, including primary care, chronic disease management, and specialized services such as telemonitoring and telerehabilitation. A scoping review was chosen for its ability to map key concepts, types of evidence, and gaps in research related to a defined area or field of interest, particularly in complex or under-reviewed topics. This approach is especially suitable for telemedicine education in Romania, given its rapidly evolving nature and the need to synthesize diverse sources of information

Research Question

The primary research question guiding this scoping review was: “What is the current state of telemedicine education in Romania, and what are the key challenges and opportunities for its integration into medical curricula?”. This question was formulated to encompass the broad scope of telemedicine education, including formal educational programs, professional development initiatives, and digital literacy efforts.

Literature Search Strategy

A systematic search of peer-reviewed journal papers was conducted across multiple databases, including PubMed, Scopus, Web of Science, and Google Scholar. The search covered articles published between January 2019 and December 2023. The following keywords and their combinations were used: telemedicine, telehealth, digital health, medical education, telemedicine education, Romania, eHealth, and digital literacy.

Additional filters were applied to include only papers available in English or Romanian, with a focus on education, telemedicine implementation, and health care policy in Romania. Papers were limited to those that addressed telemedicine within the context of health care education, the use of digital tools in clinical training, and barriers or facilitators to telemedicine adoption.

In addition to peer-reviewed papers, relevant gray literature was included in the scoping review. Sources of gray literature encompassed reports from governmental and nongovernmental organizations, policy briefs, and institutional documents related to telemedicine education in Romania. These documents were identified through searches of online repositories and institutional websites, and they provided critical context on legislative developments, pilot projects, and educational initiatives that may not have been extensively covered in academic databases.

Study Selection

The study selection process involved 2 independent researchers (MF and VR) who screened titles, abstracts, and full texts to ensure alignment with the inclusion and exclusion criteria. Any disagreements were resolved through discussion, and when consensus could not be reached, a third researcher reviewed the articles to make the final decision. The process was facilitated using Rayyan platform, allowing efficient tracking and documentation of the selection process.

The initial search yielded 105 journal papers, screened for relevance based on titles and abstracts. Articles that focused on telemedicine in clinical practice without addressing educational aspects were excluded. After this preliminary screening, 35 papers remained for full-text review. A further screening based on inclusion and exclusion criteria led to the identification of 19 papers deemed highly relevant to the study’s aims.

Eligibility Criteria

The inclusion and exclusion criteria are listed in Textbox 1.

Textbox 1. Inclusion and exclusion criteria

Inclusion criteria

- Studies published between 2019 and 2023.
- Studies addressing telemedicine education or digital literacy training in medical or health care fields.
- Studies conducted in or relevant to the Romanian context.

Exclusion criteria

- Articles focusing exclusively on telemedicine in clinical practice without reference to education.
- Studies not available in English or Romanian.

Data Extraction

For each of the 19 selected peer-reviewed papers, data were extracted using a standardized data charting form, which included the following variables: (1) author(s), publication year, and country of origin; (2) study design (eg, qualitative, quantitative, and mixed methods); (3) the focus of the study (eg, telemedicine education, barriers to digital health adoption, and telemedicine curriculum development); (4) key findings relevant to telemedicine education, digital literacy, and health care training; and (5) recommendations for telemedicine integration into medical education.

Data Analysis

Two independent researchers conducted a thematic analysis to identify recurring patterns and themes within the selected literature. An inductive approach allowed themes to emerge naturally from the data. The analysis involved coding and categorizing data using manual methods, followed by a review of the themes to ensure consistency and relevance. The themes were grouped into broad categories, such as the current status of telemedicine education in Romania, barriers to telemedicine education, opportunities for development, and digital literacy challenges.

Ethical Considerations

Since this study was based on a review of publicly available literature, no ethical approval was required. However, all articles were reviewed with a commitment to academic integrity and transparency, and any potential conflicts of interest were disclosed.

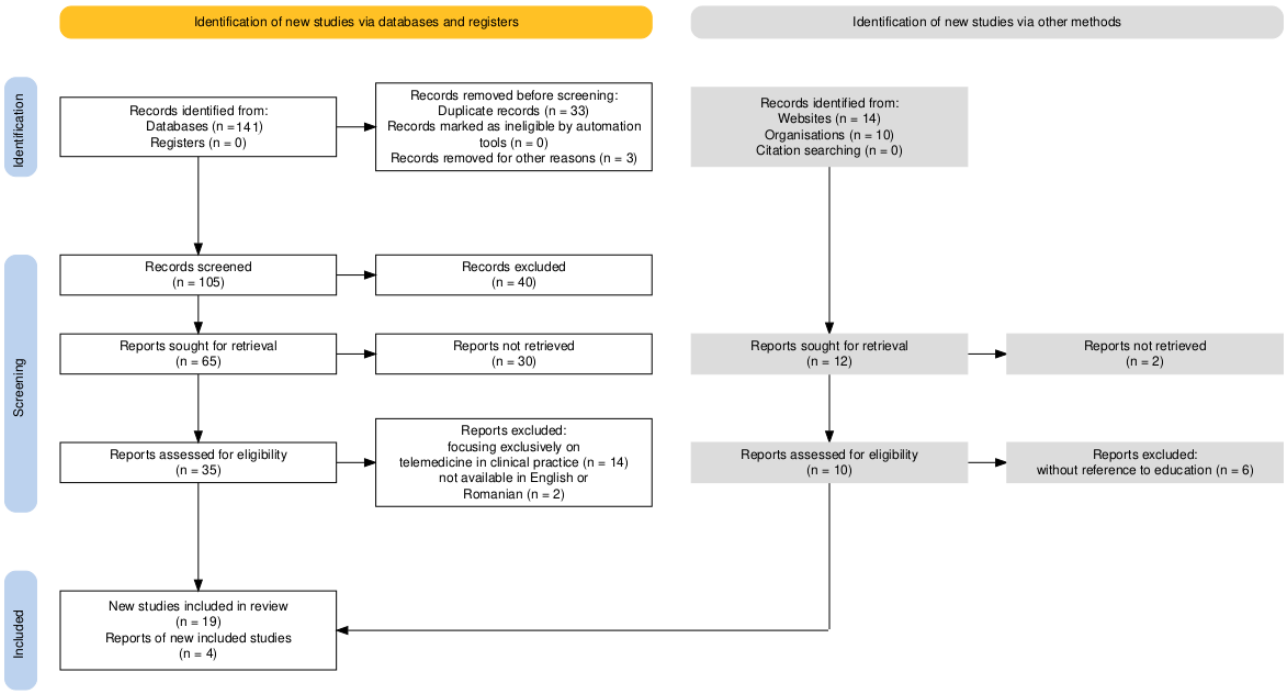
Results

Included Studies

The initial search yielded 105 journal papers, screened for relevance based on titles and abstracts. Articles that focused on telemedicine in clinical practice without addressing educational aspects were excluded. After this preliminary screening, 35 papers remained for full-text review. A further screening based on inclusion and exclusion criteria led to the identification of 19 papers deemed highly relevant to the study's aims (Figure 1 and Checklist 1) .

The results presented are based on themes identified through inductive thematic analysis, which highlighted key areas such as the integration of telemedicine into curricula, barriers to adoption, and digital literacy as a critical enabler for telemedicine education.

Figure 1. PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) flowchart for identification and selection of studies.



Current State of Telemedicine Education in Romania

The data collected and synthesized in Table 1 offers a comprehensive overview of recent research in telemedicine, eHealth, and artificial intelligence (AI)-based health care interventions in Romania. It includes various study designs such as cross-sectional, prospective, case-control, and system architecture studies and spans diverse health care topics, including telemedicine-driven rehabilitation, the impact of virtual communities on telemedicine adoption, and the integration of AI and Internet of Things (IoT) technologies in health care. The analysis covers key aspects of telemedicine's role during and post–COVID-19 and its relevance for both chronic diseases and mental health management. The studies underscore the positive reception of telemedicine in various medical fields, from diabetes management to cardiac rehabilitation, with the technology being especially vital during the COVID-19 pandemic. However, challenges such as digital literacy, accessibility, and infrastructure remain.

While Table 1 provides a summary of the reviewed studies, the specific components of telemedicine education and digital literacy training are discussed in greater detail within the following subsection, to align with the thematic approach of this scoping review.

Table . Overview of recent research in telemedicine, eHealth, and artificial intelligence–based health care interventions in Romania [5-23].

PMID	The focus	Key findings	Recommendations
35879930 [5]	Openness of medical students to telemedicine	Moderate-to-high acceptance, need for practical exposure	Integrate telemedicine into medical curricula, enhance digital literacy
35935629 [6]	Evaluating telemedicine benefits for cardiovascular patients during COVID-19.	Telemedicine facilitated patient management, including medication adjustments, but barriers like data security and reimbursement need addressing.	Improve telemedicine frameworks and regulations for cardiovascular care beyond the pandemic.
37297692 [7]	Perceptions of telemedicine among health care professionals	Positive outlook, concerns over digital literacy	Increase digital education for health care professionals
37510969 [8]	Telemedicine-driven pulmonary rehabilitation for post–COVID-19	Significant improvement in physical and mental health	Integrate telerehabilitation into postacute COVID-19 management
36141685 [9]	AI[a] in eHealth, telemedicine, and remote monitoring	AI advances in eHealth and telemedicine	Enhance integration of AI into eHealth for better health care services
36141899 [10]	Home-based robotic cardiac telerehabilitation system	RoboTeleRehab system is feasible, positive feedback	Further testing on cardiac patients, integration into rehabilitation programs
33923842 [11]	Blockchain-enabled framework for mHealth[b] systems	Improves security, transparency, and immutability	Implement blockchain for secure patient data management in mHealth
35062129 [12]	AI in primary care and telemedicine	AI aids in primary care diagnosis, treatment, and decision-making	Enhance AI systems to support primary care and telemedicine workflows
36141297 [13]	Impact of virtual communities on telemedicine usage	Virtual communities influence patient satisfaction and usage intention	Use virtual communities to promote telemedicine services
35954526 [14]	Adoption of eHealth and mHealth for mental health	Accessibility and data security are critical for adoption	Improve accessibility and data security in digital mental health tools
36556027 [15]	Management of dilated cardiomyopathy during COVID-19 using telemedicine	Telemedicine maintains clinical stability in patients with home monitoring	Use multiparametric home monitoring to manage dilated cardiomyopathy during crises
33953605 [16]	Perception of Romanian family doctors on telemedicine during COVID-19	Positive view, but tele-diagnostic challenges and time constraints	Training for family doctors and continued telemedicine reimbursement
34898981 [17]	Assessing patient adherence to telemedicine in diabetes	Developed reliable and valid tool for telemedicine adherence in diabetes care	Use the instrument to optimize telemedicine platforms based on patient needs
35150518 [18]	Attitudes toward eHealth during the COVID-19 pandemic	Negative attitudes in Greece due to forced usage	Address technical skills gaps and improve ease of access
37372846 [19]	Telemonitoring for cardiovascular disease during and post-COVID-19	Telemedicine improved cardiovascular prevention during the pandemic	Universal access to home telemonitoring for high-risk cardiovascular patients
36900948 [20]	Virtual assistant in cardiac rehabilitation	Similar results for virtual versus in-person rehabilitation	Optimize virtual assistants for cardiac rehab
33800728 [21]	IoT[c]-based biometric monitoring system for elders	Scalable solution for monitoring and cognitive assessment	Expand to predictive analysis for cognitive and physiological data
35979169 [22]	Telerehabilitation for Parkinson disease	Improved walking performance using telerehabilitation	Expand telerehabilitation for other neurorehabilitation settings
31407668 [23]	Use of telemedicine for rare diseases in Romania	Telemedicine improves access to rare disease care	Increase telemedicine use for remote consultations in rare diseases

[a]AI: artificial intelligence.

[b]mHealth: mobile health.

[c]IoT: Internet of Things.

University Programs and Curricula

In Romania, prominent medical universities in Timisoara, Cluj-Napoca, Iasi, and Bucharest have incorporated telemedicine and digital health into their educational programs. These changes were particularly accelerated following the COVID-19 pandemic, which highlighted the need for digital health competencies among health care professionals. New curricula encompass various aspects, such as telemedicine applications, electronic health records (EHRs), and data management strategies. Despite these inclusions, the development of dedicated disciplines and laboratory classes specific to telemedicine remains ongoing.

While telemedicine education in Romania has introduced theoretical foundations and basic digital health tools, it remains limited in scope and practical application. Key gaps include the lack of hands-on training, comprehensive and stand-alone telemedicine courses, and interprofessional education initiatives. Furthermore, advanced topics such as AI and patient engagement strategies remain underexplored, emphasiing the need for structured and innovative approaches to telemedicine education.

On October 14, 2023, the Center for Innovation and e-Health at the University of Medicine and Pharmacy “Carol Davila” in Bucharest hosted a specialized course titled “Telemedicine - Current Information and Skills.” [24]. This initiative covers fundamental theoretical concepts of telemedicine, including applicability and legal frameworks, alongside practical skills for using associated technologies.

Many health care professionals participate in continuing medical education (CME) programs to stay updated on telemedicine. These programs focus on skills for telemedicine platforms, data privacy laws, and improving remote patient interaction. The Digital Innovation Zone Association [25], affiliated with the North-East Regional Development Agency, offers comprehensive 1- to 2-month programs delivered in a hybrid online and on-site format.

A significant milestone in telemedicine education within the country was marked by the launch of the Erasmus+ project “TEAM: Supporting Innovation in Telemedicine Education with Cross-European Collaboration” in November 2023. The University of Medicine and Pharmacy “Victor Babes” in Timisoara is a principal participant in this consortium, which also includes partners from Belgium, Slovenia, Croatia, Greece, and Ukraine. The project aims to develop adaptable learning pathways that conform to international best practices, focusing on surmounting challenges such as limited digital literacy and fostering cross-sectoral cooperation. Targeting higher education students in health care and IT, educators, and institutions, the project also extends its reach to health care and IT professionals and policymakers. One of the primary outcomes of this initiative is the establishment of flexible microcredentials in Telemedicine designed to enhance proficiency in digital health among students and professionals alike.

Professional Development Workshops and Seminars

Universities and health care institutions in Romania proactively conduct workshops and seminars to offer practical training in telemedicine technologies. These educational sessions frequently use case studies and practical simulations to enrich the learning experience. They cover a spectrum of topics, from fundamental telemedicine principles to advanced applications such as the integration of AI tools in clinical settings.

Across Romania, hospitals and medical associations also organize workshops and seminars aimed at practicing health care professionals. These sessions foster proficiency in telemedicine platforms, digital communication skills, and data security. Participants, including doctors, nurses, and ancillary staff, benefit from the self-paced learning environment these workshops provide. They typically include hands-on sessions where attendees can interact with telemedicine software, acquire best practices for conducting virtual consultations, and gain insights into the legal and ethical dimensions of remote health care.

A notable initiative was the establishment of the ROHEALTH cluster in 2015, which brought together various entities within the health and bioeconomy sectors to enhance their competitive edge. This cluster supports an online platform offering diverse courses and webinars, including specialized offerings such as “eTELEDOC, emergency telemedicine” [26]. These resources aim to bolster the competencies of health care professionals in the evolving landscape of telemedicine.

Digital Literacy Programs

Several nongovernmental organizations offer training programs and workshops to enhance digital literacy among health care providers. Initiated in 2022 by PALMED, the Patronage of Private Medical Service Providers, the project titled “Digital Skills for Employees - Support for SMEs in the Health Sector to Assimilate Technologies and Develop Telemedicine Services (TELMed)” is a notable endeavor under the Human Capital Operational Program for 2014–2020 [27]. This project specifically aims to augment the digital competencies of personnel across 35 small and medium-sized enterprises in the health care sector, including hospitals, clinics, offices, and laboratories. By enhancing these skills, the initiative not only supports the adaptation and expansion of telemedicine activities but also prepares the workforce for advancements related to Industry 4.0 and smart specialization areas.

Challenges in Telemedicine Education

The challenges identified in this section were derived from thematic analysis of the 19 peer-reviewed papers and relevant gray literature, including institutional reports and policy briefs. These sources highlighted common barriers such as limited digital literacy among health care professionals, the lack of standardized curricula, and inadequate infrastructure for telemedicine training.

The pandemic propelled telemedicine into prominence, shedding light on Romanian family doctors’ diverse experiences and perceptions [16]. Over a quarter of general practitioners reported that remotely addressing patients’ health care needs was more manageable, demonstrating adaptability to telemedicine modalities. Nevertheless, challenges such as the time-intensive nature of teleconsultations, diagnostic uncertainties, and patients’ difficulties with technology have surfaced. These issues highlight the critical need for specialized training programs in

telemedicine for both health care professionals and patients to mitigate disruptions in health care delivery effectively.

Furthermore, the moderate-to-high acceptance of telemedicine among Romanian medical students emphasizes the necessity of integrating telemedicine education early in their medical training. Telemedicine fundamentally transforms the patient-physician relationship, requiring physicians to develop new communication skills, known as "webside manner." The methodological norms for telemedicine services in Romania also emphasize the importance of well-trained professionals who can navigate legal, ethical, business, and practical challenges. Training should start at the undergraduate level and continue through all professional stages for medical staff in all specialties.

While the primary objective of this paper is to explore telemedicine education for health care professionals, patient experiences with telemedicine offer indirect yet critical insights. These experiences highlight areas where health care providers may require additional training, such as building virtual rapport, managing technological issues, and addressing patient concerns about telemedicine efficacy and privacy. Integrating these considerations into training programs can better align telemedicine education with real-world practice.

In 2021, a study [17] evaluating the desirability, acceptability, and adherence to telemedicine among diabetes patients underscores the need for educational programs. Such initiatives targeting patients are essential to foster a positive perception and readiness to use telemedicine services, particularly in chronic conditions like diabetes, where continuous care and monitoring are essential. Patients, particularly those managing chronic diseases, require thorough education to use virtual technology effectively, including understanding how to operate software and hardware, such as mobile communication devices and other digital interfaces essential for remote health care.

Discussion

Principal Findings

This scoping review identified significant gaps in telemedicine education in Romania, despite recent legislative and infrastructural advancements supporting telemedicine adoption. While some medical universities have incorporated telemedicine content into their curricula, there remains a lack of structured, hands-on training and dedicated telemedicine courses. The study also highlighted key barriers, including limited digital literacy among health care professionals, insufficient policy support for mandatory telemedicine training, and a lack of standardized competency frameworks. These findings underscore the need for formalized telemedicine education initiatives, integrated into both undergraduate and CME programs, to enhance digital health preparedness among health care providers.

The findings of this scoping review highlight the significant progress and persistent challenges in telemedicine education in Romania. This discussion will interpret these results, explore their implications, and propose strategies for advancing telemedicine education in the country. To advance telemedicine in Romania, several strategic directions need to be pursued.

Medical schools must develop comprehensive programs that include hands-on training with telemedicine platforms and technologies, such as conducting teleconsultations or using telemonitoring devices in simulated or real clinical environments. The launch of specialised courses and international collaborations, such as the Erasmus+ TEAM project, demonstrates a commitment to enhancing telemedicine education.

In Romania, health care professionals are required by law to participate in CME programs to retain their licenses. While telemedicine-specific education is not yet a mandatory component of these requirements, its growing integration into CME programs highlights the recognition of telemedicine as an essential skill set for modern medical practice. This approach aligns with recommendations from the EHTEL, which emphasizes the importance of ongoing training in digital health for all health care providers [28]. The involvement of industry clusters like ROHEALTH in providing specialized webinars indicates a promising collaboration between academia and industry.

However, the review also suggests that these efforts may not be sufficient to meet the rapidly evolving needs of the health care system. There appears to be a need for more structured, comprehensive, and widely accessible professional development programs in telemedicine. While beneficial for updating specific skills, self-directed CME is often insufficient in providing a holistic understanding of telehealth practice. Without structured education, health care professionals may lack critical knowledge of professional telehealth standards, guidelines, and best practices, placing them at risk of learning by trial and error. Comprehensive, formalized training programs are essential to equip professionals with the competencies needed to deliver high-quality, safe, and effective telehealth care.

The identified gaps in digital literacy among both health care providers and patients represent a significant barrier to the effective implementation of telemedicine. The initiatives aimed at enhancing digital skills, such as PALMED's "Digital Skills for Employees" project, are steps in the right direction. These efforts align with European Union–wide initiatives like the Digital Education Action Plan (2021 - 2027) [29], which emphasizes the importance of digital skills across all sectors, including health care. However, these efforts need to be scaled up and integrated more systematically into both medical education and public health initiatives. The review also highlights the need for patient education in telemedicine, particularly for managing chronic conditions. In addition, robust policy support, increased public awareness, and education are crucial for the effective implementation of telemedicine, ultimately improving health care access and outcomes across Romania.

To fully realize the benefits of telemedicine, regulatory bodies in Romania should consider introducing mandatory education requirements for telemedicine practice. While technological proficiency is an important component of telemedicine education, health care professionals must also develop a broader range of competencies to provide effective telehealth care. These include clinical decision-making, patient communication, and

understanding the ethical and legal dimensions of telemedicine. Incorporating recognized telemedicine competency frameworks into educational programs can ensure comprehensive preparation for future telehealth practitioners.

Telemedicine is pivotal in advancing integrated care by fostering coordination among health care professionals and enabling patient-centered approaches. To fully realize its potential, telemedicine education must include interprofessional education and training for collaborative care, equipping health care teams with the skills to work cohesively in delivering seamless and effective telehealth services [30].

The results highlight a diverse range of technologies relevant to telemedicine education, including mobile health platforms, IoT devices, EHR systems, and continuous monitoring technologies. Although only a minority of reviewed studies explicitly addressed AI, its inclusion underscores the importance of preparing professionals for future technological advancements. While AI is not yet pervasive in all areas of health care, equipping professionals with foundational knowledge will prepare them for its growing integration into clinical practice.

Creating a thorough telemedicine education program necessitates teamwork between health care professionals, educators, technology specialists, and policymakers. Collaborating can help ensure the curriculum meets health care system needs, includes cutting-edge telemedicine technologies, and prepares providers and patients for future health care delivery.

Implications of Findings

To close the skills gaps, it is essential to develop educational programs that address the points mentioned below.

Improve Digital Literacy

Training must concentrate on enhancing the digital skills of health care professionals and patients so they can successfully navigate eHealth and mobile health platforms. While improving, digital literacy among Romanian health care professionals remains largely dependent on voluntary initiatives such as webinars, workshops, and seminars. This fragmented approach highlights the need for structured and comprehensive education programs to ensure that professionals are fully equipped to leverage telemedicine technologies effectively.

Integrates AI Technologies

Educational initiatives must cover foundational AI and machine learning (ML) concepts relevant to health care applications, including data privacy, ethical considerations, and interpreting AI-generated insights.

Develop New Skills

Training for telemedicine should include soft skills such as remote patient interaction, digital communication etiquette, and managing online patient relationships to adapt to remote health care dynamics. It also includes educating patients on how to use telemedicine services, getting ready for virtual visits, and handling their health data online.

Promote Trust in the Efficacy of Telemedicine

The research suggests the importance of increasing trust among health care providers and patients regarding telemedicine's effectiveness. For that purpose, telemedicine training should cover not only the technical aspects but also the clinical relevance and influence on patient outcomes, especially in managing chronic conditions.

Deal With Ethical and Privacy Concerns

Telemedicine training should incorporate adherence to recognized telehealth and telemedicine standards and guidelines, such as GDPR (General Data Protection regulations) and those created by the International Society for Telemedicine and eHealth [31]. Training should address ethical issues, privacy concerns, legal regulations, patient privacy protection strategies, and ethical guidelines for virtual patient interactions, ensuring alignment with global best practices.

Limitations and Future Directions

This scoping review, while comprehensive, has certain limitations. The focus on English and Romanian language publications may have excluded relevant studies in other European languages. In addition, the rapid evolution of telemedicine, particularly in response to the COVID-19 pandemic, means that some recent developments may not be fully captured in the published literature.

Future research should focus on (1) longitudinal studies assessing the long-term impact of telemedicine education on health care delivery and outcomes in Romania; (2) comparative analyses of telemedicine education approaches across different European countries, particularly comparing Eastern and Western European contexts; and (3) in-depth qualitative studies exploring the experiences and perspectives of medical students, health care providers, and patients regarding telemedicine education and implementation in the Romanian and broader international context.

Conclusion

Despite significant advancements, telemedicine in Romania still faces challenges. Infrastructure deficiencies, digital literacy gaps, and regulatory hurdles remain significant obstacles. However, ongoing investments in infrastructure, education, and regulatory frameworks are expected to address these issues, paving the way for broader adoption of telemedicine and improved health care access across the country.

The integration of telemedicine into medical education in Romania is crucial for the future of health care delivery. By addressing the current challenges and learning from successful global models, Romania can enhance its telemedicine capabilities and ensure that health care providers are well-prepared to leverage telemedicine technologies to improve health care access and quality. Moving forward, efforts should focus on enhancing digital health literacy, optimizing telemedicine systems, and expanding the use of AI and IoT for more integrated health care.

The future of telemedicine in Romania looks promising. As the country continues to invest in telemedicine education and infrastructure, health care providers will be better prepared to

leverage digital health technologies, ultimately enhancing the quality and accessibility of health care services for all Romanians.

Acknowledgments

We would like to acknowledge Victor Babes University of Medicine and Pharmacy Timisoara for their support in covering the costs of publication for this research paper. Part of the activities described in this manuscript were supported by funding from the EU Erasmus+ program under the TEAM project.

Abstract

Background: Technological advancements have significantly reshaped health care, introducing digital solutions that enhance diagnostics and patient care. Artificial intelligence (AI) stands out, offering unprecedented capabilities in data analysis, diagnostic support, and personalized medicine. However, effectively integrating AI into health care necessitates specialized competencies among professionals, an area still in its infancy in terms of comprehensive literature and formalized training programs.

Objective: This systematic review aims to consolidate the essential skills and knowledge health care professionals need to integrate AI into their clinical practice effectively, according to the published literature.

Methods: We conducted a systematic review, across databases PubMed, Scopus, and Web of Science, of peer-reviewed literature that directly explored the required skills for health care professionals to integrate AI into their practice, published in English or Spanish from 2018 onward. Studies that did not refer to specific skills or training in digital health were not included, discarding those that did not directly contribute to understanding the competencies necessary to integrate AI into health care practice. Bias in the examined works was evaluated following Cochrane's domain-based recommendations.

Results: The initial database search yielded a total of 2457 articles. After deleting duplicates and screening titles and abstracts, 37 articles were selected for full-text review. Out of these, only 7 met all the inclusion criteria for this systematic review. The review identified a diverse range of skills and competencies, that we categorized into 14 key areas classified based on their frequency of appearance in the selected studies, including AI fundamentals, data analytics and management, and ethical considerations.

Conclusions: Despite the broadening of search criteria to capture the evolving nature of AI in health care, the review underscores a significant gap in focused studies on the required competencies. Moreover, the review highlights the critical role of regulatory bodies such as the US Food and Drug Administration in facilitating the adoption of AI technologies by establishing trust and standardizing algorithms. Key areas were identified for developing competencies among health care professionals for the implementation of AI, including: AI fundamentals knowledge (more focused on assessing the accuracy, reliability, and validity of AI algorithms than on more technical abilities such as programming or mathematics), data analysis skills (including data acquisition, cleaning, visualization, management, and governance), and ethical and legal considerations. In an AI-enhanced health care landscape, the ability to humanize patient care through effective communication is paramount. This balance ensures that while AI streamlines tasks and potentially increases patient interaction time, health care professionals maintain a focus on compassionate care, thereby leveraging AI to enhance, rather than detract from, the patient experience.

(JMIR Med Educ 2025;11:e58161) doi:10.2196/58161

KEYWORDS

artificial intelligence; healthcare competencies; systematic review; healthcare education; AI regulation

Introduction

Technological advancements have transformed health care, improving diagnostics and patient care through solutions such as diagnostic support systems and telemedicine. These technologies reduce costs and enhance care quality, but their adoption faces challenges, particularly in terms of infrastructure, training, and education [1,2]. To address these challenges, the European Commission's DigComp framework [3] outlines key competencies needed to adapt to new technologies, with a particularly challenging issue being the integration of artificial intelligence (AI) into health care.

AI systems use complex algorithms to analyze large datasets, identify patterns, and improve decision-making [4]. AI

classification is multifaceted. The European Commission distinguishes between AI software, such as virtual assistants, and AI embedded in physical devices, such as robots [3]. Alternatively, Russell and Norvig's [5] taxonomy assesses AI based on cognitive and behavioral capabilities, differentiating systems that emulate human or rational thought and action.

Each AI approach is designed to refine its problem-solving abilities, whether by mimicking human behavior or optimizing logical decisions [4]. AI improves clinical decision-making by addressing human limitations in data processing, supporting evidence-based practices through technologies such as machine learning and deep learning [6]. Various AI applications, such as image processing and convolutional neural networks, enhance clinical outcomes [6].

While human interaction remains central to health care, AI mitigates cognitive biases and provides faster, more precise outcomes [7]. For example, AI can process millions of medical images far faster than a human radiologist, improving accuracy through continual learning [6].

The integration of AI into health care is not just a technological advancement but a profound transformation of the operational, cultural, and ethical frameworks of health care organizations. This shift requires professionals to develop specialized knowledge in AI disciplines, such as machine learning, deep learning, and natural language processing, to use these tools effectively and ethically [8].

AI's integration demands expertise and regulatory oversight to ensure ethical use, bias mitigation, and privacy protection [9]. The US Food and Drug Administration is exploring regulatory frameworks for AI-based algorithms in medicine, though a definitive process has yet to be established [10]. A recent study in *JAMA Ophthalmology* [11,12] highlighted the risks of AI misuse, including sophisticated models such as ChatGPT. Professionals are essential in identifying data falsifications that may not be evident to untrained individuals [12].

Addressing these challenges requires a concerted effort to enhance AI literacy and redesign clinical processes, fostering synergy between human judgment and AI-augmented decision-making [13,14]. This transition demands rigorous training in technical, procedural, and collaborative skills to ensure health care professionals can effectively integrate AI into practice, enabling them to adapt to the evolving technological landscape and improve clinical practice [15].

Numerous studies have explored the integration of AI in medical education, demonstrating its potential to enhance practical skills and personalize the learning experience for students. However, most of these reviews focus on the application of AI to improve medical education [16], which examines the use of various AI methods to enhance training in different medical domains.

Some studies [17] propose that training health care professionals in AI requires specialized roles, such as health information management professionals, to manage and adapt AI technologies in clinical settings. This approach ensures that AI integration occurs safely and efficiently, considering data quality, ethical, and legal aspects.

A review of how training programs for health care professionals deal with AI shows both the relatively low number of programs available and their significant limitations [18]. The authors recommend future curricula be designed with AI-related core competencies in mind.

This review aims to identify and highlight the critical competencies necessary to guide the development of educational programs designed to optimize the use of AI in clinical settings, thus addressing a growing need at the intersection of medicine and technology. By analyzing and synthesizing the existing literature on AI training for health care professionals, our goal is to provide a comprehensive framework that informs continuous education and specialized training in AI, ensuring the safe and effective implementation of these advanced technologies in daily clinical practice.

The integration of AI into health care presents several critical challenges. This study aims to consolidate and articulate the specific skills and knowledge required for health care professionals to effectively implement AI in routine clinical practice. Our research question is as follows: "In healthcare professionals, what specific skills and competencies are necessary for the effective implementation and use of AI technologies in daily clinical practice compared to their current skill set?" This question focuses on identifying and defining the critical competencies required for health care professionals to effectively use AI, providing a solid foundation for the development of educational and training programs in this emerging field.

Methods

Study Design

In conducting a systematic review between November and December 2023, we adhered to the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) guidelines [19] (Multimedia Appendix 1 and Checklist 1).

Data Sources and Search Strategy

Comprehensive searches were performed across databases including PubMed, Scopus, and Web of Science, using Health Science Descriptors and Medical Subject Headings descriptors pertinent to AI in health care and associated skills. The search strategy was refined using Boolean and truncation operators. The search queries included combinations such as ("Artificial Intelligence" OR "AI") AND "Healthcare Professionals" AND ("Skills" OR "Competencies" OR "Education"), ("Artificial Intelligence" OR "AI") AND ("data analysis" OR "ethical considerations").

Inclusion and Exclusion Criteria

We established specific selection criteria, prioritizing peer-reviewed original articles, review articles, editorials, and commentaries that directly explored the required skills for health care professionals to integrate AI into their practice. Regarding the inclusion criteria, studies were considered if they: were published in English or Spanish, taking advantage of the linguistic accessibility for the research team in order to reflect the possible specific characteristics of the Spanish-speaking

community; published from 2018 onward, to ensure the relevance and timeliness of the research given the rapid advancements in AI technologies in recent years; focused on the necessary skills for the effective use of AI by health care professionals, encompassing both technical and management competencies; and included aspects related to training in digital health, highlighting the importance of specific training in the use of emerging technologies.

Conversely, studies were excluded if they did not meet these criteria: studies written in languages other than English or Spanish, as they could not be accurately analyzed by the research team; studies published before 2018, to focus on the most recent trends in AI in health care; studies not specifically related to the skills or needs of health care professionals for the use of AI tools, excluding research that did not directly address this focus; and studies that did not refer to specific skills or training in digital health, discarding those that did not directly contribute to understanding the competencies necessary to integrate AI into health care practice.

This selection methodology was designed to identify studies that provided significant evidence on the key competencies health care professionals need to develop for effectively integrating AI into their clinical practice, thus, ensuring that the systematic review focused on research offering practical and applicable insights.

Data Extraction and Study Quality Assessment

The search strategy was developed iteratively to optimize the retrieval of relevant studies. An initial search used the aforementioned databases and descriptors. Titles and abstracts underwent rigorous review for relevance by 2 independent researchers (JG-G and CLS-B), with duplicates removed and articles not meeting inclusion criteria or fitting exclusion criteria discarded. Mendeley (Elsevier Ltd) served as the reference management tool, not involved in the data extraction process.

Subsequently, full-text articles were retrieved for an in-depth content review based on the inclusion criteria specified earlier. However, 3 articles were not retrievable despite repeated efforts. Two articles were inaccessible due to subscription restrictions, and attempts to obtain them via interlibrary loans were unsuccessful. The third article had a broken link, and the authors were unresponsive after multiple contact attempts. These articles have been documented in the “reports not retrieved” section of the PRISMA flow diagram in the Results section.

To assure methodological integrity, discrepancies were resolved through consultation with a third researcher (JLS), reaching consensus on study admissibility. The screening process was manual, without the use of automation tools, and each study was carefully evaluated. Mendeley was used again for reference management, without affecting the data extraction process. The PRISMA flow diagram is provided in the Results section.

Data were extracted and synthesized from eligible studies, encompassing details such as authors, publication year, study design, identified skills, and methodological quality assessment. Tables served as the primary method for tabulating and visually presenting the results and their synthesis.

The data search spanned all pertinent dimensions of these outcomes, including variables relevant to the analyzed studies. These variables covered aspects such as humanization, social skills, and participants’ AI usage experience, offering a comprehensive perspective on the competencies necessary for integrating AI into health care practices.

The GRADE (Grading of Recommendations Assessment, Development, and Evaluation) framework [20] was applied to assess the evidence quality of the included works, considering the quality of studies, result consistency, imprecision, potential bias, and other pertinent factors. Mixed methods or qualitative studies were appraised using the mixed methods appraisal tool [21].

Bias in the examined works was evaluated following Cochrane’s domain-based recommendations [22], considering five types of bias, each with its domains. Bias risk was independently assessed by at least 2 reviewers, with discrepancies resolved via discussion or consultation with a third reviewer when necessary.

Synthesis Method

The research question guided the synthesis groupings, focusing the analysis on the skills and competencies necessary for the effective implementation of AI technologies by health care professionals. No standardization metric was applied. The synthesis method involved extracting relevant sections of the studies related to the identified skills and competencies. Overall, the risk of bias assessment of the studies showed no critical results. Consequently, the included studies were synthesized with equal weight.

The categorization of skills and competencies was based on a qualitative synthesis approach, where 2 independent reviewers extracted and coded data from each study. The categories were developed iteratively by grouping competencies that were conceptually aligned. The final domains were determined based on the frequency with which competencies appeared across the studies, with higher-frequency competencies categorized as key domains. For example, “AI fundamentals” and “ethical and legal considerations” were identified as critical due to their frequent mention in the selected studies, whereas others such as “data governance” and “programming” appeared less often but were still considered relevant.

Study design was not restricted, so a meta-analysis was not performed due to the heterogeneity of the studies and the differing amounts and qualities of information reported on skills and competencies. The reported effectiveness of the competencies was synthesized based on each study’s findings. The identified competencies are presented in the results section. Tables and figures aggregate information about this study’s characteristics and focal areas of this review (skills and competencies).

This review aimed to identify and delineate the skills and competencies essential for health care professionals to use AI in their clinical practices effectively. The objective encompassed various outcome domains, not limited to interpreting results from machine learning models, managing AI biases, ethical

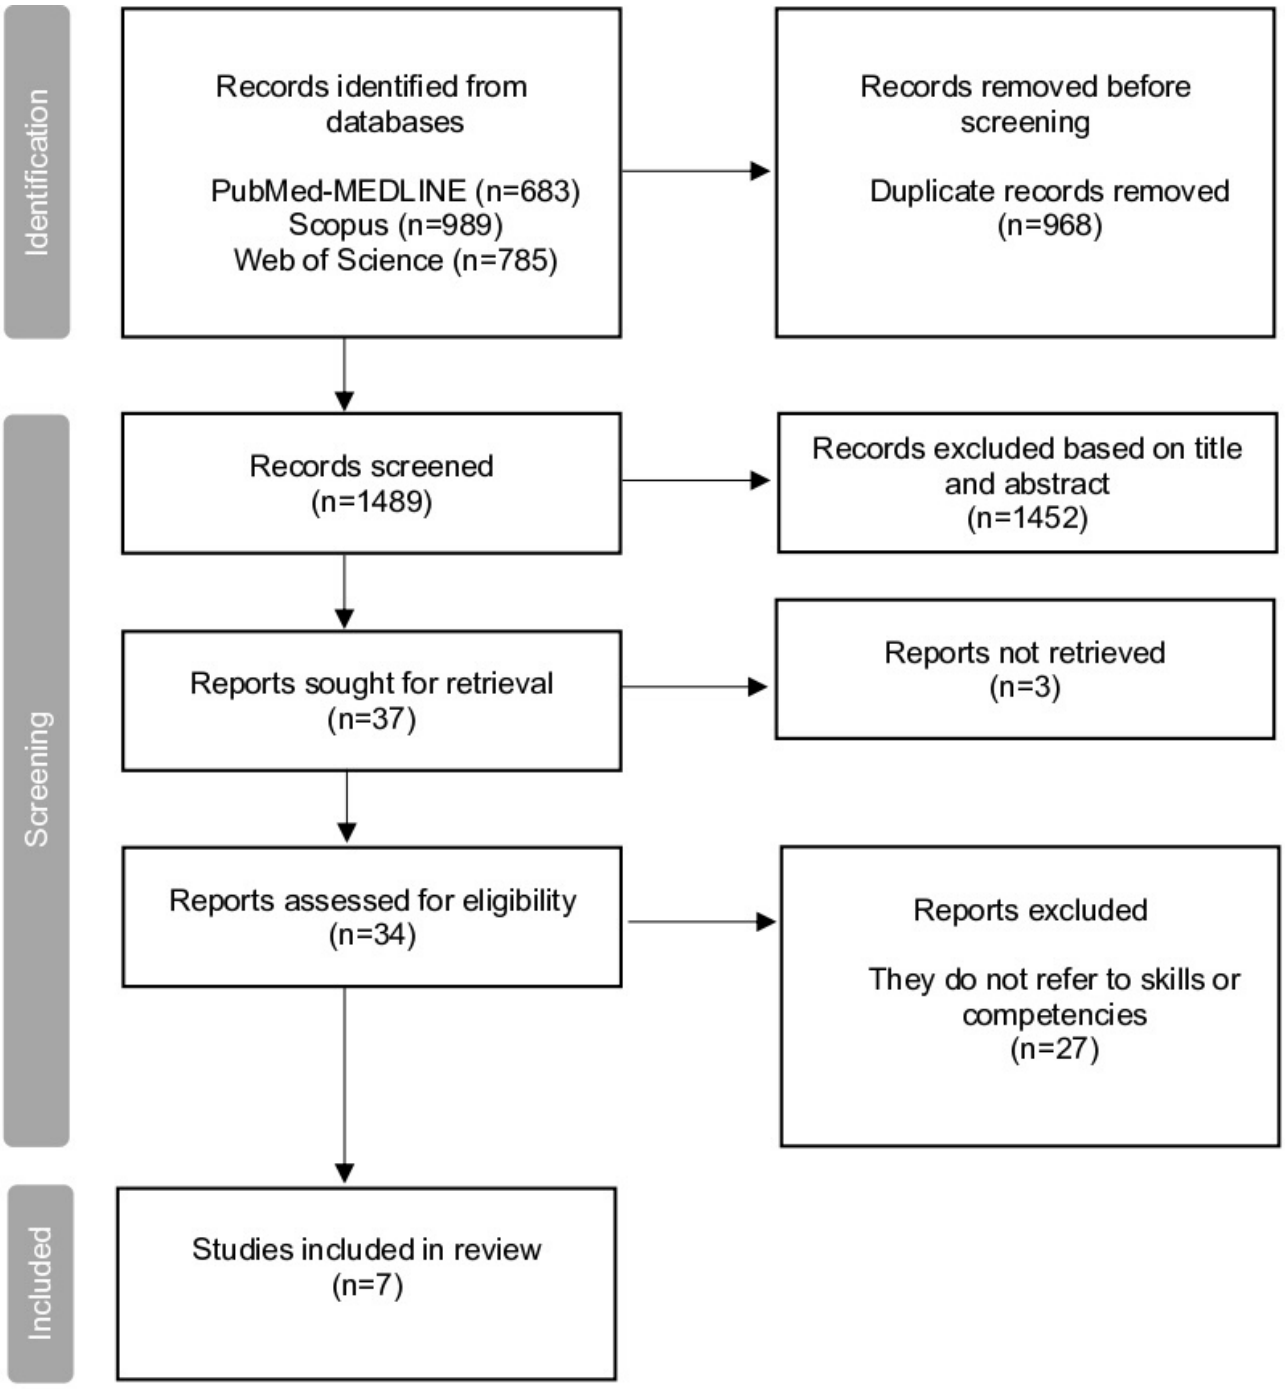
considerations in AI-assisted decision-making, and the technical skills required for effective AI tool use.

Results

Overview

The initial database searches yielded a total of 2457 articles (Figure 1). After deleting duplicates and screening titles and abstracts, 37 articles were selected for full-text review. Out of these, only 7 met all the inclusion criteria for this systematic review [23-29]. Each selected article specifically concentrated on the competencies essential for the integration of AI into routine clinical practice. A substantial number of the excluded articles (n=28) made reference to, but did not directly engage with, the competencies in question. Table S1 in Multimedia Appendix 1 delineates the characteristics of these studies and the principal competencies identified therein.

Figure 1. PRISMA flow diagram. PRISMA: Preferred Reporting Items for Systematic Reviews and Meta-Analyses.



The review identified a diverse range of skills and competencies necessary for the effective implementation of AI in health care. These competencies were categorized into several key areas based on their frequency of appearance in the selected studies. The identified skills, definitions, and the number of studies that reported each are summarized in Table S2 in Multimedia Appendix 1.

Identified Skills

The analysis of the selected studies highlights several key competencies deemed essential for the effective integration of AI into routine clinical practice.

AI fundamentals were identified as an essential competency by 86% of the studies [23-27,29]. This indicates a strong consensus on the importance of foundational AI knowledge for health care professionals. The studies emphasize that a solid understanding of AI principles is crucial for effectively implementing and using AI technologies in clinical settings. This foundational knowledge forms the bedrock upon which more advanced competencies are built, ensuring that professionals can confidently engage with AI tools and integrate them into their practice.

Ethical and legal considerations were emphasized by 71% of the studies [23-26,29]. The studies underscored the importance of having a solid knowledge base in various aspects of ethics, including patient privacy, data security, biases in algorithms, and transparency and explainability.

Data analysis and management skills were highlighted by 43% of the studies [24,26,28]. These studies emphasize several secondary skills crucial for effective data handling. For instance, McCoy et al [26] stress the importance of data acquisition, cleaning, and visualization as foundational steps in preparing data for AI applications. Singh et al [24] underline the need for robust data management practices to ensure the integrity and reliability of AI outputs. Wiljer and Hakim [28] highlight the necessity of developing capabilities in data governance, which includes the secure storage and regulatory compliance of health care data.

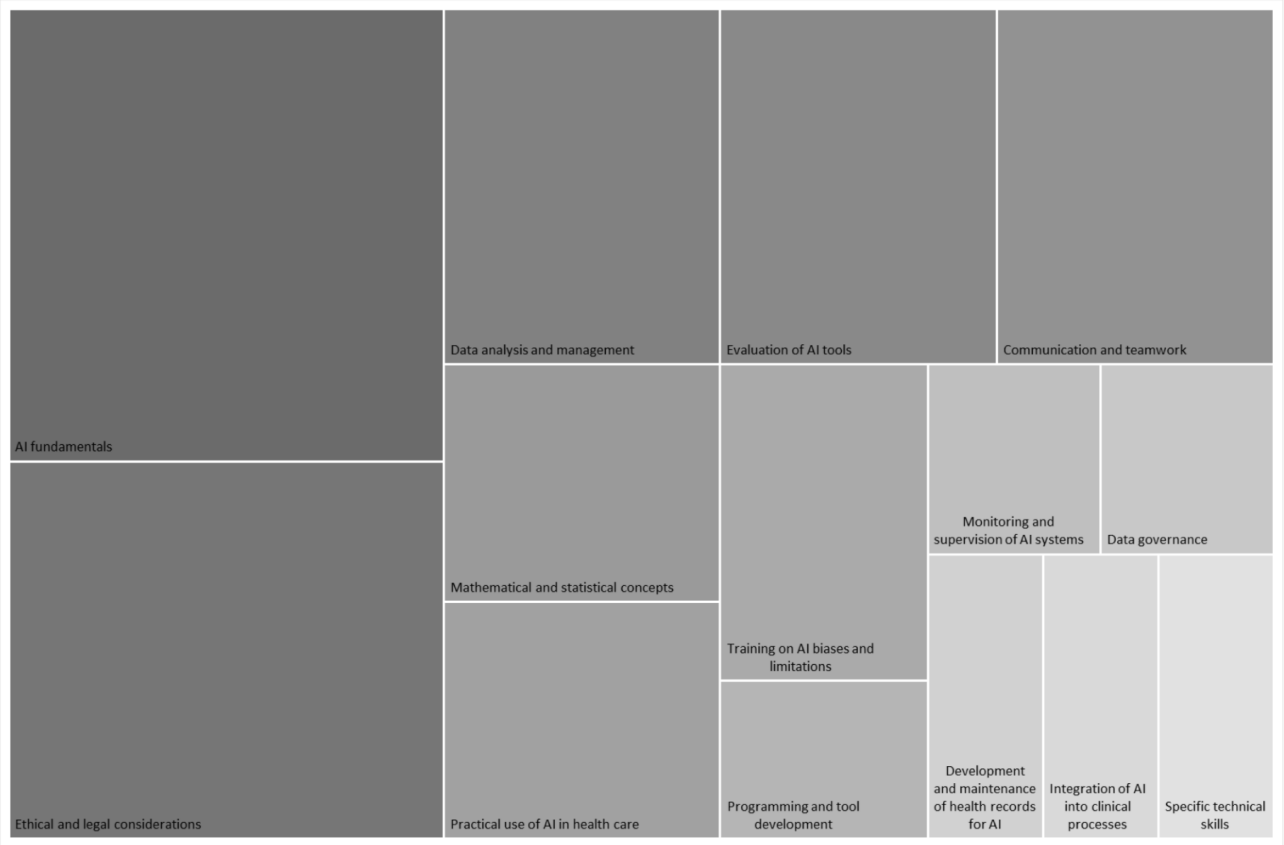
Communication and teamwork were identified as important competencies by 43% of the studies [23,25,27]. These studies underscore the critical need for effective communication skills to convey complex AI-related information to both colleagues and patients. Çalışkan et al [23] emphasize the role of interdisciplinary teamwork in the development and implementation of AI applications, highlighting the necessity for seamless collaboration between health care professionals and AI experts. Liaw et al [25] point out the importance of clear and empathetic communication with patients regarding the use of AI in their care, ensuring transparency and maintaining trust. Sujan et al [27] stress the need for health care teams to work cohesively to monitor and supervise AI systems, ensuring their safe and ethical use.

Evaluation of AI tools was mentioned by 43% of the studies [25,26,29]. These studies highlight several essential secondary skills necessary for the rigorous assessment of AI technologies. Liaw et al [25] emphasize the importance of understanding evidence-based evaluation methods to critically assess the performance and utility of AI tools in clinical practice. McCoy et al [26] discuss the need for health care professionals to be proficient in performing critical evaluations, including assessing the accuracy, reliability, and validity of AI algorithms. Sapci and Sapci [29] stress the significance of ongoing evaluation and monitoring of AI tools to ensure they consistently meet clinical standards and enhance patient outcomes.

Some investigations highlight more technical abilities, such as programming [26], or a deeper mathematical acumen [24,28]. These skills, while crucial, were not as frequently cited as the previously mentioned competencies. Conversely, a capability deemed highly significant across the literature is the aptitude for evaluating AI tools to ascertain their quality and rationalize their application, in addition to scrutinizing potential biases and limitations [24,25].

Figure 2 presents a mosaic plot displaying the distribution of identified competencies based on the percentage of studies that reported each skill. The size of each tile corresponds to the proportion of studies mentioning that competency, providing a visual representation of the relative importance of each skill across the reviewed literature.

Figure 2. Distribution of identified competencies. AI: artificial intelligence.



Discussion

General Aspects

This review underscores the critical need for health care professionals to acquire competencies related to the effective use of AI in clinical practice. Five key areas of competence were identified as essential for AI integration in clinical practice: AI fundamentals, ethical and legal considerations, data analysis and management, communication and teamwork, and the evaluation of AI tools. These competencies are essential to ensure the safe and reliable integration of AI technologies into routine health care workflows. Furthermore, ethical and legal considerations, such as data security and transparency, are crucial for building trust in AI-driven decisions (Table S2 in Multimedia Appendix 1).

In line with our findings, recent studies have emphasized the growing need to define and standardize AI competencies within clinical settings. A 2022 exploratory review [30] highlighted this gap, calling for more structured educational programs to support the integration of AI into health care practice. Additionally, a survey among nursing staff [31] indicated that most professionals had acquired their AI skills independently, further reinforcing the need for formalized training curricula.

Skills

AI Fundamentals

The consensus across the literature highlights the essential nature of AI fundamentals [23-27,29]. This foundational knowledge is crucial for health care professionals to effectively implement and use AI technologies, providing the bedrock upon which more advanced competencies are built. AI fundamentals encompass a basic understanding of machine learning, neural networks, and deep learning. While health care professionals are not expected to have deep expertise in these technical areas, a solid grasp of how AI models function—how they are trained, how they process data, and how they support clinical decision-making—is necessary. This understanding allows professionals to effectively integrate AI into their workflows and ensure the appropriate use of AI-driven tools in patient care.

A key competency is the ability to critically assess AI algorithms, identify biases, and interpret the results. Studies, such as those by Faes et al [32], provide guidelines to help clinicians evaluate AI outputs without needing advanced computational skills, allowing them to focus on patient care. For example, clinicians should recognize when AI models may be limited by biased data or poor generalizability. Similar to using ultrasound technology—where clinicians do not fully understand the physics but can accurately interpret images—the same principle applies to AI. Health care professionals must develop the skills to interpret AI-generated information and effectively communicate it to patients, fostering trust and transparency in AI-driven care [33].

Ethical and Legal Considerations

Ethical and legal considerations were emphasized in 71% of the reviewed studies [23-26,29], highlighting the importance of health care professionals understanding and adhering to the ethical principles and legal frameworks governing the use of AI in clinical practice. These considerations include ensuring

patient privacy, data security, and compliance with relevant regulations, which are critical for maintaining the trust and safety of patients.

Stöger et al [34] emphasized the crucial role of managing high-quality data and the risks associated with its mismanagement, underscoring both the ethical and legal implications for health care professionals using AI systems. In this context, health care providers must be familiar with the laws and regulations governing AI to ensure that the technology is implemented in compliance with legal and ethical standards.

In the European Union, the recent approval of the AI Act introduces comprehensive regulations [35] aimed at safeguarding fundamental rights and democracy by controlling AI systems based on their potential risks and impact. The AI Act establishes stringent requirements for high-risk AI systems, including mandatory impact assessments and prohibitions on certain AI practices that threaten fundamental rights. For health care professionals, this underscores the need for a thorough understanding of these legal frameworks to ensure that AI is used responsibly and safely in clinical practice.

Moreover, the opacity of machine learning algorithms, often referred to as “black boxes” due to their complex and abstract problem-solving methods, represents a significant challenge in ensuring accountability and transparency in AI-driven health care solutions [36]. Although efforts to make these algorithms more interpretable are still developing [37], health care professionals must rely on regulated AI tools that meet established standards for safety and efficacy. Regulatory bodies such as the US Food and Drug Administration have already approved specific AI tools for medical applications [38], providing a level of assurance that these technologies meet rigorous safety and legal standards. This regulatory oversight is critical for fostering trust in AI among clinicians and patients, while also mitigating liability concerns for health care providers.

Data Analysis and Management

Data analysis and management were identified as key competencies in 43% of the reviewed studies [24,26,28], emphasizing the critical role these skills play in the effective implementation of AI in health care. This domain encompasses the ability to handle large volumes of health care data, including data acquisition, cleaning, visualization, and governance. Health care professionals need to be proficient in organizing and managing these datasets to ensure the integrity and reliability of AI outputs.

A core competency in this area includes the preparation of clean and structured datasets for AI models, as highlighted by McCoy et al [26], who stress the importance of data preparation steps such as cleaning and visualization to optimize AI performance. Singh et al [24] underline the need for robust data management practices to guarantee that the data used by AI systems is accurate, reliable, and compliant with health care regulations.

Wiljer and Hakim [28] further highlight the significance of data governance, which includes not only managing data but also ensuring its secure storage and adherence to regulatory requirements. Proficient data handling is crucial, as health care professionals are often the primary data generators. Their ability to manage and interpret large datasets ensures that AI methodologies are applied effectively in clinical practice, supporting both the accuracy of AI predictions and the quality of patient care [39].

Evaluate AI Tools

The ability to evaluate AI tools emphasises the need for health care professionals to critically assess the performance, accuracy, and reliability of AI technologies in clinical practice. Effective evaluation is closely tied to a foundational understanding of AI principles, which allows professionals to determine whether AI tools are suitable for their specific clinical settings.

A key competency in this domain involves assessing AI tools with the same rigor applied to new drugs, diagnostic tests, or treatment protocols. AI-based tools must undergo extensive testing for accuracy, generalizability, efficacy, and fairness to ensure they meet clinical standards [25]. This evaluation process is crucial for ensuring that AI technologies deliver reliable outcomes and can be integrated safely into health care workflows.

Additionally, health care professionals must develop skills for the ongoing evaluation and monitoring of AI tools to detect any performance shifts or biases that may arise over time [40]. Given the continuous learning nature of AI systems, regular reassessment is necessary to maintain their reliability across diverse patient populations and clinical scenarios.

Communication and Teamwork

Communication and teamwork were identified as key competencies in 43% of the reviewed studies [23,25,27], focusing on the dual importance of effectively conveying AI-related insights to patients and facilitating collaboration among health care professionals. Health care providers must clearly explain AI-generated results, addressing patient concerns with empathy, ensuring transparency, and maintaining trust in the use of AI technologies in clinical care.

Equally important is the interdisciplinary collaboration required for integrating AI into clinical workflows. Health care professionals need to work closely with AI specialists, data scientists, and other colleagues to ensure the safe and effective use of AI tools. Studies such as those by Çalışkan et al [23] stress the necessity of seamless teamwork between health care providers and AI experts, while Liaw et al [25] underscore the need for clear and compassionate communication with patients, ensuring they understand how AI is applied in their care and the potential implications.

This competency involves not only understanding AI outputs but also contextualizing them for patients in a way that fosters trust and humanizes AI-assisted care. At the same time, health care teams must collaborate cohesively to monitor and manage AI systems. As AI streamlines routine tasks, health care providers will have more time for patient interaction, making effective and empathetic communication even more critical [25]. Ensuring that both patients and professional teams feel supported and understood is essential for the ethical and successful integration of AI in health care practice.

Competencies Based on Identified Skills

Based on the previously identified skills, and following an approach similar to that outlined by the Association of American Medical Colleges in 2021 [41], we propose a set of competencies that health care professionals should acquire to effectively integrate AI into clinical practice. These competencies, derived from the literature reviewed, encompass the key domains and provide a framework to guide educational programs and ongoing training in AI-driven tools in health care settings.

Table S3 in Multimedia Appendix 1 outlines the competencies for each skill, offering a structured approach to developing AI proficiency. This framework ensures that professionals not only grasp AI fundamentals but also apply these technologies ethically, manage health care data effectively, rigorously evaluate AI tools, and communicate insights to both patients and interdisciplinary teams. However, these competencies should be considered only a first proposal; this list may be modified depending on the specific profile of the training program, on foreseeable technological developments, as well as on the evaluation of the academic results of the new curricula.

AI in Health Care Training

Recent data from Rock Health, a venture capital firm specializing in digital health, have underscored an exponential increase in investments directed toward digital health enterprises and related technologies [42]. This trend distinctly signals an evolving health care landscape, increasingly reliant on novel technologies, thereby accentuating the imperative for health care professionals to proficiently integrate such advancements into their clinical practices [43].

Despite widespread agreement on the necessity for comprehensive AI training from the outset of medical education, there is a lack of consensus on the specific content and approach of such training [15]. The discussion around this issue is abundant, yet concrete resolutions are rare. The findings of this review aim to provide an approach to the possible competencies required, offering a structured framework for developing comprehensive AI training programs for health care professionals.

Integrating AI education into health care curricula presents several challenges due to the variability and lack of standardization of required competencies. To address this need, we propose general guidelines for the development of essential AI competencies for health care professionals. These guidelines provide a reference framework that educators and course coordinators can use to design training programs, assess student progress, and establish performance criteria. For example, health care professionals should acquire the ability to assess the quality of algorithms and their interpretations, as well as identify and mitigate potential biases. This approach facilitates the integration of AI into clinical practice and provides a clear guide for curriculum development and performance evaluation.

Augmenting the education and training of health care professionals is posited to elevate their confidence in using these tools. Although concerns persist regarding AI's potential to supplant human roles, a more discerning view proposes that AI will primarily alleviate the burden of mundane tasks. This reallocation of time and resources is anticipated to enhance patient interactions and elevate the quality of health care services provided [39].

Several authors argue that the existing academic infrastructure is ill-equipped to incorporate AI education, citing time constraints and a lack of teaching expertise as significant obstacles. An alternative proposed involves the use of specific AI tools not only for clinical applications but also to elucidate the underlying algorithms, focusing on their practical use and ethical implications [44].

A solution for integrating AI education into health care curricula, addressing the shortage of instructors with expertise in clinical AI applications, involves leveraging established training programs from other institutions [45]. Programs by Stanford University [46] and Harvard University [47] serve as examples, providing access to high-quality educational content. These programs offer a comprehensive curriculum that covers essential AI concepts, practical applications, and ethical considerations, enabling health care professionals to gain a deep understanding of AI technologies.

The integration of AI into clinical practice is expected to augment, not replace, the roles of health care professionals. It calls for a workforce proficient in digital health and communication, capable of leveraging AI's benefits while recognizing its limitations and ethical considerations [48]. This paradigm shift offers an opportunity to enhance patient care, delegating computational tasks to AI and focusing on the human aspects of health care delivery [37].

Limitations

This systematic review encounters several challenges, primarily due to the limited availability of literature specifically addressing the competencies required for integrating AI into health care practice. The scarcity of targeted studies can be attributed to the nascent and rapidly evolving nature of AI applications in health care.

To mitigate this issue, the search criteria were broadened to include general terms related to AI in health care and competencies required by health care professionals. While necessary, this broadening may have introduced studies that do not exclusively focus on AI competencies, potentially affecting the homogeneity of the findings. The review also faced potential language bias, as it primarily focused on literature in English and Spanish. Pertinent studies in other languages might have been excluded. Despite rigorous and independent review processes, the selection could still be influenced by subjective interpretation of the inclusion and exclusion criteria.

Limiting the review to studies published after 2018 aimed to capture the most recent advancements, but this restriction might omit emerging research. Despite these efforts, there remains a clear knowledge gap in the specific skills required for effective AI use in health care. The literature predominantly addresses AI applications and benefits, but lacks detailed research on the precise skills health care professionals need. Current research is often fragmented and varies significantly in scope and depth. Few studies offer comprehensive models or curricula for AI competency training in health care. This inconsistency highlights

the need for more robust research to identify essential AI skills and explore effective methods for integrating these skills into health care education and practice.

Conclusions and Future Works

This systematic review has identified essential competencies for health care professionals to effectively integrate AI into clinical practice. The analysis reveals a consensus on the importance of five key areas: AI fundamentals, ethical and legal considerations, data analysis and management, communication and teamwork, and evaluation of AI tools. These competencies are crucial for leveraging AI technologies to enhance patient care and health care delivery. A consensus within the scholarly discourse suggests the necessity for health care professionals to attain proficiency in these domains to ensure the judicious application of AI tools, thereby accruing benefits for both patients and the health care ecosystem.

AI fundamentals form the backbone of necessary knowledge, enabling health care professionals to understand and use AI technologies effectively. Ethical and legal considerations ensure that AI applications adhere to patient privacy, data security, and transparency standards, maintaining trust and compliance within health care settings. Data analysis and management skills are vital for handling large datasets, ensuring accurate AI outputs, and supporting informed clinical decisions.

Communication and teamwork are also critical, facilitating the clear conveyance of AI-related information among health care professionals and to patients, thereby promoting transparency and trust. The ability to evaluate AI tools is essential for assessing the performance and reliability of AI technologies, ensuring they meet clinical standards and deliver safe, effective patient care.

Augmenting the education and training of health care professionals is posited to elevate their confidence in using these tools. Although concerns persist regarding AI's potential to supplant human roles, a more discerning view proposes that AI will primarily alleviate the burden of mundane tasks. This reallocation of time and resources is anticipated to enhance patient interactions and elevate the quality of health care services provided.

In this context, the importance of communication skills becomes increasingly paramount. The introduction of AI tools is expected to afford health care professionals additional time per patient encounter, potentially heightening patient satisfaction and care quality.

The ambition extends beyond merely acquiring proficiency in disciplines ancillary to traditional health care paradigms. Considering the already intricate and comprehensive nature of health care education, particularly in medicine, the emphasis is placed on fostering an in-depth comprehension of AI's functionalities, inherent biases, pragmatic utility, and cost-effectiveness compared to abstaining from AI applications.

The integration of AI into health care is indispensable for advancing patient care but requires a concerted effort to develop and standardize competencies among health care professionals. Regulatory oversight and enhanced educational frameworks are essential for overcoming existing barriers and leveraging AI's full potential in clinical settings.

Despite the progress highlighted in this review, significant gaps remain in the literature, particularly concerning the specific educational frameworks and training programs needed to develop these competencies. Most existing research focuses on the potential applications and benefits of AI, with less emphasis on the precise skills required for effective implementation.

Future research should prioritize the development and validation of standardized AI competency frameworks tailored for health care professionals. These frameworks should cover technical skills, ethical and legal aspects, and data management practices. Collaborative efforts between academic institutions, health care organizations, and AI experts can create comprehensive training programs to address these competencies.

Additionally, longitudinal studies are necessary to evaluate the long-term effectiveness of AI training programs. Research should explore how health care professionals apply their AI training in clinical settings, assessing the impact on patient outcomes, clinical decision-making, and health care efficiency.

Acknowledgments

This work has been partially supported by the Telefonica Chair on "Intelligence in Networks" of the Universidad de Sevilla.

Data Availability

All data generated or analyzed during this study are included in this published article. This encompasses detailed descriptions of the databases consulted, the search criteria used, the selection process for the included studies, and the analytical methods applied. Specifically, this paper delineates the comprehensive search strategy, including the exact search terms, the databases accessed (PubMed, Scopus, and Web of Science), and the filters used (such as publication date ranges and language restrictions). Additionally, the criteria for study selection—both inclusion and exclusion criteria—are explicitly outlined to ensure reproducibility and transparency of the review process. The methodologies used for data extraction and analysis are also described, providing insight into how the findings were synthesized and interpreted. Through this approach, we aim to ensure that our systematic review process is fully transparent, enabling other researchers to replicate this study or to conduct further analysis based on the procedures and datasets detailed within this article.

Authors' Contributions

All authors contributed significantly to this literature review. Specifically, each author participated in one or more of the following: conceptualization and design of the review, data acquisition, analysis, interpretation, or critically revising this work. All authors approved the final paper for publication and agree to be accountable for all aspects of this work, ensuring the integrity and accuracy of their contribution.

Abstract

Background: The motivational design of online instruction is critical in influencing learners' motivation. Given the multifaceted and situated nature of motivation, educators need access to a range of evidence-based motivational design strategies that target different motivational constructs (eg, interest or confidence).

Objective: This systematic review and directed content analysis aimed to catalog the motivational constructs targeted in experimental studies of online motivational design strategies in health professions education. Identifying which motivational constructs have been most frequently targeted by design strategies—and which remain under-studied—can offer valuable insights into potential areas for future research.

Methods: Medline, Embase, Emcare, PsycINFO, ERIC, and Web of Science were searched from 1990 to August 2022. Studies were included if they compared online instructional design strategies intending to support a motivational construct (eg, interest) or motivation in general among learners in licensed health professions. Two team members independently screened and coded the studies, focusing on the motivational theories that researchers used and the motivational constructs targeted by their design strategies. Motivational constructs were coded into the following categories: intrinsic value beliefs, extrinsic value beliefs, competence and control beliefs, social connectedness, autonomy, and goals.

Results: From 10,584 records, 46 studies were included. Half of the studies (n=23) tested strategies aimed at making instruction more interesting, enjoyable, and fun (n=23), while fewer studies tested strategies aimed at influencing extrinsic value beliefs (n=9), competence and control beliefs (n=6), social connectedness (n=4), or autonomy (n=2). A focus on intrinsic value beliefs was particularly evident in studies not informed by a theory of motivation.

Conclusions: Most research in health professions education has focused on motivating learners by making online instruction more interesting, enjoyable, and fun. We recommend that future research expand this focus to include other motivational constructs,

such as relevance, confidence, and autonomy. Investigating design strategies that influence these constructs would help generate a broader toolkit of strategies for educators to support learners' motivation in online settings.

Introduction

The internet has become a preferred modality for health professions education (HPE) in the postpandemic landscape [1]. A recent global survey found that 60% of health professionals preferred blended learning, while 32% preferred fully online learning [2]. Online instruction can ameliorate barriers due to geography, scheduling, and cost that make in-person learning infeasible for many health professionals and trainees [3]. However, one challenge of online learning is keeping learners motivated. Motivation—the energetic force that instigates and sustains behavior [4]—is key to success when learning online [5,6]. A lack of face-to-face interaction and the metacognitive demands associated with learning online can lead to feelings of isolation, frustration, and diminished motivation [7,8]. To address these challenges and keep learners motivated, educators must build motivational support into online instruction through a process known as motivational design [9].

Motivational design is defined by Keller [9] as "the process of arranging resources and procedures to bring about changes in people's motivation." This process involves selecting, adapting, and applying motivational design strategies, which are resources and procedures that facilitate the motivational processes underpinning learning. For example, Colonnello et al [10] enhanced medical students' motivation by supplementing surgical videos with emotionally salient patient information. Other studies have demonstrated that other motivational design strategies, such as using narration in online modules, can impact learner motivation [11,12].

Motivational design strategies work by influencing various motivational constructs—cognitive factors that shape learners' moment-to-moment motivation [4]. Broad categories of motivational constructs include goals ("What am I aiming to do?"), competence beliefs ("Can I do it?"), value beliefs ("Do I want to do it? Why?"), and attributional beliefs ("Why did it happen this way?") [13]. For example, an educator might use a strategy to make learning seem more relevant, increase learners' interest, or boost their confidence that they can learn the material.

Theories of motivation emphasize that learners' motivation is influenced by several motivational constructs, any one of which may be the cause of poor motivation during online learning [4]. For example, medical students completing an online module on a basic science topic may be confident in their ability to learn but struggle to see the value in the material beyond their next examination. Conversely, students completing a virtual examination with a standardized patient may see the value in what they are learning but not feel confident in their ability to succeed. In the first case, an educator could use a strategy that targets learners' value beliefs (eg, a prompt to reflect on the clinical relevance of the material [14]), while in the second, an educator could use a strategy that targets' learners competence beliefs (eg, providing a demonstration that learners can observe beforehand [9]). Given the multifaceted and situated nature of motivation, educators need access to a range of evidence-based motivational design strategies that target different motivational constructs, such as strategies for enhancing confidence or perceived value [15].

Researchers can support educators by providing evidence on the effectiveness of different motivational design strategies [16]. However, we do not have a good understanding of which motivational constructs are most frequently targeted in research on online motivational design. For example, are researchers disproportionately focused on testing ways to make online instruction more interesting or enjoyable? An expanding literature on serious games and gamification in HPE suggests this may be the case, as games are often framed as a strategy to enhance interest [17-24]. While enhancing interest is important, if researchers focus too narrowly on this construct at the expense of others (eg, confidence), then educators may not receive the full range of design strategies needed to support learner motivation [4]. To inform future research, it is important to identify which motivational constructs have been most emphasized and which remain under-studied.

To address this gap, our review aims to catalog the motivational constructs targeted in studies of online motivational design strategies. This is a novel objective, as no previous reviews have organized the instructional design literature based on the motivational constructs that strategies aim to influence. By identifying which constructs have received the most attention, we aim to guide future literature syntheses on the most effective design strategies for supporting these constructs. Additionally, by identifying under-studied constructs, we aim to guide areas for future primary research. Ultimately, our review is intended as a resource for researchers interested in conducting future studies on motivational design for online instruction. Stimulating ongoing research in this area will ensure that educators have access to evidence-based guidance to design more motivating online instruction.

We hypothesize that there are two reasons why certain motivational constructs may be underrepresented in research on online motivational design strategies: (1) studies are not informed by a theory of motivation or model of motivational design, or (2) studies are informed by such theories but choose

not to focus on specific constructs. To disentangle these explanations, we posed two research questions: (1) Which theories or models of motivation, if any, inform experimental comparison studies of motivational design strategies for online instruction? (2) Within experimental comparison studies of motivational design strategies for online instruction, which motivational constructs, if any, have been targeted?

Methods

We conducted a systematic review and directed content analysis focused on experimental comparison studies in HPE [25]. Experimental comparison studies, which compare 1 version of online instruction to another, are uniquely positioned to generate empirical evidence for the causal effects of motivational design strategies [25-28]. Motivational design is, at its core, a process of making predictions about the causal effects of motivational design strategies ("If I use this strategy, will it cause my learners to be more motivated?"). Since experimental comparison studies are best suited for making causal claims, we consider them a necessary source of evidence for educators and serve as the focus for our review. Bajpai et al [29] adopted a similar position in their recent review of learning theories in randomized trials of digital instruction in HPE.

Given our focus on experimental comparison studies, we identified a systematic review as the most appropriate review methodology [30]. We registered (PROSPERO CRD42022359521) and published a review protocol [31], and report our findings in accordance with the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) 2020 updated guidelines [32], with a few exceptions. We omit items 12 (effect measures), 14 (reporting bias assessment), 15 (certainty assessment), 19 (results of individual studies), 21 (risk of bias due to missing results), and 22 (certainty of evidence), as we did not intend to appraise nor synthesize the outcomes of included studies. Further details on our methods can be found in our published protocol [31]. To increase the clarity and brevity of reporting, this paper omits data related to a few research questions listed in our published protocol. Additional data regarding these questions is available upon request.

Eligibility Criteria

Study Characteristics

We included individual and cluster randomized controlled trials and quasi-experimental studies published in English from 1990 to August 2, 2022 (for databases) and September 15, 2022 (for registries). Our date range aligns with prior reviews of digital education in HPE [33]. We included protocols for planned or ongoing studies but excluded conference abstracts and unpublished studies. Studies were not excluded based on quality or risk of bias as we did not aim to synthesize the results of studies. However, we appraised the risk of bias to provide readers with additional context regarding the quality of studies.

Participants

We included studies focusing on learners in the health professions regardless of training status (see protocol for list of health professions), either exclusively or when mixed with other learners (eg, psychology students).

Interventions

We included studies comparing online instructional designs (or that could have been delivered online, such as CD-ROM instruction), which targeted a motivational construct (eg, interest) or motivation more generally. By "targeting" motivation, we mean that researchers stated that their instructional design aimed to enhance learner motivation to engage with instruction. Several studies demonstrated a cursory treatment of motivation, for example, by discussing the impact of design strategies on constructs (eg, interest) without grounding the construct in a theoretical framework. We decided to include these studies because they contribute to our understanding of the foci among researchers interested in this area of HPE. Studies comparing online instruction against paper-based or face-to-face instruction were excluded.

Outcomes

We included studies that assessed any learner outcome.

Search Strategy and Selection Process

Database Searching

Strategies were developed for Ovid Medline, Embase, Emcare PsycINFO, EBSCO ERIC, and Web of Science Core Collection (Social Sciences Citation Index; Arts & Humanities Citation Index; Book Citation Index-Social Sciences & Humanities; Conference Proceedings Citation Index-Science; Emerging Sources Citation Index; Science Citation Index; Book Citation Index-Social Sciences & Humanities; and Conference Proceedings Citation Index-Social Science & Humanities) by a health sciences librarian (MA) in collaboration with the review team (Multimedia Appendix 1). Appropriate subject headings and keywords for motivation, online instruction, and HPE focused on the licensed professions were used for each database. The results were limited to those published from 1990 to the date of the searches. The searches were run on August 2, 2022, and the 14,736 results were uploaded to Covidence for screening.

Registry Searching

For the Open Science Framework Registries, we developed 12 searches, comprised of different combinations of the highest yielding terms in our database searches (Multimedia Appendix 2). The searches yielded between 7277 and 16,018 hits for each combination of terms. AG manually screened the first 10 pages of results (10 results per page) for each search (1200 studies screened in total) and uploaded 19 potentially relevant studies to Covidence.

Hand and Reference Searching

AG manually screened several published literature reviews on online instruction in HPE [18-23,34-39] and the references of included studies and uploaded 161 potentially relevant studies to Covidence.

Screening

After removing duplicates, we screened 10,584 records. Two team members independently screened abstracts and, as necessary, the paper's full text. Before independent screening, all 6 team members who participated in the screening process practiced screening the same 30 abstracts, and then discussed and refined the inclusion criteria. AG also developed a decision tool to support full-text screening. As screening progressed, AG periodically reviewed conflicts for any systematic issues and further refined the inclusion and exclusion criteria. Two senior team members (EM or RB) not involved in the initial decision resolved all conflicts. We included 61 studies in the data extraction phase. During the extraction phase we excluded an additional 15 studies. In 12 cases, the papers were excluded because they did not discuss the potential motivational effects of a strategy in the introduction or did not state an objective to assess the effects of a strategy on motivation. Therefore, we concluded that these were not motivational design strategies [40-51]. This yielded 46 studies included in our review.

Data Collection and Synthesis Methods

Overview

The data items we extracted can be found in Multimedia Appendix 3. We conducted a directed content analysis during the extraction process [52], coding each study deductively regarding the motivational theories used and the motivational constructs targeted. We piloted and refined the extraction process in Covidence with a few included studies. AG trained team members to extract and code data. Two team members independently extracted data from each study. Conflicts were resolved through discussion, with an experienced team member (ie, currently in, or having completed, a PhD program) not involved in the initial decision leading to resolution.

Theories of Motivation (Aligned With Research Question 1)

We developed an a priori list of 6 prominent theories of motivation and 1 model of motivational design to deductively guide our coding. We defined theories as "prominent" based on meeting one of the following criteria: (1) they were included in a 2020 special issue of *Contemporary Educational Psychology* titled "Prominent Motivation Theories: The Past, Present, and Future" [53-57], or (2) they have been the subject of an AMEE Guide in *Medical Teacher* [58,59]. We also added Keller's ARCS model of motivational design, which we assumed would be cited in HPE studies [24]. Brief descriptions of these theories can be found in Table 1. Beyond this initial list, we considered any theory aiming to explain the energetic basis and direction of learners' engagement to be a theory of motivation [60]. We also coded whether these theories informed 4 key aspects of the research process: the research questions, the design of the experimental conditions, the selection of methods and measures, and the interpretation of results [61].

Table 1. Overview of and reported use of established theories of motivation and models of motivational design.

Theory or model	Description	Frequency used, n (%)	References
SDT[a] [55]	Ryan and Deci's SDT differentiates between types of motivation depending on learners' reasons for engaging in learning, such as feeling pressured to satisfy external demands (external regulation), feeling pressured to quell feelings of guilt or shame (introjected regulation), identifying with the value of an activity (identified regulation), or finding the activity inherently interesting (intrinsic motivation). SDT also emphasizes the influence of the social environment on learners' motivation, as mediated by the satisfaction of feelings of autonomy (ie, being in control of one's actions), competence (ie, feeling efficacious in one's actions), and relatedness (ie, feeling connected to others).	8 (17)	[10,11,62-67]
ARCS[b] model [9]	Keller's ARCS model states that, for learners to become and remain motivated to learn, their attention must be captured via feelings of curiosity, they must perceive instruction to be relevant to their current needs and long-term goals, they must feel confident that they can succeed, and they must feel satisfied with the intrinsic and extrinsic consequences of engaging with instruction.	6 (13)	[5,68-72]
SCT[c] [56]	Bandura's SCT emphasizes the primary role of learners' self-efficacy beliefs (ie, that they can execute courses of action needed to attain particular outcomes) and outcome expectancies (ie, that courses of action will lead to particular outcomes) in motivating their learning goal pursuit.	3 (7)	[64,73,74]
CVT[d] [75]	Pekrun's CVT posits that the achievement emotions that learners experience (as well as their self-regulation and learning) are most proximally a function of the subjective control and value beliefs they ascribe to actions and outcomes for an activity. Subjective control beliefs are based on action-control expectations (ie, expectations that actions can be performed) and action-outcome expectations (ie, expectations that particular actions will lead to certain outcomes). Subjective value beliefs are based on the perceived intrinsic and extrinsic value of engaging in the activity and attaining resultant outcomes.	2 (4)	[10,63]
EVT[e] [53]	Eccles and Wigfield's EVT (now called situated expectancy-value theory) posits that learners' motivation is most proximally a function of their expectations of success and the subjective value they ascribe to an activity. Subjective value is composed of interest value (ie, the interest or enjoyment an activity brings), utility value (ie, an activity's usefulness for attaining other valued goals), attainment value (ie, an activity's importance in confirming a salient aspect of one's identity), and cost (ie, the drawbacks of completing an activity).	1 (2)	[76]
Other theories or models	Theory of narrative engagement [77,78]; 4-phase model of interest development [11]; engagement modes model [73]; information and communication acceptance model [79]; social interdependence theory [80]; Guthrie and Wigfield engagement model [81]	N/A[f]	See description
None mentioned	N/A	24 (52)	[82-105]

[a]SDT: self-determination theory.

[b]ARCS: attention, relevance, confidence, and satisfaction.

[c]SCT: social cognitive theory.

[d]CVT: control-value theory.

[e]EVT: expectancy-value theory

[f]N/A: not applicable.

Motivational Constructs (Aligned With Research Question 2)

We used our list of theories and previous research [13] to create a priori categories of motivational constructs to deductively guide our coding. During the coding process, our categorization scheme changed slightly from that documented in our protocol [31], as we determined that a more parsimonious categorization scheme involved aggregating more constructs into fewer categories (Multimedia Appendix 4). Our list included the following categories of motivational constructs: intrinsic value beliefs (eg, interest), extrinsic value beliefs (eg, instrumentality), competence and control beliefs (eg, self-efficacy), social connectedness (eg, relatedness), autonomy, and goals. Intrinsic value refers to the value derived from the experience of completing an activity (eg, interest or enjoyment), whereas extrinsic value refers to the value derived from attaining outcomes external to an activity (eg, progress toward future goals) [53,55].

Study Risk of Bias Assessment

We rated each study's risk of bias across 9 dimensions contained within the Cochrane Collaboration's Effective Practice and Organization of Care risk of bias tool: random sequence generation, allocation concealment, similar baseline outcome measurements, similar baseline characteristics, incomplete

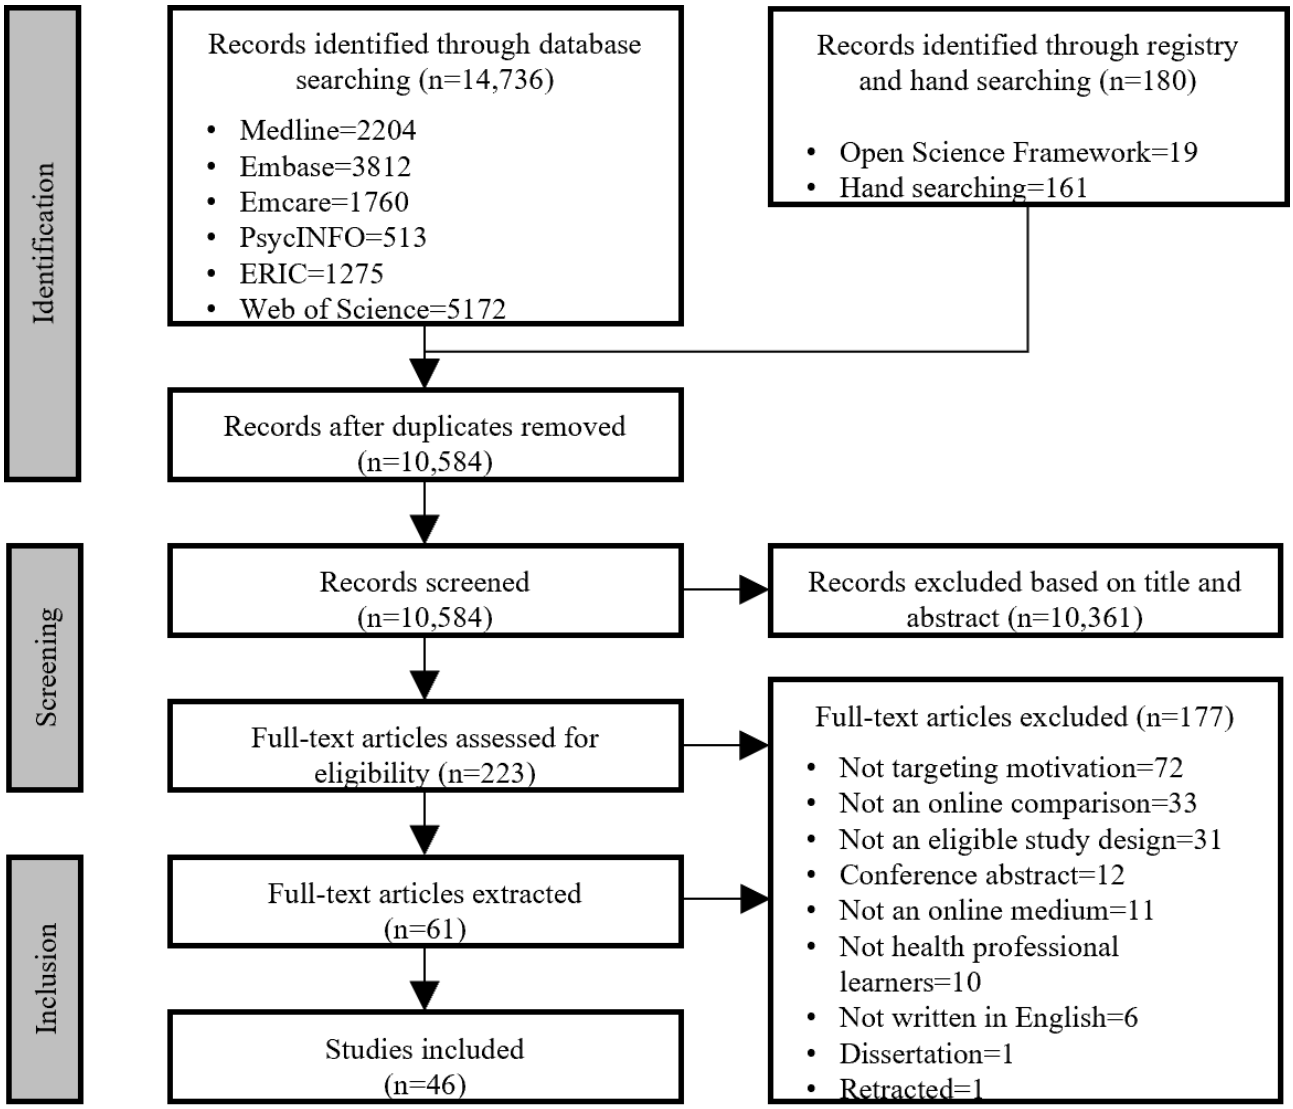
outcome data, blinded outcome measurement, protection against contamination, selective outcome reporting, and other risks of bias [30]. This tool has been used in similar systematic reviews of online instruction in HPE [19,36]. Team members reported particular difficulty in identifying "other risks of bias," and we observed that raters frequently documented different sources of bias (or no bias) within this broad category. Accordingly, we decided to exclude this dimension.

Results

Characteristics of Included Studies

The characteristics of the included studies are presented in Multimedia Appendix 5. Most studies were conducted with trainees (n=40), primarily medical students (n=17) and nursing students (n=11). Study designs were predominantly randomized parallel-group trials (n=27), followed by quasi-experimental trials (n=12), randomized cross-over trials (n=4), and cluster randomized trials (n=3). The risks of bias for each study are presented in Multimedia Appendix 6. Although 74% (34/46) of the included studies were identified as randomized trials, only 30% (14/46) were rated as low risk of bias for random sequence generation, and 33% (15/46) were rated as low risk of bias for allocation concealment. For other dimensions of bias, low risk was observed in 35% (16/46) of studies for baseline outcome measurements, 37% (17/46) for baseline characteristics, 50% (23/46) for blinded outcome measurements, 50% (23/46) for contamination, 57% (26/46) for missing outcome data, and 80% (37/46) for selective outcome reporting. The PRISMA flowchart for our review is presented in Figure 1, and the PRISMA checklist can be found in Multimedia Appendix 7.

Figure 1. PRISMA flowchart. PRISMA: Preferred Reporting Items for Systematic Reviews and Meta-Analyses.



Which Theories or Models of Motivation Inform Existing Experimental Studies of Motivational Design Strategies?

Table 1 presents the number of studies that were informed by a theory of motivation or model of motivational design. SDT and the ARCS model were the most commonly used theories, while 24 studies did not cite any theory. Five studies cited more than 1 theory of motivation. Among the 22 studies that used at least 1 theory, we judged the theory as informing the research questions in 20 (91%) studies, informing the experimental conditions in 15 (68%) studies, informing methods and measures

in 17 (77%) studies, and informing the interpretation of results in 17 (77%) studies. Nine studies used theory to inform all 4 aspects of their research process [5,10,11,62,63,68,69,77,80].

Which Motivational Constructs Have Studies Targeted With Their Motivational Design Strategies?

Studies investigated motivational design strategies that targeted intrinsic value beliefs in 23 of the 46 (50%) studies, extrinsic value beliefs in 9 (20%) studies, competence and control beliefs in 6 (13%) studies, social connectedness in 4 (9%) studies, and autonomy in 2 (4%) studies. Ten (22%) studies targeted more than 1 construct; of these, 5 (11%) were informed by the ARCS model. Sixteen (35%) studies did not report targeting any specific motivational construct, instead aiming to enhance motivation in general.

While intrinsic value beliefs were the most commonly targeted construct, researchers drawing on a prominent theory or model (as listed in Table 1) tended to be more pluralistic in their foci. Specifically, studies that used a motivation theory or model targeted intrinsic value beliefs (n=11) at a similar level to extrinsic value beliefs (n=9) and, to a lesser extent, competence and control beliefs (n=6). By contrast, studies that did not use a theory or model focused solely on intrinsic value beliefs (n=10) compared to extrinsic value beliefs (n=0) and competence and control beliefs (n=0).

Discussion

Key Findings and Implications for Future Research

In this systematic review, we analyzed experimental comparison studies of online motivational design strategies in HPE. We aimed to identify which motivational constructs have been most frequently targeted in these studies and which remain understudied, offering insights into potential areas for future research.

A significant finding was that nearly one-third of the studies in our review did not specify which motivational constructs their design strategy was targeting, instead broadly aiming to enhance motivation. We argue that such research is of limited value to educators. Motivational design expertise relies on educators understanding how strategies work, specifically what constructs they influence and under what conditions they are most effective [106,107]. Studies that do not clarify which constructs a design strategy influences, either conceptually or empirically, cannot provide educators with the information needed to build expertise [16]. Therefore, we recommend that researchers explicitly define the motivational constructs their strategies aim to influence and test their impact on those constructs. This recommendation can be supported through the greater use of motivational theories, which were cited in fewer than half of the studies in our review. This lack of theory use is consistent with other reviews, such as those by Maheu-Cadotte et al [19] and Bajpai et al [29], who found similarly low levels of theory use in their reviews of serious games and digital education in HPE. Motivational theory should be used to inform the research questions, the design strategy, the outcome measures, and the interpretation of results. Excellent examples of theory use are present in our sample [5,11,80].

Among the studies that did specify targeted constructs, most focused on intrinsic value beliefs (eg, interest or enjoyment), compared to extrinsic value beliefs, competence and control beliefs, social connectedness, and autonomy. Accordingly, research in this area is disproportionately focused on ways to make online instruction more interesting and enjoyable. Given the volume of studies on design strategies targeting intrinsic value beliefs, we recommend that future research synthesize existing findings to identify the most effective strategies for enhancing interest and enjoyment and outline areas for future research.

A disproportionate focus on enhancing intrinsic value beliefs aligns with an increased uptake of SDT in HPE, as documented in our studies and other reviews [24,108]. SDT emphasizes the role of intrinsic motivation—which is grounded in feelings of interest and enjoyment—in effective learning [55]. However, we found that studies using SDT were often pluralistic in the constructs they targeted, suggesting a more nuanced approach than studies without a theoretical basis. A theoretical perspective, whether based on SDT or another theory, may help researchers avoid equating motivation solely with enjoyment and interest, thus neglecting other facets of motivation, such as confidence and relatedness, despite evidence suggesting that these constructs may be particularly at risk when learning online [7,8]. Supporting this perspective, we found that studies informed by the ARCS model—which explicitly states the importance of supporting learners' attention, relevance, confidence, and satisfaction—were most likely to report targeting multiple motivational constructs. We recommend that studies test design strategies targeting a broader range of motivational constructs to expand the set of design strategies that educators can choose from (eg, confidence-enhancing strategies or relatedness-enhancing strategies). For example, though serious games are often framed as ways to enhance interest and enjoyment, they may also be configured to support feelings of practical relevance or boost confidence [24]. Researchers could build on the serious games literature by investigating ways to design serious games to support feelings of extrinsic value, confidence, social connectedness, and autonomy.

We encourage researchers to study ways of motivating learners in established online modalities (eg, asynchronous modules or webinars) and by using emerging technologies such as virtual reality and artificial intelligence. For example, artificial intelligence chatbots have the potential to provide personalized coaching and feedback during learning [109,110]. Providing such support and scaffolding instruction in a learner's zone of proximal development may foster a sense of autonomy and confidence. As research on the motivational design of emerging online modalities is still in its infancy, future studies could investigate how to design emerging technology-enabled instruction to optimize learner motivation.

The risk of bias was a concern across many of the included studies. To ensure that future research can make more defendable claims regarding the effects of design strategies, researchers should clearly specify procedures for random sequence generation and allocation concealment, which are often missing from published papers. They should also capture

relevant variables at baseline, blind assessors to condition, and attempt to limit attrition and contamination [27].

Limitations

Several limitations are worth noting. We did not include any synonyms for the word "motivation" (eg, "engagement" or "satisfaction") or motivational constructs (eg, "value," "relevance," or "confidence") in our search terms because we believed these terms would greatly increase the number of nonrelevant studies in our search results. We assumed that studies using synonyms for "motivation" or referencing motivational constructs would also use the word "motivation" and thus would be retrieved in our searches. Consequently, we may have missed some otherwise eligible studies that exclusively referenced concepts that are related to, or treated as synonymous to, motivation (eg, engagement) or motivational constructs (eg, confidence). We also chose to exclude studies written in a language other than English, which may have resulted in missed studies.

We decided to focus our review on experimental studies because they provide a critical source of evidence regarding the effectiveness of design strategies. We acknowledge that many different kinds of studies can generate evidence to support educators' motivational design efforts when producing online learning [31,111]. For example, qualitative studies can help us understand how learners make meaning of instructional designs in context [112], and single-group studies can investigate the factors influencing engagement with motivational design strategies [113]. It may be that studies leveraging nonexperimental designs demonstrate a different distribution of foci regarding motivational constructs. We recommend that a breadth of methodologies, including but not limited to experimental comparison studies, be used to investigate novel motivational design strategies in the future.

Finally, our review focused on online instruction in HPE, and it is unclear whether the trends we observed apply to other types of HPE, such as in-person simulation. While the trend toward enhancing interest and enjoyment may also be present in other HPE contexts—such as through the gamification of in-person instruction [114-116]—we cannot make definitive claims about the generalizability of our results to other types of HPE. Conducting similar reviews in other areas of HPE may be a focus of future research.

Conclusions

A key challenge for educators when teaching online involves keeping learners motivated. To address this challenge, educators need access to motivational design strategies that target a range of motivational constructs. The existing research provides an important starting point, but there is much work to be done. Researchers can use our findings to guide future primary and secondary research that generates a more robust evidence base for educators wishing to motivate their learners.

Abstract

Background: The concept of online learning in medical education has been gaining traction, but whether it can accommodate the complexity of higher-level psychiatric training remains uncertain.

Objective: This review aims to identify the various online-based and technology-assisted educational methods used in psychiatric training and to examine the outcomes in terms of trainees' knowledge, skills, and levels of confidence or preference in using such technologies.

Methods: A comprehensive search was conducted in PubMed, Cochrane, PsycINFO, Scopus, and ERIC to identify relevant literature from 1991 until 2024. Studies in English and those that had English translations were identified. Studies that incorporated or explored the use of online-based or technology-assisted learning as part of psychiatric training in trainees and had outcomes of interest related to changes in the level of knowledge or skills, changes in the level of preference or confidence in using online-based or technology-assisted learning, and feedback of participants were included. Studies were excluded if they were conducted on populations excluding psychiatric trainees or residents, were mainly descriptive of the concept of the intervention without any relevant study outcome, were not in English or did not have English translations, or were review articles.

Results: A total of 82 articles were included in the review. The articles were divided into 3 phases: prior to 2015, 2015 to 2019 (prepandemic), and 2020 onward (postpandemic). Articles mainly originated from Western countries, and there was a significant increase in relevant studies after the pandemic. There were 5 methods identified, namely videoconference, online modules/e-learning, virtual patients, software/applications, and social media. These were applied in various aspects of psychiatric education, such as theory knowledge, skills training, psychotherapy supervision, and information retrieval.

Conclusions: Videoconference-based learning was the most widely implemented approach, followed by online modules and virtual patients. Despite the outcome heterogeneity and small sample sizes in the included studies, the application of such approaches may have utility in terms of knowledge and skills attainment and could be beneficial for the training of future psychiatrists, especially those in underserved low- and middle-income countries.

KEYWORDS

online learning; telepsychiatry; remote learning; virtual; training; education; psychiatry; trainees; residents

Introduction

The incorporation of online-based or technology-assisted methods in medical education is not new. Virtual grand rounds, web-based learning, online journal clubs, and virtual clinical cases and labs are among the many examples of their ubiquitous implementation [1]. The mass adoption of technology-based education is attributed to its numerous perceived advantages, including the ability to transcend geographical boundaries, the presence of learner-centered approaches, the development of students' self-directed learning skills, and the asynchronous interaction between teachers and students. As education is getting more globalized due to increasing connectivity, these benefits are being increasingly valued [2].

However, questions remain about whether the many advantages of online education are as intuitively apparent and relatable in the field of psychiatry. Traditionally considered as a face-to-face medical discipline, concerns arise regarding the unique interpersonal nature of psychiatry, with its emphasis on empathetic responsiveness toward patients. These concerns are particularly relevant when considering a virtual or simulated patient, and this represents one of the frontier aspects of online education [3]. It is an undeniable fact that appreciating cues from patients is an experiential aspect of knowledge, which is often deemed irreplicable in online sessions.

As technology-based education is increasingly recognized as being noninferior to physical education in undergraduate studies [4], it is imperative to investigate its application in training postgraduate students. The outcome is significant, as it pertains to the production of future psychiatric specialists. This inquiry is especially relevant today, given the radical and drastic transition to technology-based education at all levels due to the recent COVID-19 pandemic [5]. Most medical fraternities are able to integrate online-based and technology-assisted components in their syllabi to enhance the training of trainees or residents without much difficulty. However, acknowledging the distinct nature of psychiatry, which often can be rather ambiguous and subject to nuance, it is important to evaluate the suitability of such an approach to augment the training of future psychiatrists.

Given these considerations, the overarching goal of this study is to systematically map and summarize the existing literature on online-based and technology-assisted psychiatric education for trainees. Specifically, this review aims to identify the various online-based and technology-assisted educational methods used in psychiatric training and to examine the outcome of the aforementioned technologies in terms of trainees' knowledge, skills, or levels of confidence or preference in using such technologies. We hypothesized that online-based and technology-assisted education can be integrated into psychiatric training to improve trainees' knowledge, skills, and competency levels.

This review is aimed at psychiatric educators and training directors looking for ways to incorporate technology into their programs, psychiatric trainees who want to understand how online learning fits into their training, and policymakers or accreditation bodies shaping the future of psychiatric education. It is also relevant for researchers and academics interested in digital learning and medical education trends.

Methods

Search Strategy

The scoping review was conducted according to the recent methodological framework by Westphaln et al [6], which was derived from the earlier work of Arksey and O'Malley [7]. Five databases (PubMed, PsycINFO, Cochrane, Scopus, and ERIC) were searched from March until June 2024. The keywords applied in PubMed were as follows: ((“resident*”[Title/Abstract] OR “trainee*”[Title/Abstract] OR “postgrad*”[Title/Abstract] OR “graduate*”[Title/Abstract]) AND (“psychiatr*”[Title/Abstract] OR “psychologic* medicine”[Title/Abstract]) AND (“education”[Title/Abstract] OR “training”[Title/Abstract] OR “development”[Title/Abstract] OR “learning”[Title/Abstract] OR “teaching”[Title/Abstract] OR “internship”[Title/Abstract] OR “traineeship”[Title/Abstract] OR “residency”[Title/Abstract] OR “course”[Title/Abstract] OR “lesson”[Title/Abstract] OR “program”[Title/Abstract] OR “programme”[Title/Abstract] OR “class”[Title/Abstract] OR “workshop”[Title/Abstract] OR “module”[Title/Abstract] OR “mooc”[Title/Abstract] OR “academic”[Title/Abstract] OR “clerkship”[Title/Abstract] OR “curriculum”[Title/Abstract]) AND (“on-line”[Title/Abstract] OR “online”[Title/Abstract] OR “digital”[Title/Abstract] OR “virtual”[Title/Abstract] OR “internet-based”[Title/Abstract] OR “internet based”[Title/Abstract] OR “web-based”[Title/Abstract] OR “web based”[Title/Abstract] OR “telepsychiatry”[Title/Abstract] OR “tele-psychiatry”[Title/Abstract] OR “cyber”[Title/Abstract] OR “electronic”[Title/Abstract] OR “e-learning”[Title/Abstract] OR “tele-education”[Title/Abstract] OR “videoconferencing”[Title/Abstract] OR “elearning”[Title/Abstract] OR “distance”[Title/Abstract])).

Different search configurations were used for the databases, and the search strategies are presented in Multimedia Appendix 1.

To ensure completeness, the authors also conducted backward citation searches from key articles and performed searches in Google Scholar to look for grey literature, such as conference proceedings and theses, relevant to the topic. Google Scholar was adopted as it has extensive coverage of academic work and is one of the commonly used search engines for grey literature [8].

Inclusion and Exclusion Criteria

Acknowledging the emergence of the field and the relatively limited number of studies, the authors made a conscious decision to include a variety of publication types in this review, including original articles, empirical and brief reports, case reports, and short communications. Studies were included in the review if they met the following criteria: (1) incorporated or explored the use of online-based or technology-assisted learning as part of psychiatric training or education; (2) were conducted in populations that included psychiatric trainees or residents; (3) had an outcome of interest related to changes in the level of knowledge or skills or the level of preference or confidence in

using online-based or technology-assisted learning, or included feedback of participants on the aforementioned approach (regardless of qualitative or quantitative results); and (4) were written in English or had English translations.

Studies were excluded if they (1) were conducted on populations excluding psychiatric trainees or residents; (2) were mainly descriptive of the concept of the intervention without an evaluation or any relevant study outcome related to the application of online-based or technology-assisted psychiatric education; or (3) were review articles. In addition, studies that only used online questionnaires to conduct pre-post assessments for psychiatric education, which were otherwise not delivered through an online or technology-assisted platform, and studies that primarily assessed the learning needs in online-based or technology-assisted psychiatric education without an evaluation of the intervention itself were also excluded. Studies conducted in languages other than English and those without an English translation were omitted due to limitations in language proficiency and to prevent inaccuracies or misinterpretation of the study findings.

Data Screening and Extraction

The search results from the 5 databases were exported to Rayyan online reference manager. Duplicates of similar articles detected by Rayyan were screened manually by MAMK and SMYAS to minimize errors in excluding articles. Prior to the title and abstract screening process, both MAMK and SMYAS underwent screening training to promote standardization and to identify possible conflicts. Then, according to the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) approach, the titles and abstracts were screened by MAMK and SMYAS to assess suitability for further examination based on the following predetermined criteria:

- Did the study use online-based or technology-assisted instruments as part of the education approach?
- Was the study focused on psychiatric education or related necessary skills?
- Was the study conducted in samples that included psychiatric trainees or residents?

In this phase, articles were divided into the following categories: accept, maybe, and exclude. Subsequently, the full texts of eligible articles (accept and maybe categories) were retrieved. This was followed by a blinded screening phase during which MAMK and SMYAS independently examined the articles in accordance with the inclusion and exclusion criteria. Any disputes regarding the acceptability of the articles in the title and abstract screening phase and in the full-text screening phase were resolved by an impartial third referee (JTYL or TIMD). Data extraction from all included studies was then conducted, gathering parameters such as author names, study year and country, aims and objectives, interventions applied, and key outcomes of interest. The data were extracted by MAMK and SMYAS to Excel (Microsoft Corp) sheets with predefined data fields.

The quality of the studies was assessed according to the 10-item Medical Education Research Study Quality Instrument (MERSQI) for quantitative studies [9] and the Standards for Reporting Qualitative Research (SRQR) for qualitative studies [10]. Previously, a scoping review adopted the SRQR as a 21-score checklist to assess the quality of included qualitative studies within the review [11].

Ethical Considerations

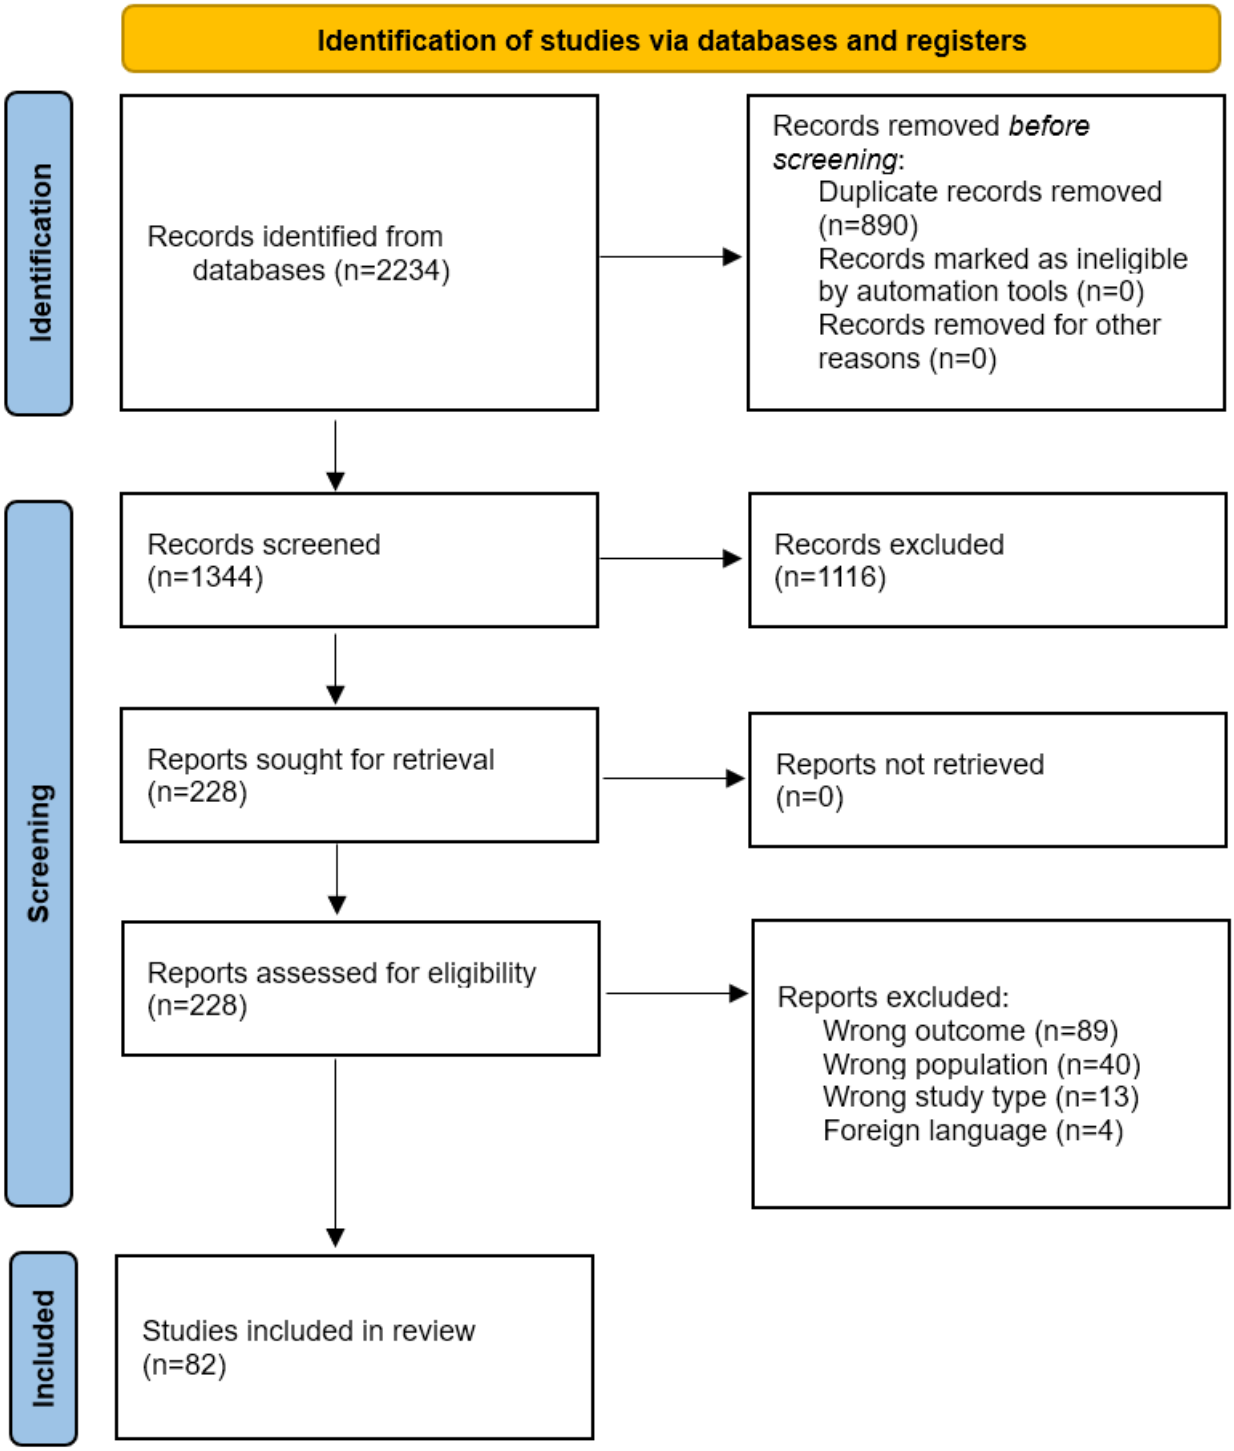
This review received ethical approval from the Research Ethics Committee of the National University of Malaysia (JEP-2023-789).

Results

Overview of the Included Studies

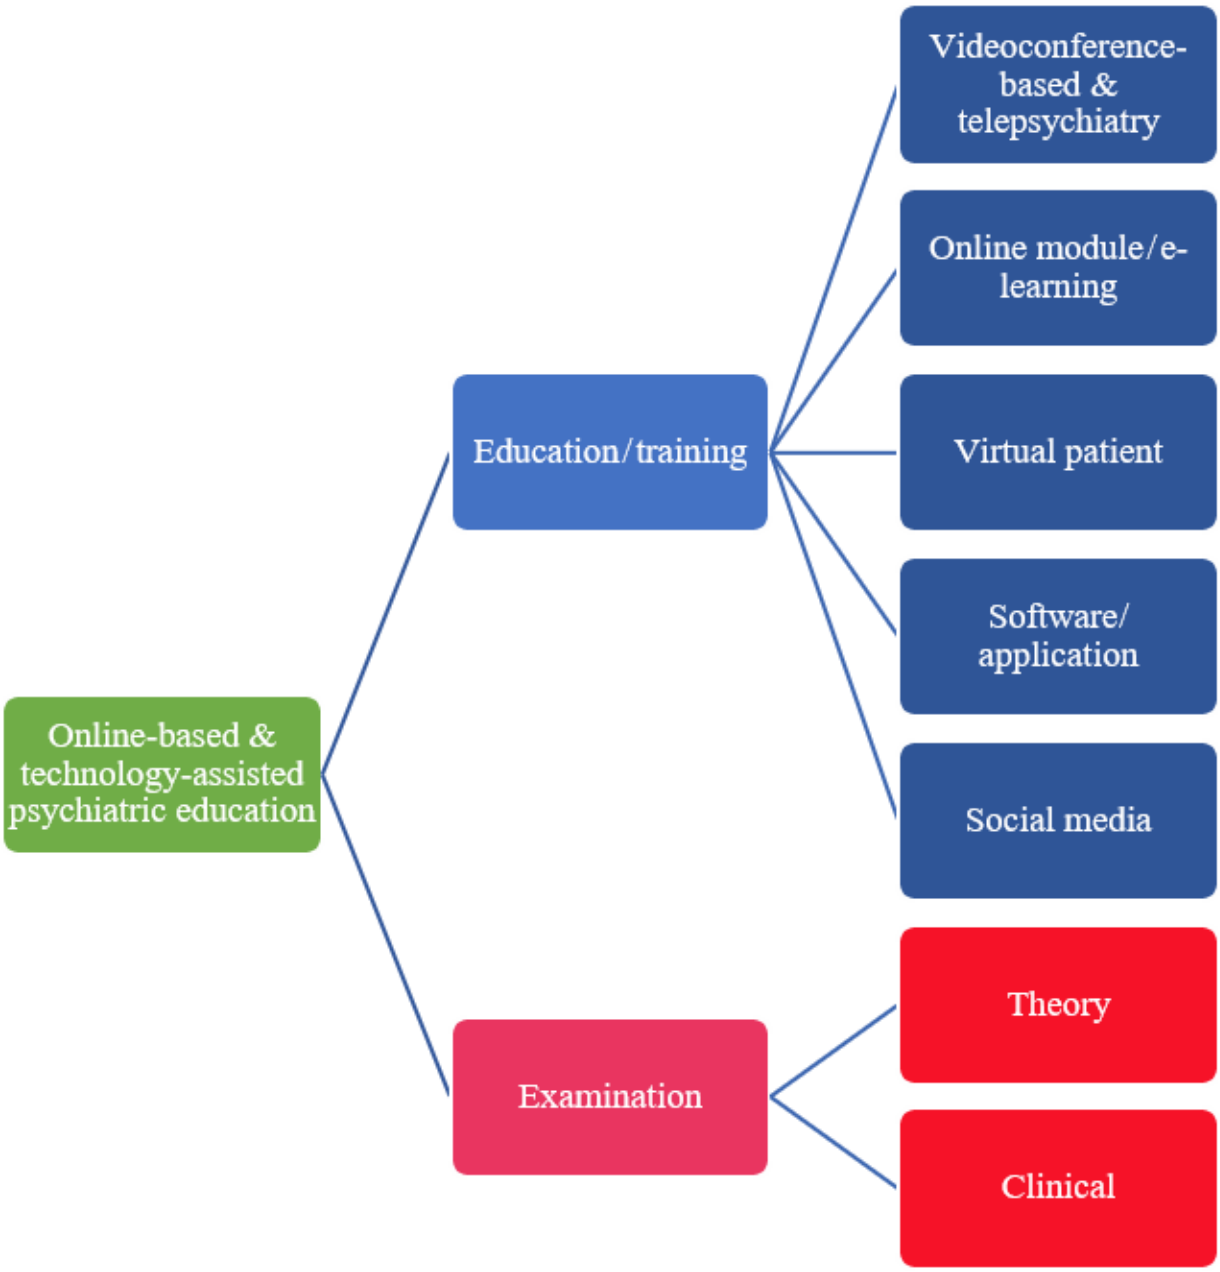
The initial search across the 5 databases yielded a total of 2234 articles, from which 890 duplicates were subsequently removed. After screening the titles and abstracts, 1344 articles were excluded and 228 articles proceeded to full-text screening. Of these, 89 articles were excluded for wrong outcomes (not evaluating the outcome of interest), 40 articles for wrong population (samples excluded psychiatric trainees or residents), 13 articles for wrong study type (review study design), and 4 articles for being in a foreign language. Thus, 82 articles were included in this review (Figure 1).

Figure 1. PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) flow diagram.



Among the 82 articles included, 2 themes were identified: education and assessment (Figure 2). Under education, the trend could be divided into 5 subthemes, namely online software (or e-learning platform or massive open online course [MOOC]), videoconference (or telepsychiatry), virtual patient (or simulation), software/application, and social media. Under assessment, there were 2 subthemes, namely theory and clinical examination.

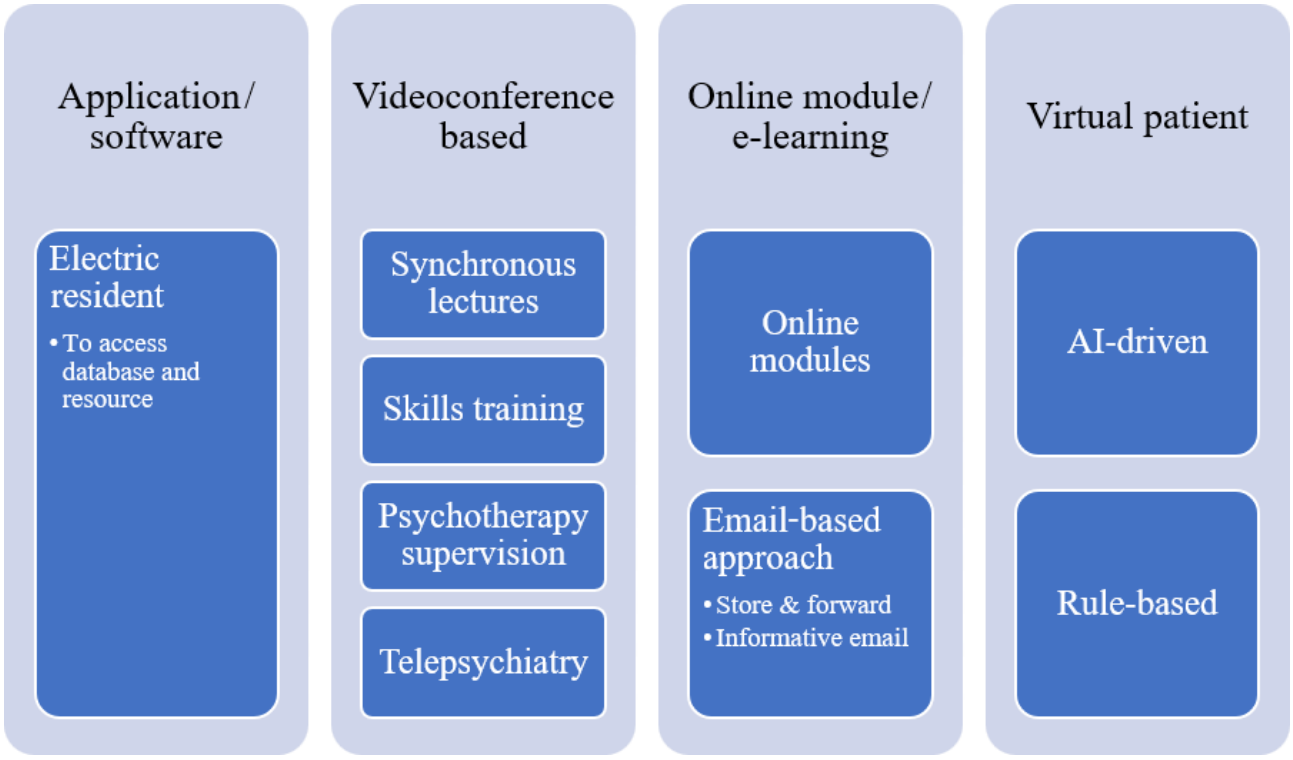
Figure 2. Trend of the implementation of online-based and technology-assisted psychiatric education.



Studies Prior to 2015

A total of 20 articles published before 2015 were included (Table S1 in Multimedia Appendix 2). Specifically, 2 articles were from the 1990s, 9 articles were from the 2000s, and 9 articles were from 2011 to 2014. These articles were mainly from Western countries, such as the United States and Canada. The articles primarily involved telepsychiatry and videoconferencing as tools for education, training, and supervision (n= 10/20, 50%), followed by web-based approaches or e-learning (n= 5/20, 25%), virtual patients (n= 3/20, 15%), and software (n=1/20, 5%). The taxonomy of the methods applied in psychiatric education during this period is presented in Figure 3. Studies mainly had a 1-group, posttest-only study design; 1-group, pretest-posttest study design; and randomized controlled trial design. Out of the 20 articles, 8 had objective measures, such as the change in the level of knowledge before and after the intervention, while the other 12 had subjective measures, such as the level of satisfaction and participant feedback.

Figure 3. Taxonomy of online-based and technology-assisted learning prior to 2015. AI: artificial intelligence.



Despite the limitation of the internet in earlier years, there have been some attempts to integrate IT as part of training. Within this period, depending on financial capabilities and regions, few types of internet connections were available, for example, dial-up connection (especially in the 1990s), Integrated Service Digital Network (ISDN), and broadband connection. The type of internet connection has influenced the strategy and the experience in the education process. With slower internet, an indirect instructional model or independent study was used, with trainees searching for relevant information to enhance their knowledge in particular topics or cases that they had been consulted on. One of the earliest studies highlighted the use of computers and the internet for accessing MEDLINE to assist residents with their consultations, checking drug interactions, and reviewing literature pertinent to cases that they were consulted on [12]. In a survey, printed materials were preferred when learning something new, but digital media or online resources were preferred when revising or searching for resources during patient care [13].

As seen in other fields of medicine, the advancement of relevant infrastructure enabled faster internet connectivity, which allowed widespread and accessible knowledge sharing through videoconference-based seminars, and this is also applicable in the field of psychiatry. This has allowed direct instructional models through approaches such as online lectures and seminars. However, these approaches were met with mixed feedback. One study in the United States in 2004 highlighted that satisfaction with videoconference-based lecturers was contingent on the internet speed, with trainees or residents in centers having a slower internet speed reporting less satisfaction with the lecture experience and the overall sound quality [14]. Another study in Australia in 2008 reported higher preference among participants to attend seminars from remote sites, and most participants felt that the videoconference-based seminars were beneficial for their practice [15]. Meanwhile, in a study in South Africa by Chipps et al [16], while videoconferencing was perceived as an excellent education tool by half of the psychiatric registrars, only 39% of them felt that it was as effective as face-to-face teaching. This led to decreased interest in further videoconference-based training. Additionally, another randomized controlled trial in Iran in 2014, which aimed to compare the effectiveness of face-to-face communication skills training sessions against distant learning in improving empathy, found that the level of empathy was significantly increased in the attending group but not in the distant learning group [17].

One study in Norway in 1998 explored the use of videoconferencing technology in terms of psychotherapy supervision [18]. The psychiatric trainees conducted face-to-face psychotherapy sessions with their patients and later had alternating face-to-face and online psychotherapy supervisions with their supervisors. Through semistructured interviews after the completion of the psychotherapy session, it was noted that while the reduced nonverbal cues were an issue, the limitations of the videoconferencing supervision paradoxically had some positive effects among the trainees in terms of the supervision process, such as verbalization and structure. The positive effects were also contributed by the ease of logistics and by having a neutral space separate from the supervisor's office.

As an extension to videoconference use, telepsychiatry serves as a valuable tool to expand the reach of psychiatric services. As such, it has been incorporated as part of training for psychiatric trainees or residents. In terms of supervision, most of the studies included direct, side-by-side supervision by attendings for assessing patients [19-22]. On the other hand, 1 study adopted a different approach, with attending psychiatrists sitting in with residents during their first session to help

familiarize them with conducting treatment via telepsychiatry, and in later sessions, the involvement of supervising attendings was on an "as needed basis" [23]. Most feedback by trainees on telepsychiatry programs indicated that telepsychiatry enhanced their skills and knowledge, with majority of trainees stating that it was interesting and enhanced their training. However, some trainees mentioned technical issues with this approach and the difficulty in assessing the influence on patients.

On the other hand, improved access to the internet has expanded the utility of asynchronous learning methods. In earlier years, a web-based email approach was applied to promote exposure or learning about stigma education [24] and child and psychiatry cases [25] through approaches such as the "store and forward" concept. However, in Western countries where technology was more advanced compared to the rest of the world at that point of time, e-learning materials were typically in the form of slides of didactic content with recorded audios and videos. This delivery method was used in learning evidence-based medicine [26] and to improve electrocardiogram reading skills [27]. A study by Garside et al [28] in 2009 managed to introduce direct and interactive instruction strategies to learn about how to fill Form 1 of the Mental Health Act. This was achieved by integrating slides of relevant materials regarding Form 1 and the laws related to it, together with interactive Flash animations and practice cases, using questions, and there was immediate expert feedback for each question. Throughout these studies, there were statistically significant improvements in the levels of knowledge and skills of the trainees, suggesting the potential of such an approach to augment the training of psychiatric trainees.

Interest in a virtual patient as an education tool for psychiatric training emerged in the 2000s and 2010s, and facilitated more immersive learning. Within this period, 2 types of virtual patients were studied: artificial intelligence (AI)-driven virtual patients and rule-based virtual patients. Kenny et al [29] and Pataki et al [30] described the use of an AI-driven virtual patient to simulate an adolescent patient with posttraumatic stress disorder (PTSD) ("Justina"). The virtual patient was developed according to the criteria of PTSD based on the Diagnostic and Statistical Manual of Mental Disorders (DSM) [31] and involved technologies such as voice recognition, response selection, behavior generation, and a visual graphics engine. "Justina" received good feedback from residents who mentioned that the experience they had from assessing the virtual patient closely matched their actual experience, but there were times when the virtual patient was not able to understand the questions from the residents. In another study, the rule-based virtual patient concept was applied to assess the doctor's competence in obtaining informed consent before prescribing antipsychotics in a simulated patient with psychosis [32]. A Flash-based video was shown to introduce the clinical scenario, followed by a series of menu options from which they could choose their next action. After completion of the scenario, the program provided a feedback screen regarding the appropriateness of their actions, as well as a link to relevant resources to improve their knowledge. There were statistically significant improvements in all items of the Confidence Scale (pretest to posttest).

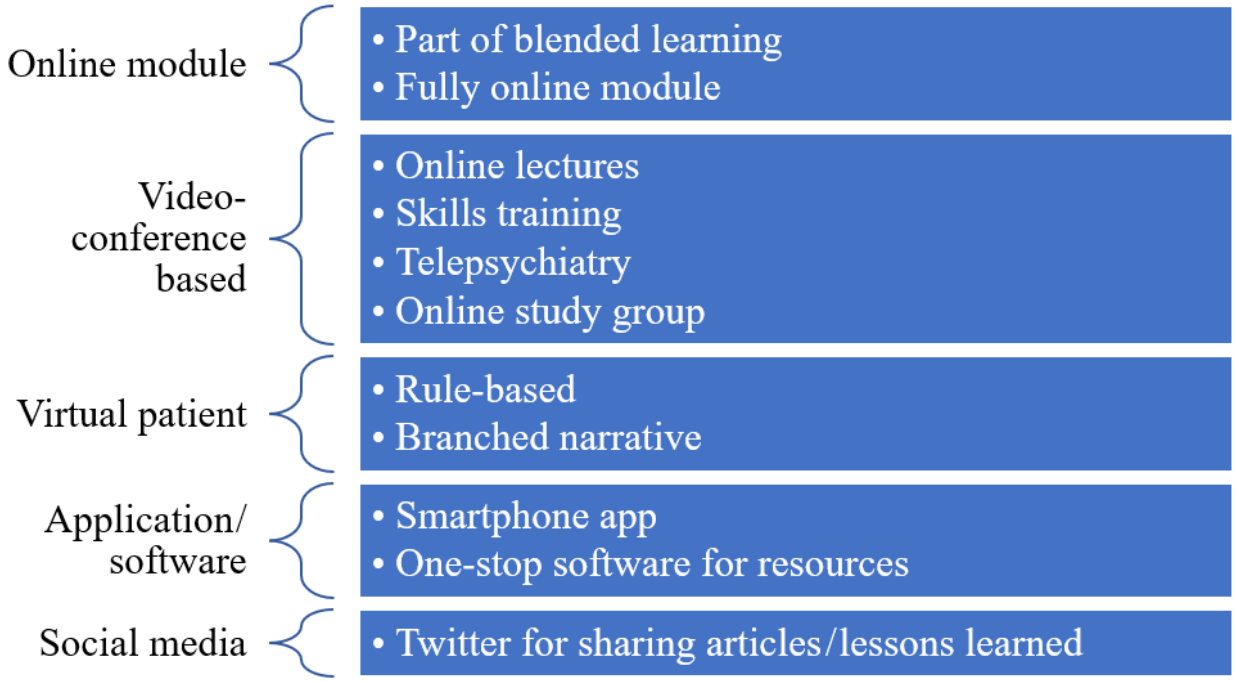
Studies From 2015 to 2019 (Before the COVID-19 Pandemic)

During the period from 2015 to 2019, there was an acceleration of internet-based or technology-assisted education in psychiatry, with 21 studies identified over 5 years (Table S2 in Multimedia Appendix 2). Western countries, particularly the United States and Canada, were at the forefront of these initiatives. Majority of the studies involved videoconference-based learning (n= 7/21, 33.3%), followed by use of online modules or e-learning platforms (n= 5/21, 23.8%), development of software or applications (n= 3/21, 14.3%), adoption of virtual patient approaches (n= 3/21, 14.3%), and use of social media as a learning tool (n= 1/21, 4.8%) (Figure 4). The most common study design was a 1-group, pretest-posttest design, followed by a 1-group, posttest-only design. There was only 1 randomized controlled trial and 1 crossover intervention study. Studies mainly applied subjective measures to assess the outcome of interest, and there was an increasing trend of objective measures in 9 studies, mainly to assess changes in knowledge.

There was more organized and comprehensive use of online resources, with UpToDate, PubMed, Wikipedia, and e-journals being popular among trainees [33]. However, some residents cited insufficient time, insufficient faculty guidance, and lack of resources specific to psychiatry as barriers to using online resources in their practice. Moreover, 86% of respondents felt that there is a need for more psychiatry-specific online resources, and 79% believed that online resources should be more visual and interactive. In another survey, some trainees preferred to read or take notes on paper for academic purposes [34]. However, they still preferred on-screen reading for checking medication dosing and information.

As accessibility to the internet improved with wider coverage and greater stability, there was an increased effort to conduct online modules or e-learning to complement the traditional methods of psychiatric learning, at least for delivering theoretical aspects. For example, Hickey et al [35] conducted a blended course of traditional lectures, online modules, and videotape reviews in psychotherapy education. The authors developed 2 modules on Davanloo Intensive Short-term Dynamic Psychotherapy (IS-DTP), which consisted of PowerPoint presentations, videos, and pre- and posttests. In a crossover intervention design, residents were divided into 2 groups, with each group receiving an online module and a face-to-face lecture but in a different order for 2 topics. It was found that there was a statistically significant improvement in knowledge acquisition in both the online module group and face-to-face lecture group, and there was no significant difference in comparison between both groups regardless of how the topics were delivered.

Figure 4. Taxonomy of online-based and technology-assisted learning in 2015-2019.



Three studies described blended learning but with a different model compared to the earlier study [36-38]. For example, a bookend blended learning model was adopted, in which there was self-paced virtual learning via online modules in the beginning, followed by synchronous in-person interactive discussion, and the approach ended with case supervision or reflection. This approach was used in learning PTSD [36] and in an integrative psychiatry curriculum [37], and residents appreciated the convenience and suitability to augment their training owing to 2 main factors. The first factor was that the self-paced online modules allowed for more time for personalized training and to process materials, and the second factor was the ability to access quality information linked directly to published sources. In another variation of blended learning, another study applied the flipped classroom model, in which the required reading was provided earlier, and then, participants engaged in interactive asynchronous discussion [38]. Interestingly, less than half of the participants indicated improvement in their knowledge, while the rest felt no difference, and a small number of participants felt that the approach had a negative impact on their knowledge, indicating the need to re-evaluate the suitability of the asynchronous flipped classroom approach for psychiatric training.

Fully online courses or modules have been continuously adapted to different aspects of psychiatric training. Brief online courses or modules were employed in rather specific topics under psychiatric-related theoretical knowledge, such as catatonia [39], tobacco use disorder [40], and substance use disorder [41]. Certain modules can be completed in 10 minutes, and brief modules often include slide presentations and relevant videos (recorded webinars, patient interviews, or demonstrations of symptoms and signs), which trainees can complete at their own pace. Despite the brevity of the approach, there were significant increases in knowledge [39,40] or improved levels of stigma [41] between pre- and posttests, with some of the improvements being retained at the 3-month or 6-month follow-up, suggesting the utility of such an approach.

Videoconference-based discussions or webinars remain useful tools in psychiatric education. Few studies used videoconference platforms to deliver online lectures and online case discussions tailored for aspects of psychiatric training, such as career development activities [42] and continuous education in conflict zones [43]. Videoconference platforms have also been used for skills training. Puspitasari et al [44] conducted a study on online behavioral activation training over 4 weeks with the aim to compare trainer-led online training and self-paced online training. There was a significant increase in behavioral activation skill assessment total scores in both groups, and there were significant between-group differences favoring the trainer-led online group at both the posttraining assessment and 3-month follow-up. Although direct instructional strategies were applied in both groups and both approaches were conducted online, the interactive component of the session in the trainer-led group caused a significant difference in the improvement of the skills of the trainees.

Building on the earlier work of Pignatiello et al [21] and Volpe et al [22], a study by Teshima et al [45] focused on feedback from over 300 residents in telelink telepsychiatry training in Canada. The trainees appreciated the opportunity to learn about different approaches to interviewing clients. Although the residents found the technology a “bit unnatural” at the beginning of the session and realized that it was “challenging to interview [patients] at a distance,” they were still able to obtain nonverbal cues, which were important to understand their patients. Almost all participants agreed that the telepsychiatry experience was interesting, while 97% agreed with the statement “the experience helped me understand more about providing psychiatric services to underserved areas.” As the telelink program was an established and mandatory program for psychiatric trainees in University of Toronto, this study had one of the largest sample

sizes in comparison to other studies, enhancing its reliability despite its single study site.

Davidson and Evans [46] illustrated how a videoconference platform was employed for an online study group as an augmentation tool in preparing for the Royal Australian and New Zealand College of Psychiatrist (RANZCP) objective structured clinical examination (OSCE). Four New Zealand trainees used Google Hangout (now known as Google Meet) for their online OSCE practice, with the exam questions based on online past papers on the RANZCP website [46]. The members rotated their role to be a candidate, examiner, or role-player, adding to the experiential learning. The 4 trainees passed their OSCE and acknowledged the benefit of a virtual study group in enhancing their preparation.

As demonstrated by earlier studies, the concept of a rule-based virtual patient was proven useful in learning PTSD and significantly improved the knowledge and confidence level of residents in managing PTSD [47,48]. In another variation, Wilkening et al [49] employed a branched-narrative virtual patient for advanced psychopharmacology sessions, in which residents were presented with a challenge and given choices, and the consequences would depend on the choice selected. The integration of the virtual patient concept led to statistically significant improvements in knowledge levels in advanced psychopharmacology, supporting the efficacy of the virtual patient concept as part of psychiatric education.

Abundance of reliable resources is a boon to evidence-based medicine; however, due to the hectic nature of clinicians, a quick decision must be made quite often. Thus, few software programs were developed to act as a 1-stop center for reference to help expedite and guide their practice. Adeponle et al [50] developed the Psychiatry Toolkit, which allowed direct, immediate, and full access (institutional login) to desired journals, articles, and relevant databases, including PubMed, PsycINFO, and UpToDate [50]. Another study by Dirlam et al [51] described Mental Health EMR Tools, which is a large database that allows residents to access prevetted, curated, and continuously updated information to help with their clinical practice. In addition, acknowledging the potential of a smartphone as an educational tool, Zhang et al [52] developed the Delirium University Health Network Application as a tool for delirium education. It was initially developed as an online application and was later piloted as a smartphone app via the Android Play Store. The app included many important contents related to delirium, such as the DSM-5 diagnostic criteria for delirium, common causes of delirium, pharmacological and nonpharmacological interventions for delirium, and objective assessment questionnaires (eg, Confusion Assessment Method [CAM]). Overall, Mental Health EMR Tools and the delirium smartphone app received good feedback from users, who appreciated the convenience of getting information from a consolidated source. On the other hand, while the Psychiatry Toolkit helped residents to look for answers to their clinical questions, the adoption rate of the toolkit among respondents was relatively low at 47% [50].

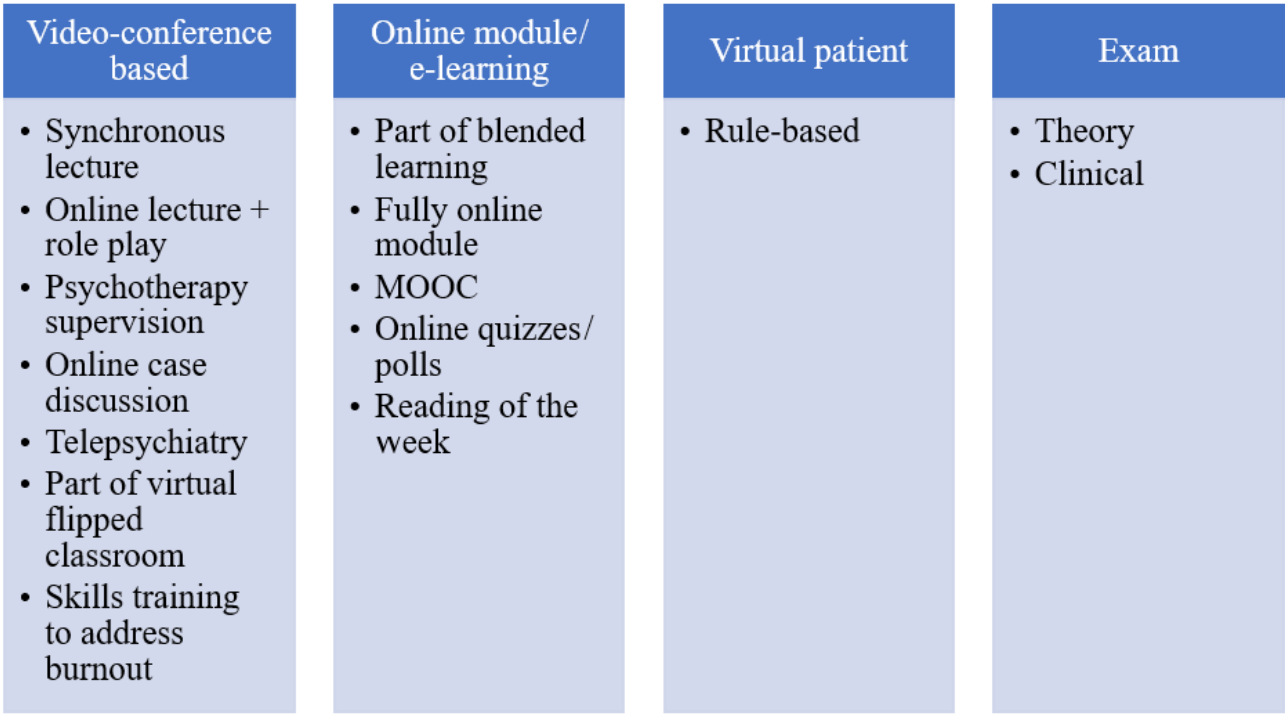
An interesting study described an innovative approach to adjunct psychiatric education using social media. Walsh et al [53] described the use of Twitter to disseminate education resources considered helpful in training. Under Twitter account @PhippsPsych, residents took turns to post tweets or retweet contents, such as take-home points from psychiatry grand rounds, links to journal articles, and references to psychiatry in current events. While the study had a rather small sample size with 49 residents, there was a significant increase in the proportion of participants using Twitter for medical education from 8.2% to 28.6%. However, residents' ratings regarding the usefulness of social media in medical education did not change from pre- to postsurvey, and corroborated by the fact that 60% of residents reported that the knowledge gained from following the account had no impact on their clinical practice, 37.2% reported a minimal or average impact and only 2.8% reported a great impact.

Studies From 2020 Onward (After the COVID-19 Pandemic)

The number of articles on online-based or technology-assisted learning in psychiatry education for psychiatric residents or trainees saw a significant spike during and after the COVID-19 pandemic. There were 41 relevant articles from 2020 until June 2024 (Table S3 in Multimedia Appendix 2). While the United States, Canada, and the United Kingdom had the highest number of studies, there was also notable involvement from Global South countries, such as Malaysia, Thailand, Pakistan, India, and Tunisia. Majority of the articles involved the application of videoconference-based learning or webinar concepts (n= 24/41, 58.5%) and online modules (n= 8/41, 19.5%) (Figure 5). Studies mainly had subjective measures as outcomes and had a 1-group posttest-only study design. There were 11 studies with a 1-group pretest-posttest design and 1 study with a nonequivalent group posttest-only design.

Transition to videoconference-based learning and webinars was necessary for the continuation of training and education during the COVID-19 pandemic, including for psychiatric residents. There were few variations in how videoconference-based learning was applied. In some articles, it was rather straightforward with synchronous online lectures through the videoconference platform, and some of the lectures were then followed by virtual group discussions or brainstorming sessions in the breakout rooms of the platform to make it more interactive. This approach was commonly used in the theoretical aspects of psychiatric training, such as in alcohol use disorder [54], fundamentals of remote psychotherapy [55], research in psychiatry [56], digital psychiatry [57], complex child and adolescent cases [58], biostatistics and methodology courses [59], and journal clubs [60].

Figure 5. Taxonomy of online-based and technology-assisted learning in 2020-2024. MOOC: massive open online course.



In another variation, the online lecture was paired with virtual role-play or simulation sessions. With the added experiential learning component, residents were able to apply their knowledge accordingly in case scenarios. In a study by Blamey et al [61], psychiatric trainees attended a 2-hour virtual lecture on the necessary skills for their on-call work, and then, the trainees participated in a series of 2-hour simulated on-call shifts once a week for 10 weeks, covering 10 common scenarios for psychiatric on-call work. Acknowledging the importance of understanding the complexities of health systems in delivering effective and safe patient care, Li et al [62] developed an online curriculum for core competencies in health systems science. The residents underwent 10-minute virtual didactics prior to the virtual simulation of case scenarios using the Zoom platform.

Looking at the outcomes, trainees or residents perceived a high level of satisfaction with the program and its online delivery, as well as an increase in confidence in skills and perceived learning gains [56,57,60]. Among the studies, 1 study had an objective outcome, in which significant improvements in the knowledge level regarding alcohol use were noted among residents after the videoconference-based lecture and recorded training video session, indicating the potential efficacy of such a program [54]. The virtual role-play concept was especially credited to be a useful technique to enhance the interactive learning of residents [61]; however, the virtual format can be awkward owing to the need for turn-taking, which in turn affects the interactivity, especially when there are few residents involved concurrently in a single case scenario [62].

As demonstrated by Gammon et al [18], a videoconference platform may be used for psychotherapy supervision. Due to the COVID-19 pandemic, this was of value, and there were 2 studies involving psychiatric trainees receiving psychotherapy supervision virtually. There were concerns regarding the loss of nonverbal cues or subtleties of communication during remote supervision, in addition to the "Zoom fatigue" phenomenon, all of which influenced residents to favor face-to-face supervision more than remote supervision [63]. However, the flexibility of remote supervision and the option to allow residents to attend the supervision even when they were busy with their ward work or were on-call were certainly advantageous, and the quality of psychotherapy skills attainment based on subjective assessments by supervisors was not significantly different between remote supervision and traditional face-to-face supervision [63,64]. In fact, as reported by Famina et al [65], supervising attendings noted that the quality of psychiatric care was not different between remote sessions and in-person sessions, and there was not much difference in terms of the ability to empathize and to interpret nonverbal cues.

With regard to telepsychiatry, the authors of an article mentioned their experience of a sudden unprecedented change to their service, which involved a transition to telepsychiatry due to the COVID-19 pandemic [66]. The service initially involved phone consultation, and residents and attendings subsequently switched to video consultation after obtaining approval to use a video platform [66]. While both trainees and attendings strongly agreed that the change to virtual care was necessary, the attendings felt that trainee supervision and training worsened during the pandemic. The trainees also felt less comfortable conducting virtual care and less confident in their assessments to the extent that they found video consultations "frustrating," especially when attempting to interview patients who had difficulty engaging in virtual interactions (eg, those with delirium, neurocognitive disorders, or mania) [66]. This

experience was echoed in a survey by Cruz et al [67], which showed that the top 5 concerns shared by residents and the faculty about telepsychiatry were the inability to perform a physical exam, poor internet connection, unknown liability risks related to telepsychiatry, certain cultures being less accepting, and nonverbal cues being missed.

Contrary to that experience, the authors of another study described their telepsychiatry experience in a rather positive note. Because of a rapid shift, telepsychiatry sessions were still following the prior model of in-person direct supervision involving attendings and residents, and both had to don a mask while conducting the telepsychiatry sessions, which affected the voice projection and the ability of the patient to hear the treatment plan [68]. Subsequently, with further understanding of the videoconference platform, they were able to continue direct supervision with slight modification as attendings joined the session from their private offices, allowing residents and attendings to remain mask-free and improving the audio for patients. Majority of the residents felt that telepsychiatry had positively impacted their clinical education experience, and it was significantly associated with comfort with practicing telepsychiatry in the future [68].

The flipped classroom model, which is a type of blended learning, reversed the settings, with direct instructions to be provided at home and learning activities involving higher order thinking to be done at school. COVID-19 restrictions necessitated the change to a fully virtual flipped classroom, and psychiatric training was not an exception. A study from Pakistan described a program using the flipped classroom model for an online trauma curriculum [69]. Under this program, reading materials and videos were provided to trainees earlier, and then, the trainees participated in virtual brainstorming, role-play, and case-based discussions. On a larger scale, the Metis didactic courses for psychiatric residents in Sweden (the pedagogical model has been in line with the flipped classroom concept from its inception in 2007) were switched to a digital format to ensure continuation of learning [70]. Each course consists of 3 phases: distance-based self-study, classroom-based meeting days for lectures and supervision, and distance-based examination. The second phase was subsequently transitioned to an online classroom for the same activities. While the fully online flipped classroom concept improved the level of knowledge and skills of psychiatric trainees, some residents preferred to return to face-to-face learning [69,70]. Interestingly, female participants and those aged younger than 50 years were more inclined to continue with online-based course meetings [70].

There was a growing issue of burnout among psychiatric trainees due to the pandemic and its consequences. As such, training programs included skills training as a necessary curriculum component to address burnout, and these were delivered virtually using videoconference platforms, such as the virtual Balint group [71,72], Mind-Body skills program [73], brief mindfulness-based cognitive behavioral therapy (CBT)-informed virtual well-being program [74], and virtual medical improvement program [75]. An interesting example was the virtual Balint group, an initiative that provides a cathartic space and helps to improve morale. With the idea to improve the understanding of patients' problems rather than finding solutions, residents were encouraged to participate with the camera on and the mic on mute when someone was presenting, and the presenter was free to express their experience of doctor-patient interactions, with the guarantee of nonjudgment and confidentiality [72]. During the discussion, the hands-up function of the Zoom platform was used when someone wanted to speak in order to control flow and avoid interruption. Participants were very positive of the virtual Balint group, with trainees feeling well supported by this initiative. However, many participants preferred face-to-face sessions but nevertheless would choose an online session over no session at all. In another study, the virtual Balint group was credited for promoting a sense of connectedness among peers and providing freedom to speak without needing to censor themselves. However, the virtual nature of the Balint group itself led some participants to feel an abrupt ending to the session, which does not occur in face-to-face sessions [71].

In terms of online modules, the most common design was problem-focused case vignettes, alongside interactive presentation and audiovisual content. Some of the modules also had tests at the end. This design was adopted in few of the studies to cover various aspects of psychiatry training, such as forensic psychiatry [76], catatonia [77], neuropsychiatry [78], tobacco use disorder [79], cultural sensitivity [80], and antiracism intervention [81]. A study by Owais et al [82] used the same online module concept in a blended learning approach for an electroconvulsive therapy curriculum, together with didactic seminars and hands-on clinical management. By combining indirect and direct instruction strategies, there was significant improvement in terms of knowledge attainment after the modules (smaller sample sizes) [76-78,82], and generally, the modules had high satisfaction levels reported by residents [80,81].

While most modules were confined to certain training institutions or regions, 1 article described a larger-scale MOOC to augment psychiatric training. Gargot et al [83] described the First European Psychiatric Association MOOC on CBT, which lasted for a month. With a focus on the theoretical aspects of CBT through recorded lectures, presentations, online forums, and online examinations, the self-paced MOOC had large participation, with 7116 participants enrolling from at least 49 countries. Although the eventual completion rate was 26%, a large number of participants (n=1828) completed the MOOC and the average score for the tests increased steadily from 21.4 out of 25 in the first week to 23.13 out of 25 in the final week, indicating the potential of the MOOC to fill the training gap.

In another study, a website was developed as an innovative, free psychiatry Continuing Professional Development (CPD) resource for Canadian psychiatrists and residents. Referred to as Reading of the Week, this website summarizes the latest psychiatric literature, provides expert commentaries, and promotes discussions on social media platforms [84]. The innovations in psychiatric education as described in these articles received good feedback from trainees. For the Reading of the Week initiative, in which the survey evaluation was based on the 6-level evaluation framework by Moore et al [85], positive feedback and satisfaction were reported by participants across

the 6 levels, including knowledge outcomes (level 3), behavior outcomes (levels 4 and 5), and practice outcomes (level 6) [84].

The pandemic also forced the examination process to be performed in a digital format. Generally, examinations in psychiatric training can be divided into theory examinations and clinical examinations (including OSCE). The Royal College of Psychiatrists conducted Member of the Royal College of Psychiatrists theory examinations via a digital platform using a combination of AI and in-person online proctoring [86]. Multiple choice questions were directly assessed, but for questions involving very short answers, smart algorithms were developed to recognize versions of correct answers, and answers that were nonexact matches were reviewed by a designated examiner. On the other hand, for the assessment of clinical psychiatry skills, there was mixed feedback from both examiners and trainees. Depending on the format of the clinical examination, examiners generally manned the stations or the breakout rooms. Integrating videoconference technology for the purpose of clinical examinations had inherent issues, such as connectivity problems, a sense of disconnect, lack of a framework to mentally reset, difficulty in building rapport, and an inadequate capacity to assess clinical skills [87]. However, some residents believed that online assessments were convenient for both participants and patients, reducing anxiety by being in a familiar environment and improving patient access [88]. Some of the candidates even stated that virtual communication was nearly as good as face-to-face communication and online examination was “better than expected” [89].

There is a paucity of studies comparing online training or learning with face-to-face or in-person training. In a quasiexperimental study in Germany to explore whether the satisfaction of online CBT training is noninferior to that of in-person CBT training, the 2 study groups had the same theoretical CBT content, a similar duration of training, comparable audiences, and an identical trainer [90]. The online training was conducted according to the inverted-classroom concept, with participants being required to watch recorded video lectures on the Moodle platform and then have a Zoom discussion at a fixed time for 6 to 7 sessions. It was found that evaluations of the online training group were noninferior to those of the in-person group in terms of information content, didactic presentation, assessment of the trainer as a suitable role-model, working atmosphere, own commitment, and practical relevance, suggesting that the delivery of CBT knowledge through an online platform may be sufficient.

In another study, Hewson et al [91] described a rather indirect comparison between face-to-face basic psychiatry skills simulation training and synchronous online training. The transition to online training via Zoom was due to evolving COVID-19 restrictions at that time and was not in the initial plan. In subgroup analyses, the face-to-face group showed statistically significant improvements in confidence across all psychiatry skills tested, whereas the online group showed significant improvements in confidence in all but 2 skills, namely psychiatric risk assessment and assessment of physical health problems in elderly patients with cognitive impairment. However, the face-to-face group included foundation doctors (junior doctors) and the online group included psychiatry and general practitioner trainees, suggesting that the lack of a significant improvement in confidence in those 2 skills could be related to a higher baseline self-confidence level prior to the simulation training.

A rule-based virtual patient appears to be a mainstay model of a virtual patient in psychiatric education. Rakofsky et al [92] developed a virtual patient-based assessment simulator as a tool to assess the proficiency of residents regarding psychopharmacological knowledge and practice. Combining virtual human avatars, AI, and an advanced pedagogical design, it allows for a realistic interaction, including live voice communication. According to the rule-based virtual patient concept, residents had choices of questions and answers to choose from, and they were given immediate feedback on all their choices alongside the rationale. Looking at the performance of the residents, the mean total score of the simulator by class correlated significantly with the mean score of the somatic therapies subscale of the Psychiatry Residency in Training Exam (PRITE), suggesting construct validity of the virtual patient simulator.

In a survey assessing residents’ perceptions of the pandemic’s impact on their didactic experience and training preferences, it was found that trainees appreciated several positive aspects of virtual didactics, such as being easy to attend and being engaging, and they were able to invite guest speakers from other institutions easily [93]. However, some negative experiences were also reported, including the “Zoom fatigue” phenomenon and frequent distractions, and some topics did not translate well to a virtual environment. Residents from Thailand, which was hit hard by the pandemic and had a significant shift in psychiatric training to online sessions, also reported mixed experiences. Although all residents had good results and passed their examinations, they felt that studying online and the uncertainty with virtual psychotherapy were major inconveniences in their training [94]. In another study, residents were ambivalent. They perceived face-to-face teaching to be superior, but majority of them did not think a complete return to in-person learning would be the most effective option when this becomes possible, implying a preference to continue with some online components in the training [95].

A summary of the key benefits and limitations of the 5 different online-based and technology-assisted educational methods (videoconference, online module/e-learning, virtual patient, software/applications, and social media) is provided in Table 1.

Table 1. Summary of the implementation of online-based and technology-assisted psychiatric education.

Method	Key benefits	Limitations
Videoconference	• Flexible and applicable for various objectives (lectures, skills training, psychotherapy supervision, etc) • Accommodates different instructional strategies (direct, indirect, interactive, and experiential) • Convenience of attending sessions regardless of location or schedule	• Relies on the internet speed • Struggles with nonverbal cues • Frequent distractions and Zoom fatigue
Online module	• Allows self-paced learning • Numerous relevant materials can be designed and included (animations, prerecorded videos, and quizzes) • Possibility of reaching a wide range of audiences via a MOOC[a]	• Lacks direct supervision • More suitable for theoretical aspects of training than clinical aspects • Often requires collaboration and resources to design the modules
Virtual patient	• Valuable for learning uncommon cases • Engaging learning experience	• Requires high levels of resources for development • Can be frustrating to interact in case of speech recognition issues
Software/applications	• Serves as a convenient point of reference • Integration with a smartphone • Highly favored in checking medication dosing and information	• Requires certain levels of resources for development • Software that primarily acts as a gateway for institutional logins to certain websites is not often used
Social media	• Promotes a continuous learning opportunity • Possibility of greater dissemination of knowledge to a larger audience • Provides information on current evidence-based studies	• Reported knowledge gain that translates into clinical practice is still less significant • Relies on the effort of the individual to follow the account and review the shared resource

[a]MOOC: massive open online course.

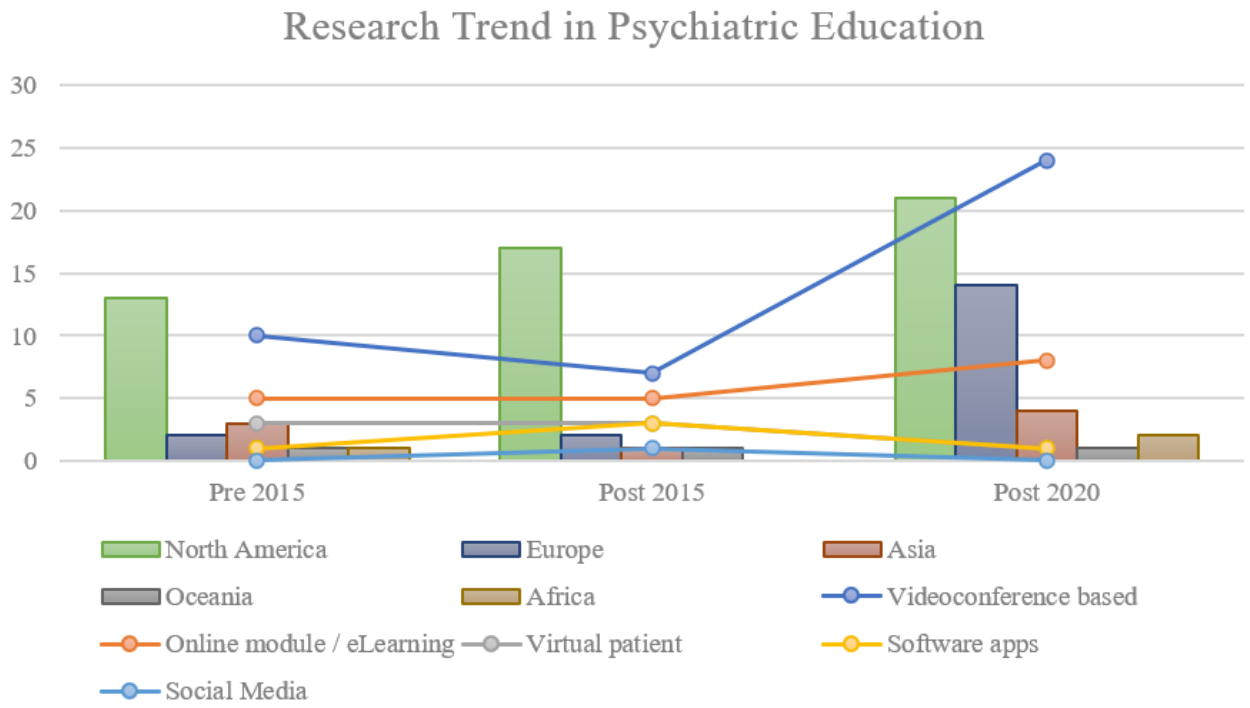
Discussion

Summary of the Results

The findings across the 3 phases (prior to 2015, 2015-2019 [prepandemic], and 2020 onward [postpandemic]) illustrated the creative integration of online-based and technology-assisted learning in psychiatric education for trainees (Figure 6). Five approaches were identified: videoconference, online module/e-learning, virtual patient, software/applications, and social media. These methods were used for various objectives, including but not limited to teaching theory knowledge, skills training, psychotherapy supervision, and information retrieval. North American countries were leading in research output, followed by European countries. There was consistent research presence from countries in Asia, Africa, and Oceania throughout the 3 phases, with a slight increase after 2020.

The trend of online-based and technology-assisted psychiatric education showed changes from one phase to another. Videoconference-based learning was consistently the preferred way of integrating technology into the learning or training of trainees. Meanwhile, there was a growing trend of online module/eLearning platform use, virtual patient use, and development of applications or software from the "prior to 2015" phase until the prepandemic phase (2015-2019). The trend however stagnated in the postpandemic phase. Videoconference-based learning was more dominantly used due to 3 factors. First, as seen in other fields, the sudden shift to online was not accompanied by the readiness of other technology modalities to assume the responsibility to continue the learning process [96]. Second, the improved accessibility and availability of videoconference platforms, such as Zoom, Google Meet, and Microsoft Teams, served as a plus point [97], and less resources were needed to shift learning to those platforms rather than developing online modules in an expedited manner. The third factor corresponds to the nature of psychiatric learning, which is preferably face-to-face, but among the choices that were presented, videoconference-based learning was a method that may offer some compromise in terms of allowing direct and synchronous instructional methods despite physical distance [98].

Figure 6. Trend of online-based and technology-assisted psychiatric education in the 3 study phases (prior to 2015, 2015-2019 [prepandemic], and 2020 onward [postpandemic]).



In terms of didactic teaching, evidence showed that online-based or technology-assisted learning is beneficial and well-tolerated by residents. Barring minor issues pertaining to connectivity, a recurring problem reported by several studies [59,65,78], theoretical learning of core knowledge in psychiatry through online platforms has been helpful in improving knowledge, and the impact cannot be understated. Some trainees or residents even expressed their preference for receiving academic or continuous professional development activities virtually, citing convenience and ease of access as important factors that encourage participation despite their busy schedules [72,93]. Nevertheless, psychiatry is not purely a theoretical field in medicine. Psychiatry knowledge must be paired with competency in necessary skills, such as communication skills and psychotherapy skills, to ensure robust and quality training. Learning these skills through an online platform is possible, and a study showed that learning CBT online was not inferior to learning it through in-person training [90]. Nonetheless, proper hands-on guidance remains necessary for mastering these skills, as it might not be possible to fully replicate or demonstrate those subtle, nuanced techniques through a screen. Hence, harmonizing virtual theoretical learning and practical hands-on learning to develop comprehensive blended learning may be a more interesting proposition [82]. Nevertheless, it must be highlighted that the approach of providing knowledge about certain skills and evaluating knowledge levels in trainees is vastly different from teaching skill competencies and then evaluating the levels of competencies of trainees. Because of this issue, some practitioners preferred in-person learning to ensure an optimum level of skill attainment, as compared to through online learning.

As demonstrated by many studies successfully integrating simulation in their medical training, the virtual patient concept (essentially simulating the experience of seeing a patient with the assistance of technology) has been quite helpful in psychiatry education. This concept has a unique strength: the ability to simulate cases that may be uncommon in clinical practice [99]. For example, a study used this concept to portray a refugee with PTSD symptoms, enriching the training of psychiatric trainees and increasing their confidence in managing PTSD cases [48]. Adjacent to the virtual patient concept is the virtual reality (VR) concept. VR allows for an immersive experience, frequently described as "being there," which involves more senses beyond just sight [100]. It has been used as part of the training curricula in medical fields, including orthopedics [101], surgery [102], and ophthalmology [103], with varying degrees of success. In psychiatric services, VR has been implemented as part of therapy or treatment, for example, exposure therapy for phobic disorders [104] and social skills training in patients with autism spectrum disorder [105]. Unfortunately, VR has not been extensively used in psychiatric education yet, perhaps due to the limitation of the current technology in grasping the complexity of psychiatric cases. As technology rapidly evolves, it remains an exciting avenue to explore in the future.

Competency is often assessed through an examination process. During the pandemic, the transition to online examinations became common worldwide, and psychiatry was no different. Online assessments were applied to various aspects of the psychiatry curriculum. While there were few issues with online theory examinations [86], the same cannot be said for other aspects. For example, an article described the challenges in sitting for the virtual Clinical Assessment of Skills and Competencies (CASC) under the Royal College of Psychiatrists, United Kingdom, where constant worry about internet issues, a sense of disconnect, and an inability to mentally reset between stations affected performance and the overall experience [87].

Another article described the experience of the online Basic Specialist Training examination under the College of Psychiatrists of Ireland [89]. Despite acknowledging the superiority of face-to-face examinations, the online examination was described as nearly as good and more favorable in view of respondents being in a familiar environment as well as saving cost and time to travel [89]. Although it is not possible to compare these examinations directly, the Basic Specialist Training examination highlighted that such examinations could be conducted virtually, but thorough preparation and strong technical support are warranted.

Another interesting aspect of how technology can be valuable in psychiatric training is through the development of cultural competence. Cultural competence refers to the capacity to respond to the unique needs of the population. In the context of psychiatry, it refers to the development of knowledge, skills, and attitude, which can enable the formulation of an intervention that considers the sociocultural backgrounds and sensitivities of psychiatric patients. In turn, this allows for a comprehensive and tailored treatment for patients, especially those from racial and minority ethnic groups. Previous measures to promote cultural competence included learning trips and student exchange programs. However, technology can also offer interesting and possibly cheaper options to achieve the same goals. Trinh et al [80] described an online module program to promote culture sensitivity in a psychiatry department. Three modules were developed, including presentation slides, case vignettes, and recorded videos, covering important topics, such as DSM-5 Outline for Cultural Formulation, Cultural Formulation Interview, and cultural identity as a multidimensional construct. This program was initially met with surprising feedback, with most clinicians indicating that they were not familiar with what questions to ask to elicit a cultural history; however, after completion, the respondents endorsed the module as useful and reported that they would change their practice, suggesting that a brief online module may have potential in this area.

Exploring the application of online-based or technology-assisted learning in psychiatry education for trainees holds significance in the training of future psychiatrists, especially in low- and middle-income countries (LMICs). To put this in context, most African countries have a massive shortage of psychiatrists, with an average of 0.1 per 100,000 people in the 47 countries across the World Health Organization African region [106]. Moreover, both Liberia [107] and Timor-Leste [108] had only 2 trained psychiatrists, indicating the pressing need to support the mental health systems in these countries. While there is no easy fix for this situation, efforts to increase the number of psychiatrists is of utmost importance. In this context, a concerted and collaborative effort among universities or training programs across regions or continents for the training of future psychiatrists in LMICs is needed to alleviate this issue, and the use of online platforms could be the key to bridging the gap.

Limitations

Our review has some limitations. First, we did not limit the types of publications, resulting in variations in the quality and rigor of the studies. Additionally, majority of the articles were from Western countries, with very few from LMICs, which might reduce generalizability. It is important to note that while a healthy number of studies were included in this scoping review, ultimately obvious heterogeneity was present in terms of the outcomes measured. Majority of the studies had a 1-group intervention study design and had a rather small sample size. Therefore, while some of the included studies might have shown positive responses or outcomes, the findings need to be interpreted carefully in the context of these factors, which might affect generalizability. Moreover, the lack of well-designed comparative intervention studies limits the understanding of the effectiveness of online learning in comparison to traditional face-to-face learning. Another key limitation is the profound lack of an objective assessment as part of the outcome measure within the included studies. Most of the studies assessed satisfaction and attitudes toward the interventions, rather than the actual impact of the interventions.

Moving forward, more well-designed studies in psychiatric education for trainees are needed, especially with objective assessments, to truly evaluate the suitability of online-based and technology-assisted learning. There is a clear paucity of studies evaluating the efficacy of psychotherapy skills training delivered virtually, which may be of significance to LMICs that need a higher number of competent mental health professionals. Lastly, the emergence of AI systems, such as ChatGPT and DeepSeek, can be a game changer for the psychiatric education of trainees, and further exploration is required on how to maximize the benefits of these systems while developing safe and competent psychiatrists in the future.

Conclusion

Videoconference-based learning was the most widely implemented approach, followed by online modules and virtual patients. Despite the outcome heterogeneity and small sample sizes in the included studies, the application of such approaches may have utility in terms of knowledge and skills attainment. With further fine-tuning, these approaches could become effective solutions to address the significant deficiency of psychiatrists, especially in LMICs.

Acknowledgments

The authors would like to thank Professor Dr Samy Azer for his input in preparing the manuscript. No funding was received to assist with the preparation of this manuscript.

Data Availability

The data supporting the findings of this study are available from the corresponding author upon reasonable request.

Authors' Contributions

MAMK and SMYAS: conceptualization, data collection, data analysis, and writing – original draft preparation. TIMD and JTYL: conceptualization, data analysis, writing – review and editing, and supervision. All authors contributed to the article and approved the submitted version.

Abstract

Background: Despite recent improvements, gender inequality persists within the higher education sector, as evidenced by the proportionally greater number of student and academic leadership positions occupied by male students and staff. Gender equality education and training for students may help to develop awareness, knowledge, and skills among individual students, building capacity to address biases and accelerate culture change in higher education institutions.

Objective: We aimed to identify and explore the existing literature on gender equality training interventions for students in tertiary education, with a particular emphasis on training content, methodology, and outcome evaluation.

Methods: The 6-stage framework developed by Arskey and O'Malley was used to map the literature related to current best practice in gender equality training for students in higher education. Systematic database searches of peer-reviewed literature were carried out and 3142 titles, 333 abstracts, and 52 full-text articles were screened for eligibility with 14 (27%) articles selected for inclusion in this review.

Results: The selected studies detailed a range of pedagogical approaches, including didactic lectures, participatory and co-design workshops, reflective writing, and service-learning, with durations ranging from a single interaction to 1 year. Most articles reviewed did not explicitly state their study aims or research question, and the theoretical underpinnings were generally vaguely described. The longer-term impact of most interventions was unclear, as evaluation metrics seldom go beyond the level of adoption.

Conclusions: This scoping review shows that the literature base for gender equality training for tertiary students lacks coherence, highlighting the need for further work to evaluate its impact. This work provides a foundation for developing training design recommendations.

(JMIR Med Educ 2025;11:e60061) doi:10.2196/60061

KEYWORDS

gender equality; tertiary education; students; training; higher education institutions

Introduction

Background

Higher education institutions (HEIs) can be effective allies in the fight for diversity, inclusion, and gender equality in the education context and in society as a whole. The leadership, academic and administrative staff, and students of HEIs are increasingly mobilized by the United Nations 2030 Agenda for Sustainable Development Goals [1]. The Higher Education Sustainability Initiative [2] recommends that all formal education curricula should feature education for sustainable development. The principles of gender equality are integral to the goals, targets, and indicators of all sustainable development goals and goal 5, "Achieve gender equality and empower all women and girls," is of particular importance. Regrettably, HEIs continue to be organizations that are both gendered and gendering [3]. Gender equality at HEIs is persistently hindered by structural, institutional, and cultural barriers [4].

Recent statistical reports on gender equality data in the European Union show that female students make up most of the undergraduate population in HEIs, yet several published reports highlight ongoing cultural, institutional, and structural barriers inhibiting gender equality from true realization in this sector [5]. Male students remain a majority among postgraduates [5]. In addition, research highlights the gender inequality that exists in student leadership, demonstrating that although women made up 55% of the student body, they represented only 33% of the leadership in student organizations [6].

In Ireland, the undergraduate student population is comprised of approximately equal numbers of women and men. However, in 2016, the Higher Education Authority [7] reported that most of the country's student unions' officers tended to be young, White, and male, an inequality also evident internationally. This gender imbalance has been replicated in senior leadership in tertiary institutions [7]). While much has been achieved since 2016, the subsequent report maintains the recommendation to embed gender equality, and equality more broadly, into teaching, learning, research, and quality assurance processes [8].

The assertion that education and training foster durable change is supported by a substantial body of research emphasizing the transformative potential in both individual and societal contexts. The concept of critical pedagogy by Freire [9] underscores education as a means for empowering individuals to challenge existing inequalities and contribute to social transformation. The United Nations Educational, Scientific and Cultural Organization [1] identifies education as a cornerstone for achieving sustainable development, emphasizing its role in fostering long-term changes in health, gender equality, and environmental sustainability. The European Institute for Gender Equality (EIGE) argues that gender equality training should empower participants to define gender equality principles, identify inequalities, incorporate gender into planning, monitor progress, and assess work from a gender perspective [10]. EIGE defines gender equality training as "A tool and strategy to develop awareness, knowledge, and skills among individuals and to influence organizational processes to promote gender equality and tackle gender-based discrimination" [10].

Coe et al [11] advocate for the integration of equity, diversity, and inclusion training into medical curricula to embed diversity and inclusion as foundational institutional and cultural values. Connolly et al [12] highlight the necessity of training to raise awareness and develop competencies in student leaders, enabling them to proactively tackle gender inequality. These authors assert that such training will have a broader impact on the entire HEI community. Acai et al [13] argue that change must start early in a student's academic career to address and combat gender inequality in the higher education setting.

Preliminary literature reviews [14-16] suggest that gender equality-based training is being conducted in secondary and tertiary education settings, which includes didactic teaching, face-to-face collaboration projects, site visits, case studies, and coaching. To date, a comprehensive review collating and synthesizing the available evidence on gender equality training for tertiary students has not yet been carried out.

Scoping reviews are designed to examine the scope and limits of knowledge within an emerging field. The scoping review approach allows identification and synthesis of all relevant literature regardless of study design and is useful in clarifying key concepts and definitions in the literature. As detailed in our published protocol [17] we adopt the theory of change (ToC) as the theoretical framework to guide the analysis and interpretation of our findings [18]. The ToC provides a deliberate process for analyzing and outlining how an intervention is likely to be effective, who will benefit, in what ways, and the conditions necessary for its success.

The United Nation women's approach to gender equality training is grounded in the ToC recognizing that achieving gender equality requires a long-term institutional commitment, in addition to the development of key competencies for individuals [19]. ToC offers a conceptual foundation for how gender equality can be achieved through training, by emphasizing the interconnected roles of knowledge, desire, and ability as the necessary components for lasting change. It also aligns with the broader goal of embedding gender equality into institutional and cultural norms.

Objectives

Our work aimed to support gender equality in HEIs by working with the leaders of the future (men, women, and nonbinary) to address biases and accelerate culture change. This review is a component of a detailed needs assessment following the Kern's 6-step framework for curriculum development and implementation [20]. Understanding the nature of interventions and approaches currently being used to improve the knowledge, skills, and attitudes of students is an integral step in the design of an effective training program. The findings of this scoping review will inform education researchers, faculty, and academic administrators on the application of gender equality training, pinpoint gaps in the literature, and help identify opportunities for instructional designers and subject matter experts to improve course content.

The primary objectives of this scoping review were to produce a descriptive overview of gender equality training and interventions for students in higher education or postsecondary

education, which will inform curriculum development for skills training in the domain of gender equity. The secondary objectives were (1) to determine the methodology and content of gender equality training delivered to students; (2) to establish the skills and competences that are required by students to promote gender equality; (3) to ascertain how gender equality training is evaluated; (4) to review the extent to which the concept of leadership is included in gender equality interventions; and (5) to establish how gender equality leadership skills are fostered among students.

Methods

Overview

The review was structured using the 6-stage framework developed by Arksey and O'Malley [21], as follows: (1) identifying the research question; (2) identifying relevant studies; (3) study selection; (4) charting the data; (5) collating, summarizing, and reporting the results; and (6) expert consultation. This approach was chosen due to its well-established rigor and effectiveness [22]. Our review protocol has been peer reviewed to ensure the appropriateness and effectiveness of our methods [17].

This review involved the analysis of publicly available empirical research and the production of secondary data; therefore, ethics approval was not required.

Identifying the Research Question

Using the population, concept, context framework [23], the primary and secondary research questions were developed (Textbox 1) in alignment with the previously stated objectives. The population included students in higher education; the concept, gender equality training; and the context encompassed all HEIs.

Textbox 1. Primary and secondary research questions that guide this scoping review.

Primary

- What is the current nature and scope of gender equality training and interventions delivered to students in higher education?

Secondary

- How is gender equality training delivered to students, and what are the key topics included in the intervention?
- What specific skills and competences are taught to students to enable them to promote gender equality?
- How is gender equality training evaluated? To what extent is the concept of leadership included in gender equality interventions?
- How are gender equality leadership skills fostered among students?

Identifying Relevant Studies

Following a preliminary search to identify key terms, the search strategy was designed in consultation with an experienced research librarian. The search terms comprised 3 thematic combinations, including: (1) gender equality training, (2) HEIs, and (3) students, each separated with the Boolean operator AND. Within each thematic combination, search terms were separated using the Boolean operator OR. Wildcards were used to ensure the inclusion of plurals and variation in spelling across the search terms. The search was limited to studies and other sources published between January 2011 and November 2021.

An example of the search strategy used in 2 of the key databases is shown in Textbox 2.

Textbox 2. Search strategy showing the search string for the APA, Psycinfo, and CINAHL databases.

1. TI (gender N2 training OR bias N2 training OR discrimination N2 training OR diversity N2 training OR equality N2 training OR inclusion N2 training OR sexuality N2 training) OR AB (gender N2 training OR bias N2 training OR discrimination N2 training OR diversity N2 training OR equality N2 training OR inclusion N2 training OR sexuality N2 training)
2. TI (gender N2 course$ OR bias N2 course$ OR discrimination N2 course$ OR diversity N2 course$ OR equality N2 course$ OR inclusion N2 course$ OR sexuality N2 course$) OR AB (gender N2 course$ OR bias N2 course$ OR discrimination N2 course$ OR diversity N2 course$ OR equality N2 course$ OR inclusion N2 course$ OR sexuality N2 course$)
3. TI (gender N1 program* or bias N1 program* or discrimination N1 program* OR diversity N1 program* or equality N1 program* OR inclusion N1 program* OR sexuality N1 program*) OR AB (gender N1 program* OR bias N1 program* OR discrimination N1 program* OR diversity N1 program* OR equality N1 program* OR inclusion N1 program* OR sexuality N1 program*)
4. TI (gender N1 awareness* or gender N1 bias or gender N1 equality OR gender N1 inclusion OR gender N1 equity OR sex N1 bias) OR AB (gender N1 awareness* or gender N1 bias or gender N1 equality OR gender N1 inclusion OR gender N1 equity OR sex N1 bias)
5. 1 OR 2 OR 3 OR 4
6. TI ("higher education" OR "third level education" OR "tertiary education" OR university* OR college$) OR AB ("higher education" OR "third level education" OR "tertiary education" OR university* OR college$)
7. TI (Undergraduate$ OR postgraduate$ OR student$) OR AB (Undergraduate$ OR postgraduate$ OR student$)
8. 1 AND 2 AND 3
9. LIMIT 8 to 2010-2021

Systematic searches were carried out by the librarian in 6 databases of peer-reviewed research, including APA PsycInfo, CINAHL, Embase, MEDLINE (Ovid), Scopus, and Web of Science, and 3 additional databases, MedEdPortal, MedEdPublish, and Open Grey, to identify any gray literature that could further inform the review. The search was limited to titles, abstracts, and key words, to optimize the return of articles and sources of evidence with an appropriate focus on the topic in hand. All identified citations were collated in EndNote 20.2.1 (Clarivate Analytics) and duplicates were removed. This EndNote library was exported to Rayyan (Rayyan Systems, Inc) [24] to facilitate collaborative evidence screening.

Study Selection

In line with the recommendations from Peters et al [23], evidence selection was based exclusively on agreed eligibility criteria. These inclusion and exclusion criteria were developed in accordance with the previously stated research questions, building on the elements of the population, concept, context framework (Textbox 3). A reflexive approach was used throughout the selection process to adapt and develop the eligibility criteria in an iterative fashion through discussion within the research team throughout the course of the screening process.

Using Rayyan, CC and MP screened the titles of all sources independently and disagreements were resolved through discussion. The included abstracts were then screened by CC and MP in a similar fashion. The full-text studies were retrieved and CC, MP, SL, PH and TD collectively reviewed the first 10 texts to pilot the eligibility criteria framework. Group discussion was used to further clarify and develop the criteria. The remaining texts were then reviewed by 2 reviewers independently, with any disagreements between these reviewers resolved by discussion. CC and MP acted as third reviewers if a consensus could not be reached.

The reference lists of the included texts were back searched by MM and CC for further relevant studies and sources. Title and abstract screening by MM and CC of articles from all issues of 2 key journals, *Gender, Work & Organization*, and the *Journal of Gender Studies*, published between January 2011 and November 2021, did not yield any additional studies which met our inclusion criteria.

Textbox 3. Eligibility criteria for evidence selection.

Inclusion criteria

- Population: undergraduate or postgraduate students in higher education
- Concept:
  - interventions (eg, campaign or workshop) promoting gender equality awareness or gender equality competences
  - intervention that includes a specific goal or objective to educate or raise awareness of gender equality or to foster competence in gender equality
  - interventions inside or outside of the academic curriculum, for example, project within a module or exercise within a module, or course or program external to course of study
  - articles or sources focusing on the experience of participation in an intervention
  - interventions can also focus on other aspects of equity, diversity, and inclusion training, provided gender equality is included
  - interventions involving gender equality in terms of gender diversity (transgender, nonbinary, and gender diverse students)
  - training in gender equality for student teachers
- Context: higher education institutions
- Publication dates: between January 2011 and November 2021
- Sources:
  - peer-reviewed literature and gray literature (dissertations, websites, conference papers, corporate documents, government reports, preprints, proceedings, research reports, and periodicals)
  - secondary research, that is, literature, systematic or scoping reviews
- Language: studies in English

Exclusion criteria

- Population: primary or secondary students, higher education staff, and general public
- Concept:
  - measuring gender balance in higher education courses
  - strategies to promote equality among applicants to courses
  - experiences of gender or gender inequality among students
  - impact of gender on subject-specific competences, for example, programming or spatial awareness, among others
  - recruitment or retention of female students in academic courses
  - gender equality in health care
  - mentorship programs
  - diversity or equity, diversity, and inclusion programs that do not include a gender aspect
  - gender studies modules in which the goal is to inform on a variety of gender-related theories
  - articles focusing on a whole-of-campus institutional change
  - research on students' attitudes to gender equality unless these form part of a specified intervention
  - exploring the perceptions or experiences of people delivering the intervention
- Context: primary or secondary schools, youth services, and community services
- Publication dates: before January 2011
- Sources: books and book and film reviews
- Language: studies for which no English translation is available

Charting the Data

A standardized data charting tool (Textbox 4) was developed to extract data. This tool was adapted by the research team from the Joanna Briggs Institute template data extraction instrument [23] to align with the review objectives and questions.

Textbox 4. Data charting form to collect extra data and chart data for each paper.

Heading

- Study details (authors, year, title, and citation)
- Location
- Context
- Type of source
- Study aims or intervention aims
- Participants details and sample size
- Research questions addressed
- Study design
- Intervention style and duration
- Intervention content
- Intervention methods
- Outcome evaluation measures
- Key findings

Miscellaneous

- Interesting observations
- Gender equality theories employed
- Incorporation of gender equality and leadership
- Incorporation of intersectionality
- Incorporation of transgender and gender diverse inclusivity

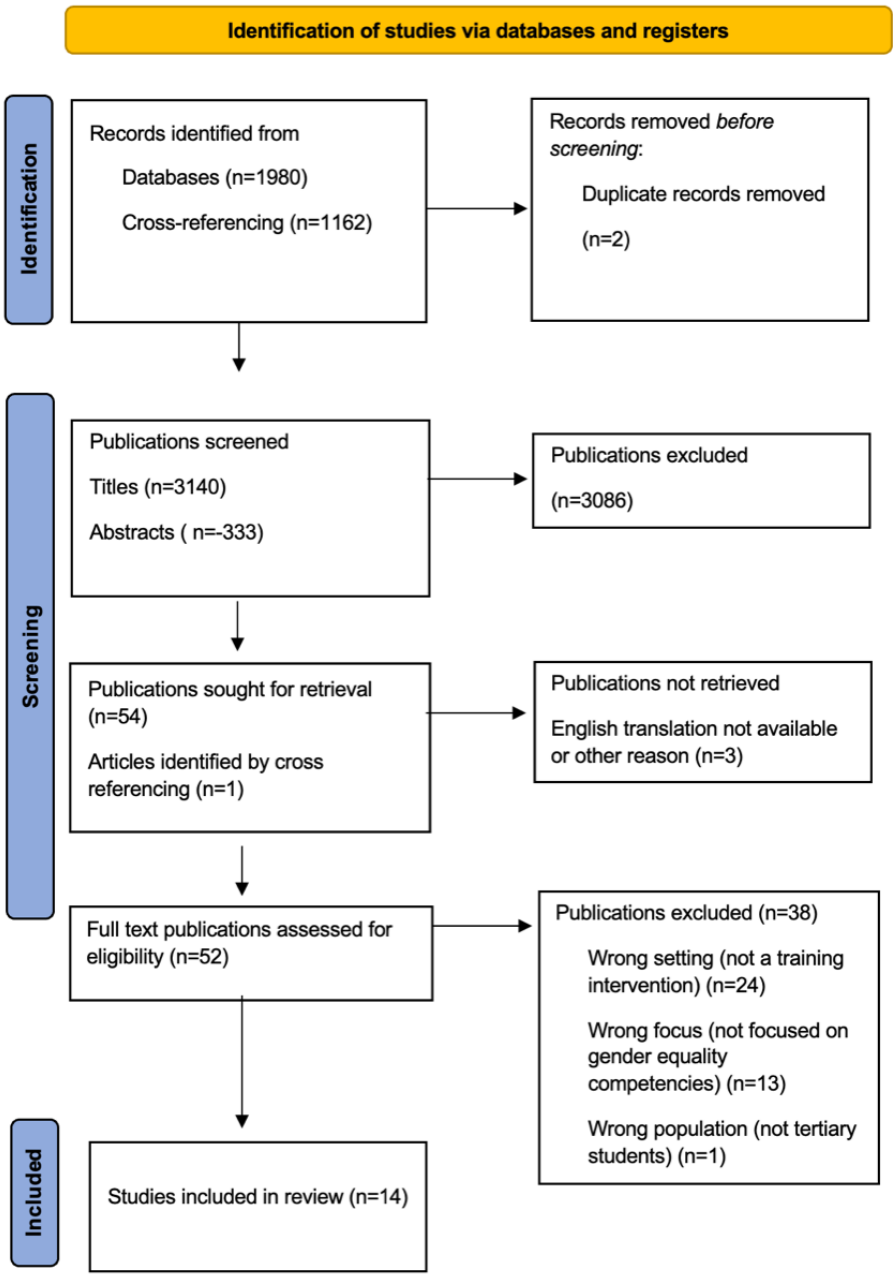
The charting form was expanded and refined in an iterative fashion by all authors during the full-text screening process. Data extraction was carried out by 2 reviewers working independently, with a single finalized form for each study agreed through collaborative discussion and communication.

Results

Collating, Summarizing, and Reporting the Results

The study selection process is presented in a flow diagram (Figure 1) as per the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses Extension for Scoping Reviews) in Multimedia Appendix 1 [25]. On the basis of the database searches, and the subsequent hand search of other sources as described in the Identifying Relevant Studies section, 3142 titles were screened. This yielded 333 abstracts for further screening. In total, 14 full-text articles were selected for inclusion in the review.

Figure 1. PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses Extension for Scoping Reviews) diagram detailing the process for identification and selection of articles included in this study.



Study Characteristics

Basic descriptive analysis is the most suitable approach to data analysis given the exploratory nature of a scoping review [23]. In total, 13 of the publications included in the final sample were peer-reviewed academic articles and 1 was a conference paper. The details of each article, including the country in which the study took place, the participants, aims, methodology, evaluation, and outcomes, are summarized in Table 1. Much (5/14, 36%) of the work in this field has been conducted in the United States and in Europe, with Spain (3/14, 21%) and Sweden (1/14, 7%) contributing. A further 3 (21%) studies were conducted in Turkey, with a single study located in each of Taiwan (1/14, 7%) and South Africa (1/14, 7%). In keeping with the agreed search strategy for this review, the included studies were published from 2011 to 2021. The published studies demonstrate a growing interest in the topic, as 57% (8/14) of the studies were published in the latter 3 years of the selected period (2019 to 2021).

Table 1. Summary of included studies.

Study	Country	Population	Aims	Methodology	Evaluation	Outcomes
Shields et al [26], 2011	United States	N=118; female: n=62, 52.5%; male: n=53, 44.9%; nonresponders: n=3, 2.5%; mean age: 19 y	To evaluate game-like simulation in teaching the nature and consequences of unconscious biases and stereotyping, which underlie gender inequity.	Experimental group divided into 2 teams, who participated in WAGES[a]–Academic, a game that simulates academic career progression with and without advantages. Separate control group played Chutes and Ladders; 3 phase study; pretest evaluations, immediate and delayed posttest evaluations; Kolb's experiential learning model used [27].	Neosexism scale at pretest; KGE[b] scale at all 3 stages; single open-ended question in final evaluation, "Since you played the game, have you thought about issues or made observations that you might not have before? If so, what are they?"	No difference in sexism scores among WAGES–Academic participants; no difference in KGE scores at baseline. Significant increase in KGE scores for intervention (both teams) versus control. KGE scores remained higher for intervention group at third evaluation; 24 participants indicated that they had thought about or made observations related to issues raised by WAGES–Academic; 15 noted gender bias, 5 wanted to learn more, 4 were unsure.
Kennedy et al [28], 2011	Turkey	N=546 students taking 2 introductory courses in Sociology and Psychology; gender: not reported; age: not reported	To assess the merit of showing movies as critical pedagogy; to develop student interest in serious social issues, including gender equality, and encourage critical agency in society.	In total, 3 cohorts of students watched 3 different movies over 3 successive academic terms; no comparator or control group; post-movie discussion undertaken	Postevent analysis of 3 student essays completed after watching the movies; 14-item survey completed by 112 students	Student essays indicated a development of consciousness in 3 critical subject matters, the death penalty, gender inequality and prejudice. Students rated the utility of watching movies favorably concluded that "movies help the students build critical perspectives on the 'social' through interest development on sociological topics;" 105 students reported development of a high level of critical perspective or a critical perspective; 7 students indicated that they had not developed a critical perspective.
Falk et al [29], 2012	Sweden	N=9 students participated in a gender module; gender: not reported; age: not reported	To evaluate Euro-Education: Employability for all, a multi-center project in which 4 course modules relating to different aspects of employability were developed: gender, age, disability, and ethnicity.	The module consisted of tutorial groups, lectures, tasks, and seminars. Students used a variety of electronic learning applications. Activities included a critical review of the labor market, an "exchange" in a university Occupational Therapy Department, and development of a "course" to address gender impact as the final assignment.	Continuous evaluation by students and teachers as part of feedback process throughout; postcourse oral feedback; questionnaire; overall assessment by EU[c] Commission (method not stated)	Students' evaluation was positive about increasing awareness and knowledge of gender theory, its application to employability, and development of new skills; technical aspect was challenging at times; teachers recommended precourse training on the electronic learning applications; the project received a global score of 8/10 from the EU Commission.
Case et al [30], 2014	United States	Study 1: n=177, 80% female; study 2: n=131, 71% female	To examine the effectiveness of 2 interventions (privilege list handout and testimonial video), coupled with reflective writing, in raising awareness of heterosexual (study 1) and male (study 2) privilege.	Study 1: participants assigned to control and 2 comparator groups, who received either a privilege list or watched a video); study 2: same method with different content	Study 1: pre- and postsurvey with 3 scales (heterosexual privilege awareness, internal and external motivation to respond without prejudice) and a reflective summary; study 2: pre- and postsurvey with 5 scales (male privilege awareness, modern sexism, hostile and benevolent sexism, and the motivation scales as above) and reflective summary	Study 1: Neither intervention had a more significant impact than the other. The authors indicated that both techniques were helpful in enhancing learning about heterosexual privilege; study 2: The video intervention increased male privilege awareness, but the handout did not. The authors concluded that further research is required to target aspects of sexism which neither intervention addressed.

Study	Country	Population	Aims	Methodology	Evaluation	Outcomes
Abrams et al [31], 2016	United States	N=13; male undergraduate (n=10, 77%) and graduate (n=3, 23%) engineering students invited to participate. One withdrew, one deemed not suitable, one went on placement for second semester; 10 students participated in full program	To evaluate the AWE[d] program, which aims to improve women's retention in engineering fields by promoting allyship among student population. Content focused on gender equity, implicit bias, micro aggressions, and sociocultural conversations.	Participants completed the 1-y AWE program consisting of initial training (workshops, seminars, and speakers) over 4 d; up to 5 hr. per wk. in semester 1 spent on reflection, further training sessions and planning outreach activities, which were then delivered to 447 students and staff on campus; Broido's Model of Allyship was used as framework for training design [32].	Authors intended to assess using a mixed methods approach, including qualitative and quantitative techniques; pre- and postsurveys, focus groups and interviews; this paper presents the results of the presurvey and 2 free-text response questions	After the initial 4 d training, most participants agreed that they could identify and explain microaggressions, knew how to address bias and discrimination, and were comfortable to do so; participants gained insight, awareness, confidence, and new perspectives from attending the training; participants felt they would change their behaviors, have increased awareness, have more confidence to speak up, become more inclusive daily, and become a role model for their peers.
Freedman et al [33], 2018	United States	N=143 college students; female: n=65, 45.4%; male: 77, 53.8%; nonresponder: 1, 0.7%; mean age: 20 y (a second study involved high-school students, which is not reported here)	To examine the impact of experiencing an "aha" moment about assumptions about women in science on subsequent attitudes toward women in science.	Randomized controlled trial in which participants play a logic-puzzle game that is won by making a realization about a character. In the control game, the character is a professor; in the intervention game, the character (a scientist) is a woman. Numbers of participants in each group not reported.	Questionnaire included a monetary allocation task in which participants had to allocate US $500 among 14 college organizations, 2 of which supported women in STEM[e]; shortened version of the Attitudes toward Women in Science Scale; the ambivalent sexism inventory	Most students who used gendered pronouns assumed that nongendered scientist characters were men; contrary to hypotheses, the intervention condition did not increase positive attitudes toward women in science, decrease sexism, or increase donations to women in STEM organizations.
Altınova et al [34], 2016	Turkey	N=65 social-work students; female: n=39, 65%; 26 male: n=26, 40%); age: not reported	To examine the impact of the HREP[f] on improving the gender perceptions. The HREP aims to raise social consciousness concerning human rights violations that women encounter.	Pretest posttest design with experimental group (n=32) participating in HREP and control group (n=33) who did not participate; participants engaged in narration, role play, case study, and problem-based learning during 12 two-h training sessions.	25-item Gender Perception Scale	GP[g] levels of the experimental group were increased; no change in GP levels for control group; concluded that the HREP is effective
Segovia-Pérez et al [16], 2019	Spain	N=50 female students from a variety of academic backgrounds over 2 consecutive years with 25 students in each cohort; mean age: 22 y	To evaluate a women's leadership program for university students which sought to ensure acquisition of skills, competencies, and tools for leadership by the participants, in addition to increased self-confidence.	The program involved 24 h of classes, a case study, visits to companies, and the European Parliament, and a coaching system. Subjects included personal branding, communication, networking, public speaking, negotiation, leadership techniques, and business management; the second cohort also completed a leadership test.	A self-administered survey with 9 questions using a 10-point Likert scale related to the program, prior knowledge, potential future impact, and a global evaluation; 3 focus groups with 8 participants in each group; 4 individual informal interviews	The participants rated the course highly, with scores of 8 out of 10 in all areas of the survey, other than prior knowledge; the qualitative data indicated an improvement in specific tools and skills, and a positive change in attitudes and self-confidence of the participants.

Study	Country	Population	Aims	Methodology	Evaluation	Outcomes
Toraman and Özen [14], 2019	Turkey	N=433 students in the Faculty of Education; female: n=319, 73.7%; male: n=144, 3.2%; age: not reported	To determine the opinions of the participants regarding gender equality, and to compare their opinions before and after taking a compulsory gender equality course; later, described third goal to explore association with participant variables.	Students participated in a training course over one semester, which included the following topics; the concept of gender, sociology of gender, gender and family, gender and religion, gender and language, gender and media, gender and body images, gender, work life and labor, feminist movements, and social change. Limited description of learning and teaching activities.	Descriptive study with pre- and postintervention administration of the Gender Equality Scale, with validation of the scale for university students included in the methods; data were also collected on background participant variables; logistic regression used to assess the extent to which background variables affected participants' opinions	Initially, most participants did not believe that men were superior to women. Unexpectedly, after the course, participants were more likely to develop the opinion that men are superior to women, whereas there was no impact on opinions relating to women being dependent on men; men were more likely to believe that they are superior, and that women are dependent on men; significant variables in the regression analysis included academic background, father's education status, newspaper reading by family members, and location of family home.
Gorrotxategi et al [35], 2020	Spain	N=64 social education students; female: n=52, 81%; male: 11, 17%; and 1 did not identify themselves as male or female; mean age: 20 y	To measure the students' knowledge about transgender people, and the attitudes of students toward gender and transgender people, before and after an education program.	Training was based on the "Creative Factory" intervention model and consisted of a weekly training session on gender and transgender learning over a 4-mo period. The goal of the Creative Factory model is to "enable students...to analyze social realities to generate discussion and innovate ideas to design successful practices."	Pre- and postintervention questionnaires; 12-item short version of the Gender and Transphobia Scale; transgender knowledge assessed with single item scale	Level of transgender knowledge was increased by the intervention (P<.05); improvements were noted in gender bashing and transphobia dimensions but these were not statistically significant; the data suggests that men had higher levels of gender bashing attitudes (P<.05) and transphobia, but this latter difference was not statistically significant.
Liao and Wang [36], 2020	Taiwan	N=82 medical students; gender: not reported; age: not reported	To investigate whether the integration of the gender perspective into literature studies would create any difference among students in gender awareness and critical thinking.	Intervention entailed twice weekly literature study sessions over 15 wk, self-study, electronic discussion between both groups. Experimental group received gender perspective training and were introduced to gender-related terms to facilitate discussion. Through literature, this group were encouraged to consciously reflect on traditional and socially constructed gender norms.	Quasi-experimental study with a control group (n=41) and experimental group (n=41); both groups completed the CTDA[h] and the Chinese version of the Gender Awareness Scale pre- and postintervention	With respect to gender awareness, the findings show that following the integration of the gender perspective into literature studies, medical university students had significantly higher posttest scores for "public gender consciousness" and "private gender consciousness;" regarding critical thinking, they also had significantly better posttest scores in "systematicity and analyticity," "maturity and skepticism," and "inquisitiveness and conversance."

Study	Country	Population	Aims	Methodology	Evaluation	Outcomes
Locke et al [37], 2021	United States	Male undergraduate and graduate STEM students; this paper includes the reflections of a male engineering student ally, and a research adviser	Update of Abrams et al [31]; the success of the AWE program led to the development of a leadership course that has been offered in the College of Engineering every semester since autumn 2016.	A total of 14-week course incorporating videos, workshops, case studies, and group discussions; participants engaged in: information gathering to develop awareness of gender equity challenges in engineering; meaning making to examine personal biases; and, contextual application of strategies that promote inclusive engineering climates.	Pre- and postcourse survey with Likert-type scales	Increase in self-reported efficacy of participants; this course helped the male ally to "develop the skills and mindset needed to make...difficult conversations productive." It gave him "the tools needed to identify the various kinds of situations that contribute to a hostile environment and how to better diffuse them;" created "an enhanced supportive environment" in a research laboratory, as reported by a female research adviser.
Bosch et al [38], 2021	Spain	N=19 final year students taking a sociology of gender course female: 15, 79%; male: 4, 21%; age: not reported	To evaluate a SL[i] project, in which students deliver workshops in high schools on gender and technology. The optional project within the sociology of gender course was intended to enhance student understanding of topics covered in the course.	For each workshop, students created a presentation with interactive activities, and showed a video. Their assessment consisted of an oral presentation to the rest of their university class and a self-reflection; 13 workshops were carried out over 4 y.	Qualitative analysis of 16 university student self-assessment reports; quantitative survey data from high-school students (n=284) and teachers (n=13) on a range of items, such as usefulness, alignment with student need, evaluation of pedagogical tools, opportunities for participation and a global evaluation. This quantitative data are not relevant for this review but the abovementioned description is included for completeness.	All students were satisfied with the experience and the course grades for these students were higher than the class average. The authors felt that these students went "far beyond the curriculum" and "reached a deep understanding of the multiple dimensions on the topics of gender and technology." Other themes which emerged included social transformation through SL, acquisition of competences, such as improved communication, putting empathy into practice, empowerment and "professionalization" of the participants.
de Villiers et al [39], 2021	South Africa	N=15 "student leaders" from various faculties; all male; age range: 20-25 y	To evaluate the OMC[j] intervention for university settings. OMC aims to encourage development of equitable relationships between men and women, thereby preventing gender-based violence and HIV transmission.	A case study design describing the adaptation and implementation of OMC, in which 5 participatory workshops were conducted. Content was related to personal values, belief systems, societal gender-based norms, rape and consensual sex, courage and bystander intervention, and healthy relationships.	Qualitative data collection methods, including pre- and postintervention focus groups, discussion content and researchers' field notes documented during the intervention workshops, participant reflections were collected after each workshop via open-ended questions and 5 semistructured interviews were conducted 6 mo after the intervention; thematic data analysis was used.	The data demonstrated "increasing accountability" on the part of the male student leaders to prevent sexual violence. The authors note that critical engagement and dialogue on sexual violence is shown to shift key norms on gender equality, on being a man and reflection on their role in preventing sexual violence; this work resulted in the development of the Men with Conscience intervention; a 6-h adapted intervention based on OMC.

[a]WAGES: Workshop Activity for Gender Equity Simulation.

[b]KGE: knowledge of gender equity.

[c]EU: European Union.

[d]AWE: allies for women engineers.

[e]STEM: science, technology, engineering, and mathematics.

[f]HREP: Human Rights Education Program for Women.

[g]GP: gender perception.

[h]CTDA: Critical Thinking Disposition Assessment.

[i]SL: service-learning.

[j]OMC: One Man Can.

Settings

All these educational programs (N=14) took place at individual tertiary academic institutions. One involved collaboration with secondary schools within the same country requiring participants to present to school students, 2 programs incorporated workplace visits, and 1 used an online discussion forum. Most studies did not provide information on how the program was financially supported. Some of the training interventions were undertaken as official curricula to which the participants were enrolled as part of their required studies. Most studies recruited volunteers, one via a competitive recruitment process and another accepted nomination from teachers. One study reported that learners were incentivized to participate in the training experience with a US $300 book token per term [31].

Participants

All studies provided some demographic information on participants and the number of participants in the studies ranged from 9 to 546, with an average of 134 participants. With respect to gender of the participants, some of the interventions specifically targeted either women [16] or men [31,37,39]. In the remainder of the studies which reported participant gender (7/14, 50%), the majority were female. When reported, the age range was typical for higher education as most participants were in their early twenties. Most studies involved participants from single faculties. There was a slight predilection for interventions involving students in education and the social science programs [14,28,34,35,38]. There was also representation from health sciences, including medicine [36] nursing [39] psychology [26,30] and occupational therapy [29], in addition to engineering faculties [31,37]. In 2 (14%) studies, the participants were from a variety of academic programs: Business, Social Sciences, Law, Engineering, and Architecture [16,37]. Freedman et al [33] recruited participants from student accommodation. One study did not provide information on participant specialty.

Content

The works reviewed were from countries with considerable variation in political-cultural contexts, civil liberties, and personal freedoms and thus the content of the courses was widely varied reflecting local needs.

The language used to describe content themes was also disparate. The main content areas covered in the training programs are listed in Table 2. In total, 5 (36%) of the studies from this heterogeneous group explored the impact of courses, modules, or programs, which directly aimed to increase awareness of gender and gender-based issues or enhance gender equality knowledge [14,29,34,35,37]. Another group of studies sought to enhance knowledge and skills indirectly through another medium, such as movies [28], testimonial videos [30], games [26,33], and literature studies [36]. In addition, 2 (14%) studies reported on the same initiative, an allyship program in a college of engineering that encompassed gender equity issues [31]. A subsequent paper [37] described the extension of the initial project. A single study was identified which related specifically to a leadership program for women [16]. The final study related to a service-learning project on gender and technology [38].

Table 2. Content themes identified and the frequencies of inclusion in the individual curricula from studies examined in this study (N=14).

Theme	Frequency, n (%)
Allyship	2 (14)
Gender awareness	2 (14)
Gender barriers	1 (7)
Gender equality	5 (36)
Implicit bias	5 (36)
Intersectionality	1 (7)
LGBT[a] marginalization	2 (14)
Male privilege	1 (7)
Microaggressions	1 (7)
Stereotypes	1 (7)

[a]LGBT: lesbian, gay, bisexual, and transgender.

Gender Equality Leadership Skills

The concept of leadership featured explicitly in 2 (14%) of the included articles [16,37]. Both publications detailed how gender equality leadership skills were fostered among the participants. The concepts of social identity, privilege, microaggressions, and implicit bias were explored by Locke et al [37] in a leadership program for male student allies. In contrast, Segovia-Pérez et al [16] ran a leadership program for female students which covered topics such as personal branding, communication, networking, public speaking, negotiation, leadership techniques, and business management.

Study Design: Inputs and Activities

The most common (4/14, 29%) study type was an interventional mixed methods pre-post design, wherein a single group of participants completed self-assessments of confidence, ability, and knowledge before the intervention and then participated in a module or workshops. The learners completed the same assessments after the intervention in addition to participating in focus groups or interviews [14,26,31,35]. Interventional

studies using pre- and postintervention questionnaires were the next most common (3/14, 21%) study design [16,30,37]. Moreover, 2 (14%) studies used a quasi-experimental design [36,39], and 1 (7%) used a randomized controlled trial design [33]. The final pool of articles comprised 5 (36%) qualitative studies using after event analysis only ranging from educators' reflections (2/14, 14%) to analysis of student diaries or essays (2/14, 14%) [28,38] and an after event questionnaire with oral feedback (1/14, 7%) [29].

Delivery Methods

Methods of delivery varied widely. Most studies (11/14, 79%) were described as longitudinal events that occurred over multiple sessions, ranging from several months to a year. One study consisted of 15 European Credit Transfer and Accumulation System (ECTS) where 1 ECTS is equal to between 25 and 30 hours. In addition, 2 (14%) studies described single event game base interventions. The format of teaching was also wide-ranging and included lectures and workshops, guest speakers, small group discussions, workplace visits, role play, videos, movies and literature analysis, student presentations, and online discussion.

Assessment and Evaluation: Outcomes

Most studies reported no assessments of learner competency after training. Most studies (8/14, 57%) measured learner outcomes via survey instruments examining perceptions, sympathies, or confidence. In total, 2 (14%) studies assessed outcomes with participant focus groups. Moreover, 2 (14%) studies measured learning by thematically analyzing reflection writing or diaries. No study reported on transfer of learning.

Significant increase in knowledge of gender equity scores [26], gender perception scores [34], and higher posttest scores for "public gender consciousness" and "private gender consciousness" [36] were demonstrated for intervention participants versus control.

Students self-reported the development of critical perspective [28], increased male privilege awareness [30], increased awareness and knowledge of gender theory [29], and increased level of transgender knowledge [35]. Students agreed that they could identify and explain microaggressions and knew how to address bias and discrimination [31].

In qualitative studies, data from focus groups with participants following training indicated "increasing accountability" on the part of the male student leaders to prevent sexual violence [39], and a positive change in attitudes and self-confidence [16].

Unexpectedly, participants from a course in the faculty of education in a Turkish university were more likely to hold the opinion that men are superior to women postintervention and there was no impact demonstrated on opinions relating to women being dependent on men. Regression analysis included academic background, father's education status, newspaper reading by family members, and location of family home [14]. In addition, contrary to the study hypotheses, a logic-puzzle game intervention from the United States did not increase positive attitudes toward women in science, decrease sexism, or increase in-game donations to women in science, technology, engineering, and mathematics organization [33].

Theoretical and Conceptual Foundations

The array of theoretical and conceptual foundations cited by the authors is displayed in Table 3. Most studies (12/14, 86%) introduced and discussed theoretical underpinnings as a reason to provide training and less so for instructional design and program content. Furthermore, there was little or no reference to educational learning theories or pedagogical approaches when designing learning objectives, delivery methods, or evaluation and assessment of the programs. Exceptions include the use of Broido's model of allyship [32] by Abrams et al [31] and Kolb's experiential learning model [27] by Shields et al [26].

Table 3. Underpinning theories.

Study	Gender equality theories used
Shields et al [26], 2011	Work-family balance, salary, mentoring, workplace climate, and token status
Kennedy et al [28], 2011	Critical teaching
Falk et al [29], 2012	Gender theory and gender as a social construction
Case et al [30], 2014	Privilege, modern sexism, hostile and benevolent sexism, and prejudice
Abrams et al [31], 2016	Gender equity, implicit bias, micro aggression, and sociocultural conversations
Altınova et al [34], 2019	Gender equality from a human rights perspective
Freedman, et al [33], 2020	Gender stereotypes; implicit and explicit gender bias; social psychology—challenging the assumption of invulnerability to bias
Segovia-Pérez et al [16], 2019	Stereotypes and social role theory. Inclusive and equitable quality education, gender equality, and empowerment
Toraman and Özen [14], 2019	Social cognitive theory; gender and its inequalities originate from learned or taught behaviors
Gorrotxategi et al [35], 2020	Gender bashing, transphobia, and genderism
Liao and Wang [36], 2020	Socially constructed gender norm, patriarchal system, gender politics, and ideology
de Villiers et al [39], 2021	No explicit gender equality theories

Discussion

Principal Findings

This scoping review explored and mapped the evidence related to gender equality training and interventions for university students using a ToC lens. We described inputs and activities in terms of content areas, delivery modes, participants, and settings. We described outcomes and impact in terms of evaluation and assessment.

It was not possible to measure the long-term systemic impacts of the interventions due to limited postintervention follow-up and the absence of transfer of learning assessments. The studies collectively indicate potential for improved gender equity knowledge and leadership skills in diverse educational contexts and increased capacity to address microaggressions, implicit bias, and gender-based discrimination. However, it is important to note that self-reported data are typically considered low-quality evidence for evaluating the effectiveness of teaching interventions [40], especially if the questions focus primarily on learner satisfaction rather than assessing actual knowledge acquisition or behavioral change. Improvement or impact on skills to support gender equality is less frequently observed or demonstrated as an outcome in the literature we reviewed, as is any change at the organization level. Critical assumptions underpinning these studies included the willingness of participants to engage actively with the material and the alignment of local cultural contexts with course content.

The study by Toraman and Özen [14] highlights the unintended reinforcement of gender stereotypes, emphasizing the impact of cultural and political contexts. Similarly, the adverse effects of the Freedman et al [33] training intervention on explicit attitudes toward women in science serve as a cautionary tale, highlighting the importance of educational research in designing interventions that reduce biases without provoking defensiveness.

The usefulness of the studies we identified to inform curriculum design and provide actionable insights for educators is constrained by a lack of theoretical grounding, limited long-term follow-up, and reliance on self-reported data. This aligns with the findings of Guthridge et al [41] who, in their systematic review of interventions, aimed at enhancing gender equality and questioned whether the interventions they examined effectively led to substantive change. The EIGE understands developing competence in gender equality as being able to identify and change gender stereotypes and gendered roles [10]. Thus, gender equality training should enable and empower participants to (1) define and understand gender equality principles, (2) identify gender inequalities in their field, (3) incorporate gender in their planning and policy implementation, (4) monitor progress, and (5) review and assess their work from a gender perspective [10]. We have incorporated these concepts with developments from the wider gender equality training literature in subsequent sections and used a ToC to provide a lens through which we can consider and synthesize our findings. From this synthesis, combined with our own experience as educators and consultation with experts in gender equality, we have created recommendations for both practice and future research to help close the gap between the current practice and desired outcomes.

Instructional Design

Pedagogical frameworks should guide the design and implementation of educational activities. These frameworks are based on established principles of teaching and learning and provide a structured approach to designing effective and engaging learning experiences. Without a solid theoretical foundation, it can be challenging to determine the best instructional strategies to use, how to sequence and structure the content, and how to assess whether learners have achieved the desired learning outcomes. A lack of underpinning theory in the instructional design of training can lead to an inconsistent approach and potentially ineffective training. By grounding an approach in theory, educators aiming to upskill university students in gender equality skills can design training that is more likely to be effective in achieving the EIGE 5 categories of learning outcomes. Interventions to combat biases are particularly effective when they involve active participation rather than passive learning [26,33].

Diversity of Content

Ensuring diversity of content to cover knowledge, skills, and attitudes is critical for designing effective learning experiences. Not only must learners develop a deeper understanding of the subject matter and its various dimensions, but they must also develop the skills and attitudes to bring about change in behaviors [19]. The terminology used to describe content themes varies widely in the reviewed papers. The key content areas addressed in the training programs include knowledge of gender and gender-based issues, allyship, leadership, and bias. Communication skills, teamwork, and leadership skills training can support learners to become more adaptable and better equipped to promote a gender equality agenda.

Leadership

Within the body of evidence included in this scoping review, the concept of leadership appears underrepresented in most gender equality training initiatives. One notable exception is the women's leadership program for female university students described by Segovia-Pérez et al [16]. The authors demonstrated that leadership training enhanced learner self-confidence and their view of their own capacities, providing tools and guidelines for professional communication and personal branding. Enhancing leadership skills were also considered by Locke et al [37] who described a course that focused on gender equity and the practice of inclusive leadership for male allies in the STEM fields. The authors stated that this course would continue to be offered, with plans to explore changes in student behaviors in addition to investigating potential trends or differences in students in varying engineering majors and academic careers stages. Furthermore, a similar workshop for new engineering staff at a prominent state company has also been offered, thereby demonstrating the potential of gender equality training initiatives to promote linkages between higher education and industry, and indeed society more widely.

Intersectionality

Case et al [30] recommends an intersectional approach for future work: "Future research considering several forms of privilege within the same intervention would provide information about the learning process." They conclude that "teaching and learning about LGBT psychology through an intersectional lens allows students from a variety of backgrounds to connect seemingly irrelevant systems of oppression and privilege to their own social identities and social locations." These authors suggest that training which addresses intersections of identity to allow further understanding of sexism, heterosexual privilege, and male privilege will further raise awareness of not only privilege but also the complexities of identity and the matrix of oppression [30]. Gorrotxategi et al [35] demonstrates that interactive training in gender education using the Creative Factory methodology creates a context of reflection and knowledge generation and promotes a significant improvement in knowledge about transgender and slight improvements in transphobia. Bosch et al [38] report on a service-learning intervention, using community engagement pedagogies that facilitate learners to volunteer with an agency and engage in reflection activities to deepen understanding. After the experience in schools with a great diversity of social backgrounds, learners were motivated to reflect on intersectionalities, such as origin or class.

Delivery, Implementation, and Evaluation

The nature of gender equality training interventions identified for this review are heterogeneous. This can be seen in terms of the format of interventions, and whether gender equality knowledge and skills were directly seen in terms of the population, concepts, and contexts. Delivery, implementation, and evaluation are critical components of any effective learning program, and standardization of these components can help ensure that training is effective, efficient, and consistent and will allow evaluation of its impact. Impact is best identified through a range of evidence that provides robust verification for enhanced knowledge, behaviors, and practices, Furthermore, researchers are advised to consider both quantitative and qualitative forms of evidence. A longitudinal approach to evaluation is recommended in preference to singular measurements to ensure that the full value of an intervention can be captured over time and skills retention is measured. Program designers may also wish to consider evaluation at both participant and institutional level.

Faculty Development

Verge et al [42] stated that it is crucial to enhance the teaching staff's required qualifications, account for institutional opposition to gender-related change, and implement monitoring and evaluation systems. These steps are important to ensure that training outcomes are regularly assessed and improved when integrating gender equality training into higher education programs.

Compulsory Training

The United Nations Educational, Scientific and Cultural Organization [1] recommends that gender equality should be integrated into the whole program of faculties of education, rather than being included as a course. Toraman and Özen [14] found that the gender equality training offered as a compulsory-elective course in the faculty of education did not produce the expected results for their students. De Villers et al [39] noted that student leaders who volunteer may have leadership value systems and may not reflect the student body. Abrams et al [31] indicated plans to embed their program in the engineering curriculum and participants would be recruited as future teaching assistants to enhance sustainability. It has been demonstrated that elective courses in general receive more favorable responses than the required courses using both scaled response evaluation formats and open‐ended response evaluation forms [43] and these observations have relevance for gender equality training. When participation is voluntary, those who opt in are likely to have a preexisting interest, motivation, or alignment with the course's objectives, which can positively influence their engagement and satisfaction. Self-selection bias may skew evaluations and limit the generalizability of findings regarding the course's effectiveness. In addition, voluntary participants are typically intrinsically motivated, which enhances their willingness to engage deeply with course material and reflect on their learning. In contrast, students who are required to take part in such courses may approach the material with skepticism, resistance, or apathy, potentially lowering their engagement and perceptions of the course [44].

Mandating participation can broaden the reach of training; however, course evaluations should account for differences in participant motivations. Care should be taken to ensure that the course's status as elective or required is considered for evaluation purposes [43]. Combining qualitative and quantitative assessment methods can provide a more nuanced understanding of the course's impact, particularly on participants who might initially be less engaged. Furthermore, longitudinal studies tracking behavior change or attitude shifts after training can help determine the broader efficacy of these programs beyond immediate satisfaction ratings [45].

Lau et al [46] proposed that a key reason for the lack of progress in gender parity in organizations lies in the predominance of empirical research focusing on the causes and manifestations of gender inequality, while insufficient attention has been given to exploring solutions. To advance gender equality, they argue that a paradigm shift from problems to solutions is critical and urgent.

Significant research is required to bring gender mainstreaming to higher education. The Swedish Secretariat for Gender Research [47] distinguishes between gender-mainstreamed teaching as a pedagogical practice and the integration of gender and gender equality knowledge into the subject content. They call for resources for research-based pedagogical development for the implementation of teaching activities.

ToC Framework

Overview

Applying the ToC framework can enhance the practical value of our findings, offering a structured approach for educators to better understand the pathways through which gender equality

training can lead to desired outcomes. Viewed through the ToC lens, the findings from this review demonstrate the importance of aligning gender equality training programs with a clear, structured pathway from inputs and activities to outcomes and impact. To achieve transformative change in attitudes, behaviors, and institutional practices, the following elements emerge as critical:

Inputs and Activities

Effective programs must begin with carefully designed interventions rooted in robust pedagogical frameworks. These interventions should actively engage participants, address intersectional perspectives, and incorporate diverse methodologies, such as service-learning or active, immersive simulation-based activities, and leadership-focused training.

Outputs

Outputs should be aimed at improving participants' awareness, knowledge, and attitudes toward gender equity. Training activities must also equip participants with practical skills, such as leadership and communication skills, and encourage and motivate the application of these skills.

Outcomes

The outcomes from training programs should focus on fostering shifts in individual behaviors and attitudes, including a heightened ability to identify and address implicit biases, privileges, and microaggressions. Critical success outcomes would include embedding these skills and behaviors within institutional practices to promote systemic change.

Impact

To move toward the desired systemic impact of gender equality within higher education and beyond, interventions need to demonstrate sustainable behavior changes at the organizational and societal levels. Embedding gender equity principles into institutional structures—such as curriculum design, faculty development, and organizational policies—will help to create a ripple effect, influencing broader cultural norms and reducing structural barriers to equality.

Assumptions and Contextual Factors

The success of training interventions depends on several assumptions, such as participant willingness to engage, institutional buy-in, and adequate resources for program implementation and evaluation. The evidence suggests that voluntary participation may enhance learner engagement, but care must be taken to mitigate self-selection biases by complementing elective offerings with strategically designed mandatory components.

To bridge the gap between current practice and desired outcomes, a ToC-driven approach should prioritize longitudinal, multilevel evaluations that measure not only immediate knowledge gains but also the sustainability and transferability of learning outcomes. This includes tracking participants' ability to influence institutional and societal change over time. By connecting theory, evidence, and practice, this framework provides a cohesive road map for designing and implementing impactful gender equality training programs in higher education.

Strengths and Limitations

The search strategy was comprehensively developed by all authors with the support of an experienced librarian to facilitate a thorough and extensive database search. The searches carried out were limited to the 9 databases available to the authors. However, following consultation with the librarian, the process of hand-searching the reference lists of the included articles to identify important studies and gray literature may be considered a strength of this review. It is also important to note the lack of relevant literature available, highlighting a significant gap in the evidence base for this area and this should encourage further research. Considering the accelerating interest in equality, diversity, and inclusion issues in most recent years, relevant work may have been missed in the months since the main literature search was conducted. Excluding studies which focused on mentorship programs, gender equality in health care delivery, and gender studies modules may have excluded potentially useful information. However, following the preliminary database searching and screening, we concluded that these studies did not fully align with the research objectives for this review.

Implication for Practice

This review aimed to map the depth and breadth of gender equality training for student leaders in HEI to support curriculum development for training. Our findings suggest room for improvement in the conduct and reporting of research on training interventions with particular attention to theoretically informed decisions about the development of learning activities, the choice of instructional methods, and tools and resources to implement the interventions. In addition, a more effective approach to evaluation that goes beyond the immediate reaction of learners and assesses behavior change is required to allow continuous improvements in this field. Educational programs for gender equality can play a significant role in fostering awareness, knowledge, and skills necessary to address gender disparities in the higher education sector. However, they cannot operate in isolation. There is a real risk that stand-alone educational initiatives will fail to create lasting, systemic change if they are not integrated into a broader, multipronged strategy that addresses the structural, cultural, and institutional barriers perpetuating gender inequality [40].

Conclusions

Initiatives such as the Athena Swan Charter, a framework to support gender equality within higher education and research, seek to advance equal opportunities for all genders in HEIs across the globe. However, significant gender inequality remains and encouraging positive leadership among students may help to build capacity to support equality. Appropriate sustainable and effective skills training is needed to increase awareness and nurture competencies for male, female, and nonbinary student leaders to actively address gender inequality. Investments in gender equity training demonstrate organizational commitment to inclusivity. Long-term dedicated financial support is essential for the sustainability of training interventions aimed at promoting gender equity. Adequate funding enables the development of high-quality training materials, the engagement of skilled facilitators, and the integration of innovative

methodologies. Funding also facilitates the evaluation and monitoring of programs, ensuring that interventions remain effective and adaptable to changing needs and contexts. Without sustainable funding, training programs risk becoming fragmented or short-lived, limiting their impact on fostering institutional change.

Acknowledgments

This review forms part of the study 'LIBRA: Future-proofing Gender Equality in Irish Higher Education Institutions'. This research is funded by the Irish Higher Education Authority.

Abstract

Background: Artificial intelligence (AI) is increasingly integrated into health care, including psychiatry and psychology. In educational contexts, AI offers new possibilities for enhancing clinical reasoning, personalizing content delivery, and supporting professional development. Despite this emerging interest, a comprehensive understanding of how AI is currently used in mental health education, and the challenges associated with its adoption, remains limited.

Objective: This scoping review aimed to identify and characterize current applications of AI in the teaching and learning of psychiatry and psychology. It also sought to document reported facilitators of and barriers to the integration of AI within educational contexts.

Methods: A systematic search was conducted across 6 electronic databases (MEDLINE, PubMed, Embase, PsycINFO, EBM Reviews, and Google Scholar) from inception to October 2024. The review followed Preferred Reporting Items for Systematic Reviews and Meta-Analyses Extension for Scoping Reviews (PRISMA-ScR) guidelines. Studies were included if they focused on psychiatry or psychology, described the use of an AI tool, and discussed at least 1 facilitator of or barrier to its use in education. Data were extracted on study characteristics, population, AI application, educational outcomes, facilitators, and barriers. Study quality was appraised using several design-appropriate tools.

Results: From 6219 records, 10 (0.2%) studies met the inclusion criteria. Eight categories of AI applications were identified: clinical decision support, educational content creation, therapeutic tools and mental health monitoring, administrative and research assistance, natural language processing (NLP), program/policy development, students' study aid, and professional development. Key facilitators included the availability of AI tools, positive learner attitudes, digital infrastructure, and time-saving features. Barriers included limited AI training, ethical concerns, lack of digital literacy, algorithmic opacity, and insufficient curricular integration. The overall methodological quality of included studies was moderate to high.

Conclusions: AI is being used across a range of educational functions in psychiatry and psychology, from clinical training to assessment and administrative support. Although the potential for enhancing learning outcomes is clear, its successful integration requires addressing ethical, technical, and pedagogical barriers. Future efforts should focus on AI literacy, faculty development, and institutional policies to guide responsible and effective use. This review underscores the importance of interdisciplinary collaboration to ensure the safe, equitable, and meaningful adoption of AI in mental health education.

Introduction

Cloud computing, artificial intelligence (AI), machine learning (ML), telehealth, digitally assisted diagnosis and treatment, and consumer-focused mobile health applications have reshaped the landscape of health care delivery. These technologies are now widely used in clinical care, scientific research, and self-management [1]. These developments offer the potential to improve treatment outcomes, promote greater patient engagement, and enable earlier diagnosis and intervention [1]. In addition to enhancing conventional clinical procedures, such as teleconsultation and patient record management, these advancements have made way for fresh, data-driven methods of diagnosing and treating patients with a wide range of illnesses [2]. Particularly in the fields of psychology and psychiatry, new research highlights the expanding impact of AI online learning environments, and e-therapies, all of which could potentially reshape clinical practice, educational routes, and health policy [3,4]. As they provide new avenues for psychiatric condition screening, diagnosis, and monitoring, AI and ML have, in fact, attracted a lot of attention in the field of mental health care [3]. Self-guided mental health apps and web-based cognitive behavioral therapy (CBT) modules are examples of digital interventions that can help address systemic gaps in mental health care by improving access in underserved areas, reducing stigma, and lowering infrastructure costs. Still, limitations, such as weakened therapeutic alliance, limited support for complex conditions, and digital literacy barriers persist, highlighting the need for complementary innovations, such as AI [5]. The goal of ML, a branch of AI, is to empower computers to learn from data and make predictions or judgments by using statistical models and algorithms [6]. Potential applications of ML include predicting the effectiveness of antidepressant medicine, defining depression, estimating the risk of suicide, and predicting psychotic episodes in people with schizophrenia [7-14]. Beyond individual diagnosis and prognosis, ML has also been explored for system-level uses, such as optimizing service triage, forecasting population mental health trends, and informing resource allocation strategies [3]. Although promising, these uses raise critical concerns about the limits of algorithmic decision-making in capturing complex human experiences, therapeutic nuance, and clinical judgment.

In any case, any increase in accuracy or efficiency must be balanced against possible drawbacks, including algorithmic bias, concerns about data privacy, and the requirement for open systems to maintain patient confidence [15]. There are concerns over chatbots and other automated therapy tools' ability to give compassionate care and uphold therapeutic boundaries, despite being promoted as affordable ways to provide mental health help [16]. Therefore, the use of AI-based technologies (eg, chatbots, virtual assistants, or automated therapy platforms) necessitates careful evaluation of any potential negative effects, such as algorithmic bias, transparency issues, patient confidentiality, and wider ethical issues [16,17]. These tools are already transforming the patient-clinician relationship and raise complex questions about how therapeutic alliances can be established and maintained in digital environments [18]. The traditional roles and responsibilities of health care providers may change because of the advent of automated evaluations and AI-driven therapy recommendations. As a matter of fact, clinicians will soon have to balance the results of algorithms with their professional judgment [2].

These factors highlight the need for careful consideration for psychologists, psychiatrists, and other medical practitioners to gain a thorough understanding of the ethical and therapeutic aspects of developing technology [19]. Numerous experts stress that substantial training for aspiring professionals is necessary for a meaningful integration of AI into mental health treatment, especially when it comes to e-therapy techniques or semiautomated diagnostics [19,20]. Beyond the purview of one's initial licensing, lifelong learning in order to keep up with technological advancements to guarantee that mental health practitioners stay knowledgeable about the rapidly changing field of e-therapies and digital health solutions could be seen as nonnegotiable [21]. This need aligns with constructivist and experiential learning theories, which emphasize that learners build knowledge most effectively through active engagement and real-world application, both of which are necessary for the safe and ethical use of AI in clinical practice. The requirements for certification and continuing education programs, which may include specific workshops, learning modules centered on digital proficiency, or periodic re-examinations, reflect these needs [22]. Education researchers warn that lectures or brief seminars alone will not be sufficient to close the knowledge gap; clinical and research experiences that enable practitioners to assess, adjust, and use AI technologies with confidence in a safe and ethical way are also necessary [23].

The purpose of this scoping review was to determine the types of AI that are currently used in academic programs and educational curricula in psychology and psychiatry. Furthermore, it attempted to identify the barriers to and facilitators of such uses. By evaluating various apps, this review aimed to synthesize existing apps and highlight areas where further development or inquiry may be warranted. These included not only content delivery and assessment but also more challenging domains, such as teaching clinical judgment, fostering empathy, assessing nuanced interpersonal interactions, and supporting therapeutic decision-making—areas that are often context dependent and difficult to replicate algorithmically. Finally, suggestions were offered for future research directions to support the responsible and effective incorporation of AI into mental health education.

Methods

Search Strategies

A broad scoping search was systematically performed to retrieve the recent literature from multiple electronic databases, including

Medline, PubMed, Embase, PsycNet (PsycINFO), EBM Reviews – Cochrane Database of Systematic Reviews, and Google Scholar, covering records from database inception through October 2024. The review adhered to the Preferred Reporting Items for Systematic Reviews and Meta-Analyses Extension for Scoping Reviews (PRISMA-ScR) guidelines [24]. The search strategy integrated both free-text keywords and controlled vocabulary (Medical Subject Headings [MeSH] terms), centering on themes related to AI (eg, "artificial intelligence," "AI") and medical education (eg, "education," "medical," "students"), in accordance with the study's aims. Full search strategies are detailed in Multimedia Appendix 1. The search strategies were designed by an experienced librarian in the field of mental health (author MD). They were also cross-validated by another librarian using the Peer Review of Electronic Search Strategies (PRESS) approach. The methodology was designed by the corresponding author; searches were conducted by author AH and independently verified by author JP. No filters were applied concerning geographical location or institutional setting. The completed PRISMA-ScR checklist is available in Multimedia Appendix 2.

Study Eligibility

Studies were eligible for inclusion if they met the following criteria: (1) study focused on a topic within the fields of psychiatry or psychology education; (2) involved the use of an AI tool, model, or approach; (3) included a discussion of facilitators of or barriers to the use of AI; and (4) were available in either English or French. Papers that did not pertain to psychiatry or psychology or that referenced AI technologies without a clearly defined implementation or application were excluded. In addition, studies were excluded if they featured AI tools outside the domain of relevance, such as rule-based expert systems or search algorithms unrelated to data-driven models. Unpublished studies and gray literature were not considered for inclusion.

Data Extraction

A standardized data extraction form was developed to systematically collect and organize relevant information from each included study. Data extraction was performed independently by at least 2 of the authors, with discrepancies resolved through discussion and consensus or by consulting a third author, when necessary. The process was guided by the research objectives for examining the integration of AI in health profession education.

The following elements were extracted from each study:

- Authors: citation details, including the first author and year of publication.
- Population: description of the study participants, including the sample size, educational level (eg, undergraduate, postgraduate, continuing professional development), and discipline (eg, psychiatry, psychology, medical education).
- Use of AI: specific application or role of AI within the educational context, such as adaptive learning platforms, natural language processing (NLP) tools, intelligent tutoring systems, virtual patient simulations, or predictive analytics.
- Main outcomes: primary findings related to educational effectiveness, learner satisfaction, knowledge acquisition, clinical reasoning, engagement, or other measured outcomes. Where applicable, outcomes were categorized by study design (qualitative, quantitative, or mixed methods).
- Facilitators: factors that supported the successful implementation or perceived value of AI-enhanced educational interventions, such as user-friendliness, institutional support, personalization of learning, or alignment with curricular goals.
- Barriers: reported challenges or limitations in the adoption of AI tools, including technical constraints, ethical concerns, paucity of digital literacy among users, limited evidence of effectiveness, or resistance to change within educational environments.

Extracted data were tabulated in Microsoft Excel (version 17.0) to allow comparison across studies and to identify patterns, gaps, and emerging themes related to the integration of AI in teaching and learning within the fields of psychiatry and psychology.

Quality Assessment

To examine the included studies' methodology, clarity, and transparency, we carried out a systematic evaluation. Considering the variety of research designs seen in the literature on AI in psychiatry and addiction education, this phase attempted to improve the findings' interpretability. We used evaluation instruments that were specific to each research type's design to guarantee methodological adequacy.

The Joanna Briggs Institute (JBI) Checklist for Analytical Cross-Sectional Studies was used to assess both quantitative and observational research [25]. The methodological soundness of studies looking at correlations between exposures and outcomes at a specific moment in time can be evaluated with this tool. Items on the checklist evaluate the appropriateness of statistical analyses, the identification and control of confounding factors, the validity and reliability of exposure and outcome measurements, and the clarity of the inclusion criteria.

The JBI Checklist for Qualitative Research was also used [25]. This tool assesses how well research methodology and research topics align, how data are collected, how participant voices are represented and interpreted, and how much the researcher has influenced the study. To guarantee that qualitative insights are obtained through a thorough and reliable process, it also evaluates ethical issues and the openness of data analysis techniques.

Mixed methods studies were appraised using the Mixed Methods Appraisal Tool (MMAT), 2018 version [26]. The MMAT is a validated tool specifically developed for the assessment of studies that combine qualitative and quantitative approaches. It allows for concurrent evaluation of the components of each methodology within a single study and includes criteria for the integration of qualitative and quantitative data, the appropriateness of the design to the research questions, and the coherence of interpretations drawn from the combined methods.

For nonempirical contributions, such as viewpoints, editorials, and conceptual papers, we used the authority, accuracy, coverage, objectivity, date, and significance (AACODS) checklist [27]. This framework assesses 6 key domains: authority (credibility of the author or source), accuracy (evidence supporting claims), coverage (comprehensiveness of content), objectivity (balance and absence of bias), date (currency and relevance), and significance (contribution to the field). It is particularly useful for evaluating gray literature and opinion-based texts where conventional empirical criteria may not apply.

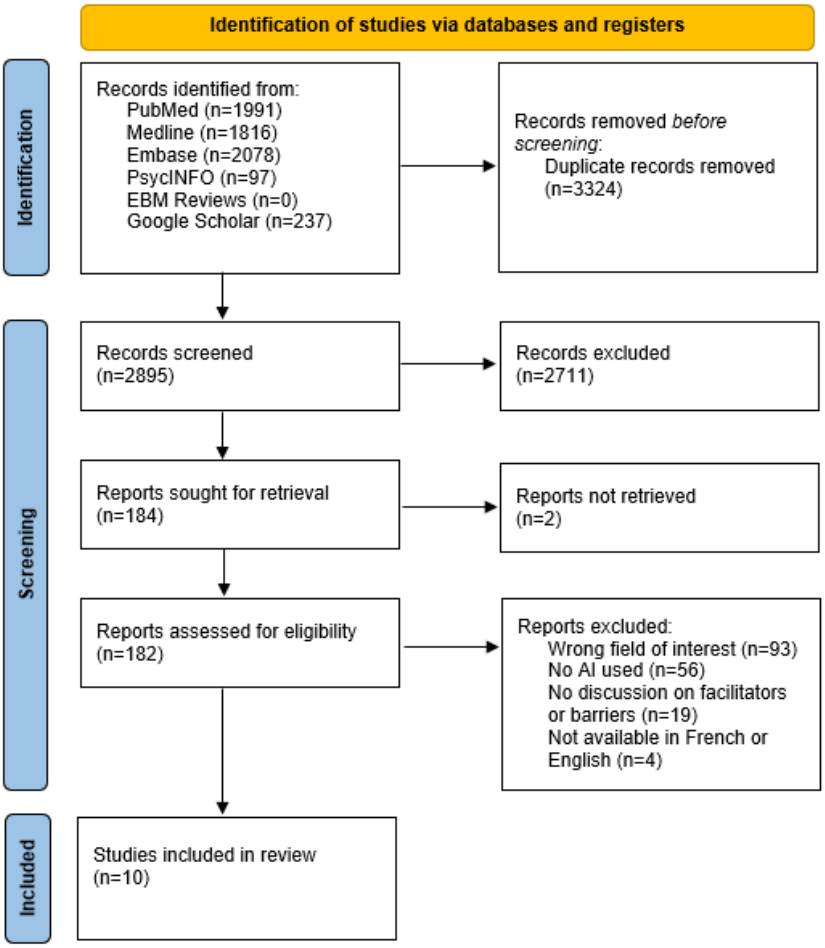
All studies were reviewed independently by 2 researchers (JP and AH). Each appraisal tool includes a set of key domains that were rated as "yes," "partial," or "no" based on the extent to which the methodological criteria were clearly addressed and appropriately implemented in each study.

Results

Description of Studies

The scoping review explored the use of AI in teaching and learning within psychiatry and psychology. The initial search across 6 electronic databases yielded 6219 records. After removing 3324 (53.4%) duplicates, 2895 (46.6%) records were screened by title and abstract. Of these, 2711 (93.6%) papers were excluded for not meeting the inclusion criteria. A total of 184 (6.4%) full-text papers were sought for retrieval, with 2 (1.1%) reports not successfully retrieved. The remaining 182 (98.9%) papers were assessed for eligibility in full. Following detailed evaluation, 172 (94.5%) papers were excluded due to being outside the field of interest (n=93, 54.1%), lacking the use of AI (n=56, 32.6%), not addressing facilitators or barriers (n=19, 11%), or not being available in English or French (n=4, 2.3%). Ultimately, 10 (5.5%) studies met all inclusion criteria and were included in the final analysis. A flowchart summarizing the selection process is presented in Figure 1, and details of the included studies can be found in Multimedia Appendix 3.

Figure 1. PRISMA-ScR flowchart for the inclusion of studies.



Main Uses of Artificial Intelligence

Across the 10 studies [28-37] included in this scoping review, AI was applied to a variety of educational functions in psychiatry and psychology. The most frequently observed category was *clinical decision support* (n=5, 50%), where AI tools were used to train learners in diagnosis, prognosis, risk assessment, and early intervention strategies. This was followed by 5 categories that each appeared in 3 (30%) studies: *educational content creation and enhancement*, *therapeutic tools and mental health monitoring*, *administrative and research*

assistance, *NLP applications*, and *program/policy development*. These categories reflect AI's growing role in the development of educational materials, therapeutic simulations, and institutional planning. Less frequently, studies addressed AI's applications in *professional development and assessment* (n=1, 10%) and *student/applicant support* (n=1, 10%), highlighting emerging but less explored domains. This distribution suggests a strong current emphasis on clinical reasoning, content automation, and digital service integration in educational contexts.

Clinical Decision Support

AI tools are increasingly integrated into psychiatry and psychology education to train learners in diagnosis, prognosis, and risk assessment. Through exposure to AI-driven systems, such as ML models and NLP tools, trainees can learn how to identify suicide risk, detect patterns in substance use disorders, or evaluate the progression of neurodegenerative conditions [28]. Banerjee et al [29] emphasized the importance of training programs that illustrate how AI can triage patients or generate diagnostic suggestions, helping doctors understand both the power and limitations of these technologies. Furthermore, students are being introduced to AI's role in treatment personalization, such as adapting therapy plans or medication regimens using predictive modeling [30]. These systems also facilitate early intervention, teaching clinicians how AI can flag high-risk patients in real time, thus embedding preventive care principles into training [31].

Educational Content Creation and Enhancement

Generative AI is transforming the design and delivery of educational content in psychiatry and psychology. One example is the use of ChatGPT to develop script concordance tests (SCTs), which promote clinical reasoning in undergraduate medical education. Hudon et al [32] demonstrated that AI-generated SCTs are nearly indistinguishable from those written by human experts, highlighting AI's potential to rapidly generate quality training materials aligned with psychiatric diagnostic frameworks. In addition, AI can support exam preparation, providing structured explanations, study plans, and interactive feedback for licensing exams and clinical cases [28]. Spallek et al [31] noted that although AI tools require human oversight, they offer accessible and customizable resources that align with the best practices in mental health communication and literacy, ultimately empowering educators and enhancing learner engagement.

Student/Applicant Support

AI can now be used to assist learners with the residency and fellowship application process, offering new educational opportunities in self-presentation and professional writing. Mangold and Ream [33] explored how students and faculty use AI to draft and refine personal statements and letters of recommendation, improving clarity and grammar and reducing biased language. From a pedagogical perspective, this practice teaches students to reflect critically on AI-generated outputs and engage in iterative editing processes. Moreover, AI is being proposed for application screening, potentially reducing human bias and increasing efficiency in admissions, which prompts institutions to educate both applicants and reviewers on ethical and equitable AI use [33]. These developments signal a shift in how learners engage with professional identity formation and how educators must adapt guidance accordingly.

Therapeutic Tools and Mental Health Monitoring

A body of literature highlighted AI's use in therapeutic education, particularly around digital interventions, such as CBT- or acceptance and commitment therapy (ACT)-based apps and chatbots. Blease et al [30] and Gratzer and Goldbloom [34] emphasized the need to train future psychiatrists to evaluate and potentially integrate these tools into treatment plans. E-therapy technologies, including AI-powered chatbots, provide psychoeducation on demand and demonstrate how therapy can be delivered asynchronously [34]. Trainees also learn about real-time symptom tracking, which is increasingly used in digital platforms to monitor patient well-being and guide interventions. These digital tools expose students to new care modalities, challenging them to assess efficacy, ethics, and clinical utility in both individual and population-based care models [34].

Administrative and Research Assistance

AI is also reshaping how clinicians and students interact with administrative and scholarly tasks, including documentation, summarization, and literature reviews. Banerjee et al [38] observed that AI is viewed as helpful in reducing the time spent on clinical documentation, allowing more focus on direct learning and patient care. Additionally, AI tools are being used in academic psychiatry to assist with automated literature searches, summarization, and even initial drafting of manuscripts, offering educational insights into how information is synthesized and presented in research [28]. These uses favorize critical thinking and teach students to evaluate AI-generated content, thereby strengthening their roles as both users and producers of scientific knowledge.

Professional Development and Assessment

In postgraduate and continuing education contexts, AI supports competency-based assessment and professional development. Anzia [35] discussed how longitudinal assessment platforms, potentially enhanced by AI, are replacing traditional high-stakes exams in psychiatry, promoting lifelong learning and more reflective practice. These tools can track learning progress, provide feedback, and recommend tailored educational pathways. Moreover, AI may be integrated into clinical skills evaluations, simulating patient scenarios or providing automated assessments of diagnostic reasoning. This shift calls for educators to incorporate digital literacy and AI fluency into curricula, ensuring that learners are prepared to navigate evolving certification and assessment landscapes [35].

Natural Language Processing Applications

NLP tools powered by AI are being introduced in educational settings to illustrate how clinical language can be analyzed, interpreted, and used for real-time support. Banerjee et al [29] noted NLP's utility in automating clinical documentation, reducing the clerical burden and highlighting the importance of clear, structured input. In psychiatry training, NLP is also applied to suicide risk detection, teaching learners how digital footprints and language cues from online interactions can signal

crisis [28]. Additionally, NLP technologies are integrated into telehealth platforms, enhancing communication between patients and providers, and offering opportunities for students to learn how AI can support culturally sensitive, evidence-based interactions [31].

Program/Policy Development

Finally, AI's influence on institutional teaching structures is growing, particularly through the design of AI-compatible teaching modules and the creation of policies to guide AI use. Manjunatha et al [36] illustrated how telepsychiatry programs in India are incorporating AI into remote learning for primary care doctors, serving as a scalable model for underserved settings. These modules reflect a shift toward digital curricula that embed clinical translation and evidence-based AI use. Similarly, Mangold and Ream [33] emphasized the need for training programs to define guidelines for AI use in admissions and evaluation, prompting educators to prepare learners for ethical dilemmas and policy engagement in the evolving digital landscape.

Facilitators

A number of facilitators support the integration of AI into teaching and learning in psychiatry and psychology.

Technological Readiness and Tool Availability

A recurring theme across the 10 studies was the availability and accessibility of AI tools, particularly large language models, such as ChatGPT, which simplify the creation of educational content and customization of learning materials for diverse learner needs [31,32]. These tools are perceived as valuable due to their ability to generate structured and accessible outputs, supporting educators in preparing mental health scenarios or assessments rapidly and effectively. Moreover, other technologies, such as telepsychiatry and mobile-based learning platforms, are supported by the widespread use of smartphones and digital infrastructure, increasing scalability and access to remote or underserved areas [36].

Educational and Efficiency Enhancement

Several studies have emphasized that structured prompting or prompt engineering significantly enhances output quality, improving both relevance and accuracy for educational use [33]. In clinical training contexts, AI is seen as a time-saving facilitator, capable of reducing administrative burdens, such as documentation, and allowing learners to focus on clinical reasoning and decision-making [29]. In addition, generative AI technologies and related models can facilitate the production of highly realistic synthetic data and the seamless integration of unstructured content across diverse formats [37]. These innovations have the potential to transform core practices, such as risk assessment, diagnostic decision-making, and treatment planning, while simultaneously creating new opportunities in educational and training environments.

Learner Engagement and Openness

Finally, positive attitudes from students and trainees, particularly their willingness to explore new tools, and their recognition of AI's role in increasing efficiency, accuracy, and engagement, are essential to AI adoption in educational environments [30]. These facilitators reflect a confluence of technological readiness, user engagement, and curricular flexibility.

Barriers

Despite growing enthusiasm, several barriers hinder the seamless integration of AI into psychiatry and psychology education.

Digital and Educational Gaps

A dominant concern is the absence of formal training and digital literacy among students and educators, which limits their ability to interpret and critically evaluate AI-generated outputs [29,30]. Many studies have noted a limited presence of AI content in medical curricula, resulting in missed opportunities to prepare learners for evolving clinical environments where AI plays a central role [30].

Ethical and Legal Issues

There are also ethical and legal concerns, particularly around data privacy, algorithmic bias, and informed consent, which raise questions about the responsible use of AI tools, such as chatbots or diagnostic aids [31,34]. The scarcity of high-quality data and the opacity of AI algorithms, often referred to as the "black box" problem, are also cited as major obstacles to trust and widespread adoption [28]. Additionally, concerns persist about the accuracy and reliability of AI-generated educational materials, particularly when outputs are not subject to expert review, posing risks of misinformation or oversimplification [31,32].

Pedagogical Limitations

Finally, several papers highlighted that AI outputs can lack nuance, empathy, or personalization, making them less suitable for teaching relational and humanistic aspects of psychiatric care [33].

These barriers highlight the need for comprehensive strategies that include AI literacy, ethical guidance, and faculty support to ensure safe and effective integration into educational practice.

Quality Assessment of the Identified Studies

Overall, the methodological quality of the included literature was moderate to high. Mixed methods and empirical studies demonstrated clear objectives, coherent data collection and analysis strategies, and ethical transparency. However, several studies lacked detailed descriptions of sampling procedures or integration of data types. Nonempirical papers were generally strong in authority and relevance but limited by the absence of primary data or systematic methodology. Despite variability in design and depth, most studies provided valuable insights into the educational applications of AI in psychiatry and psychology. The full quality appraisal is presented in Multimedia Appendix 3.

Discussion

Principal Findings

This scoping review aimed to identify the different ways AI is currently used in the teaching and learning of psychiatry and psychology. A total of 10 studies were fully analyzed, and 8 categories of AI applications were identified: clinical decision

support, educational content creation and enhancement, therapeutic tools and mental health monitoring, administrative and research assistance, NLP applications, program and policy development, student/applicant support, and professional development and assessment. These categories reflect the diverse roles AI plays in shaping educational strategies, curricular design, and learner engagement in mental health training. The studies included were overall of moderate-to-high quality. The most notable facilitators to AI integration in teaching and learning in psychiatry and psychology are technological readiness and tool availability, educational and efficiency enhancement, and learner engagement and openness. The barriers that hinder the integration of AI into psychiatry and psychology education are digital and educational gaps, ethical and legal issues, and pedagogical limitations.

Comparison With Prior Work

The findings of this scoping review confirm and expand on other studies that demonstrate the growing integration of AI into psychological and psychiatric education, especially through clinical decision support technologies. Previous research has shown, for example, that ML models can help forecast the risk of depression, schizophrenia, and suicide. Our study also noted that similar predictive technologies are already being used in educational contexts [38,39]. This is consistent with the findings of Rajkomar et al [40], who observed that clinical AI tool exposure aids in the development of important data literacy in health care trainees. Our work showcases the potential of AI in supporting students as they develop their critical reasoning. However, it is important to keep in mind that these critical reasoning skills are still mostly shaped over time through clinical exposure and case discussion, both of which cannot be replaced by algorithms or AI. The multidisciplinary team also holds a significant place in clinical management and risk sharing. AI can give theoretical advice to students regarding how to lead a team, but it cannot teach a student how to lead a team in real time. Although previous research has often emphasized clinical outcomes, we focused here on the learning process itself, with the understanding that AI is only one of many educational tools.

The literature on AI also supports the increasing use of generative AI in the production of instructional materials. Recent research has switched to looking at how tools such as ChatGPT, GPT-4, and Claude might scaffold learning in medical education, whereas the majority of earlier applications were on patient-facing educational interventions (eg, mental health apps) [41]. These studies support our findings by demonstrating that AI is capable of creating excellent test questions, simulating clinical situations, and even co-creating course curricula. However, critical gaps still exist, notably the possibility that students will passively accept AI outputs without engaging sufficiently. In fact, some of these critical knowledge gaps might be due to the current state of research, which remains limited when it comes to assessing how heavy reliance on dialogue AI may affect decision-making, critical thinking, and analytical reasoning in both educational and research contexts [42]. Meskó [43] shared this concern and called for clear instruction in AI prompt engineering, appropriate medical professional tutorials, and verification skills. The findings of this scoping review highlight that such competencies are increasingly essential in psychiatry and psychology, where nuance and context matter deeply.

According to certain studies, an important area of AI integration in training is mental health apps and therapeutic chatbots, which is consistent with previous research [44,45]. According to these studies, chatbot-based psychotherapy and psychoeducational tools are beneficial teaching tools, in addition to being successful for patients. When included in clinical simulations, they give students an opportunity to analyze intervention results, gauge the therapeutic tone, and practice making moral decisions. Our results highlight the need for directed education to guarantee that students acquire abilities in digital empathy, data protection, and cultural adaptation, even when these tools show promise. Training programs need to change in a way that assists clinicians in interpreting AI-driven outputs, while upholding person-centered treatment and therapeutic alliances, as D'Alfonso et al [46] contended.

Lastly, the findings confirm that faculty development, institutional preparedness, and ethical advice are drivers of AI adoption, which is in line with research on digital transformation in health professions education [47]. Although students frequently use AI tools for convenience, educators are nevertheless worried about the loss of critical thinking, professional identity, and interpersonal skills. These difficulties point to the necessity of organized curricula, such as one that incorporates AI literacy into psychology and psychiatry undergraduate and graduate education programs [48].

Directions for Further Research

This scoping review revealed that slowly but surely, the integration of AI, although remaining nascent in psychology and psychiatry education, is nonetheless there to stay. Future research should prioritize rigorous, outcome-based studies that evaluate further the impact of the AI-enhanced educational tools that this paper described, such as diagnostic stimulation, e-therapies, AI-assisted clinical decision-making, and the impact on real-life learning performance. Another important aspect that would be crucial to investigate is the management of algorithmic bias and transparency and understanding the extent of protecting one's private data. Research that captures the perspectives of students and educators could shed light on readiness, perceived barriers, and opportunities for meaningful adoption of AI.

Furthermore, given the fact that the majority of studies analyzed are from Euro-American and high-income contexts, there is a clear need for research that centers on diverse populations, including Indigenous, racialized, and culturally distinct groups. Together, these directions can help guide the development of inclusive and ethically grounded approaches to AI integration into mental health education.

Recommendations for Institutions

To ensure that psychology and psychiatry programs prepare trainees for a rapidly evolving clinical landscape, educational institutions should take proactive steps toward integrating AI literacy into core curricula. For example, digital literacy could be integrated early into medical education, with foundational topics such as ML and data ethics. This effort would benefit from interdisciplinary collaboration among health sciences,

computer science, and bioethics departments to ensure a well-rounded approach.

The extent to which a person believes that a technology can enhance their performance at work (or enhance their learning experience, for that matter) is commonly referred to as "perceived usefulness," and it plays a pivotal role in determining whether individuals are likely to adopt new technologies [49]. A meta-analysis by Scherer and Teo [50] identified perceived usefulness as a strong predictor of a teacher's readiness to engage with digital tools. Conversely, barriers included anxiety and a lack of AI-specific training [51]. Thus, to effectively deal with the growing threats posed by AI, it seems crucial to promote the various uses of AI among the professors. Teachers who understand AI better are more equipped to use it in ways that meet the varied needs of their students [52]. In addition, when educators develop a solid understanding of AI, they are better equipped to tackle its ethical issues, such as algorithmic bias, data privacy, and the risk of becoming overly dependent on AI [53].

Hence, educators require adequate training, resources, and institutional support to effectively teach and oversee the responsible use of emerging digital tools in clinical and academic settings.

How will universities effectively manage the growing threats that AI presents to medical education? Those threats, as previously mentioned, include academic dishonesty in assessments (eg, plagiarism), the spread of misinformation, and the difficulty AI-using students face in discerning some of the nuances in fields where human interaction is key, such as psychiatry and psychology. Because these threats are often multifactorial in nature, their management requires an inclusive approach involving all key actors (students, educators, institutions) [54]. In practice, at the university level, an interesting avenue would be the constitution of a task force (or a committee) comprising students, faculty members, AI scholars, and IT personnel. This task force would be aimed at determining permissible uses of AI versus prohibited uses of AI and how to detect the latter. The detection of AI-generated content can be facilitated by applications such as GPTZero and QuillBot, for example. Higher education institutions (HEI) should not only establish such thorough guidelines but also review them periodically to ensure their continued relevance [54]. Bozkurt [55] suggested that HEI also require transparent disclosure of AI usage by their personnel and students (eg, in a given assessment, the students would be expected to explicitly declare the sections drafted by ChatGPT with human oversight). HEI could also offer some new job positions focused on AI or hire professionals specifically trained to identify AI-related academic misconduct and sanction such ethical issues. These professionals would ideally also have some degree of experience with the efficient implementation of AI in an academic context.

Strengths and Limitations

The authors brought diverse disciplinary perspectives to this review, including training in psychology, psychiatry, medical education, and digital health. These backgrounds informed the framing of the review and the interpretation of its findings.

This scoping review also has a few limitations. First, although a comprehensive search strategy was used across multiple databases, it is possible that relevant studies were missing, particularly those published in nonindexed journals or categorized under broader terms not captured by the search keywords. Second, the authors acknowledge the potential for disciplinary bias rooted in Western academic systems. An effort was made to include literature from a range of geographic regions and institutional contexts; however, due to the limited published research available on the subject, the review was limited to studies published in English or French, potentially excluding valuable insights from non-English/French literature; in addition, the majority of published research available in English originated from Euro-American or high-income settings, which may limit the generalizability of the review's conclusions. Third, due to the heterogeneity of study designs and the inclusion of both empirical and conceptual papers, no formal meta-analysis was conducted, and the synthesis remained primarily narrative. In addition, although efforts were made to assess study quality using validated tools, some included papers, particularly perspectives and editorials, lacked sufficient methodological detail, which may limit the generalizability of their conclusions. Finally, because the field of AI in mental health education is rapidly evolving, newer studies and technologies may have emerged since the time of data collection, warranting future updates to this review.

Conclusion

To conclude, this scoping review provided an overview of how AI is being integrated into the teaching and learning of psychiatry and psychology. By analyzing 10 studies, 8 distinct categories of AI uses were identified, ranging from clinical decision support and educational content generation to digital therapeutic tools and policy development. These findings highlight the emerging role of AI not only as a clinical adjunct but also as a transformative educational tool that can support adaptive learning, promote efficiency, and broaden access to mental health training. Although the overall quality of the studies included was moderate to high, important challenges remain, particularly related to ethical considerations, digital literacy, and institutional readiness. As AI technologies continue to evolve, future research and curriculum development efforts should focus on promoting safe, equitable, and pedagogically sound integration of AI in mental health education. Equipping educators and students will require the integration of AI literacy into core curricula, embedding foundational topics such as ML and data ethics and fostering interdisciplinary collaboration between various departments. Faculty personnel development, institutional preparedness, and student involvement are essential drivers for successful AI adoption. Future research should prioritize rigorous, outcome-based studies and capture diverse perspectives in order to guide the development of inclusive and effective AI integration strategies in mental health education. This review underscores the need for ongoing interdisciplinary collaboration between educators, clinicians, technologists, and policymakers to ensure that future practitioners are well equipped to engage with AI in meaningful and responsible ways.

Acknowledgments

This study was funded indirectly by the La Fondation de l'Institut universitaire en santé mentale de Montréal and operating funds from IVADO for AH.

Authors' Contributions

AH and JP were involved in conceptualization. Data curation, writing—original draft, and writing—review and editing were performed by all the authors; formal analysis by AH and JP; funding acquisition, investigation, project administration, resources, and supervision by AH; methodology by AH and MD; and validation by AH and JP.

Abstract

Background: Medical education now focuses on developing skilled and dependable professionals, with particular attention to the hidden curriculum and its influence on professionalism and humanism.

Objective: This scoping review aimed to analyze the available evidence on the benefits and adverse effects of the hidden curriculum in medical education.

Methods: A scoping review of the literature available in the indexed databases PubMed, Scopus, ScienceDirect, and Latin American and Caribbean Health Sciences Literature (LILACS) with MeSH (Medical Subject Headings) descriptors was conducted on the effects of the hidden curriculum in medical education between January 2000 and April 2024. A total of 29 papers were selected for the review.

Results: Our review included studies from 10 countries, most of which were descriptive and cross-sectional, revealing both positive and negative impacts of the hidden curriculum in medical education. These include the transmission of implicit values and the influence on forming skills and professional identity. It was found that some elements contributed to the integral development of students, and others generated challenges that affected the quality of medical education. Likewise, the need for further research to design implementation strategies in different medical schools was described.

Conclusions: The hidden curriculum proves to have both a positive and negative impact on the attitudes and values of medical students. The findings highlight the need to generate greater awareness and proactive strategies in educational institutions to improve the quality of training and promote the holistic development of future health professionals.

KEYWORDS

hidden curriculum; medical education; professionalism; concept formation; professional ethics; humanism

Introduction

Background

Over the years, medical education has undergone essential transformations to train skilled and reliable professionals who promote health in all people without forgetting the humanistic attitude that the profession demands [1]. In response, medical schools have committed themselves to building a curriculum that allows them to provide society with physicians who respond adequately to the population's health needs and who are efficient in the practice of their profession [2].

Thus, the curriculum has been the subject of research, where it has been explored in such a way that more than one type of curriculum has been found within the educational process [3]. This has led to the recognition that medical education is a cultural process influenced by external forces, which is how, in 1968, the term 'hidden curriculum' gained importance. Jackson [4] described it as "the tacit ways in which knowledge and behavior are constructed, outside the formally programmed courses and subjects" [5]. A study by Hafferty and O'Donnell [6] first documented the hidden curriculum phenomenon in medical education by observing how students develop their professional identity through hidden curriculum instead of formal learning experiences. According to Hafferty and O'Donnell [6], "Hidden curriculum are the customs, rituals, and taken-for-granted aspects of education in the health professions, particularly those that learners experience during interactions with faculty and clinicians in practice settings." In contrast to formal and null curricula with clear rules and expectations, the hidden curriculum is rarely planned or stated. Through the use of hidden curriculum, instructors were able to shape students' ideas about the significance and applicability of patients' knowledge. During this process, learning is generated with no apparent relation to what has been previously established, which is why it can be seen as not very significant; however, evidence shows that it plays an essential role in the fulfillment of educational goals and that it should be included in academic training programs [6,7].

The term hidden curriculum is frequently, though inaccurately, used interchangeably with informal or implicit curriculum; however, these terms have distinct conceptual meanings in medical education literature. Lawrence et al [8] describe the hidden curriculum as the implicit influences arising specifically from institutional culture, organizational structure, and social interactions, significantly shaping professional development and medical identity. In contrast, the informal curriculum refers to spontaneous, unstructured learning that occurs without formal planning, either inside or outside formal educational environments. Meanwhile, the implicit curriculum includes educational content integrated implicitly into institutional practices and expectations, though never explicitly documented [8]. Clearly distinguishing these terms is essential, as the unique nature of the hidden curriculum presents particular methodological challenges for objective measurement and evaluation of its impacts. To facilitate understanding and conceptual differentiation among hidden, informal, and implicit curricula, Table 1 summarizes their key characteristics and provides illustrative examples within medical education.

Table 1. Differentiating hidden, informal, and implicit curricula in medical education[a].

Curriculum type	Definition and key concept	Examples
Hidden	Implicit influences arising from institutional culture, organizational structure, and social interactions	Implicit hierarchy among medical specialties and gender biases in clinical practice
Informal	Spontaneous, unstructured learning experiences occurring without formal planning	Informal discussions among students and faculty and spontaneous clinical discussions in corridors or cafeterias
Implicit	Educational content implicitly integrated into institutional practices, not formally documented	Tacit expectations of professionalism and implicitly assumed ethical behaviors in clinical practice

[a]Adapted from the study by Lawrence et al [8].

Considering the points mentioned previously in the text, it is known that some skills, behaviors, and values inherent to the medical profession are learned through the hidden curriculum [9]. Empathy, respect, confidentiality, and care are among the values learned through experiences in clinical settings. In the hospital setting, the medical community faces challenges ranging from supervised and respectful knowledge construction to witnessing hierarchy, mistreatment, and exploitation by teaching and care staff during their academic process [10].

Objectives

The primary objective of this review was to conduct a comprehensive analysis of the available evidence regarding the impact of the hidden curriculum in medical education, examining both its benefits and adverse effects. This includes assessing how informal learning experiences, unstructured interactions, and observed behaviors within clinical and educational environments can positively influence the professional and personal development of medical students. In addition, the review aims to investigate potential negative outcomes, such as the perpetuation of undesirable values or stereotypes, and their impact on educational quality and student well-being.

Despite the evident impact of the hidden curriculum, much of the existing research focuses primarily on formal teaching practices, neglecting the hidden dimensions of medical education. As a result, this literature remains scattered and fails to provide a comprehensive analysis of the impact of the hidden curriculum in shaping medical education.

This study aims to address that gap by focusing on specific research questions:

- What are the main effects of the hidden curriculum on medical training, both positive and negative?
- What strategies have been proposed or implemented to mitigate the negative effects of the hidden curriculum in medical education?

By showcasing the varied importance of the hidden curriculum across different medical schools, the review seeks to provide evidence that will encourage other institutions to recognize and incorporate the hidden curriculum into their learning objectives and goals. Ultimately, the review aims to offer practical recommendations for integrating the hidden curriculum in a way that enhances overall medical education and better prepares future health care professionals.

Methods

Ethical Considerations

Written informed consent and ethics approval were not required due to the nature of the study.

Study Design

The PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses extension for Scoping Reviews) statement was used to perform this scoping review.

Eligibility Criteria

This review primarily included qualitative studies with an interpretative perspective, featuring articles that used thematic analysis and grounded theory methodology, as well as opinion pieces, systematic reviews, scoping reviews, and literature reviews. The study excluded quantitative research, focusing instead on gaining deeper insights and understanding the nuanced impact of the hidden curriculum rather than measuring it statistically. Editorial comments and letters to the editor were excluded. Eligible participants were undergraduate and postgraduate medical students. Studies involving other health professions, such as nursing, pharmacy, nutrition, dentistry, and psychology, were not included. Articles included those published between 2000 and April 2024, with full-text availability, whose titles or abstracts incorporated research on the effect of the hidden curriculum in medical education, including values such as professionalism, medical ethics, and humanism. The 2000 to 2024 timeframe was chosen to capture the evolution of research on the hidden curriculum in medical education. Other curricula different than the hidden curriculum were excluded. We included postgraduate students in residency programs such as anesthesia, surgery, family medicine, emergency medicine, and radiology because of their relevance to study objectives and the impact of the hidden curriculum within these fields.

Information Sources

The PubMed, Scopus, ScienceDirect, and Latin American and Caribbean Health Sciences Literature (LILACS) databases were systematically searched for literature published between January 2000 and April 2024.

Search Strategy

The search strategy followed systematic search principles and was guided by the population, intervention, comparison, and outcome (PICO) framework. The search terms included the keywords “Education,” “Medical,” “Curriculum,” and “Professionalism” using the Boolean operator AND to obtain results for the search query “Medical Education” [MeSH] AND “Hidden Curriculum” [MeSH] AND “Professionalism” [Mesh]. Experts were not formally consulted during the development of the search strategy. Only qualitative studies published between 2000 and 2024 were eligible for inclusion in this review. The search was limited to studies published in English, Spanish, or Portuguese. The review did not use a standardized quality assessment tool, as its primary aim was to map existing research rather than conduct a detailed critical assessment of individual studies.

Selection of Sources of Evidence

Two authors (SPL and DNC) screened the titles and abstracts of identified studies based on the inclusion and exclusion criteria. The full texts of the shortlisted studies were analyzed and evaluated independently for eligibility by the same 2 authors (SPL and DNC). In instances of uncertainty, the other 3 authors (EHHR, CLJP, and ART) were consulted, and decisions were made by consensus.

Data Charting Process (Data Extraction)

Two reviewers (SPL and DN) independently gathered relevant data from the articles included in the review. These data covered several aspects: title, article characteristics (eg, the publication year, country, and field of education), participant details (eg, educational degree and medical residency), and specifics related to the intervention (eg, actual impact and future outcomes in professional skills). Any disagreements between the reviewers were resolved through consultation with the other 3 authors (EHHR, CLJP, and ART), and decisions were reached by consensus.

Data Items

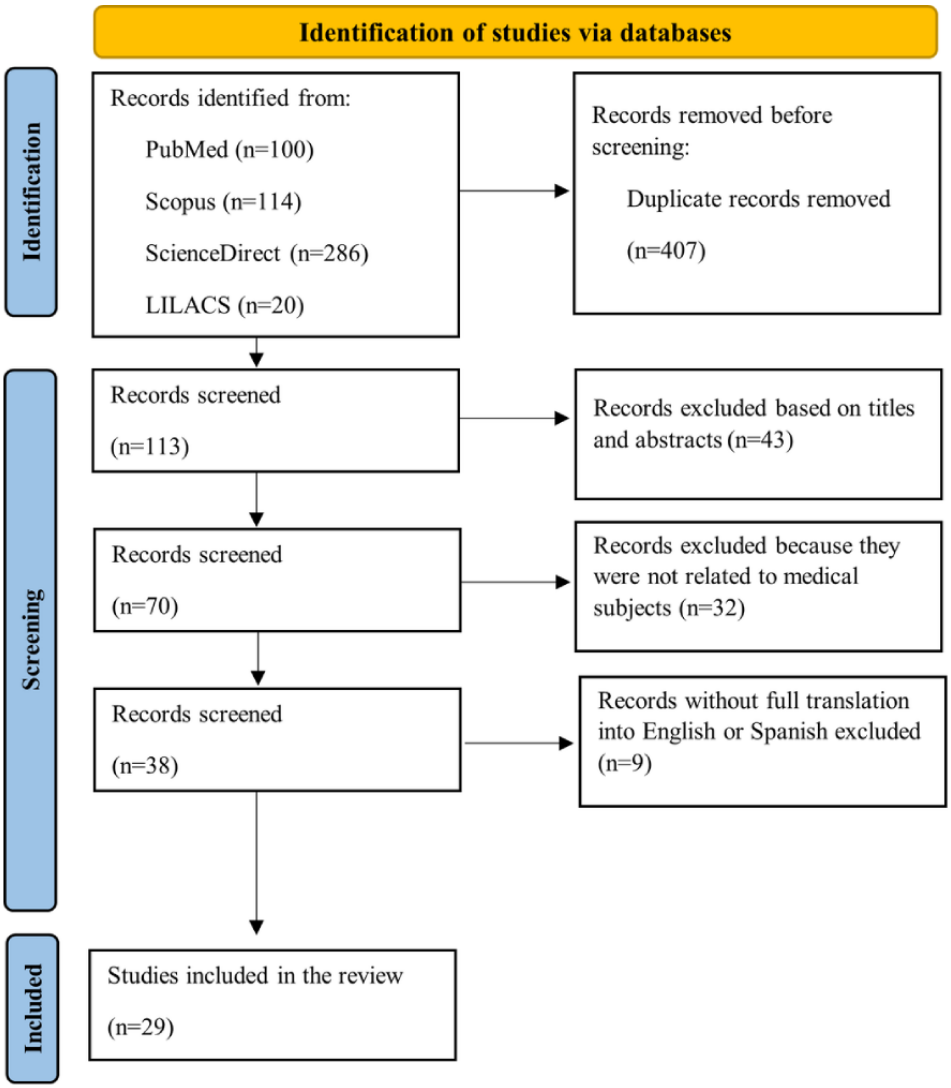
Articles were included if they featured any independent variable related to the following: presence and characteristics of the hidden curriculum (ie, implicit values, behaviors, and attitudes within medical education settings), educational contexts (ie, academic institutions and hospital settings), and educational stages (ie, undergraduate and postgraduate).

Results

Study Selection

A total of 520 documents were identified in the databases through an electronic literature search, including 100 from PubMed, 114 from Scopus, 286 from ScienceDirect, and 20 from LILACS. After duplicates were removed, 113 articles were screened. The initial title and abstract screening excluded 43 articles, leaving 70. Of these, 32 focused on health areas other than medicine, and 9 lacked full translation into English or Spanish. Excluding these 41 articles left 29 for inclusion in the qualitative synthesis of the scoping review (Figure 1).

Figure 1. PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) 2020 flow diagram for new systematic review that include searches of databases and registers only.



Study Characteristics

The characteristics of all included studies are summarized in Multimedia Appendix 1 [11-39]. Publication dates ranged from 2007 to 2024. Most studies were conducted in the United States (14/29,48%) [11,16-20,24,25,28,31,33,34,38,39], followed by the United Kingdom (4/29, 14%) [12,13,36,37], Iran (3/29, 10%) [14,15,35], Brazil (2/29, 7%) [29,32], Canada (1/29, 3%) [22], Sweden (1/29, 3%) [21], Ireland (1/29, 3%) [23], the Netherlands (1/29, 3%) [27], Israel (1/29, 3%) [26], and Argentina (1/29, 3%) [30]. In terms of methodology, qualitative studies were most common (15/29, 52%), using different designs such as thematic analysis and grounded theory (6/29, 21%) [12,13,15,24,26,29], evaluation design (3/29, 10%) [17,19,33], exploratory and observational approaches (3/29, 10%) [14,23,30], intervention studies (2/29, 7%) [16,33], and discourse analysis (1/29, 3%) [34]; other study types included literature reviews (3/29, 10%) [20,27,33], mixed methods (2/29, 7%) [18,28], systematic and scoping reviews (3/29, 10%) [21,25,35], a position paper (1/29, 3%) [11], integrative reviews (2/29, 7%) [32,36], an innovation report (1/29, 3%) [38], a retrospective study (1/29, 3%) [31], and a perspective article (1/29, 3%) [39].

Synthesis of Results

In terms of content, the articles included in this scoping review revealed different benefits [13-25] and adverse effects [26-31] of the hidden curriculum present in medical education during different moments of academic training, such as undergraduate [8,10,11,13-19,24-31] and postgraduate education [20-23], as well as tools and strategies for its implementation within the learning objectives and goals of different medical schools for the development of professional skills in medical personnel in training [11,33-37]. Similarly, 3 categories were considered for the analysis of the available literature: “benefits of the hidden curriculum in medical education,” “negative effects of the hidden curriculum in medical education,” and “implementation strategies and limitations within the medical education process.”

Categorization and Frequency of Effects of the Hidden Curriculum

The effects of the hidden curriculum were categorized and quantified into 2 primary domains: positive (beneficial) and negative (adverse). Among the 29 studies analyzed, (27/29, 93%) reported at least one positive outcome, including the development of professional identity (12/29, 41%), ethical and

moral reasoning (7/29, 24%), empathy and humanistic values (5/29, 17%), and reflective thinking (4/29, 14%). Meanwhile, (17/29, 59%) described adverse effects, such as reinforcement of medical hierarchies (6/29, 21%), emotional detachment or stress (5/29, 17%), and value incongruence between formal and informal teachings (5/29, 17%). A detailed summary of these categorizations is presented in Table 2. In this process, multiple studies reported more than one effect.

Table 2. Categorization and frequency of effects of the hidden curriculum (N=29).

Effect category and subcategory	Studies, n (%)	References
Positive[a]		
Professional identity formation	12 (41)	[11-13,16,18,20,26,29,30,32,34,37]
Ethical and moral development	7 (24)	[11,12,15,20,25,32,37]
Empathy and humanistic values	5 (17)	[13,24,25,31,36]
Reflective thinking and critical judgment	4 (14)	[12,17,18,23]
Negative[b]		
Reinforcement of hierarchy or authoritarianism	6 (21)	[10,19,20,22,28,33]
Emotional stress and detachment	5 (17)	[13,16,17,23,31]
Incongruence between taught and modeled values	5 (17)	[11,21,26,33,37]

[a]Categories are not mutually exclusive; some studies contributed to more than one subtheme.

[b]Seventeen of the 29 studies reported at least one adverse effect. The subcategories listed capture most of these, although some studies contributed negative aspects not easily classified under the three main themes.

Discussion

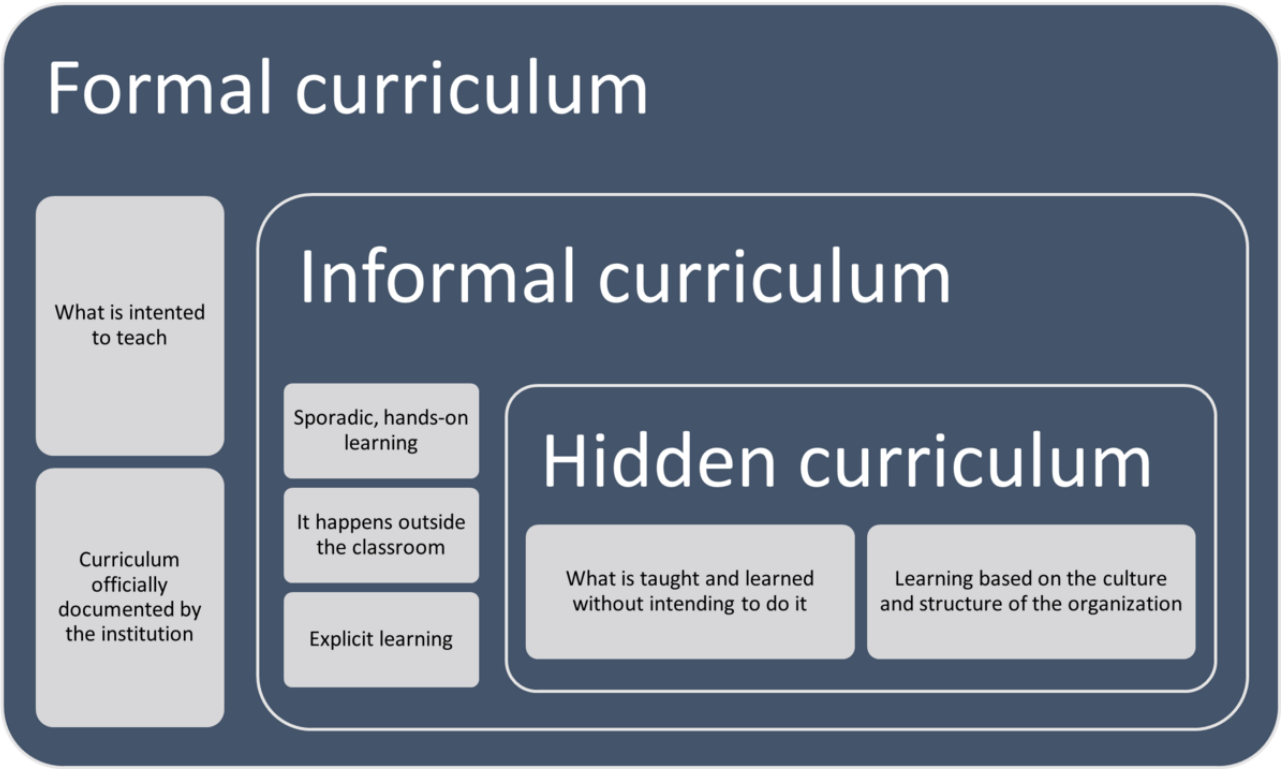
Principal Findings

This scoping review investigated the role of the hidden curriculum in medical education and its positive and negative aspects. The results highlight critical insights: one of the key findings of this study is that the hidden curriculum is an unavoidable, powerful force that shapes how medical trainees develop their professional identities, medical professionalism, and humanism. The findings of this study also show that a hidden curriculum can effectively strengthen the physician-patient relationship. The hidden curriculum proved to be the dominant factor that determines professional adaptability for medical practitioners who face ongoing changes in clinical practice. Medical students learn essential professional attitudes and behaviors through the pervasive influences of the hidden curriculum. The hidden education system surpasses traditional classroom learning because it shapes students' moral values and ethical conduct as well as their approach to making important decisions. This review also suggests that medical institutions should create proactive approaches and refine procedures for an implicit hidden curriculum that affects medical professionals.

Comparison With Prior Literature

The review aligns with the existing research showing how the hidden curriculum's power remains unrecognized in its ability to mold medical student experiences. The first description of the hidden curriculum was made in 1970 by Jackson [5]; however, it was not until 1994 that its relationship with medical education was defined by Hafferty [10], who stated that the training and learning process of the medical profession was influenced by cultural aspects and by the context in which the students developed and attributed to the hidden curriculum the reason for most of their mistakes [7]. Culture significantly shapes the hidden curriculum by influencing medical students to incorporate professional standards and core values through educational settings that differ across societies. Some cultural influences encourage patient-centered care and professionalism, but other cultural elements maintain hierarchical structures while promoting discrimination and emotional suppression. Likewise, learning has been approached through 3 dimensions of the curriculum, which are represented in Figure 2 [6,10]: the formal curriculum, what is documented to offer; the informal curriculum, how the curriculum is carried out through the interactions of the community; and the hidden curriculum, all that learning that occurs outside the expected and stipulated [11], which is where skills that cannot be taught through the formal curriculum are developed.

Figure 2. Types of curricula described in the literature (adapted from the studies by Hafferty and O'Donnell [6] and Hafferty [10]).



Given the previously mentioned positive and negative effects, several authors in the analyzed literature explore the hidden curriculum. They highlight both the benefits and drawbacks of the hidden curriculum in medical training, where values such as empathy, respect, and professionalism are cultivated. Nevertheless, even the physician-patient relationship can be affected by negative interactions and experiences in clinical practice settings [12].

However, this review expands on previous research by highlighting the benefits of the hidden curriculum. First, a benefit is described in the search, construction, and strengthening of professional identity [13]. When students face negative experiences and behaviors in the hospital environment, it is necessary to confront their own identity with the one they are expected to acquire, which generates a reflection about the professionals they wish to become in the future. The hidden curriculum gives students the skills they need to adjust to different professional situations in addition to helping them establish their identities. The development of critical soft skills, including empathy, teamwork, and communication, is positively impacted by the hidden curriculum [13]. Medical students who master the interpretation and understanding of the hidden curriculum become better prepared for dynamic health care environments, demonstrating greater resilience, innovative problem-solving, and a proactive commitment to lifelong learning [18].

This review finding aligns with the findings by Azmand et al [14] that a hidden curriculum can effectively strengthen physician-patient relationships, where the role models of teachers motivate them to dedicate adequate time to patients, recognizing their concerns beyond their medical conditions and needs. Physician-patient relationships embedded within the hidden curriculum substantially enhance patient outcomes. The hidden curriculum enhances formal medical education by incorporating patient-centered approaches into medical students' everyday lives, which eventually helps both practitioners and the patients they treat. These relationships were characterized by a sense of ethics, responsibility toward others, and the medical environment [15,16].

By contrast, the influence of the hidden curriculum on the construction of professionalism and the trust that patients and their families place in training professionals has been explored [17]. Teachers and students emphasized that the formal curriculum does not teach them the necessary skills to interact in a dynamic environment such as a hospital and that lived experiences allow them to develop skills and attitudes that are inherent to the medical profession, among which respect, responsibility, compassion, and communication, among others, stand out [18]. The hidden curriculum promotes the value of moral decision-making, transparency, and confidentiality, all of which help to foster trust with patients as well as colleagues. The hidden curriculum is evident at all stages of training [19], from undergraduate to postgraduate programs such as general surgery [20], family medicine [21], radiology [22], and anesthesia [23].

Finally, regarding its benefits, the hidden curriculum has been shown to influence dimensions such as religion, spirituality [24], and humanism [25]. Through these experiences, students developed coping strategies for emotional stress when treating patients facing serious illness, family difficulties, or death. They also acquired values such as empathy, communication, respect, and emotional stability—skills learned through real-world practice rather than the formal curriculum.

Through a scoping review of the literature, it was determined that the available evidence, to a great extent, revealed the adverse effects of the hidden curriculum in medical education. Mistreatment [26] and hierarchical dynamics toward students and residents were among the most frequently reported issues, often linked to decreased motivation and commitment to the training process [27]. The students mentioned that 2 different teachers in the same service could improve or affect the learning environment and their performance. Thus, mistreatment by colleagues and teachers during the selection process of medical-surgical specialties has even been described [28], which negatively impacts their decisions. Studies link mistreatment exposure to higher stress levels and burnout symptoms, along with diminished empathy, which harms both the students' mental state and their competency in providing patient care [28].

In addition, another component of the hidden curriculum that generates adverse effects is the burden and pressure on undergraduate and graduate students [29]. They explained that they were required to respond in an accelerated manner to their obligations to their patients, which affected their care in terms of time and quality. This attitude of immediacy in practice scenarios is often generated in teachers by a conflict between the teaching role and the caring role [30], in which, by neglecting one or appropriating the other, attention and respect for the patient or their teaching activity with students are affected. The implicit demands of the hidden curriculum may cause stress, which could have a negative impact on students' general well-being and long-term ability to adjust professionally. Addressing this role conflict is essential, as medical training should prioritize proper practice, integrating clear instruction with comprehensive patient care.

The dual impact of the hidden curriculum on medical education, its capacity to promote humanistic values and simultaneously induce stress, has been recently explored. Auckley et al [31], through their analysis of the Humanism in Medicine Initiative, demonstrate that while extracurricular humanism-focused activities significantly enhance student well-being and professional identity, moderate engagement paradoxically correlates with increased stress. Such findings underline the nuanced role of the hidden curriculum in shaping medical students' experiences and highlight the need for balanced engagement.

Regarding humanism, although some studies highlight the benefit of the hidden curriculum in integrating these qualities with medical professionalism, others suggest a disconnect between clinical skills and the humanistic aspects of medical education [32]. Skills such as communication, decision-making, respect, and autonomy are often acquired through implicit learning, which tends to receive less emphasis. This limited focus may reduce the humanistic approach to patient care when these students later practice as physicians [32]. Table 3 compares the positive and negative effects of the hidden curriculum.

Table 3. Comparison of the positive and negative effects of the hidden medical education curriculum.

Feature	Positive effects	Negative effects
Professional identity	Consolidation of professional identity through confrontation between personal and expected roles [13]	Imposed identity leading to dissonance and emotional distress [13]
Medical professionalism	Reflection spaces to analyze emotions and promote respect and empathy toward teachers, colleagues, and patients [11,17]	Mistreatment, humiliation, and hierarchy normalized as acceptable cultural patterns [11]
Physician-patient relationship	Recognition of patient concerns and needs beyond disease, fostering trust-based relationships [14-16]	Loss of patient interaction opportunities due to efficiency culture and high workload [29,30]
Wellness and mental health	Promotion of self-care, spirituality, and mental well-being [24]	Clinical distress, burnout, low well-being, and depression affecting performance [11]
Humanism	Adoption of communication, empathy, respect, and autonomy through the hidden curriculum [25]	Dehumanization in medical education and patient care perpetuated across generations [11]

Implementation Strategies and Challenges in Addressing the Hidden Curriculum

To date, the benefits and adverse effects of the hidden curriculum in medical education have been analyzed. This leads to identifying strategies to enhance the virtues and mitigate the unfavorable effects it may have on medical students and the limitations of its implementation. First, studies highlight the importance of constantly evaluating the learning environments in educational institutions and clinical practice scenarios [33,34] so that they become a safe and adequate environment for the acquisition of professional and personal skills for patient care, recognizing that the educational process is based not only on the knowledge to be acquired but also on multicultural education that strengthens professional identity and ethics [34].

Likewise, the importance of strengthening institutional culture in practice scenarios has been described based on humanistic attitudes, such as compassion, curiosity, respect, and empathy, enabling students to identify with these values and carry them into their professional practice [11]. This process should involve the student in situations where they must make ethically complex decisions and face emotions that impact them, supported by teacher guidance and opportunities for reflection [11].

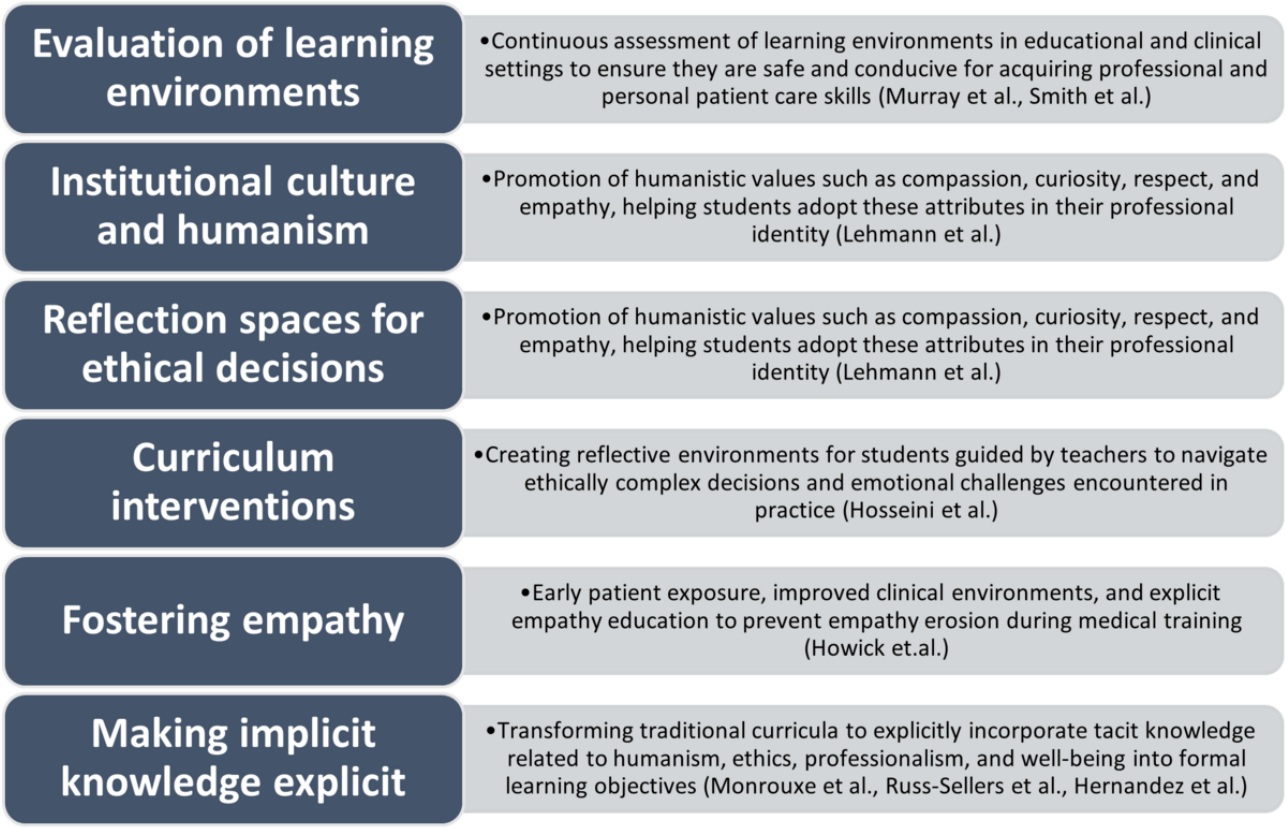
Moreover, recent literature highlights specific interventions aimed at mitigating negative impacts and optimizing the hidden curriculum. Hosseini et al [35] identify key strategies, such as the implementation of new curricula, team-based clinical clerkships, and longitudinal faculty development workshops. These strategies are essential to manage the implicit values and unintended messages conveyed through informal learning

experiences and interactions, reducing the adverse outcomes associated with the hidden curriculum.

In addition, Howick et al [36] propose a transformative approach to leverage the hidden curriculum as a tool for fostering empathy among medical students. They suggest evidence-based interventions, such as early patient exposure, improving clinical environments, and explicit empathy education as critical components of what they term an "empathic hidden curriculum." Such approaches are crucial in countering empathy erosion frequently observed during medical training.

Finally, one of the most significant challenges, with several limitations, is to include some of the knowledge acquired through the hidden curriculum within an explicit curricular objective [37]. Educational environments are increasingly aware of the dissociation that exists between what they wish to teach and what their students learn; strategies of early immersion of students with the communities they are going to serve, including an early approach to hospital environments [38] and accompaniment based on humanism, professionalism, and ethics [39], make it possible to put into practice some of the tacit learning and make it visible. The main limitation during this process and a source of future research is the transformation of traditional curriculum and strategies to include aspects of humanism, well-being, and medical professionalism within the learning objectives of future professionals [39]. Some of these strategies are illustrated in Figure 3.

Figure 3. Hidden curriculum implementation strategies and limitations in medical education.



Implications

The findings of this study have significant implications. Aspects of the hidden curriculum should be incorporated into official educational frameworks by educational policymakers. Universities ought to spend money on extracurricular activities that promote the development of professional skills.

To guide future research, several key recommendations are proposed. First, comparative studies evaluating the effectiveness of different educational approaches, such as integrating the hidden curriculum versus more explicit methods or practical versus theoretical strategies, would be valuable. In addition, incorporating digital interventions could provide insights into how technology can influence medical training, given recent advancements in this area. It is also crucial to consider implementation costs and discuss resource accessibility to enable financial and logistical analyses of proposed interventions. Long-term follow-up studies of students would be beneficial to assess how they apply learned lessons in their clinical practice. This will help determine if medical education achieves its goals of producing competent and ethical professionals and explore whether the hidden curriculum practices result in tangible benefits for patients and improvements in educational quality.

Strengths

The study's strength lies in its use of qualitative research methods, which capture detailed perspectives on the hidden curriculum in medical education. The research investigates medical education from 2000 to 2024 to provide a comprehensive analysis of historical and recent developments. The extended timeframe enables researchers to detect both evolving patterns and enduring difficulties that come from the hidden curriculum. The comprehensive range of themes studied

across different publications emerges as a key strength in this evaluation. This assessment brings together research from different medical disciplines to demonstrate how the hidden curriculum expresses itself distinctly between specialties, thus advancing our collective understanding of its effects.

Limitations

This scoping review focused primarily on qualitative studies with interpretative perspectives and excluded quantitative research, which may have limited the breadth of evidence regarding the hidden curriculum's impact. Certain studies, such as those involving other health professions (eg, nursing and pharmacy), were excluded, potentially omitting relevant insights that could provide a broader understanding of the hidden curriculum's impact across different fields. The exclusion of Web of Science, Embase, and Google Scholar may have led to the omission of relevant studies, potentially limiting the comprehensiveness of the findings. The review was limited to studies published in English, Spanish, and Portuguese, which might exclude relevant research published in other languages. In addition, the inclusion of only published studies could introduce publication bias, as studies with negative findings may be less likely to be published. One methodological limitation was not using specific Boolean operators, such as NOT, to explicitly differentiate between hidden, informal, and implicit curricula during the literature search, potentially affecting the breadth and specificity of identified studies. While the review discussed strategies for integrating the hidden curriculum into formal curriculum, it did not fully address the practical challenges and barriers that institutions might face when implementing these strategies.

Conclusions

This scoping review has described various aspects of the hidden curriculum in medical education and its potential consequences. A synthesis of the available literature shows that the hidden curriculum conveys explicit knowledge and has many subtle but significant effects on medical students. From forming attitudes and values to influencing professional identity, the hidden curriculum has emerged as a crucial factor in shaping the educational experience.

As understanding of these effects progresses, the need for greater awareness and reflection within different medical schools is highlighted. This review underscores the importance of proactively addressing the hidden curriculum, recognizing it as an essential component for the holistic development of future health professionals. Implementing strategies to maximize positive aspects and minimize negative aspects could significantly improve the quality of medical education and contribute to future physicians' personal and professional growth.

Acknowledgments

This research was derived from project MED-341-2023 at Universidad de La Sabana, Colombia.

Authors' Contributions

SPL and DNC conceptualized and designed the study. SPL conducted the data extraction and drafted the initial version of the manuscript. DNC contributed to the data analysis. CLJP critically reviewed and revised the manuscript for important intellectual content. All authors read and approved the final version of the manuscript.

Abstract

Background: Artificial intelligence (AI) has significantly impacted health care, medicine, and radiology, offering personalized treatment plans, simplified workflows, and informed clinical decisions. ChatGPT (OpenAI), a conversational AI model, has revolutionized health care and medical education by simulating clinical scenarios and improving communication skills. However, inconsistent performance across medical licensing examinations and variability between countries and specialties highlight the need for further research on contextual factors influencing AI accuracy and exploring its potential to enhance technical proficiency and soft skills, making AI a reliable tool in patient care and medical education.

Objective: This systematic review aims to evaluate and compare the accuracy and potential of ChatGPT-3.5 and 4.0 in medical licensing and in-training residency examinations across various countries and specialties.

Methods: A systematic review and meta-analysis were conducted, adhering to the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) guidelines. Data were collected from multiple reputable databases (Scopus, PubMed, JMIR Publications, Elsevier, BMJ, and Wiley Online Library), focusing on studies published from January 2023 to July 2024. Analysis specifically targeted research assessing ChatGPT's efficacy in medical licensing exams, excluding studies not related to this focus or published in languages other than English. Ultimately, 53 studies were included, providing a robust dataset for comparing the accuracy rates of ChatGPT-3.5 and 4.0.

Results: ChatGPT-4 outperformed ChatGPT-3.5 in medical licensing exams, achieving a pooled accuracy of 81.8%, compared to ChatGPT-3.5's 60.8%. In in-training residency exams, ChatGPT-4 achieved an accuracy rate of 72.2%, compared to 57.7% for ChatGPT-3.5. The forest plot presented a risk ratio of 1.36 (95% CI 1.30-1.43), demonstrating that ChatGPT-4 was 36% more likely to provide correct answers than ChatGPT-3.5 across both medical licensing and residency exams. These results indicate that ChatGPT-4 significantly outperforms ChatGPT-3.5, but the performance advantage varies depending on the exam type. This highlights the importance of targeted improvements and further research to optimize ChatGPT-4's performance in specific educational and clinical settings.

Conclusions: ChatGPT-4.0 and 3.5 show promising results in enhancing medical education and supporting clinical decision-making, but they cannot replace the comprehensive skill set required for effective medical practice. Future research should focus on improving AI's capabilities in interpreting complex clinical data and enhancing its reliability as an educational resource.

(JMIR Med Educ 2025;11:e68070) doi:10.2196/68070

KEYWORDS

ChatGPT; medical education; accuracy of ChatGPT; ChatGPT-3.5 performance; ChatGPT-4.0 performance; artificial intelligence; AI in health care; medical licensing examinations; clinical decision-making

Introduction

Artificial intelligence (AI) has penetrated virtually every field, ranging from telecommunications to medicine, as scientific literature has explored its potential impact, ramifications, limitations, and potential uses. In the health care industry, AI has made significant inroads: it has personalized treatment plans and simplified workflows [1]. Radiology has undergone a remarkable revolution: the US Food and Drug Administration approved AI-equipped devices in 2023 [2]. Through advanced algorithms and data processing techniques, it can aid in making informed clinical decisions [3]. Nevertheless, the complex procedure of clinical decision-making involves much more than pattern recognition and predictive analytics. However, some studies have highlighted the efficacy of artificial cognitive empathy, which highlights the growth of AI in the "soft skills" department, that is, empathy, ethics, and judgment, of clinical practice [3,4].

Perhaps AI's biggest breakthrough was ChatGPT, launched by OpenAI in November 2022 [5]. ChatGPT is a large language model (LLM) trained on a vast dataset designed to mimic human responses. A freely available conversational AI model, ChatGPT, has revolutionized health care and medical education. Through the simulation of clinical scenarios, students were able to gain therapeutic insights. Academic evaluation is another widely explored use. Some work has shown its potential in improving communication skills. The latest version of OpenAI's LLM has also allowed for the customization of teaching and learning plans by tailoring to individual preferences [6].

Despite the significant advancements in medical education and patient care, the performance of ChatGPT in special medical licensing examinations (MLEs) has been inconsistent, varying between countries and among specialties. One of the studies demonstrated that GPT showed the highest accuracy in Italian examinations (73% correct answers) and the lowest in French examinations (22% correct answers) [1]. Another study found that the LLM could not pass the National Specialty Examination in the Polish Education System. On the contrary, GPT-3 demonstrated tremendous performance in the United States Medical Licensing Examination (USMLE). These highlight the variance and disparity of ChatGPT's accuracy across different exams, raising questions about its reliability in particular contexts and the general structure of the examinations [7].

There is also much interest regarding the accuracy gap between ChatGPT-3.5 and ChatGPT-4. The latter version was the improved one due to its training on a larger dataset. In a study involving the USMLE, ChatGPT-4 outperformed ChatGPT, correctly answering 90% compared to ChatGPT-3.5's 2.5% [8,9].

In light of these advancements, it is evident that AI, particularly in the form of LLMs such as ChatGPT, has significantly impacted health care, medical education, and clinical decision-making. The disparity between ChatGPT-3.5 and ChatGPT-4 performances, as well as the variability between countries and specialties, underscores the importance of refining these technologies and adapting them to specific medical systems and environments. Although systematic reviews have been done, but to our knowledge, no systematic review and meta-analysis are available so far on comparative analysis and accuracy of ChatGPT versions [10-12].

Due to the inconsistent performance of AI models across various MLEs, there is a need for further research into the contextual factors that influence AI accuracy. Moreover, as AI continues to evolve, there is a pressing need to explore its potential in enhancing not only technical proficiency but also "soft skills" such as empathy and ethical judgment, ensuring that AI becomes a reliable, holistic tool in patient care and medical education. Despite the rapid advances in AI, especially LLMs such as ChatGPT, its performance on medical licensing and in-training examinations remains inconsistent across countries and specialties. This study set out to systematically evaluate and compare the accuracy of ChatGPT versions 3.5 and 4.0 when tested on real medical licensing and residency exams from around the world. Our research specifically asked: Does GPT-4 offer a meaningful improvement in answering medical exam questions compared to GPT-3.5? To answer this, we conducted a systematic review and meta-analysis of studies published between January 2023 and July 2024, following the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) guidelines. We expected, based on prior evidence, that GPT-4 would outperform GPT-3.5, given its expanded training and improved reasoning capabilities. The findings are intended to guide medical educators, exam boards, and AI developers in understanding the strengths and limitations of these tools, and how they might fit into medical training and assessment in the years ahead.

Methods

The review followed the PRISMA guidelines for conducting systematic reviews and meta-analyses.

Information Sources

Data were sourced from reputable databases such as Scopus, PubMed, Wiley Online Library, JMIR Publications, Wolters Kluwer OVID-SP, Hindawi, Taylor & Francis, Science Direct, ProQuest, Sage Publications, BMJ, and Google Scholar in July 2024.

Search String

We systematically reviewed the related literature using different sets of keywords, such as "ChatGPT" OR "medical license exam" OR "ChatGPT" OR "medical education" OR "ChatGPT" OR "USMLE" OR "AI in medical education" OR "artificial intelligence" OR "ChatGPT" OR "LLM" OR "exam performance" OR "machine learning" OR "ChatGPT accuracy" OR "Generative Pre-trained Transformer" OR "accuracy in medical exam" OR "license exam" OR "healthcare exam" OR

"clinical exam" OR "ChatGPT-3.5 and 4 in residency exam" OR "accuracy of ChatGPT" OR "ChatGPT and authenticity" AND "Generative Model" (Survey* OR qualitative* OR editorial* OR questionnaire* OR letter to editor* OR empirical study).

Inclusion Criteria

This review includes studies focused on the application of ChatGPT in medical education and its involvement in medical licensing exams, such as the USMLE and in-training residency programs, published between January 2023 and July 2024. Only English-language studies were considered to ensure clarity and accessibility. The studies included range from peer-reviewed journal articles, editorials, and case reports to letters to the editor, conference papers, meeting papers, and dissertations. By incorporating a variety of study types, the review aims to provide a comprehensive understanding of the role of ChatGPT-3.5 and 4.0 in medical education, capturing detailed research findings, expert perspectives, real-world case examples, emerging trends, and original research.

Exclusion Criteria

Studies that did not meet the specific focus of this review were excluded, including book chapters, as they tend to provide broad overviews rather than original research focused on ChatGPT's application in medical education. Additionally, any studies on ChatGPT's use in fields outside of medical education, such as higher education disciplines (eg, engineering and humanities) or unrelated health care domains, were excluded to maintain a sharp focus on the intersection of AI and medical education.

Study Selection and Data Extraction

The PRISMA diagram outlines the process of selecting 53 studies for inclusion. Each study was analyzed using a material extraction framework, which included author and publication year, title, country, methodology, key findings of ChatGPT-3.5 and 4.0, advantages and disadvantages, conclusions, and type of exam.

To ensure the reliability of the screening and eliminate duplicates, 3 independent reviewers (TRM, SA, and SMKA) reviewed abstracts. Any discrepancies between the 3 were reconciled by senior reviewers (UA and GF). Abstracts were downloaded and screened using the Rayyan.ai tool, with csv file formats. The selected manuscripts were also screened independently for full text by the authors (AJ and RMHS), and disagreements were resolved by discussion with the lead reviewer (MZB).

Authors (SA, TRM, UA, and GF) independently extracted and synthesized the comparative accuracy data from the included studies in the Rayyan.ai tool. These were done manually; no automation tools were used. Any discrepancies in extracted data were discussed and resolved by consensus with reviewers (AJ and MZB). Data extraction included sensitivity, accuracy, precision, and CIs. A meta-analysis of aggregated data was conducted with a random-effects inverse-variance model, with RevMan 5.4.

The PRISMA chart outlines the systematic study selection process for evaluating ChatGPT in MLEs. Initially, 1215 records were identified from multiple databases, including PubMed, Scopus, and Google Scholar. After removing 732 duplicate records, 496 studies underwent title and abstract screening, resulting in 79 relevant records. Of these, 75 full-text articles were assessed for eligibility, with 4 excluded due to unavailability. Nine additional articles were excluded for irrelevance, leaving 66 studies for the final review. The primary reasons for exclusion during screening included non-English language and studies unrelated to MLEs (eg, knowledge tests or library use). This rigorous process ensured a focused and comprehensive analysis of ChatGPT's performance in medical exams.

Quality Assessment

The Cochrane Collaboration tool was used to assess Risk of Bias in Nonrandomized Interventional Studies (ROBINS-I) by using the following domains (Figure 1): (1) bias due to confounding, (2) bias due to selection of participants, (3) bias in classification of interventions, (4) bias due to deviations from intended interventions, (5) bias due to missing data, (6) bias in measurement of outcome, and (7) bias in selection of the reported results. According to predefined criteria 2, the domains were rated as "low risk," "unclear risk," and "high risk." The risk in all domains was low across studies included in the comparative meta-analysis, including Flores-Cohaila et al [13], Takagi et al [14], and Lewandowski et al [15], and indicates good methodological quality and bias. A frequent finding in studies by Brin et al [16] and Meyer et al [17] is a moderate risk of confounding bias (D1) denoted by yellow symbols in this domain across multiple studies. This means that confounding factors were not entirely isolated, which possibly might affect the study outcomes [16,17].

Figure 1. Risk of bias assessment [13-17,19,20,28,31,32,35,40-52].

Studies presenting a serious risk of bias in one or more domains, such as Wang et al [46], were noted. In particular, any studies in which substantial bias was identified in either outcome measurement or in the selection of reported results (ie, domains D6 and D7) were marked with a red indicator. Examples include Angel et al [19], Moshirfar et al [43], and Toyama et al [45]. The serious risks substantially undermine the internal validity of the study findings and need to be duly considered in the context of the conclusions. Though many of the included studies were rated as having a low to moderate risk of bias, few general methodological flaws and a few critical concerns regarding confounding control and outcome reporting were identified. The strong accent on the importance of bias minimization, rigorous study design, and transparent reporting highlights the need for meticulous attention to detail to enhance the validity of evidence collated in systematic reviews and meta-analyses.

Results

Comparison of the Accuracy of ChatGPT Versions in Medical Licensing and Training Residency Examinations

Figure 2 presents the PRISMA flowchart illustrating the study selection process for ChatGPT in medical licensing and residency examinations.

Table 1 shows 53 studies carried out by several researchers showing the capability of ChatGPT-3.5 and ChatGPT-4 in medical licensing and in-training residency exams conducted in various countries around the globe. It also shows the comparative evaluation of the success rate of both versions of ChatGPT in licensing examinations. Advantages and disadvantages are also described in this table.

Figure 2. PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) flowchart of study selection process for ChatGPT in medical licensing examinations.

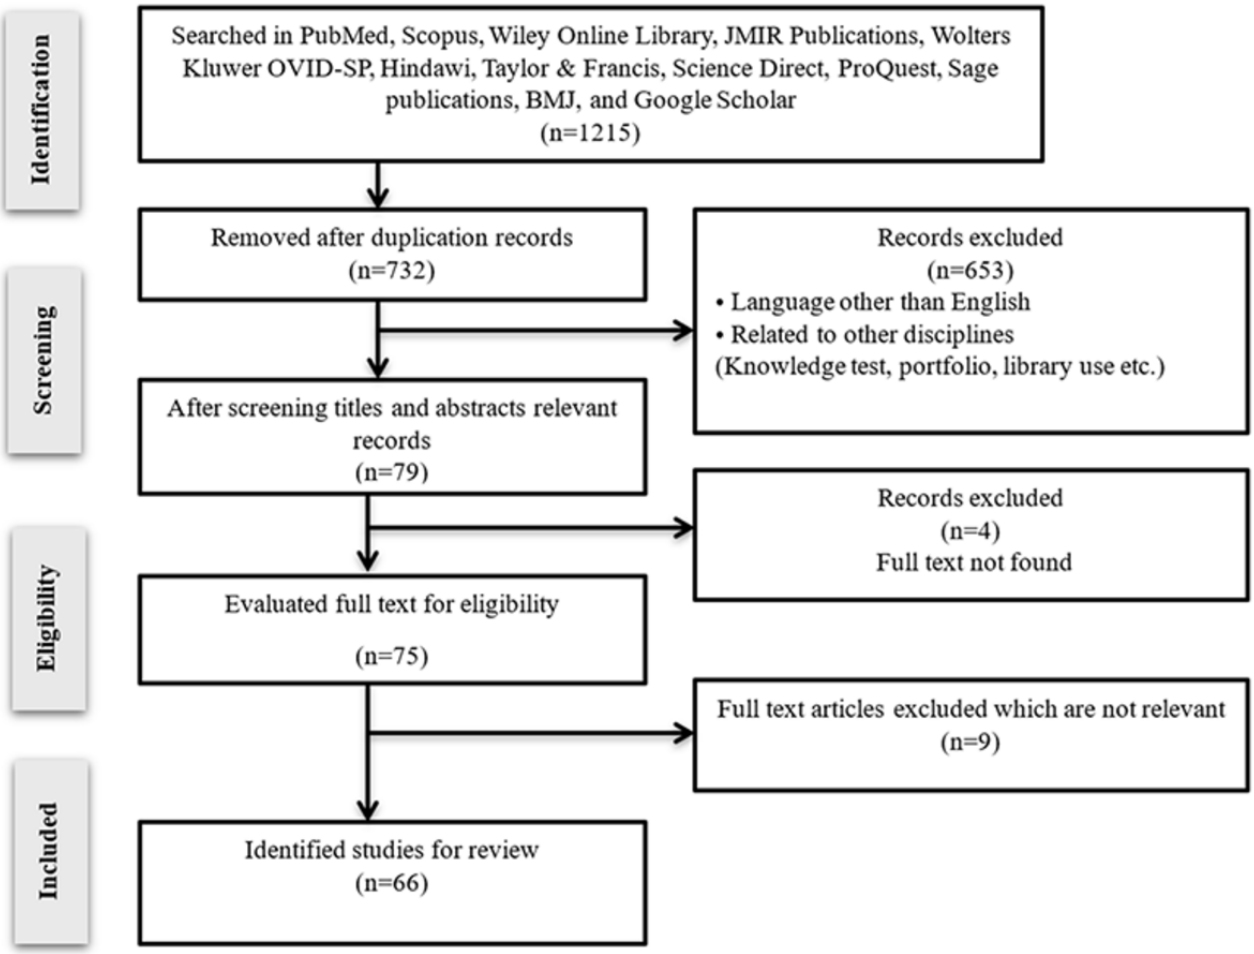

Table 1. Overview of studies comparing the accuracy of ChatGPT-3.5 and 4.0 in medical licensing and in-training residency exams.

Study ID	Exam type	Dataset and methods	ChatGPT-4.0 accuracy	ChatGPT-3.5 accuracy	Advantages	Disadvantages
Aljindan et al (2023) [18]	Saudi Medical Licensure Exam	A dataset of 220 questions across 4 medical disciplines.	88.6%	None	Useful supplementary educational tool.	A high margin of error (4-16%) emphasizes that it should be used with traditional study methodology.
Angel et al (2023) [19]	American Board of Anesthesiology (ABA) Exam	The basic exam used the full set of 60 MCQs[a] on the ABA website. The advanced exam was formulated using the book *Anesthesia Review: 1000 Questions and Answers to Blast the BASICS and Ace the ADVANCED* by randomly choosing 5/70 questions.	GPT-4 scored 47/60 (78.33%) in the basic exam. In the advanced exam, the model scored 80%.	GPT-3 scored 35/60 (58.33%).	The performance of the AI[b] in this process was impressive enough that it leads one to question whether we should not already, as highly trained clinicians, be using these AI systems to help us avoid some of the more common cognitive errors that may occur during critical events.	The models struggle to fully comprehend questions involving numerical calculations, leading to imprecise responses. Additionally, numerical calculations demand greater precision and exactness, which may not always be within the model's capabilities.
Antaki et al (2023) [20]	Ophthalmology	Two 260-question simulated exams from the Basic and Clinical Science Course (BCSC) Self-Assessment Program and the Ophthalmology Questions online question bank were solved by ChatGPT-3.5.	None	ChatGPT Plus's accuracy increased to 59.4. Accuracy improved with easier questions when controlling for the examination section and cognitive level.	Generally, we found that ChatGPT Plus provided highly consistent and repeatable results, but some variations occurred.	ChatGPT does not have the capability to process images. This is a significant limitation because ophthalmology is a field that heavily relies on visual examination and imaging to diagnose, treat, and monitor patients.
Bartoli et al (2024) [21]	Neurosurgical residents' written exam	51 questions (open-ended and MCQ) were included in the written exam, 46 questions were generated by humans (senior staff members), and 4 were generated by ChatGPT.	None	ChatGPT scored among the lowest ranks (9/11) among all the participants. ChatGPT answered correctly to all its self-generated questions.	Different ways to exploit AI for medical education and exams are imaginable; that is, a question may be posed by a human, an answer is generated by AI, and a critical appraisal is then elaborated by the human, based on their own logical thinking, knowledge, and personal experience and creativity.	At this stage, it seemed like AI did not "intend" or "think" to probe someone's specific knowledge on a topic when generating a question, like humans do.
Beaulieu-Jones et al (2024) [22]	Surgical knowledge assessments	Two surgical knowledge assessments, the Surgical Council on Resident Education (SCORE; 167 questions) and Data-B (112 questions), were solved by ChatGPT-4.0.	ChatGPT correctly answered 71% and 68% of multiple-choice SCORE and Data-B questions, respectively.	None	The study highlights the accuracy of ChatGPT within a highly specific and sophisticated field without specific training or fine-tuning in the domain.	The findings also underscore some of the current limitations of AI, including variable performance on the same task and unpredictable gaps in the model's capabilities.

Study ID	Exam type	Dataset and methods	ChatGPT-4.0 accuracy	ChatGPT-3.5 accuracy	Advantages	Disadvantages
Benirschke et al (2024) [23]	Questions from My Pathologist	61 general knowledge pathology questions were solved by ChatGPT-4.0.	98% of responses were "completely/mostly accurate," and 82% of responses had "all relevant information."	None	Answers to general pathology inquiries were accurate and complete, and LLMs[c] can potentially be used to save time for pathology professionals.	Differences were seen in the completeness of the answer, with clinical pathology answers judged as more complete than anatomic pathology answers.
Brin et al (2023) [16]	USMLE[d]	80 USMLE-style questions involving soft skills, from the AMBOSS question bank. ChatGPT-3.5 and 4.0 took the examination, and the results were compared.	90%	62.5%	LLMs demonstrate impressive results in questions that test soft skills required from physicians. GPT-4 surpassed the human performance benchmark.	Models operate based on calculated probabilities for an output, rather than human-like confidence.
Chen et al (2023) [24]	Neurology written board examination questions	509 eligible questions out of the 560 from BoardVitals QBank (without images) were solved by ChatGPT-4.0.	335/509 questions (65.8%) on the first attempt and 383/509 (75.3%) in the subsequent iterations.	None	ChatGPT was sensitive to questions regarding depression and suicide and referred us to a suicide hotline.	The base model lacks visual input and thus is unable to process image-based questions. There were differences in the accuracy of different subject fields.
Cheung et al (2023) [25]	A multinational prospective study	50 MCQs were generated by ChatGPT-4.0 with two standard undergraduate medical textbooks. Another 50 MCQs were drafted by 2 professors using the same.	None	The total time required for ChatGPT to create the 50 questions was 20 minutes and 25 seconds.	As demonstrated in our study, a reasonable MCQ can be written by ChatGPT using simple commands with a text reference provided.	Including ChatGPT, most AI models are trained by the vast content available on the internet, and their reliability and credibility are questionable. Moreover, many AI models were found to have significant bias due to their training data.
Ebrahimian et al (2023) [26]	Iranian Medical Licensing Examination	200 MCQs were translated into English. The accuracy of performance by ChatGPT-4.0 was assessed.	68.5% (surpassed the passing criteria of 45%)	None	ChatGPT is capable of answering MCQs, surpassing the pass mark by a significant margin.	The expertise and nuanced understanding of medical cases that human physicians possess are not yet matched by AI models.
Fang et al (2023) [27]	Chinese National Medical Licensing Examination	Out of 600 questions, 340 were common questions, and 260 case analysis questions were solved by ChatGPT-4.0.	442/600 (73.67%), surpassing the passing criteria, that is, 360.	None	ChatGPT exhibits a high level of answer-explanation concordance in the Chinese language.	ChatGPT's performance declines when handling encoded questions, declining by 40.5%, 9.7%, 32.4%, and 41.8% for Units 1, 2, 3, and 4, respectively.

Study ID	Exam type	Dataset and methods	ChatGPT-4.0 accuracy	ChatGPT-3.5 accuracy	Advantages	Disadvantages
Flores-Cohaila et al (2023) [13]	Peruvian National Licensing Medical Examination (ENAM)	180 multiple-choice questions were performed by ChatGPT-3.5 and 4.0, and the results were compared.	86% (155/180). GPT-4 surpassed almost 90% of examinees.	77% (139/180), with prompting. GPT-3.5 surpassed 80% of examinees.	Role-play and context-setting in prompts improved performance, reducing incorrect answers. Outperformed human performance.	LLM expertise is limited to passing a licensing exam. To be a practitioner requires communication skills, empathy, and so on.
Giannos, (2023) [28]	UK Neurology Specialty Certificate Examination	69 questions from the Pool—Specialty Certificate Examination (SCE) Neurology Web Questions bank were solved by both versions of ChatGPT.	ChatGPT-4.0 achieved the highest accuracy of 64%, surpassing the passing threshold and outperforming its predecessors across disciplines and subtopics.	ChatGPT-3.5 displayed an overall accuracy of 57%.	ChatGPT-4 has shown promise in attaining specialty-level medical knowledge. This sets a new benchmark for AI models in specialized medical education and practice.	ChatGPT3's performance in the specialized field of neurology and neuroscience is lower than that in general medical examinations. Specialty examinations require a deeper understanding of specific medical domains.
Gilson et al (2023) [29]	USMLE	4 datasets with 389 questions were solved by ChatGPT-3 and compared with medical students' performance in steps 1 and 2.	None	AMBOSS Step 1: 44% (44/100); AMBOSS Step 2: 42% (42/100); NBME[e] Step 1: 64.4% (56/87); NBME Step 2: 57.8% (59/102)	The model may facilitate the creation of an on-demand, interactive learning environment for students. Logical explanations for answers are always provided, even if incorrect.	Incorrect answers are related to logical and information-based errors mostly.
Gobira et al (2023) [30]	Brazilian National Examination for Medical Degree Revalidation	81 nonnullified and 14 nullified questions. ChatGPT-4.0 solved questions in various specialties.	For nonnullified questions, 71/81 (87.7%); for nullified questions, 71.4% (10/14).	None	There was no statistically significant difference in the performance across different specialties.	Encountered challenges when tackling questions that involved concepts related to the Brazilian public health care system and ethical decisions.
Guillen-Grima et al (2023) [31]	Spanish MIR (Medical Resident Intern)	182 questions were solved by both versions of ChatGPT and compared.	Spanish: 86.81% (81.13-90.98); English: 87.91% (82.38-91.88).	Spanish: 63.18% (55.98-69.85); English: 66.48% (59.35-72.94)	Improved consistency demonstrated by GPT-4 across multiple attempts presents the refinements in training and better underlying model architecture.	The error rate of 13.2% is of concern. 25 questions linked to an image and 3 challenge questions were excluded.
Haddad et al (2024) [32]	Ophthalmology Examinations	Questions from the USMLE Step 1 (n=44), Step 2 (n=60), and Step 3 3 (n=28) were extracted from AMBOSS, and 248 questions were extracted from the book *Ophthalmology Q&A Board Review* and solved by both versions, and results were compared for accuracy.	GPT-4.0 achieved a total of 70% of correct answers. GPT-4.0 answered 70.45% of questions correctly in step 1, 90.32% in step 2, 96.43% in step 3, and 62.90% in the remaining 248 questions.	GPT-3.5 achieved a total of 55% of correct answers. GPT-3.5 answered 75% of questions correctly in step 1, 73.33% in step 2, 60.71% in step 3, and 46.77% in the OB-WQE[f].	ChatGPT can be a great add-on to mainstream resources to study for board examinations. There have been reports of using it to generate clinical vignettes and board examination–like questions.	Many questions were excluded due to them containing images, which is a considerable limitation considering the visual nature of ophthalmology.

Study ID	Exam type	Dataset and methods	ChatGPT-4.0 accuracy	ChatGPT-3.5 accuracy	Advantages	Disadvantages
Hoch et al (2023) [33]	otolaryngology subspecialties	A dataset covering 15 otolaryngology subspecialties was collected from an online learning platform funded by the German Society of Oto-Rhino-Laryngology, Head and Neck Surgery, and was given to ChatGPT-3.5 for solving.	None	The dataset included 2576 questions (479 multiple-choice and 2097 single-choice), of which 57% (n=1475) were answered correctly by ChatGPT.	As an educational resource, the performance of ChatGPT indicated potential efficacy in offering educational assistance in specific subspecialties and question formats.	ChatGPT delivered a considerable number of incorrect responses within specific otolaryngology subdomains, rendering it unreliable as the sole resource for residents preparing for the otolaryngology board examination.
Huang et al (2024) [34]	SPTEMD[g] Stage 1	600 MCQs extracted from 3 separate tests conducted in February 2022, July 2022, and February 2023 were solved by ChatGPT-4.0.	525/600 (87.5%)	None	Potential to facilitate not only the preparation for exams but also improve the accessibility of medical education and support continuous education for medical professionals.	The model performed inconsistently across different subjects, exhibiting comparatively lower performance in anatomy, parasitology, and embryology.
Huang et al (2023) [35]	University of Toronto Family Medicine Residency Progress Test	The 108 questions were stratified into 11 areas of family medicine knowledge and solved by both versions of ChatGPT.	82.4% (89/108). It scored much higher than an average resident, that is, 56.9%.	57.4% (62/108). Its performance was comparable to the average resident, that is, 56.9%.	GPT-4 demonstrates a broad knowledge base and strong reasoning abilities in FM[h], as evidenced by its high level of accuracy and logical justification.	Hallucinations raise concerns about a model's integrity and overall accuracy, and may mislead learners into believing an incorrect response to be correct.
Jain et al (2023) [36]	Orthopedic In-Training Examination (OITE)	Of 635 questions, 360 were usable as inputs (56.7%) by ChatGPT-3.5.	None	ChatGPT-3.5 scored 55.8%, 47.7%, and 54% for the years 2020, 2021, and 2022, respectively.	The potential of machine learning in medicine is that it can automate tasks, assist in providing thought processes, and improve management.	Tendency to fabricate references or have incorrect reasoning when solving problems that require logic beyond this date.
Jang et al (2023) [37]	K-NLEKMD[i]	340 (114 questions for recall, 99 for diagnosis, and 127 for intervention) were solved by ChatGPT-4.0 and assessed.	66.18% (after model optimization)	None	We found that high consistency of response is associated with increased accuracy for questions.	Models had weak performance on questions that require understanding the Korean language and TKM[j]/Korea-adapted health care. LLMs are susceptible to hallucinations.
Knoedler et al (2023) [38]	USMLE	2069 USMLE Step 3 practice questions. 1840 entered into GPT-3.5, while a subset of 229 entered into GPT-4, and performance was compared.	84.7% (194/229)	56.9% (1047/1840)	ChatGPT-4 showcases its superiority as a newer model, with better accuracy.	ChatGPT-4 encountered difficulties in questions related to cardiology and neurology.

Study ID	Exam type	Dataset and methods	ChatGPT-4.0 accuracy	ChatGPT-3.5 accuracy	Advantages	Disadvantages
Kufel et al (2023) [39]	Polish specialty exam in radiology	This study used a PES[k] exam consisting of 120 questions, provided by the Medical Examinations Center in Lodz. The performance of ChatGPT-4.0 was assessed.	None	ChatGPT did not reach the pass rate threshold of the PES exam (52%).	We identified that questions for which ChatGPT provided a correct answer had a significantly higher confidence index. Therefore, the confidence index can be considered a parameter indicating a higher likelihood of ChatGPT providing a correct answer.	The performance of the ChatGPT model in passing the specialist in radiology and imaging diagnostics examination in Poland remains uncertain.
Kung et al (2023) [41]	Orthopedic In-Training Examination (OITE)	OITE 2020, 2021, and 2022 questions without images were input into ChatGPT version 3.5 and version 4.0 with zero prompting.	GPT-4 answered 265 of 360 questions correctly, corresponding to the average performance of a PGY-5[l].	ChatGPT answered 196 of 360 answers correctly (54.3%), corresponding to a PGY-1 level.	Multiple studies have suggested that deep learning models for automated image analysis can be synergistic with clinicians, resulting in superior predictions compared with those of clinicians alone.	Finally, in medicine specifically, there can be multiple potentially correct answers to a given question with only one best answer, which may cause difficulty for the AI when there is correct information supporting each answer.
Lewandowski et al (2023) [15]	Specialty Certificate Examination in Dermatology	Three Specialty Certificate Examination in Dermatology tests, in English and Polish, consisting of 120 single-best-answer, multiple-choice questions each, were solved by both versions of AI and compared.	The percentages of correct answers to questions in the Polish vs English versions obtained by ChatGPT-4.0 were 77.3% vs 84%, 75.8% vs 85% and 71.4% vs 80.7%, respectively.	The percentages of correct answers to questions in the Polish vs English versions obtained by ChatGPT-3.5 were 61.3% vs 68.9%, 60.8% vs 70%, and 54.6% vs 60.5%, respectively.	It is estimated that ChatGPT is capable of understanding and communicating in more than 100 languages at various levels. ChatGPT-4.0 proved to be highly effective in answering clinical picture-type questions.	An important limitation of ChatGPT and the other language models is a rare phenomenon of artificial hallucination, defined as self-conscious, seemingly realistic responses by an AI. We did not observe it in this study, but it is widely described in the literature.
Lin et al (2024) [53]	Taiwan Medical Licensing Examination	80 single-choice questions were assessed by ChatGPT-4.0.	Accuracy in medical exams ranged from 63.75% to 93.75%. The highest accuracy was in the February 2022 exam.	None	The implementation of the “Chain of Thought” prompt strategy proved effective, enabling the model to correct its initial incorrect responses and achieve an accuracy rate exceeding 90%.	Falters in questions related to surgical precautions and decision-making. It had a 100% failure rate in such questions. Overall, it is not ready for complex decision-making.
Long et al (2024) [54]	Otolaryngology Head and Neck Surgery Certification Examinations (OHNS)	21 open-ended questions were adopted from the Royal College of Physicians and Surgeons of Canada’s sample examination. The accuracy of ChatGPT-4.0 was assessed on them.	Average of 75% across 3 trials in the attempts and demonstrated higher accuracy with prompts.	None	Information provided by the AI was clinically valid; it could be used to provide equitable access to resources in low-resource settings where access to such information may not be readily available.	Hallucinations may present benign or harmful misinformation, with significant implications in the field of medicine.

Study ID	Exam type	Dataset and methods	ChatGPT-4.0 accuracy	ChatGPT-3.5 accuracy	Advantages	Disadvantages
Lum (2023) [55]	Orthopedic In-Training Examination (OITE)	Random selection of 400/3840 publicly available questions based on the Orthopedic In-Training Examination, and compared the mean score with that of residents.	None	ChatGPT selected the correct answer 47%	AI can handle large amounts of data that can be quickly accessed. The LLM performed better at recognition and recall-type questions, as well as comprehension and interpretation, than at problem-solving and application of knowledge.	The model may have limitations in terms of its ability to integrate, synthesize, generalize, and apply factual knowledge in more nuanced ways.
Mackey, et al (2024) [56]	USMLE	Questions from AMBOSS were used. 900 questions from 9 specialties, that is, 100 questions from each specialty, were randomly selected. Performance by ChatGPT-4.0 was assessed for accuracy.	89% of the total questions were answered accurately.	None	ChatGPT-4.0 had an impressive performance in areas like psychiatry, neurology, obstetrics, and gynecology.	LLMs have specialty-specific strengths and weaknesses. Its accuracy was notably lower in pediatrics, emergency medicine, and family medicine.
Mahajan et al (2023) [57]	Otolaryngology Residency In-Service Exam	1088 questions from the BoardVitals otolaryngology bank were solved by ChatGPT-3.5 and accuracy was assessed.	None	572/1088 (53%) yielded a correct answer, and 586/1088 (54%) yielded a correct explanation.	LLM can accurately answer complex multiple - choice patient care questions to an extent.	The accuracy rate is far below an acceptable level for it to be useful in a clinical or educational setting to aid in decision-making.
Maitland et al (2024) [58]	MRCP^{m} (UK)	Practice questions for MRCP 1 and 2 produced by MRCPUK were solved by ChatGPT-4.0 (images excluded).	For part 1, ChatGPT provided 170 accurate responses for 196 questions. In part 2, it provided responses for 127/128 questions correctly.	None	ChatGPT is able to answer MRCP written examination questions, without additional prompts, to a level that would equate with a comfortable pass for a human candidate.	LLMs are known to “hallucinate” plausible sounding, but false, facts, information, and even references.
Massey et al (2023) [42]	Orthopedic Assessment Examination	180 questions and answer choices from 9 different orthopedic subspecialties (excluding images). The accuracy of both versions was compared.	GPT-4 scored 47.2% with a 95% CI of 40%-54.5%. The average response time was 31.8 seconds.	GPT-3.5 scored 29.4% with a 95% CI of 23.2%-36.4%. The average response time for ChatGPT-3.5 was 12.1 seconds.	The implications and potential of ChatGPT are still quite promising. GPT-4 showed particular improvement when answering questions requiring no image interpretation.	Chatbots cannot decipher radiographic images in conjunction with clinical vignettes.
Meyer et al (2024) [17]	German Medical Licensing Examination	937 original MCQs from German medical licensing examinations were solved by ChatGPT-3.5 and 4.0, and the accuracy of both was compared.	796/937 (85%)	548/937 (58%)	There is potential for using GPT-3.5 and GPT-4.0 in a medical education tutoring environment.	The model's inconsistencies across different specialties restrain recommendations for its use by the general population for medical purposes.

Study ID	Exam type	Dataset and methods	ChatGPT-4.0 accuracy	ChatGPT-3.5 accuracy	Advantages	Disadvantages
Morjaria et al (2023) [59]	Undergraduate Medical Program	40 problems used in prior assessments were used: 30 submitted to ChatGPT-3.5. For the remaining 10 problems, we retrieved past minimally passing student responses.	None	ChatGPT-generated responses received a mean score of 3.29 out of 5, compared to 2.38 for a group of students meeting minimum passing marks, presenting higher performance.	This represents success on a different form of assessment compared to the multiple-choice format. ChatGPT's performance was shown to be comparable to students who are performing at the minimum standard.	ChatGPT's performance was shown to be comparable to students who are performing at the minimum standard on these assessments, but slightly lower when compared to a historical student cohort.
Moshirfar et al (2023) [43]	StatPearls ophthalmology questions	467 questions from the StatPearls Question Bank were solved by both versions of ChatGPT and compared.	73.2%	55.5%	GPT-4.0 outperformed humans who had an accuracy of 58.3%.	The “lens and cataract” category presented a unique challenge for the model.
Nakao et al (2024) [60]	Japanese National Medical Licensing Examination	108 questions that had 1 or more images as part of a question were solved by ChatGPT-4.0.	68% (73/108) when presented with images and 72% (78/108) when presented without images.	None	For the clinical questions, for which sufficient information was available in the text form, GPT-4V was able to choose the correct answers solely from the textual information (76/98, 78%).	GPT-4V cannot effectively interpret images related to medicine.
Oh et al (2023) [44]	Korean general surgery board exams	The dataset comprised 280 questions from the Korean general surgery board exams conducted between 2020 and 2022 and solved by both versions of ChatGPT.	GPT-4 demonstrated a significant improvement with an overall accuracy of 76.4%.	GPT-3.5 achieved an overall accuracy of 46.8%.	Active surgeons who completed their training over a decade ago may find LLMs helpful for continuous medical education, especially as a supplementary resource.	Instead of providing strictly accurate information, they generate responses based on the probability of the most appropriate words given the data they have been trained on.
Panthier et al (2023) [61]	European Board of Ophthalmology examination	GPT-4 was exposed to a series of EBO^{n} examination questions in French, covering various aspects of ophthalmology, and performance was compared to experts.	ChatGPT correctly answered 6188 out of 6785 questions, demonstrating a high level of competency in ophthalmology.	None	ChatGPT’s proficiency in clinical management and decision-making suggests that it could be a valuable resource for practicing ophthalmologists and other medical professionals seeking information and guidance on complex cases.	ChatGPT was unable to interpret figures, graphs, or tables. In addition, some epidemiological data were unavailable online, and some standards of medical care had recently changed; thus, for certain questions, ChatGPT could not give the correct answer.

Study ID	Exam type	Dataset and methods	ChatGPT-4.0 accuracy	ChatGPT-3.5 accuracy	Advantages	Disadvantages
Riedel et al (2023) [62]	German OB/GYN[o] exams	The dataset of questions from the OB/GYN course included 160 questions, and the dataset of the medical state exam included 104 questions that were solved by an AI machine.	None	ChatGPT provided correct answers 85.6% of the time. In the second round, ChatGPT achieved similarly good results for the dataset, with 88.7% of answers being correct from the OB/GYN course, and 70.4% correct in the Medical State Exam.	ChatGPT can perform intricate tasks related to handling complex medical and clinical information in the field of OB/GYN. ChatGPT provided consistent answers and explanations to medical problems and did not require help in finding the correct solutions.	Finding raises doubts about ChatGPT's adaptability to varying levels of difficulty and emphasizes the need both for further fine-tuning and for incorporating data. Another potential limitation is the inability of ChatGPT to process images.
Saad et al (2023) [63]	FRCS[p] Orthopedic Exam	Questions were sourced from a bank of FRCS (Orth) Part A mock questions compiled from various resources. We divided the questions into two mock examinations.	ChatGPT-4.0 achieved an overall score of 67.5% on Part A. For component one of the Part A exams, ChatGPT-4.0 scored 60/120. For the second component of Part A, ChatGPT-4.0 scored 102/120 (85%).	None	Its relatively stronger performance in anatomy-based and shorter questions may be attributed to its ability to recall and provide information from its training data.	The inability of ChatGPT-4.0 to effectively handle complex clinical scenarios and image-based questions suggests limitations in its understanding and interpretation of intricate medical information.
Sarangi et al (2024) [64]	Radiology Case Vignettes (FRCR2A examination)	120 MCQs were solved by both ChatGPT-3.5 and residents, and the results were compared.	None	45%	In some of the cases, AI could point out the answers, but residents could not.	AI models currently lack the accuracy levels of human professionals, as the residents outscored them (63.33% and 57.5%). AI gave an inaccurate explanation in 50% of the cases.
Scaioli et al (2023) [65]	Italian Medical Residency Exam	136 questions classified into clinical cases and notional questions. These were solved by ChatGPT-3.0, and the accuracy was determined.	None	90.44%, with higher performance on clinical cases (92.45%) than on notional questions (89.15%).	ChatGPT's performance was higher than 99.6% of the participants. Potential for being a tool for learning.	Overreliance on these tools may develop, leading to a decline in the physician's adaptive judgment.
Skalidis et al (2023) [66]	European Exam in Core Cardiology (EECC)	After filtering, 362 MCQ items (ESC[q] sample: 68; BHDRA[r]: 150; and StudyPRN[s]: 144) were included to be solved by ChatGPT-3.5.	None	ChatGPT answered 340 questions out of 362, with 22 indeterminate answers in total, and an overall accuracy of 58.8%.	ChatGPT correctly answered the majority of questions and showed consistency across all different MCQ sources, exceeding 60% in most analyses. It exceeds the passing mark.	ChatGPT is designed for natural language processing tasks and thus currently only accepts text-based inputs, resulting in the exclusion of all questions with image content.

Study ID	Exam type	Dataset and methods	ChatGPT-4.0 accuracy	ChatGPT-3.5 accuracy	Advantages	Disadvantages
Surapaneni (2023) [67]	Medical biochemistry	The performance of ChatGPT was evaluated in medical biochemistry using 10 randomly selected clinical case vignettes.	None	ChatGPT generated correct answers for 4 questions on the first attempt.	Large language models such as ChatGPT may enhance student engagement and learning by assisting in web-based learning by generating pertinent and comprehensive content.	According to the findings of our study, ChatGPT may not be considered an accurate information provider for application in medical education to improve learning and assessment.
Takagi et al (2023) [14]	Japanese Medical Licensing Examination (JMLE)	254 MCQs on essential knowledge and clinical skills were performed by ChatGPT-3.5 and 4.0 and compared (questions containing tables, images, and underlining were excluded).	79.9% overall, with 87.2% in essential knowledge, 73.3% in general clinical, and 81.7% in specific disease.	50.8% overall, with 55.1% in essential knowledge, 43.8% in general clinical, and 56.3% in specific diseases.	GPT-4 satisfied the JMLE passing criteria unlike GPT-3, showing better proficiency in Japanese.	Concerns related to hallucinations.
Toyama et al (2024) [45]	JRBE[t]	103 questions from JRBE 2022 were used. These questions were categorized by pattern, required level of thinking, and topic.	GPT-4 scored 65% (GPT-4 correctly answered 93.3% of the questions in nuclear medicine (n=15). In questions on radiological general knowledge, it scored 90%.	ChatGPT scored 40.8% (42/103). In the questions in nuclear medicine (n=15), ChatGPT scored 40% (*P*=.01). In questions on radiological general knowledge, it scored 30%.	GPT-4 passed the JRBE with an overall score of 65%.	They behaved confidently, although their responses differed from their previous choices for the same question. Such unfavorable responses, entirely grounded in incorrect evidence or factual inaccuracies, are commonly labeled as "hallucinations."
Wang et al (2023) [46]	Chinese National Medical Licensing Examination (NMLE) 2021 and 2022	4 units with 150 questions per unit were solved by ChatGPT-3.5. The performance of ChatGPT-3.5 was compared with medical students.	None	275/600 (45.8%) in the 2021 NMLE and 219/600 (36.5%) in the 2022 NMLE.	ChatGPT holds the possibility of serving as a virtual medical mentor.	ChatGPT's proficiency in questions pertaining to the Chinese NMLE is not yet at par with Chinese medical students.
Wang et al (2024) [47]	Pathology Domain-Specific Knowledge	Google Forms were sent out to 15 participants, who each asked 1 short-answer question from both versions of ChatGPT.	Met or exceeded expectations in 12/15 of the questions.	Met or exceeded expectations in 9/15 of the questions.	Can provide quick and easily accessible information about various pathology topics, with newer LLMs also having the capability to provide references for the data used in the response.	Answers included unnecessarily lengthy responses containing irrelevant material, awkwardness of language, and provision of incorrect information.
Watari et al (2023) [68]	GM-ITE[u] examination	The GM-ITE examination had 137 questions for the years 2020, 2021, and 2022 to conduct a comparative analysis with only single-choice answers, excluding audio and visual cues. These were solved by ChatGPT-4.0.	GPT-4 scores were significantly higher than the mean scores of residents.	None	GPT-4 demonstrated remarkable proficiency in the detailed disease knowledge section, which requires an in-depth understanding of diseases, as well as in more challenging questions and domains.	GPT-4 seemed to struggle with questions in the "medical interview and professionalism" and "psychiatry" categories, which are typically easier for residents.

Study ID	Exam type	Dataset and methods	ChatGPT-4.0 accuracy	ChatGPT-3.5 accuracy	Advantages	Disadvantages
Wójcik et al (2024) [69]	Polish medical specialization licensing exam (PES)	120 questions were solved by ChatGPT-4.0.	80/120 (67.1%)	None	ChatGPT may be used as an assistance tool in medical education.	Mastery over exam content based mostly on rote learning does not translate to the practice of medicine, which is fundamentally based on human interactions.
Yu et al (2024) [70]	Chinese Postgraduate Examination for Clinical Medicine	A dataset of 165 medical questions that were divided into three categories—(1) common questions, (2) case analysis questions, and (3) multiple-choice questions—was solved by ChatGPT-3.5.	None	ChatGPT scored 153.5 out of 300 for original questions in Chinese. However, ChatGPT had low accuracy in answering open-ended medical questions, with only 31.5% total accuracy.	ChatGPT demonstrated a high level of internal concordance, which suggests that the explanations provided by ChatGPT support and affirm the given answers. Moreover, ChatGPT generated multiple insights toward the same questions.	Poorer accuracy was linked to lower concordance and a lack of insight. Thus, it was hypothesized that inaccurate responses were primarily driven by missing information, which could result in reduced insight and indecision in the AI.
Zong et al (2024) [71]	Chinese NMLE[v] (2017-2021)	3000 questions across 5 exams were solved by ChatGPT-3.5.	None	Average accuracy of 53.05%.	ChatGPT excelled in questions related to clinical epidemiology, human parasitology, and dermatology. No significant difference in performance on case-based and non-case-based questions.	ChatGPT has limited training in languages like Chinese. It failed to meet the minimal benchmark of 60%.
Sahin et al (2024) [72]	Turkish Neurosurgical Society Proficiency Board Exams (TNSPBE)	100 questions from the last 6 TNSPBE were used, 77 with visual elements were excluded, leaving 523 for analysis.	79% (412 out of 523 questions answered correctly).	None	ChatGPT can quickly provide accurate explanations and supplementary learning material, making it a valuable tool for exam preparation.	ChatGPT may generate incorrect or misleading answers with convincing explanations, which can misguide candidates if not verified.
Yanagita et al (2023) [40]	National Medical Licensing Examination in Japan	All 400 questions from the 2022 NMLE in Japan were included; 292 targeted questions (after exclusion) were analyzed.	81.5% (237 out of 292 questions answered correctly).	42.8% (125 out of 292 questions answered correctly).	GPT-4 reached passing standard; performance could improve as the model relearns.	GPT is limited to written questions.
Guerra et al (2023) [73]	Congress of Neurological Surgeons Self-Assessment Neurosurgery Exam (SANS)	591 out of 643 board-style questions were included after exclusion of questions with no text.	76.6% accuracy for all questions, but 79% for text-only questions.	None	GPT-4's accuracy suggests applications in educational settings and clinical decision-making.	GPT-4 may have potential limitations without manual input for answer suggestions.
Isleem et al (2023) [74]	Orthopaedic In-Training Examination (OITE) developed by the American Academy of Orthopaedic Surgeons (AAOS)	301 self-assessment examination questions from AAOS were included.	None	60.8% (183 out of 301 questions answered correctly).	ChatGPT has the potential to provide orthopedic educators and trainees with accurate clinical conclusions for board exam questions.	Since GPT's reasoning needs to be carefully analyzed for clinical accuracy and validity, its usefulness in clinical educational contexts is limited.

Study ID	Exam type	Dataset and methods	ChatGPT-4.0 accuracy	ChatGPT-3.5 accuracy	Advantages	Disadvantages
Gupta et al (2023) [48]	Plastic Surgery Inservice Training Examination (PSITE)	250 sample assessment questions from the 2022 PSITE were obtained from the American Council of Academic Plastic Surgeons website; 242 were answered by GPT.	77.3% (187 out of 242 questions answered correctly).	None	GPT-4 has shown to be more accurate and reliable for plastic surgery resident education when compared to GPT-3.5 and should be used to enhance educational curriculum.	GPT-4 may rely on inaccurate sources and may misunderstand prompts.
Wang et al (2013) [75]	Chinese (CNMLE) and English (ENMLE) datasets of the China National Medical Licensing Examination	A total of 220 questions were extracted from the $SMLE^{W}$ test bank across 4 medical disciplines.	GPT-4 open-domain hallucinations accounted for 56% (9/16), 43% (6/14), and 83% (15/18), while close-domain hallucinations accounted for 44% (7/16), 57% (8/14), and 17% (3/18), respectively.	GPT-3.5 scored 56%, 76%, and 62% on CNMLE, ENMLE, and NEEPM, compared to GPT-4's 84%, 86%, and 82%. Verbal fluency exceeded 95% across responses.	GPT-4 is a highly valuable AI-assisted tool in medical education.	GPT-4 had difficulty in answering difficult and complex questions.
Ali et al (2023) [49]	Self-Assessment Neurosurgery Examination Indications Examination	149 questions from the Self-Assessment Neurosurgery Examination Indications Examination were used to query LLM accuracy.	Overall accuracy of 82.6%.	Overall accuracy of 62.4%.	Potential value and applications of LLMs such as GPT-4 in neurosurgical education and in clinical decision-making.	The use of multiple-choice questions to quantify LLM knowledge for higher-order neurosurgical topics incompletely captures the open-ended nature of the true neurosurgery oral board examination.
Gravina et al (2024) [76]	Italian National Residency Admission Exam (SSM23)	Multiple-choice gastroenterology-focused questions were chosen from the 140 questions in the 2023 Italian medical specialization exam.	None	Overall accuracy of 94.11%.	ChatGPT-3.5 exhibits promise in addressing gastroenterological queries, emphasizing potential educational roles.	ChatGPT-3.5 shows variable performance, mandating cautious use alongside other educational tools.
D'Souza et al (2023) [77]	Clinical Vignettes in Psychiatry	ChatGPT-3.5's responses to 100 clinical vignettes representing 100 different psychiatric illnesses were assessed by expert psychiatrists.	None	Grade A: 61/100 cases; Grade B: 31/100 cases; Grade C: 8/100 cases.	ChatGPT-3.5 has appreciable knowledge and interpretation skills in psychiatry.	Depending upon the query and information provided, ChatGPT-3.5 can provide varying responses.

Study ID	Exam type	Dataset and methods	ChatGPT-4.0 accuracy	ChatGPT-3.5 accuracy	Advantages	Disadvantages
Khan et al (2024) [50]	Anesthesiology Board-Style Examination Questions for the American Board of Anesthesiology (ABA)	A total of 884 multiple-choice questions were used from *Anesthesia: A Comprehensive Review* (6th edition), a question bank largely regarded as one of the premium study sources for ABA certification and recertification examinations.	Overall accuracy of 69.4%.	Overall accuracy of 47.9%.	GPT-4 significantly outperformed GPT-3.5.	Although GPT-4 shows promise, current LLMs are not sufficiently advanced to answer anesthesiology board examination questions with passing success.
Haze et al (2023) [51]	Japanese National Medical Examination	Questions available from three editions of the Japanese National Medical Examination administered in 2020, 2021, and 2022 were used; questions with images or those officially identified as inappropriate were excluded.	Accuracy rate of 81% and a consistency rate of 88.8%.	Accuracy rate of 56.4% and a consistency rate of 56.5%.	GPT-4 showed significantly higher percentages of correct and consistent responses than GPT-3.5.	Neither LLM reached the level required in real clinical practice.
Rizzo et al (2024) [52]	Orthopaedic In-Service Training Exams (OITEs)	All questions from the 2020–2022 Orthopaedic In-Service Training Exams (OITEs) were given to OpenAI's GPT-3.5 Turbo and GPT-4 LLMs.	2022: 67.63%; 2021: 58.69%; 2020: 59.53%.	2022: 50.24%; 2021: 47.42%; 2020: 46.51%.	GPT-4's performance is comparable to a second- to third-year resident, and GPT-3.5 Turbo's performance is comparable to a first-year resident.	The application of current LLMs can neither pass the OITE nor substitute orthopaedic training.

Study ID	Exam type	Dataset and methods	ChatGPT-4.0 accuracy	ChatGPT-3.5 accuracy	Advantages	Disadvantages
Mannam et al (2023) [78]	Congress of Neurological Surgeons (CNS) Self-Assessment Neurosurgery (SANS) Exam Board Review Prep Questions	Questions were obtained from the Congress of Neurological Surgeons (CNS) Self-Assessment Neurosurgery (SANS) Exam Board Review Prep; the ChatGPT Output Precision Ladde was developed to evaluate the quality and accuracy of the ChatGPT output.	None	ChatGPT achieved spot-on accuracy for 66.7% of prompted questions, 59.4% of unprompted questions, and 63.9% of unprompted questions with a leading phrase. In comparison to SANS explanations, ChatGPT output was considered better in 19.1% of questions, equal in 51.6%, and worse in 29.3%.	The authors envision a future where LLMs like ChatGPT are integrated into medical education, providing explanations based on the RIME (Reporter, Interpreter, Manager, and Educator) framework.	The language and phrasing of the pain questions may not have been optimally suited for the data ChatGPT was trained on.

[a]MCQs: multiple-choice questions.
[b]AI: artificial intelligence.
[c]LLMs: large language models.
[d]USMLE: United States Medical Licensing Examination.

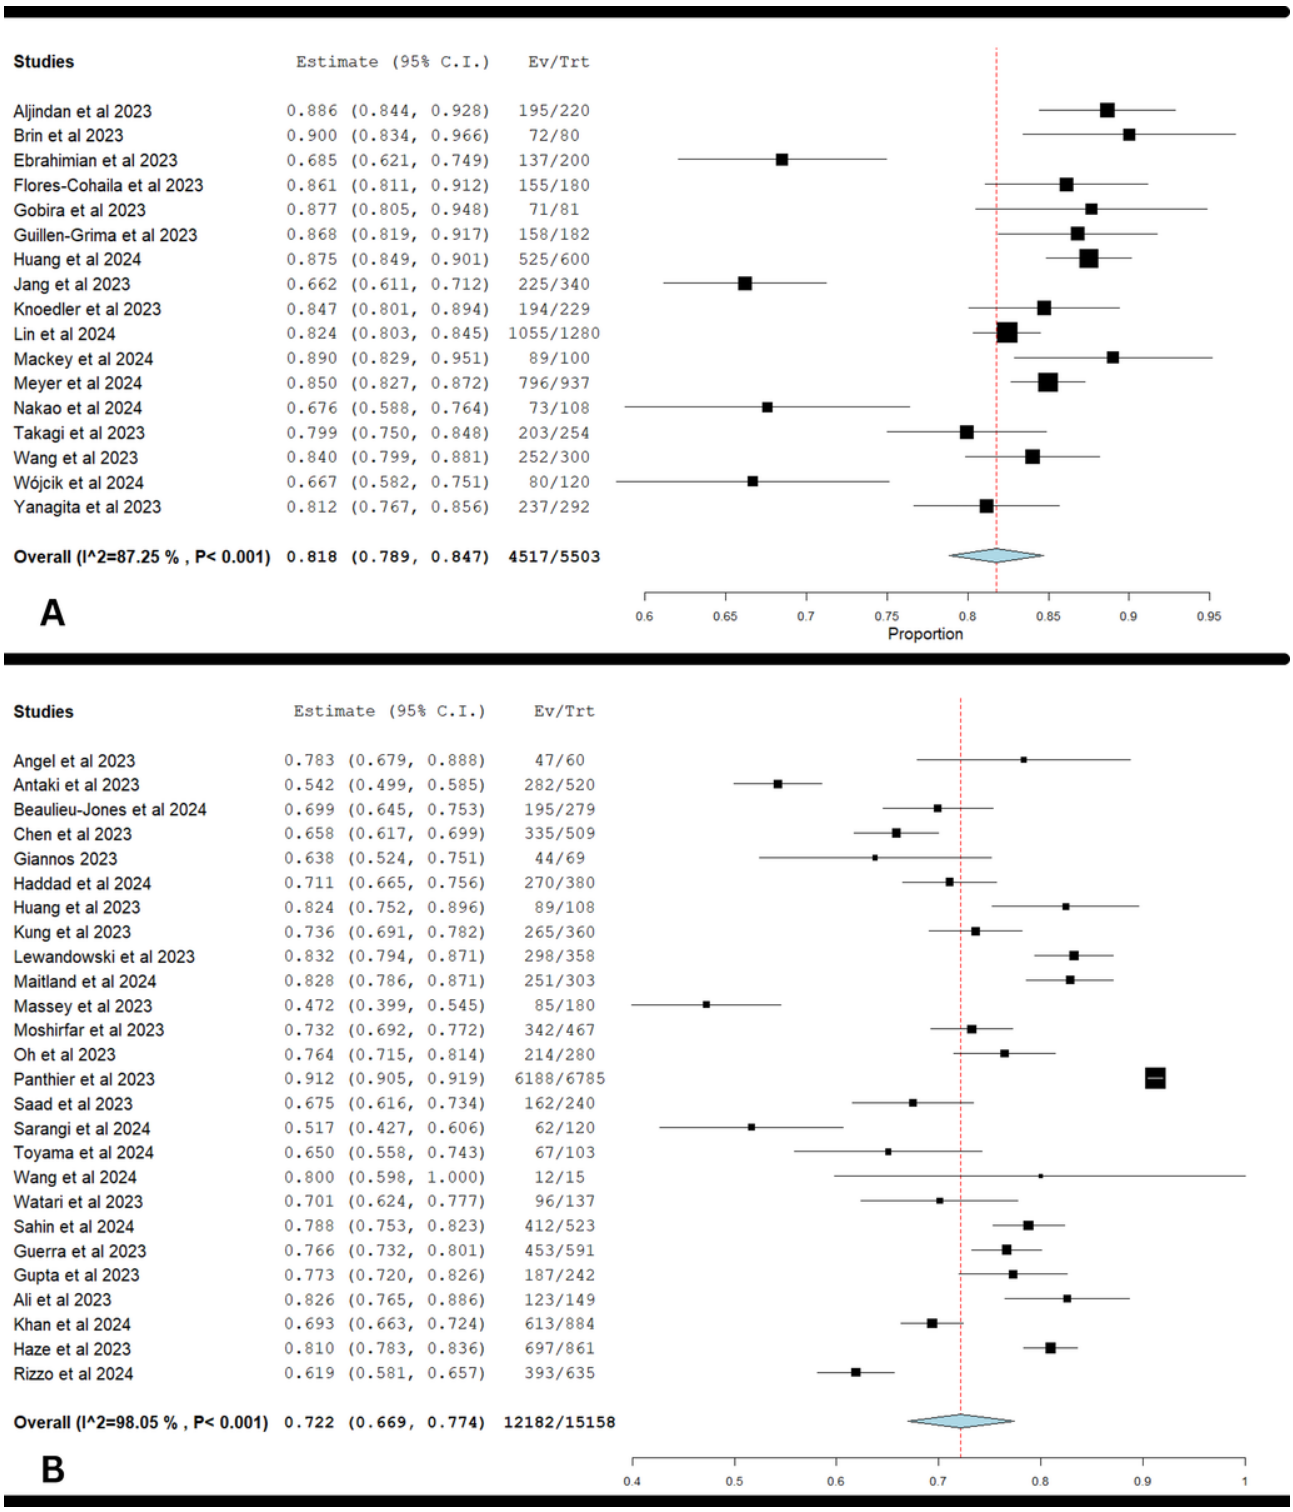
ChatGPT-4 Performance in Medical Licensing Exams

The forest plot shown in Figure 3A indicated that the subject had a pooled accuracy proportion of 0.818 (95% CI 0.789-0.847) in medical licensing exams. This means that, on average, the subject correctly answered about 81.8% of the questions. However, there was significant heterogeneity among the studies, with I^2=87.25% and χ^2_{16}=125.54 (P<.001). This high variability suggests that differences in study design, population, and exam content significantly influenced the accuracy estimates. Despite this variability, the subject's high accuracy indicates its potential utility.

Figure 3. Performance of ChaGPT-4.0 in (A) medical licensing and (B) in-training residency exams [13-20,22,24,26,28,30-32,35,37,38,40-42,44-53,56,58,60,61,63,64,68,69,72,73].



ChatGPT-4 Performance in In-Training Residency Exams

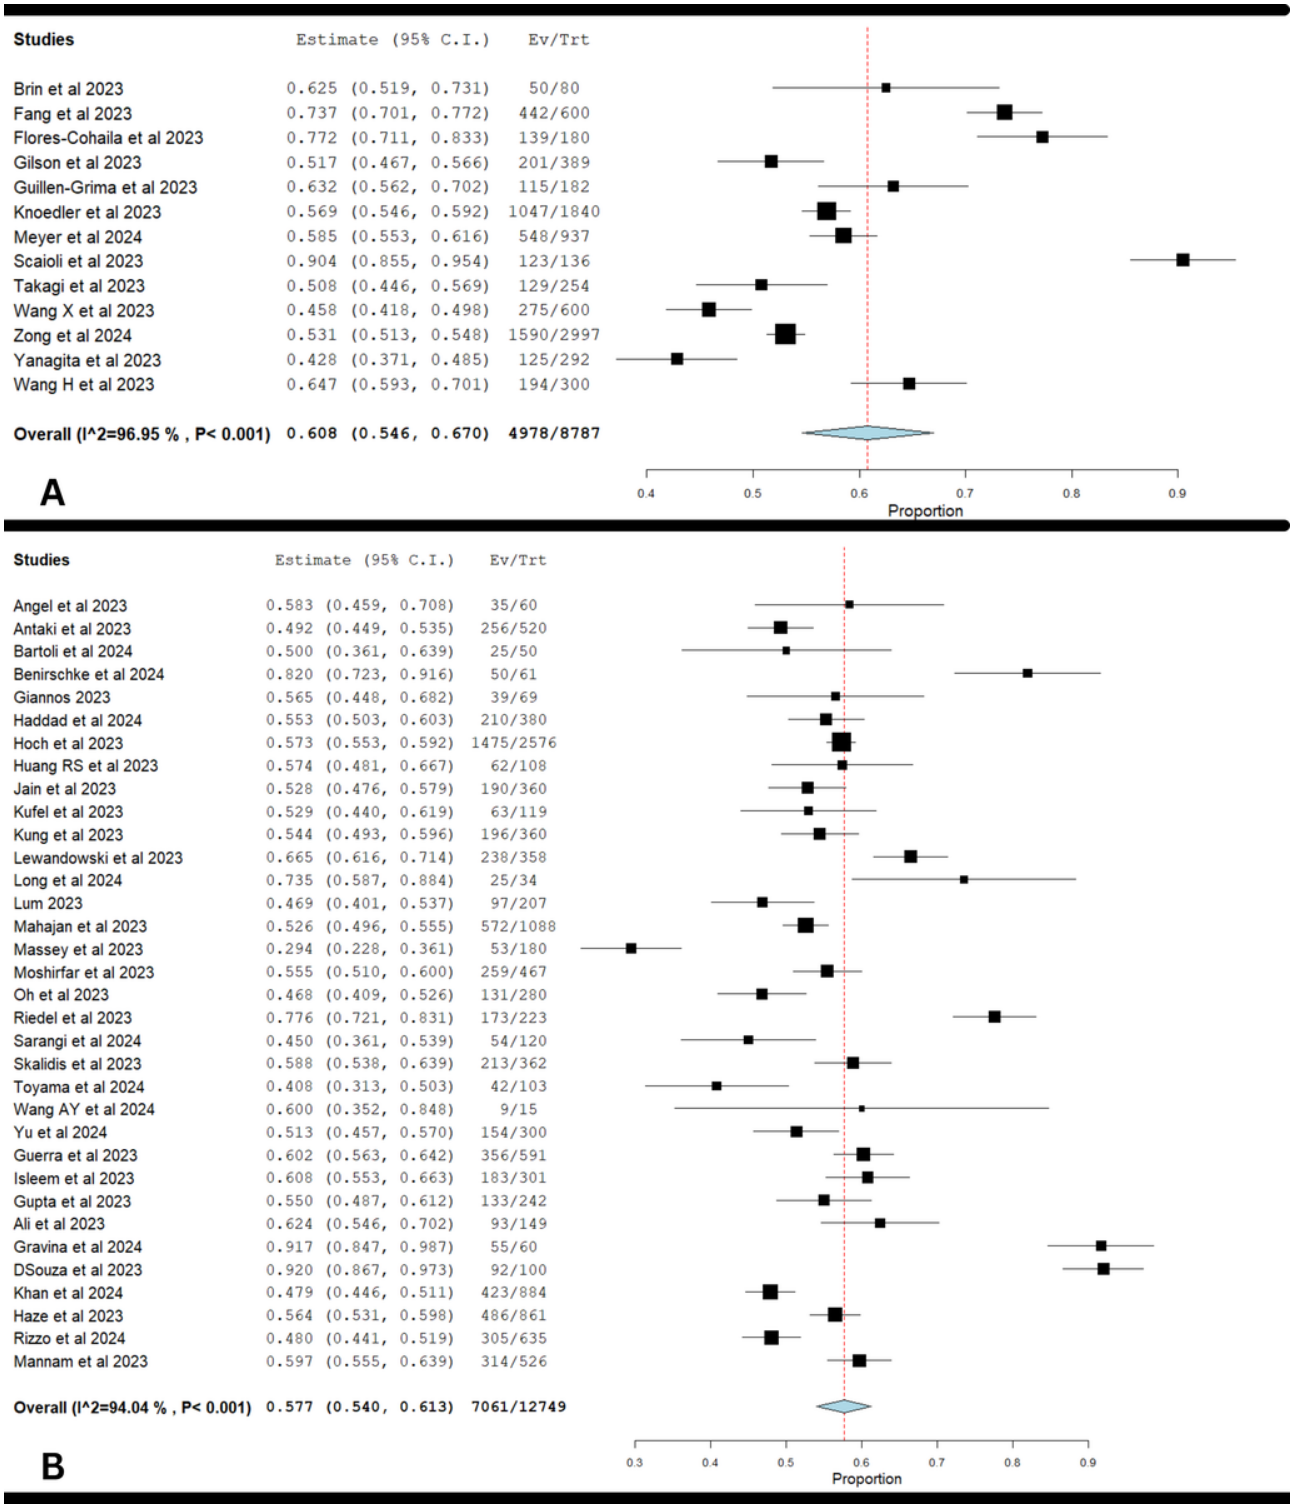
The forest plot shown in Figure 3B indicated that the subject had a pooled accuracy proportion of 0.722 (95% CI 0.669-0.774) in in-training residency exams. This means that, on average, the subject correctly answered about 72.2% of the questions. However, there was significant heterogeneity among the studies, with I^2=98.05% and χ^2_{25}=1280.36 (P<.001). This high variability suggests that differences in study design, population, and exam content significantly influenced the accuracy estimates. Despite this variability, the subject's high accuracy indicates its potential utility in medical education.

ChatGPT-3.5 Performance in Medical Licensing Exams

The forest plot showed a pooled accuracy proportion of 0.577 (95% CI 0.540-0.613), indicating a lower accuracy compared to ChatGPT-4 (Figure 4A). The heterogeneity was also high,

with I^2=94.04% and χ^2_{33}=554.02 (P<.001). This suggests considerable variability in how ChatGPT-3.5 performed across different studies. The lower accuracy and high variability underscore the need for improvements in ChatGPT-3.5's capabilities, particularly in standardizing the conditions under which it is tested to better understand its limitations and strengths.

Figure 4. Overall performance and evaluation of ChatGPT-3.5 in (A) medical licensing exams and (B) in-training residency exams [13-17,19-21,23,27,29,31-33,35,36,38-52,54,55,57,62,64-66,70,71,73,74,77,78].



ChatGPT-3.5 Performance in In-Training Residency Exams

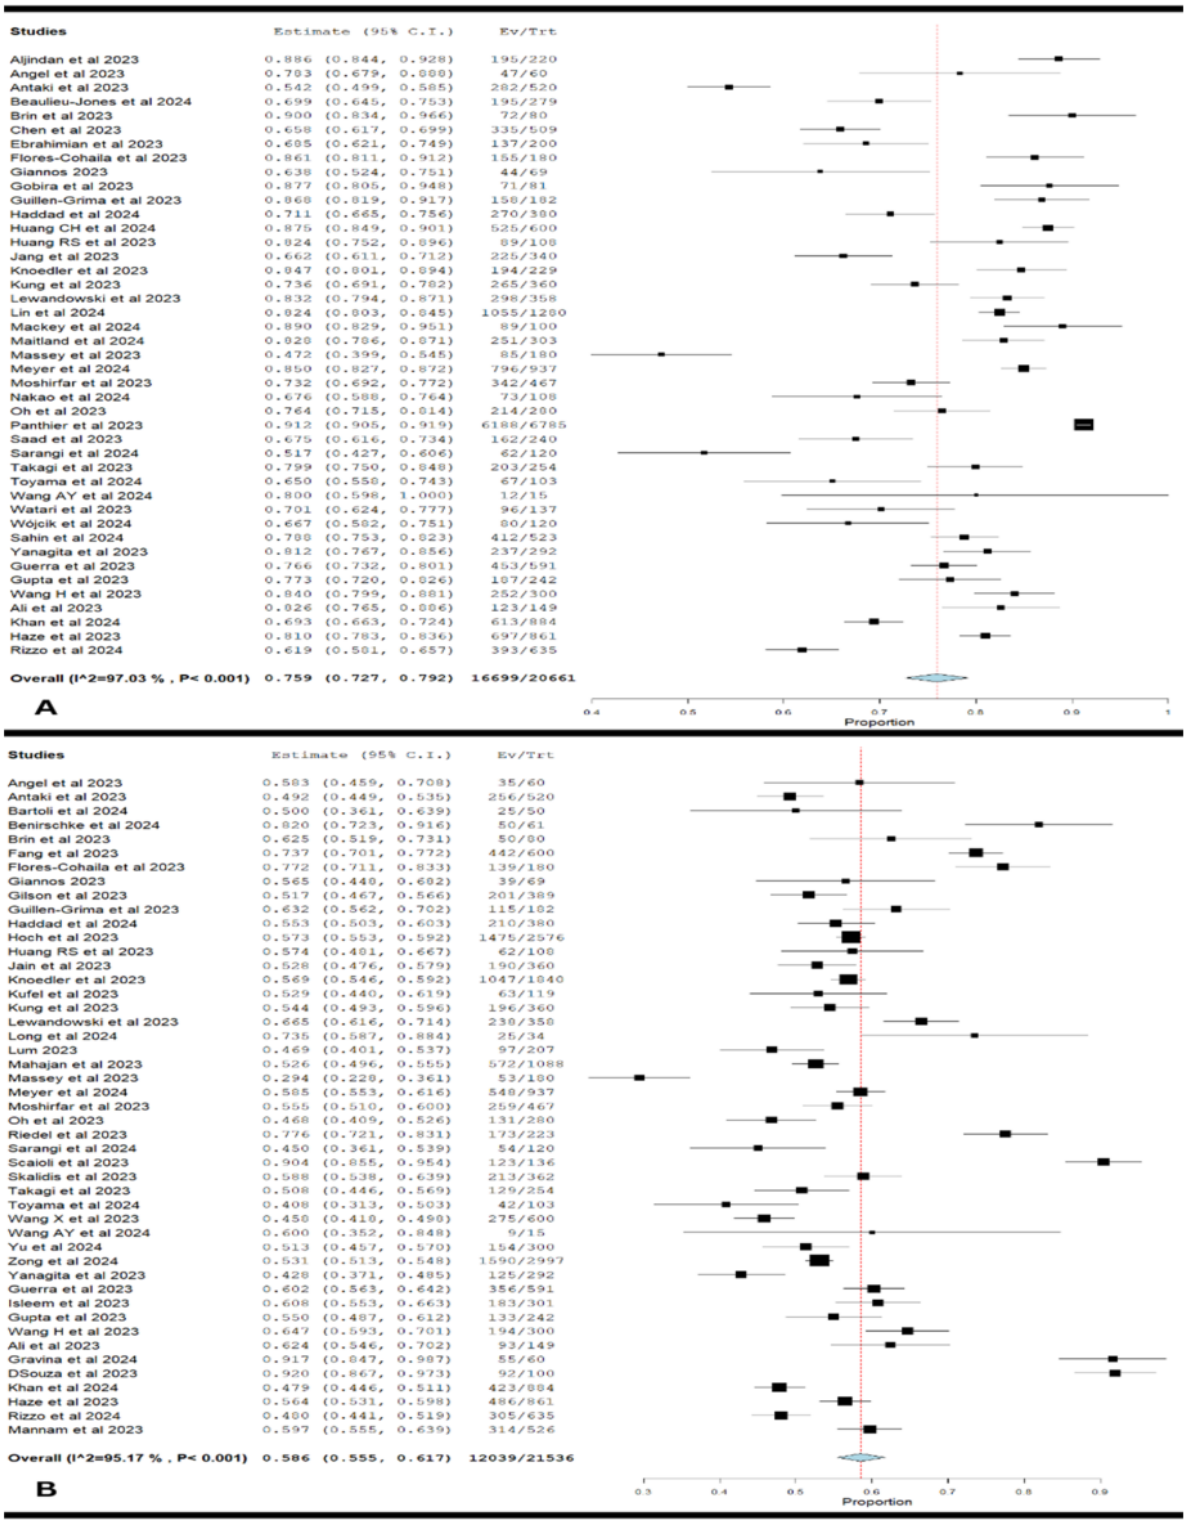
The forest plot showed a pooled accuracy proportion of 0.608 (95% CI 0.546-0.670), indicating a lower accuracy compared to ChatGPT-4 (Figure 4B). The heterogeneity was also high, with I^2=96.95% and χ^2_{12}=393.17 (P<.001). This suggests considerable variability in how ChatGPT-3.5 performed across different studies. The lower accuracy and high variability underscore the need for improvements in GPT-3.5's capabilities,

particularly in standardizing the conditions under which it is tested to better understand its limitations and strengths.

Overall Performance of ChatGPT-4

The forest plot shows that ChatGPT-4 had a pooled accuracy proportion of 0.759 (95% CI 0.727-0.792) in in-training residency exams (Figure 5A). This means that, on average, GPT-4 correctly answered about 75.9% of the questions. However, there was significant heterogeneity among the studies, with τ=0.01, χ^2_{42}=1414.01 (P<.001), and I^2=97.03%. This high variability suggests that differences in study design, population, and exam content significantly influenced the accuracy estimates. Despite this variability, ChatGPT-4's high accuracy indicates its potential utility in medical education, though further research is necessary to understand the sources of heterogeneity and enhance its performance.

Figure 5. Overall performance of (A) ChatGPT-4 and (B) ChatGPT-3.5 in medical licensing exams and in-training residency exams [13-24,26-58,61-66,70,71,73,74,77,78].



Overall Performance of ChatGPT-3.5

The forest plot showed a pooled accuracy proportion of 0.586 (95% CI 0.555-0.617), indicating a lower accuracy compared to ChatGPT-4 (Figure 5B). The heterogeneity was also high, with τ=0.05, χ^2_{46}=951.72 (P<.001), and I^2=95.17%. This suggests considerable variability in how ChatGPT-3.5 performed across different studies. The lower accuracy and high variability underscore the need for improvements in ChatGPT-3.5's capabilities, particularly in standardizing the conditions under which it is tested to better understand its limitations and strengths.

Comparative Analysis: ChatGPT-4 vs ChatGPT-3.5 in Medical Licensing and Residency Exams

The comparative forest plot presented a risk ratio (RR) of 1.36 (95% CI 1.30-1.43), demonstrating that ChatGPT-4 was 36% more likely to provide correct answers than ChatGPT-3.5 across both medical licensing and residency exams, as shown in Figure 6. For medical licensing exams specifically, the RR was 1.42 (95% CI 1.30-1.56), with high heterogeneity (I^2=85%). In residency examinations, the RR was 1.31 (95% CI 1.27-1.39), with moderate heterogeneity (I^2=49%). These results indicate that ChatGPT-4 significantly outperforms ChatGPT-3.5, but the performance advantage varies depending on the exam type. The findings suggest that while ChatGPT-4 is generally more reliable, the context of its application (eg, type of exam) plays a critical role in its accuracy. This highlights the importance of targeted improvements and further research to optimize ChatGPT-4's performance in specific educational and clinical settings.

Further subgroup analyses revealed distinct patterns in ChatGPT's performance based on exam origin or medical specialty. For surgical specialties, the pooled RR was 1.37 (95% CI 1.28-1.47), with moderate heterogeneity (I^2=49.8%) as shown in Figure 7. Orthopedic surgery showed similarly strong performance (RR 1.33, 95% CI 1.24-1.44), with notably low heterogeneity (I^2=10.8%), indicating consistent outcomes across studies. In contrast, the ophthalmology subgroup had a lower pooled RR of 1.24 (95% CI 1.11-1.38) but higher heterogeneity (I^2=65.9%), suggesting variability in ChatGPT performance possibly due to the visual or nuanced nature of the content. Performance in the Japanese Medical Licensing Exam subgroup was the most heterogeneous (RR 1.61, 95% CI 1.37-1.89; I^2=83.7%), likely reflecting the linguistic and cultural specificity of the test.

The only variable studied was the examination performance of the intervention group (ChatGPT-4.0) against the comparison group (ChatGPT-3.5). For dichotomous outcomes, RRs with 95% CIs were calculated. A random-effects model was used to pool data from both the intervention group and the comparison group. The meta-analysis was performed with the Review Manager 5.4. Subgroup analyses were performed using R software (version 4.4.1; R Foundation for Statistical Computing) based on examination level, country of origin, and specialties. OpenMeta[Analyst] (Brown University) was used to check the effect sizes of each arm, including noncomparator studies, giving a more holistic review of the existing literature.

Heterogeneity was assessed using the chi-square test and quantified with the I^2 statistic, with I^2>50% indicating substantial heterogeneity. To explore potential sources of heterogeneity, subgroup analyses and leave-one-out sensitivity analyses were conducted. A P value <.05 was considered statistically significant for all analyses.

Figure 6. Comparative analysis: ChatGPT-4 vs ChatGPT-3.5 in medical licensing and in-training residency exams [13-17,19,20,28,31,32,35,40-45,47-52,64,73].

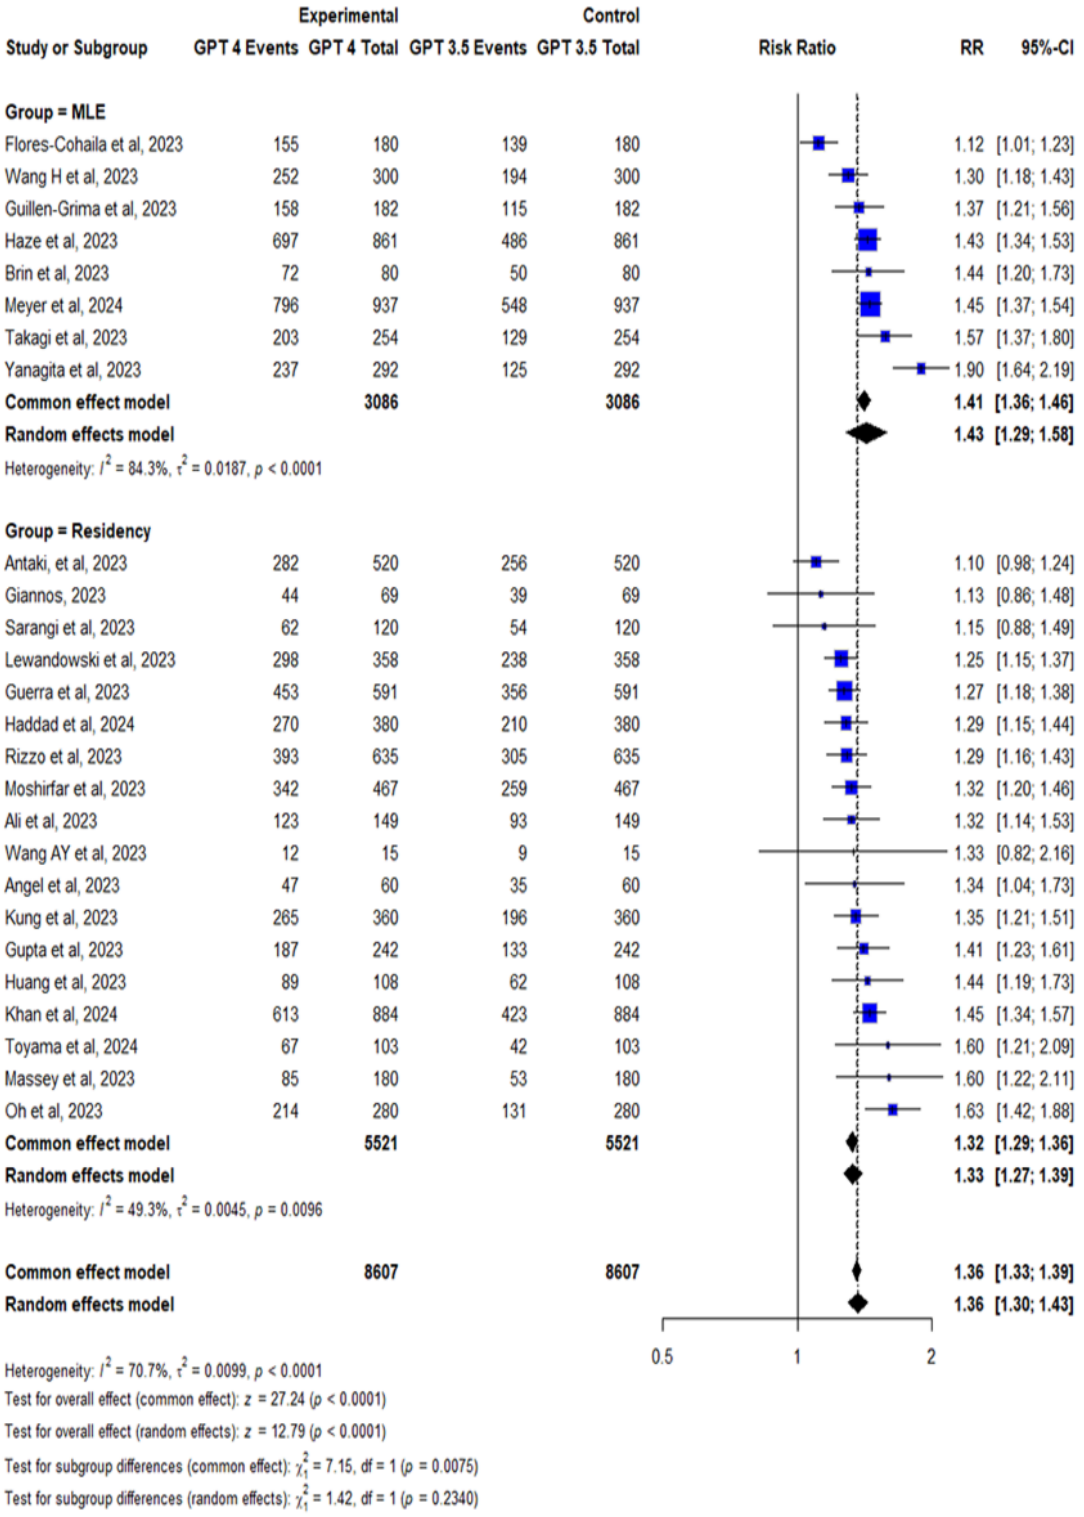


Figure 7. Further subgroup analyses: ChatGPT-4 vs ChatGPT-3.5 in medical licensing exams and residency exams [20,32,41-44,48,49,52,73].

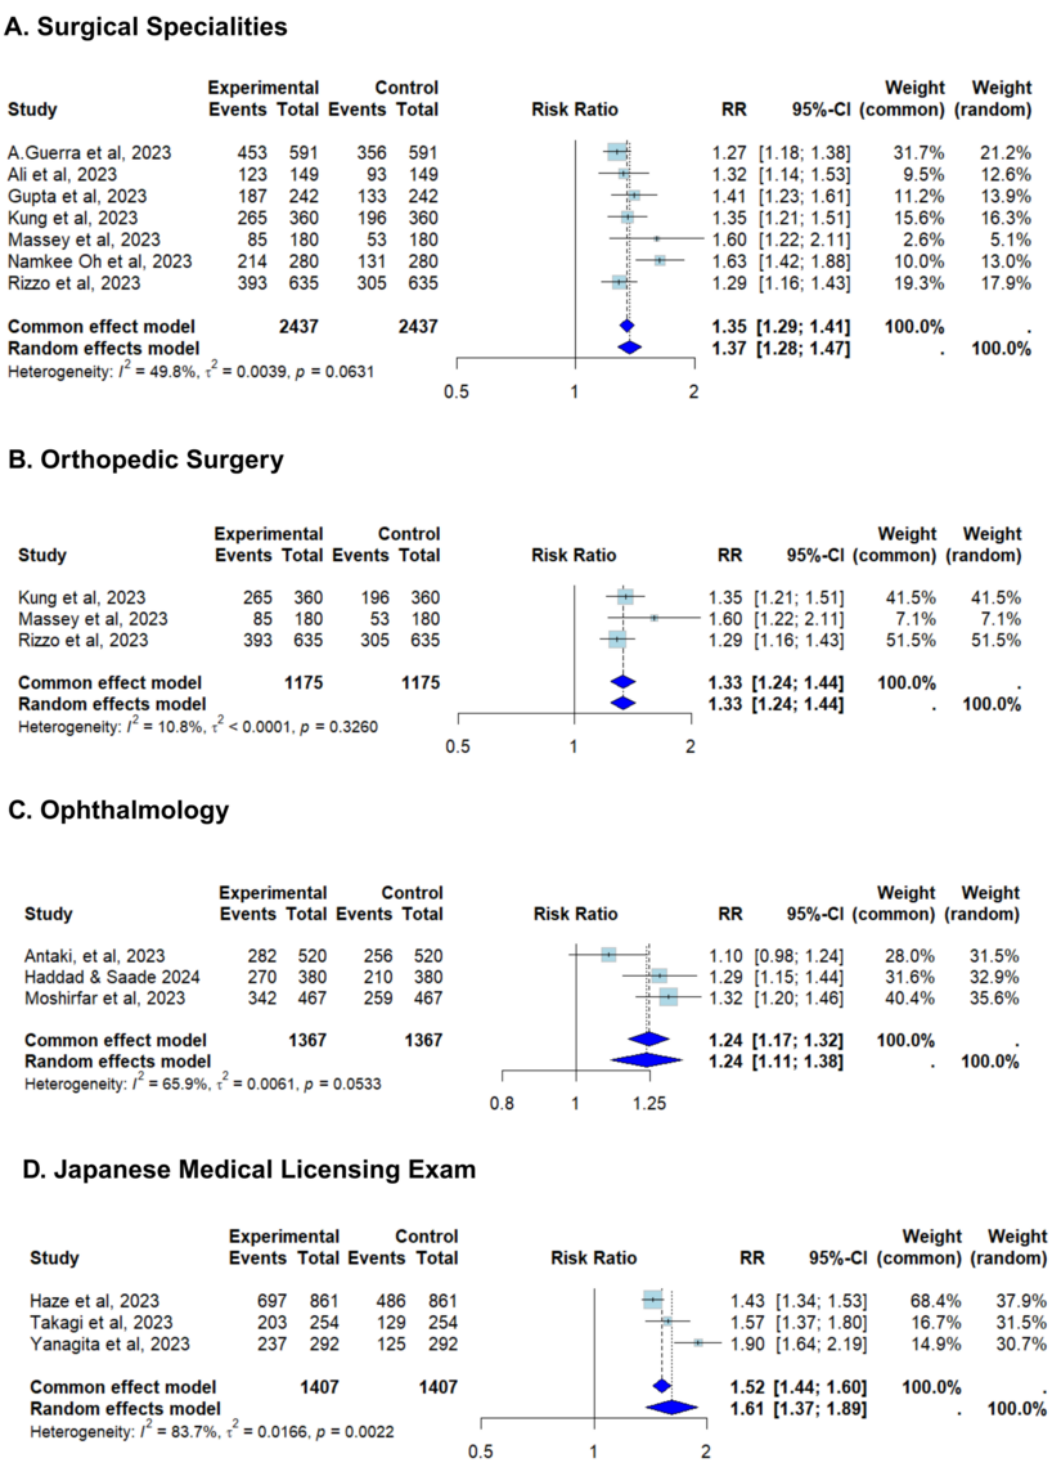


Sensitivity Analyses and Publication Bias

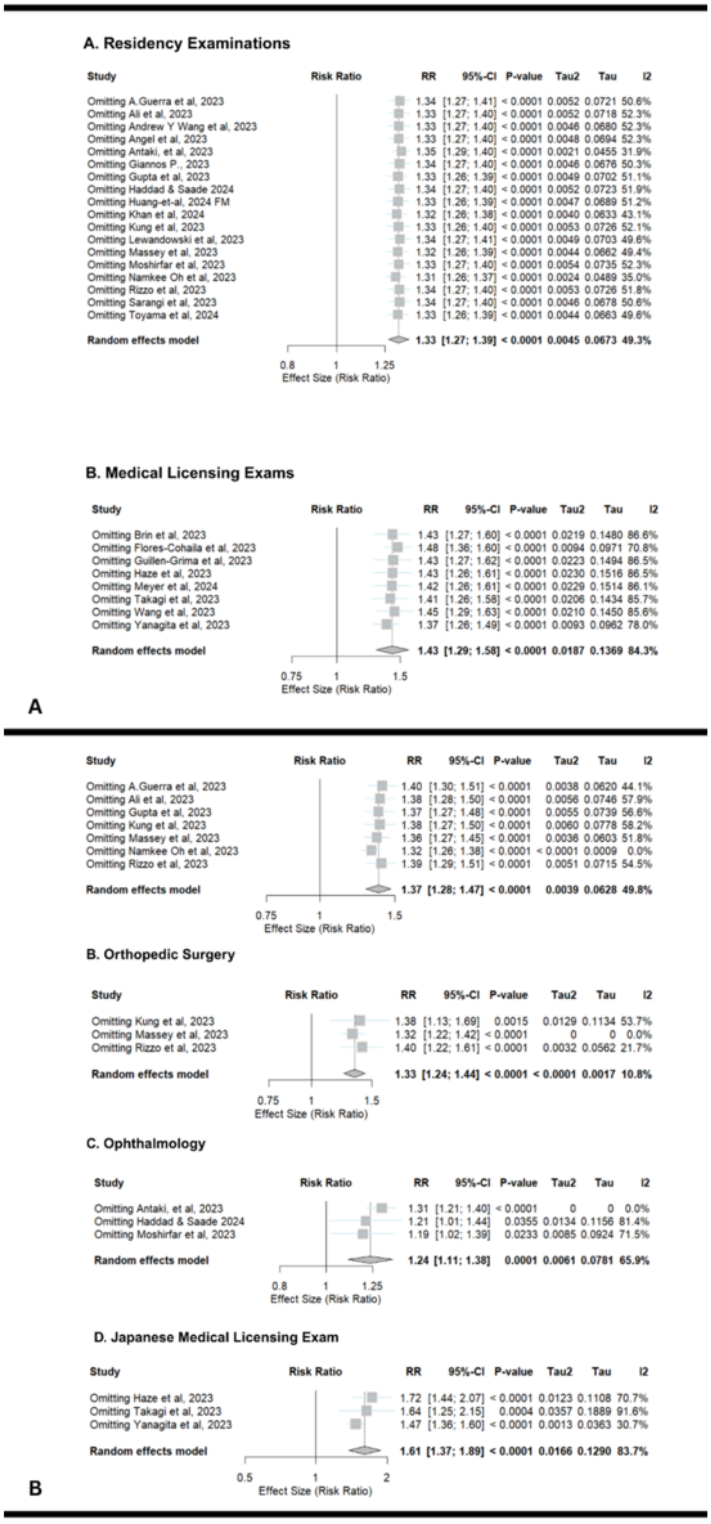
Sensitivity analyses were conducted across key subgroups to assess the robustness of the pooled RRs and the influence of individual studies on heterogeneity (Figure 8). Among broader categories, residency exams (RR 1.33, 95% CI 1.27-1.39; I^2=49.3%) exhibited consistent results across all exclusions, with negligible shifts in heterogeneity. In contrast, the medical licensing exams subgroup demonstrated persistent high heterogeneity (I^2=84.3%), even after omitting studies, indicating intrinsic variability across these assessments (Figure 8). Overall, the pooled estimates proved stable across all sensitivity models. The sources of heterogeneity appeared to be distributed across multiple studies rather than driven by a single outlier, reinforcing the internal consistency and robustness of the main findings.

For surgical specialties, no single study unduly influenced the overall estimate (RR 1.37, 95% CI 1.28-1.47), with

heterogeneity remaining moderate (I^2=49.8%) across exclusions. Notably, omitting [44] reduced heterogeneity to 0%, while other exclusions led to only marginal reductions in I^2 values. In orthopedic surgery, all leave-one-out models preserved significance (RR 1.33, 95% CI 1.24-1.44). The exclusion of [42] notably eliminated heterogeneity (I^2=0%), suggesting it was a moderate contributor to between-study variance. Ophthalmology showed more sensitivity to individual studies, with RR values ranging from 1.19 to 1.31 and I^2 fluctuating between 0% and 81.4%. Omitting [20] fully resolved heterogeneity (I^2=0%), while the exclusion of [43] led to substantial reductions in I^2, indicating a significant source of inconsistency. For the Japanese Medical Licensing Exam subgroup, heterogeneity remained high (I^2=83.7%) across all models. However, the exclusion of [14] resulted in notable reductions in I^2, confirming that all 3 studies contributed to the observed variability (Figure 8B).

Publication bias was evaluated using the Egger linear regression test for funnel plot (Figure 8) asymmetry. The test yielded a nonsignificant result (t_{24}=0.15, 2-tailed; P=.88), indicating no evidence of small-study effects or significant publication bias in the included studies. These findings suggest that the funnel plot asymmetry observed is unlikely due to publication bias and may instead reflect genuine heterogeneity across studies (Multimedia Appendix 1).

Figure 8. (A) Sensitivity analyses and (B) further subgroup sensitivity analyses of ChatGPT-3.5 and 4.0 in medical licensing exams and in-training residency exams [13-24,26-58,61-66,70,71,73,74,77,78].



Discussion

Performance Comparison of ChatGPT-3.5 and ChatGPT-4 in Medical Examinations

The study highlights the promising potential of AI-driven language models such as ChatGPT-3.5 and 4.0 in revolutionizing the medical field by assessing their performance across a range of medical licensing and in-training exams worldwide. The findings revealed that ChatGPT-4 consistently outperformed its predecessor, ChatGPT-3.5, in accuracy and proficiency [69,70], thanks to the more advanced training data and significant algorithmic improvements.

In this study, ChatGPT-4 demonstrated a pooled accuracy of approximately 75.9% in in-training residency exams, showcasing its strong overall performance. In comparison to ChatGPT-3.5, ChatGPT-4 was 36% more likely to provide

correct answers across both medical licensing and residency exams, with an RR of 1.36 (95% CI 1.30-1.43). This suggests that ChatGPT-4's advancements have translated into tangible improvements in accuracy, particularly in multiple-choice question formats. For medical licensing exams specifically, ChatGPT-4 had an even higher RR of 1.42 (95% CI 1.30-1.56), indicating a significant performance edge over ChatGPT-3.5 [71].

However, there was notable heterogeneity in the performance of both models, with high I^2 values (85% for licensing exams and 49% for residency exams), reflecting variations in study design, population, and exam content that impacted the accuracy estimates. These findings are similar to Zong et al [71]. These findings underscore the importance of contextual factors in applying AI models like ChatGPT-4. They also highlight the need for targeted improvements and further research to enhance its performance, ensuring that it becomes a more reliable and effective tool for specific educational and clinical settings [79,80,81].

Further subgroup and sensitivity analyses provide critical insights into the generalizability and robustness of ChatGPT's performance across the medical licensing exam. The lower heterogeneity among surgical and orthopedic specialties indicates that the ChatGPT models succeed in domains with structured procedural knowledge. These results suggest that ChatGPT may potentially serve as an adjunct learning tool in surgical education [35,45,59].

The above findings were in contrast with high heterogeneity in ophthalmology and Japanese licensing exams, which correspond to the fields with less predictable ChatGPT performance. Some potential explanations include the visual nature of ophthalmologic evaluations, discrepancies in linguistic constructs, and culturally specific clinical reasoning models. These findings highlight the critical requirement for more localized training datasets and a standardized mechanism to ensure generalizability [80]. The stability of effect estimates across sensitivity analyses reinforces the robustness of the meta-analytic findings. Small changes in pooled RRs after the removal of any individual study alleviate concerns about publication bias or undue influence from outliers [71,81].

These observations align closely with the findings of several systematic reviews and meta-analyses. Liu et al [10] conducted one of the most comprehensive meta-analyses to date, demonstrating that ChatGPT-4 generally outperforms its predecessors across a variety of standardized medical exams, although performance fluctuates based on question structure, language, and specialty content. The author highlighted that while LLMs are strong in knowledge-based tasks, their clinical reasoning capabilities are notably weaker, particularly in real-world scenarios or open-ended problem-solving formats [80].

The authors [80,81] presented important insights into the role of AI as an educational tool. Both studies emphasized the importance of viewing AI not as a replacement for human reasoning, but as a potential companion to strengthen formative assessment and feedback in medical education, provided its limitations are clearly understood and accounted for. LLMs' medical exam accuracy at 0.61, USMLE accuracy at 0.51, and ChatGPT's higher accuracy of 0.64 support our observation of ChatGPT-4.0's superior performance. The study also emphasized LLMs' potential to address health care challenges but stressed the need for rigorous evaluation frameworks. Their rubric framework provides a structured approach to ensure safe and ethical integration of LLMs into clinical and educational settings, aligning with our call for standardized evaluation metrics and greater transparency in future research [80].

Beyond technical accuracy, the issue of AI's ability to simulate human soft skills, such as empathy and ethical reasoning, has also been discussed extensively in the literature. The literature addressed the concept of artificial cognitive empathy, concluding that despite improvements in language generation, AI still lacks the depth of emotional understanding and situational awareness that human physicians develop through clinical experience [79,82]. Similarly, certain studies emphasized the need for careful integration of AI in both educational and clinical environments, cautioning that overconfidence in AI-generated answers could introduce safety risks if used without appropriate human oversight [83,84]. This is particularly relevant in high-stakes scenarios like licensing examinations, where even minor inaccuracies can have significant consequences. In addition, Artsi et al [11] highlighted the risk of "overreliance" on AI models during the learning process, which could unintentionally affect the development of independent critical thinking among medical students, an observation that complements the variability we observed in AI performance across exam types and specialties [11].

In our study, the performance of AI models in medical licensing exams varies widely across different countries. For example, while ChatGPT-3.5 performed relatively well in the Italian medical exam, scoring 73%, it scored significantly lower in the French exam, with only 22%. The marked difference in ChatGPT's performance between the Italian and French medical licensing exams likely reflects a combination of factors. The French exam's multiple-answer question format posed a particular challenge, as language models like ChatGPT typically perform better on single-answer questions, such as those used in the Italian exam. Additionally, longer question lengths, especially in the French set, were linked to lower accuracy. Language-specific factors, including tokenization and training data exposure, also influenced results, while differences in national exam design philosophies likely contributed to the observed performance gap [1,80]. To summarize, this variability could be attributed to differences in exam formats, language subtleties, and subject matter, highlighting the need for localization and customization of AI models for different regions and medical systems.

The analysis of various in-training exams across multiple medical specialties demonstrates both the advantages and limitations of LLMs in the medical field. These show potential in medical training exams by showing their efficiency in processing large amounts of data, coupled with improved performance in certain domains, showing potential for enhancing clinical workflows by augmenting human decision-making. However, their performance varies across specialties, with

notable limitations in problem-solving, nuanced reasoning, and explaining their logic. While ChatGPT-4 outperforms average human resident students in some cases, its accuracy is inconsistent, and it sometimes generates incorrect or misleading information [33]. These models can assist in medical education but still require human oversight, especially in complex decision-making areas.

A notable limitation identified in these models is their inability to handle questions involving figures and tables. This was demonstrated by studies on Japan's National Medical Licensing Examination, where ChatGPT-4.0 scored 81.5%, passing the exam, while ChatGPT-3.5 only scored 42.8%. Both versions struggled with visual data, which is crucial for medical exams [40,81]. Additionally, ChatGPT-4 showed limited capability in interpreting medical images, achieving only 68% accuracy on image-based questions in another Japanese exam study [9]. While textual comprehension has improved, significant gaps remain in processing and interpreting visual information, which is essential for comprehensive medical practice. The study by Yang et al [85] evaluated the performance of ChatGPT-4V, ChatGPT-4, and GPT-3.5 Turbo on medical licensing exams involving images, showing GPT-4V's high accuracy but significant limitations in image interpretation and explanation quality. While GPT-4V outperformed its predecessors in multiple-choice questions, its incorrect answers often featured poor image understanding and reasoning. The study highlights the need for further evaluation of GPT-4V's capabilities before clinical integration [86].

The performance variability of ChatGPT-3.5 and GPT-4 across different countries and medical licensing exams can be attributed to several factors. Language nuances, such as regional variations in medical terminology, phrasing, and dialect, may affect how the AI interprets and responds to exam questions [80,87]. Exam formats also play a role, with different countries prioritizing multiple-choice questions, clinical scenarios, or essay-based responses, each requiring distinct approaches from the AI. Cultural differences in health care practices, ethical considerations, and medical education systems can influence how questions are framed and what knowledge is emphasized, affecting the AI's ability to provide contextually appropriate answers. These factors combined can create significant variability in AI performance, highlighting the need for localized training and adaptation [87,85].

Despite significant advancements, ChatGPT's performance still lags behind that of trained medical students. ChatGPT performed below the student average, with a score of 80.5/100 compared to the student average of 86.21/100 in the medical microbiology exam [79]. However, in some cases, such as the Peruvian National Licensing Medical Examination, GPT-4 outperformed human students, scoring 86% and surpassing 90% of human examinees [29]. These discrepancies suggest that while ChatGPT can achieve expert-level performance on standardized medical exams, it remains limited in handling complex, domain-specific tasks requiring deep understanding and critical thinking [82].

ChatGPT-4's performance across different medical subjects further highlights its variability. In a study by Jang et al [16] on the Korean National Licensing Examination for Korean Medicine Doctors, ChatGPT-4 passed in 7 out of 12 subjects, excelling in herbology and neuropsychiatry but performing poorly in public health and acupuncture. It scored 85.9% on diagnosis-based questions, 63.2% on recall-based questions, and 53.5% on intervention-based questions, consistently outperforming ChatGPT-3.5. These results suggest the potential for AI models to specialize in certain medical fields, though challenges remain, especially with language nuances and culturally specific medical concepts [11,86,83,84].

While AI models provided mostly clinically valid information, they are not without flaws, particularly the risk of hallucinations or misinformation. Long et al [54] evaluated ChatGPT's performance on otolaryngology exams, finding that it achieved a passing mark and showed higher accuracy with specific prompts. However, caution is advised due to the risk of AI-generated hallucinations or misinformation [33]. Similarly, Takagi et al [14] found ChatGPT-4 outperformed GPT-3.5 on the Japanese Medical Licensing Exam, but both faced challenges with hallucinations and inaccurate information [14]. Maitland et al [58] identified a key reason for these misinformation issues: language models are trained "to predict the next token in a sequence rather than verify factual accuracy."

Concerns about AI misuse, such as cheating and misdiagnosis, remain significant in educational and clinical settings. A recent study highlighted the challenges posed by AI models like ChatGPT in providing relevant, readable, and accurate responses in medical exams [19,88,89]. The presence of multiple potentially correct answers poses a challenge for AI systems, as demonstrated in Kung et al's [41] study, which compared ChatGPT's performance to orthopedic surgery residents at various postgraduate levels. While AI models offer quick and accessible information, the risk of misuse and the need for further refinement cannot be overlooked. To address this issue, there should be guidelines and policies with clear ethical standards for AI usage. Transparency about AI decision-making should be ensured with accountability for misuse and error. Moreover, oversight committees must be formulated in each organization to monitor and review AI outputs and decision-making processes. There should be limited access to data with anonymization to protect privacy. Regular audits of AI models should be conducted for bias and inaccuracies, with diverse datasets being used. Training of staff on the ethical use of AI is necessary, with policies for responsible use. Validation of AI outputs with human experts' assessments should be done with continuous feedback for the improvement of AI models [87,85].

The role of AI in generating medical exam questions and educational content also presents both opportunities and challenges. A multinational prospective study conducted by Cheung et al [25] highlighted how ChatGPT demonstrated the ability to generate medical graduate exam multiple-choice questions efficiently [25]. However, the AI's questions lacked the depth, relevance, and specificity seen in human-generated content. This points to the nuanced complexities and limitations inherent in AI-driven content creation, including concerns about reliability, credibility, bias, and factual accuracy [33,90]. Thus, while ChatGPT shows potential, careful oversight is required

to ensure its effective integration into medical education. Furthermore, the findings underline the growing potential that LLMs can play in medical education and licensing exams, but highlight the need for contextualization and adaptation, particularly in any assessments that involve visual information, native language perception, or abstracted clinical reasoning.

Limitations

The study on ChatGPT-3.5 and 4.0 in medical education reveals several limitations. A primary concern is the models' inability to interpret visual data, such as medical images, which are crucial for effective practice and examination performance. Additionally, the findings may lack generalizability across different medical disciplines. Potential biases in AI-generated content raise questions about reliability and equity in diverse educational contexts.

Future Research and Gap

Further empirical data is essential to support the accuracy and utility of ChatGPT-3.5 and 4.0 in medical licensing and in-training examinations. While these versions show promising potential in processing vast amounts of medical knowledge, their application in critical, high-stakes environments requires rigorous validation. Current studies suggest variable performance, with both versions demonstrating strengths in general medical knowledge but limitations in reasoning and clinical decision-making. To solidify their role in medical education and assessment, more research is needed, especially focusing on advanced future iterations. These future versions must be scrutinized for improved understanding of complex medical scenarios, ethical considerations, and practical applications in real-world settings.

Implications and Contributions

This study highlights the implications and contributions of ChatGPT versions by analyzing their accuracy in medical examinations across the globe. By synthesizing data from diverse studies conducted in various countries, it offers a broader perspective on the performance of ChatGPT-3.5 and 4.0 in medical licensing and in-training exams. The cross-country analysis showcases the potential of these AI models in adapting to different medical curricula and standards, contributing valuable insights into their applicability in international medical education. This global evaluation established a more comprehensive understanding of the strengths and limitations of ChatGPT, providing a foundation for further research and development in medical AI tools.

Acknowledgments

We would like to acknowledge the management of Shalamar Institute of Health Sciences, Lahore, for their motivation and support. We would like to acknowledge the use of ChatGPT (OpenAI) for its assistance in drafting certain sections of this manuscript and providing support in the data processing stage. The contributions of ChatGPT were invaluable in streamlining the writing process and enhancing the clarity of the manuscript.

Abstract

Background: Free Open Access Medical Education has the potential to democratize access to medical knowledge globally; however, this potential remains largely unrealized, particularly in resource-limited settings. Content is increasingly concentrated on a small number of platforms, each hosting large volumes of material compiled from diverse sources.

Objective: This scoping review aimed to identify and synthesize reported barriers and enablers to the successful design, production, and operation of open access medical education platforms, with the goal of informing strategies to improve their impact, reach, and sustainability.

Methods: We conducted a scoping review using the Arksey and O'Malley framework. A structured search was carried out on April 17, 2023, in PubMed and EBSCOhost. Citation chaining with the SnowGlobe tool and manual reference checking supplemented the search. Studies were eligible for inclusion if they examined platforms that compile content from multiple sources and reported barriers and enablers. Two reviewers (AAEA and AB) independently screened records and extracted data, with discrepancies resolved by a third reviewer (EPOF). Beginning with an a priori framework of "barriers" and "enablers," coding was then developed inductively. Thematic synthesis categorized findings by stakeholder group.

Results: Of 1108 records identified, 1064 unique records were screened, and 64 full-text papers were assessed; 34 met the inclusion criteria. The most frequently reported barriers were concerns about content-quality control, incomplete or unstructured materials, and the resources needed to sustain platforms long-term. Key enablers included the use of validated tools to assess content quality and collaboration with existing content providers and platforms to enhance visibility and learner engagement. Findings were organized into 3 stakeholder groups: learners and training programs, content designers and creators, and platform managers.

Conclusions: Open access medical education platforms have significant untapped potential to enhance global medical training. Addressing these persistent challenges—particularly around quality assurance, content organization, and sustainability—will require more structured, collaborative, and internationally coordinated approaches.

KEYWORDS

open access publishing; medical education; scoping review; educational technology; digital learning; barriers

Introduction

Advances in technology have revolutionized medical education and training. e-Learning) has become an accepted part of medical training worldwide, at all levels, in both high- and low-income environments [1,2], offering health care professionals and students the promise of accessible and flexible learning opportunities, regardless of their location [3,4]. e-Learning can be defined as "an approach to teaching and learning, representing all or part of the educational model applied, that is based on the use of electronic media and devices as tools for improving access to training, communication and interaction and that facilitates the adoption of new ways of understanding and developing learning" [5]. Included in this definition are a multitude of different forms including asynchronous (self-directed) courses, synchronous (live) tutorials and webinars, blogs, podcasts, social media, learning communities and communities of practice, online videos and images, and more. Learners may interact with this content as part of a formal training program, as formal in-service professional development, or at their own volition. e-Learning content is hosted on a variety of platforms of different types—including learning management systems, content management systems, and learning destination sites. In this review, we will refer to all online locations hosting e-learning content as "platforms."

Open access content is "digital, online, free of charge, and free of most copyright and licensing restrictions" [6]. This is of particular importance in resource-limited settings, where open access education has the potential to alleviate persistent educational disparities [7]. The acronym "FOAM" (or "FOAMed," Free Open Access Medical Education) is often used in open access medical education, describing "a dynamic collection of resources and tools for lifelong learning in medicine, as well as a community and an ethos" [8]. As FOAM covers many different types of content, and medical education technologies are quickly evolving, it is difficult to quantify the use of FOAM across the globe and across medical specialties. However, it is clear that there is a lot of FOAM content available, that it is increasingly accepted as a valid medium for medical education, and that it is increasingly used. Taking podcasts as one example, a study looking at podcasts related to a limited set of medical specialties found 169 different English language podcasts with over 6500 combined hours of educational content [9]. Acceptance of podcasts as a medical education tool is growing. While a 2007 study found that most of the US students and physicians surveyed felt podcasts had no role in medical education [10], a 2019 study reported that 71% of residents from various US training programs supported the utility of podcasts [11]. In total, 39% of US nephrology fellows report regularly learning from podcasts [12].

Open access does not, however, mean equal access. Use is higher in high-income countries than in low- and middle-income countries (LMICs) [13], and LMIC learners face additional challenges [14]. A systematic review of e-learning for medical education in LMICs finds that it has "not met its expected potential" in such settings [15]. Even within a single LMIC institution, some learners have greater access than others [16]. Thus, due to these disparities, open access platforms may not in fact fulfill their promise of decreasing pre-existing educational [17], health care, and economic inequalities [18]. This is a profound issue: those most in need of medical education and training information, such as professionals in resource-limited settings, often find it the most elusive [19].

The total number of FOAM sites now seems to be decreasing, as open access medical education resources are increasingly consolidated in a smaller number of platforms [20-22]. Due to the effort and expense involved in producing, maintaining, and hosting e-learning content, it can be expected that this trend will continue; the number of platforms will decrease, yet the volume of content on each platform will increase, compiled from multiple sources. Barriers and enablers to the production and sustainability of e-learning material of various kinds have been described in the literature [23]. This review aims, for the first time, to identify and synthesize from the literature the barriers and enablers to the successful design, production, and operation of e-learning platforms compiling content from multiple sources. In doing so, this review looks to inform efforts to optimize the impact and reach of open access medical education resources.

Methods

Study Design

A scoping review methodology was selected "to 'map' relevant literature in the field of interest," following the framework proposed by Arksey and O'Malley [24]. The protocol was publicly registered on Open Science Framework [25]. Results are reported in line with the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses extension for Scoping Reviews) [26]. The PRISMA-ScR checklist is included as Multimedia Appendix 1.

Research Question

We defined our research question as "What is known in the existing literature about the barriers and corresponding enablers to developing, producing, and maintaining open access medical education platforms containing material from multiple sources?"

Search Strategy

Searches were conducted on April 17, 2023, using PubMed and EBSCOhost, which includes Academic Search Complete, ERIC, and CINAHL Plus with Full text. The search string used was ((resources) OR (material)) AND ((((medical education) OR (training)) AND (((((identify) OR (evaluate)) OR (integrate)) OR (compile)) OR (collect))) AND (open-access)). The SnowGlobe tool [27] was then used for citation chaining (snowballing), automatically retrieving references of included studies as well as studies citing them. Manual reference searching additionally contributed a number of papers. Search results were imported into Covidence (Veritas Health Innovation), and duplicates were removed. Gray literature, such as institutional websites, preprints, and reports, was not searched.

Study Selection

Studies were eligible for inclusion if they described open access medical education or training platforms that curate or compile content from multiple sources or institutions for use by health care providers. To be included, studies also needed to provide information on factors that facilitate or hinder the design, production, implementation, or ongoing operation of such platforms. All paper types, including reviews, were considered. No date restrictions were applied, given the emerging nature of this field. Studies were excluded if they focused solely on a single course or on materials developed by a single institution. Conference abstracts and non-English language studies were also excluded.

All identified papers underwent a 2-stage screening process. In stage 1, a total of 2 authors (AAEA and AB) independently reviewed the title and abstract of each paper against the predefined inclusion and exclusion criteria. Discrepancies were resolved with the input of EPOF. In stage 2, the full texts of potentially relevant papers were assessed for final inclusion by AAEA and AB, with EPOF adjudicating on discrepancies.

Charting the Data

Beginning with an a priori framework of "barriers" and "enablers," the data chart form was then developed through an inductive process, with input from all authors. Following initial immersion in the data, coding for each barrier and enabler was developed. Data from included papers were then independently extracted by AAEA and AB into this form. Any disagreements were resolved through discussion or with the input of EPOF. Finally, the coding for barriers and enablers was reviewed, and minor coding edits were made. To derive practical recommendations for the various stakeholder groups involved in the production, management, and use of open access educational platforms, barriers and enablers were then mapped to the appropriate stakeholder group: (1) learners and training programs, (2) content designers and creators, and (3) platform managers.

Data Synthesis and Reporting

Thematic analysis was undertaken. Once authors were familiar with the data, and coding agreed, themes were then proposed, explained, and clarified through iterative team discussion. Both barriers and enablers were then grouped under these themes, and the themes were reviewed for appropriateness. Descriptive statistics were used to analyze characteristics of the included studies.

Ethical Considerations

The review involved analysis of publicly available secondary data only. No human or animal participants were involved; therefore, ethics approval was not required.

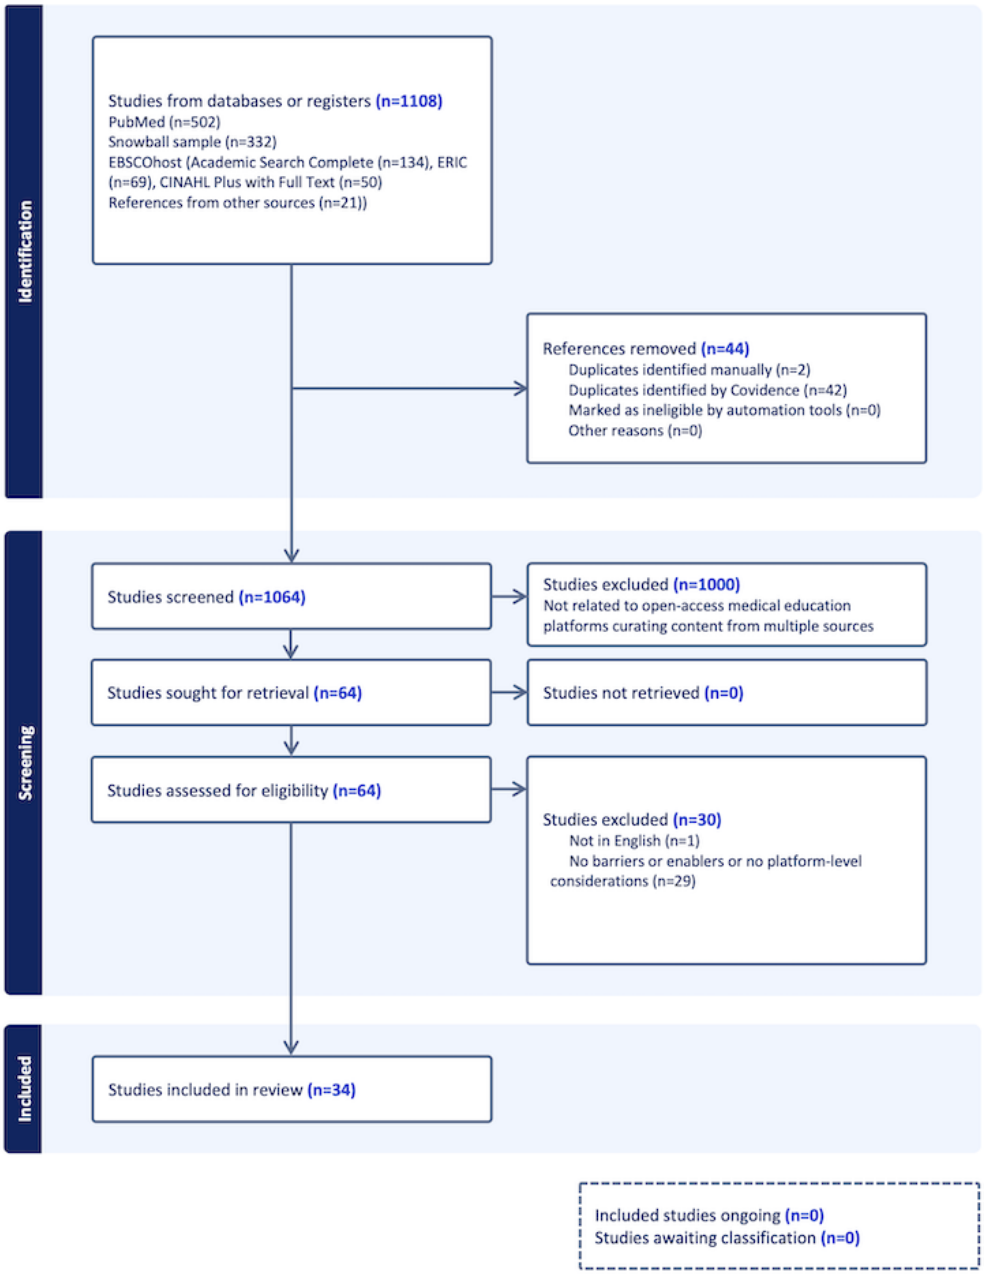
Results

Overview

Our search strategy identified a total of 1108 records from multiple sources. PubMed contributed 502 records, followed by 253 from EBSCOhost databases (including Academic Search Complete, ERIC, and CINAHL Plus with Full Text). Snowball sampling added 332 records, and 21 were identified through manual reference searching. After removing duplicates, 1064 records were screened by title and abstract. Of these, 64 full-text papers were assessed for eligibility.

A total of 29 full-text studies were excluded because, although they addressed open access content, they did not examine barriers or enablers or did not relate to platform-level considerations. Ultimately, 34 studies were included in the final review. The study selection process is shown in Figure 1.

Figure 1. PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) flow diagram.



Characteristics of the Included Studies

All 34 studies described educational resources targeted at doctors or medical students. Nurses were also targeted in 14 (41%) studies, and allied health professionals in 11 (32%) studies. Most studies did not explicitly focus on a particular geography. Some focused on LMICs [2,28], while others were explicitly "global" [29] or "international" [30] in their scope. However, most first authors were based in high-income countries, with a majority from the United States. Other first authors were from Canada, Germany, Belgium, Italy, the United Arab Emirates, the United Kingdom, Australia, Botswana, Papua New Guinea, and South Africa. In total, 16 (47%) studies were categorized as reviews or expert opinion, 11 (32%) were primarily qualitative research, 5 (15%) were primarily quantitative research, and 2 (6%) were reports on educational innovations. While all included studies discussed open access medical education platforms, this was rarely their primary focus. Most included studies focused on e-learning in medical education in general, or in specific medical education and training contexts, or specific topics and specialties, or for specific cohorts of learners. Other studies again focused on the FOAM education movement. Characteristics of the included studies are given in Table 1.

Table 1. Characteristics of included studies.

Author name (year)	Country of first author	Type of study	Platform or context	Barriers	Enablers
Kleinpell et al (2011) [31]	United States	Qualitative research	Early open online nursing education resources (blogs, wikis, repositories); emphasis on discoverability and maintenance burdens.	• Navigability, searchability • Access • Effort and cost to maintain	• Crowdsourced feedback • Interactive content • Tools to help learners find resources • Student-centered, personalized • Content integrated with curricula • Networking of educators • Tools to make content creation easier
Nieder et al (2022) [2]	Germany	Scoping review	Global or LMIC[a]-friendly open resources for medical education (FOAM[b]-style blogs or podcasts, YouTube, mobile-first sites) with attention to bandwidth and language.	• Computer, phone, internet • Time • Language • Access • Digital literacy • Learning culture	• Collaboration for awareness • Social, instructor, and cognitive presence • Learner familiarity • Low bandwidth content • Local language • External pressure • Appropriate content structure • Interactive content • Quality tool • Regular content review
Pizzolato et al (2020) [32]	Belgium	Qualitative study	Open educational websites with structured navigation and mapped content areas to guide learners.	• Incompleteness, lack of structure • Interactivity, design	• Navigable, searchable • Interactive content • Map content areas
Grock et al (2019) [33]	United States	Qualitative research	FOAM resources in emergency medicine; blogs or podcasts and their quality or appropriateness concerns.	• Volume of content • Quality control • Appropriateness of content • Incompleteness, lack of structure	• Quality tool
Schettino and Capone (2022) [34]	Italy	Scoping review	Open platforms used in undergraduate medical curricula; focus on training content creators and interactive, learner-centered design.	• Language • Digital literacy • Learning culture • Motivation • Time	• Local language • Student-centered, personalized • Appropriate content structure • Training of content creators • Interactive content
Bansal (2021) [35]	Australia	Expert opinion	Broad FOAM ecosystem across blogs, podcasts, Twitter, YouTube, and online question banks; strategies to expand reach and impact.	• Navigability, searchability • Interactivity, design • Quality control • Motivation • Learning culture • Effort and cost to maintain	• Collaboration for awareness • Networking of educators • Training of content creators
Regmi and Jones (2020) [23]	United Kingdom	Systematic review	Systematic review of digital or open resources integrated with trainee experience and formal curricula; clarity and structure emphasized.	• Digital literacy • Motivation • Interactivity, design • Appropriateness of content • Incompleteness, lack of structure • Effort and cost to build • Effort and cost to maintain	• Content integrated with trainee experience • Content integrated with curricula • Clarity of content • Student-centered, personalized • Appropriate content structure • Interactive content
Culbert et al (2022) [36]	United States	Review paper	Review of open access educational resources in medicine; integration into curricula and institutional adoption.	• Access • Quality control • Quality tool issues • Effort and cost to maintain	• Collaboration for awareness • Content integrated with curricula

Author name (year)	Country of first author	Type of study	Platform or context	Barriers	Enablers
Rodman et al (2021) [28]	United States	Needs assessment	Needs assessment for OERs[c], preference for locally authored content, and regular review cycles.	• Language • Effort and cost to maintain • Appropriateness of content	• Technological advancement • Local language • Local content creators • Regular content review
Cevik et al (2021) [30]	United Arab Emirates	Expert opinion	Expert guidance on leveraging FOAM or OER with curation and Creative Commons licensing; curated compilations to aid discovery.	• Computer, phone, internet • Awareness • Language • Interactivity, design	• Collaboration for awareness • Curated compilations • Open Access and Creative Commons
Knopf et al (2020) [37]	United States	Descriptive analytical study	Descriptive analysis of learner engagement with open platforms; emphasis on social or instructor presence and tool quality.	• Computer, phone, internet • Language • Learning culture • Quality control • Incompleteness, lack of structure	• Social, instructor, and cognitive presence • Quality tool
Chan et al (2019) [38]	Canada	Expert opinion	Critical appraisal of FOAM resources; encourages structured evaluation frameworks for blogs or podcasts and social media posts.	• Volume of content • Trust • Quality control • Incompleteness, lack of structure	• Learner familiarity • Collaboration for awareness • Peer review, editorial process • Quality tool • Crowdsourced feedback • Map content areas
Cameron and Schofield (2017) [29]	Canada	Review paper	Review of open online medical education with emphasis on ethics, intellectual property, and learner-centered design; recommends low-bandwidth delivery.	• Computer, phone, internet • Learning culture • Motivation • Effort and cost to build • Ethics • Intellectual property	• Low bandwidth content • Content integrated with trainee experience • Clarity of content • Student-centered, personalized • Appropriate content structure • Immediate feedback • Social, instructor, and cognitive presence • Existing ethical guidelines • Open Access and Creative Commons
Lin et al (2016) [39]	United States	Educational innovation report	Approved Instructional Resources initiative; curated, peer-reviewed emergency medicine FOAM blogs or podcasts aligned to curricula.	• Quality control • Quality tool issues • Incompleteness, lack of structure	• Collaboration for awareness • Curated compilations • Free tools for hosting content
Thurtle et al (2016) [40]	Australia	Qualitative research	Qualitative exploration of FOAM awareness and trust; learners relying on local creators and site familiarity.	• Computer, phone, internet • Awareness • Trust • Navigability, searchability	• Learner familiarity • Local content creators
Thoma et al (2015) [41]	Canada	Educational innovation report	Implementation of peer review on a major FOAM blog to improve quality assurance and transparency.	• Expertise of authors • Quality control	• —[d]
Thoma et al (2014) [42]	Canada	Perspective paper		• Trust • Navigability, searchability • Volume of content • Quality control	

Author name (year)	Country of first author	Type of study	Platform or context	Barriers	Enablers
			Perspective on navigating FOAM: curated compilations, mentor-recommended resources, and residency-endorsed lists.		• Tools to help learners find resources • Resources recommended by colleagues, mentors • Curated compilations • Resources recommended by training programs
Alexiou and Falagas (2008) [43]	Greece	Expert opinion	Early expert commentary on open online resources in medical education; calls for better organization and curation.	• Volume of content • Incompleteness, lack of structure • Effort and cost to maintain	• Tools to help learners find resources • Interactive content • Curated compilations
Grock et al (2021) [44]	United States	Observational study	Analysis of FOAM coverage of core curricular topics; identifies gaps relative to competency frameworks.	• Navigability, searchability • Quality control • Incompleteness, lack of structure	• —
Grock et al (2021) [45]	United States	Usability study	Revised Approved Instructional Resources initiative; curated, peer-reviewed emergency medicine FOAM blogs or podcasts aligned to curricula.	• Quality control • Quality tool issues	• Quality tool
Ghiathi et al (2020) [46]	United States	Evaluation study	Evaluation of engagement strategies and tooling that make creating and maintaining open content easier.	• Quality control • Quality tool issues	• Collaboration for awareness • Engagement strategy • Tools to make content creation easier
Misra and Lawson (2019) [47]	United States	Technical report	Technical report on operationalizing open resources; stresses maintenance effort and need for periodic review.	• Incompleteness, lack of structure • Effort and cost to maintain	• Quality tool • Curated compilations • Regular content review
Hsiao et al (2021) [48]	United States	Review paper	Review of topic-focused open resources; supports curated lists and quality tools for better navigation.	• Navigability, searchability • Volume of content • Quality control • Incompleteness, lack of structure	• Quality tool • Curated compilations
Lin et al (2022) [21]	United States	Cross-sectional study	Census of active emergency medicine or critical care FOAM blogs or podcasts; sustainability and trend analysis.	• Dated content • Effort and cost to build • Effort and cost to maintain	• Collaboration for awareness • Content integrated with curricula
Mncube and Mthethwa (2022) [49]	South Africa	Qualitative research	Qualitative study of FOAM in South Africa; emphasizes open licensing and social or instructor presence.	• Awareness • Access • Quality control • Effort and cost to maintain • Ethics	• Collaboration for awareness • Social, instructor, and cognitive presence • Open Access and Creative Commons
Zhang et al (2019) [50]	Canada	Observational study	Observational work on open platform structure and interactivity; highlights the need for quality tools.	• Navigability, searchability • Interactivity, design • Quality control • Incompleteness, lack of structure • Effort and cost to build	• Collaboration for awareness • Technological advancement • Appropriate content structure • Interactive content • Quality tool

Author name (year)	Country of first author	Type of study	Platform or context	Barriers	Enablers
Grabow Moore et al (2021) [51]	United States	Descriptive study	Descriptive account of learner-centered open content design and routine review processes.	• Computer, phone, internet • Time • Quality control • Incompleteness, lack of structure • Effort and cost to maintain	• Student-centered content design • Crowdsourced feedback • Regular content review
Lee et al (2022) [52]	Canada	Economic evaluation	Economic evaluation of creating or maintaining OERs; discusses funding or recognition mechanisms.	• Effort and cost to build • Effort and cost to maintain	• Learner familiarity • Funding and recognition for content creation
Wolbrink et al (2019) [53]	United States	Analytic review	Review of selected open resources for critical care.	• Access • Interactivity, design	• Navigable, searchable • Appropriate content structure • Interactive content • Peer review, editorial process • Quality tool • Regular content review • Map content areas
Shappell et al (2017) [54]	United States	Review paper	Review of FOAM ecosystems; maps content areas, curated compilations, and crowdsourced feedback models.	• Interactivity, design • Quality control • Incompleteness, lack of structure	• Collaboration for awareness • Appropriate content structure • Interactive content • Quality tool • Crowdsourced feedback • Curated compilations • Map content areas
Evans et al (2022) [55]	United States	Cross-sectional study	Cross-sectional study of open resources, processes, and tooling (peer review, quality instruments) across sites.	• Computer, phone, internet • Access • Interactivity, design • Quality control • Quality tool issues • Effort and cost to build • Effort and cost to maintain	• Collaboration for awareness • Interactive content • Peer review, editorial process • Quality tool
Lo et al (2018) [56]	Canada	Expert opinion	Expert commentary on integrating FOAM into formal education; highlights peer-reviewed tools and mentor-curated lists.	• Volume of content	• Resources recommended by colleagues, mentors • Interactive content • Quality tool
Ting et al (2020) [57]	Canada	Literature review	Quality appraisal or assurance techniques for FOAM; proposes methods to evaluate blogs or podcasts and social media content.	• Ethics • Quality control • Ethics	• Content integrated with curricula • Quality tool • Funding and recognition for content creation
Marée (2019) [58]	Belgium	Mini review paper	Mini review on OER or FOAM with focus on maintenance costs and intellectual property; advocates collaboration for awareness.	• Computer, phone, internet • Incompleteness, lack of structure • Effort and cost to maintain • Intellectual property	• Collaboration for awareness

[a]LMIC: low- and middle-income country.

[b]FOAM: Free Open Access Medical Education.

[c]OER: open educational resource.

[d]Not available.

Across the 34 included studies, we identified 127 instances of barriers and 122 instances of enablers. These were coded into 22 unique barriers and 33 unique enablers, and then, mapped to 1 of 3 stakeholder-based themes. A full list of the coded barriers and enablers, and the frequency with which they were identified, is presented in Tables 2 and 3.

Table 2. Frequency and detail of barriers identified.

Barrier name	Barrier detail	Values, n
Theme: learners and training programs		
Learning culture	Lack of learner culture of e-learning, and lack of culture of or dislike of interactive learning	5
Motivation	General lack of motivation and adherence	4
Digital literacy	Lack of learner digital literacy	3
Time	Learners' limited time availability or conflict of priorities	3
Trust	Learners' lack of trust in content, lack of connection to content creators	3
Theme: content designers and creators		
Quality control	Lack of quality control	18
Incompleteness, lack of structure	Material does not equally cover all required learner knowledge areas and is not presented in a logical structure	14
Interactivity, design	Lack of interactivity of resources and poor design	8
Computer, phone, internet	Learners' lack of access to adequate computer, phone, or internet	8
Navigability, searchability	Resources are difficult to find and navigate	7
Volume of content	Overwhelming volume of content	6
Language	Lack of learner competence or comfort in the language of resources	5
Quality tool issues	Issues with quality tools used	5
Appropriateness of content	Content not appropriate for learners' context and level	3
Dated content	Dated content	1
Expertise of authors	Lack of author subject area expertise	1
Theme: platform managers		
Effort and cost to maintain	Human and financial resources required to maintain and update content	13
Access	Restrictions on learner access to material (requirement to register or be a member of certain organizations)	6
Effort and cost to build	Human and financial resources required to develop content	6
Awareness	Learners' lack of awareness of resources available	3
Ethics	Ethical issues	3
Intellectual property	Intellectual property issues	2

Table 3. Frequency and detail of enablers identified.

Enabler name	Enabler detail	Values, n
Theme: learners and training programs		
Curated compilations	Use of curated compilations of resources	7
Learner familiarity	Growth of learner familiarity with and awareness of e-learning and FOAM[a] in general	4
Resources recommended by colleagues and mentors	Recommendations of resources by trusted colleagues and mentors	2
External pressure	External circumstances and pressures	1
Engagement strategy	Production of a learner engagement strategy	1
Resources recommended by training programs	Curation or recommendation of resources by training programs	1
Theme: content designers and creators		
Quality tool	Use of a tool to rate quality of online resources or framework development	13
Interactive content	Interactive content	11
Appropriate content structure	Appropriate content structure (eg, iterative, with learning objectives, using multimedia)	7
Content integrated with curricula	Integration of resources with established curricula	5
Regular content review	Regular content review	5
Student-centered, personalized	Student-centered, personalized learning approach	5
Crowdsourced feedback	Crowdsourced feedback and curriculum development	4
Social, instructor, and cognitive presence	Establishment of a social presence (peers), instructor presence, and cognitive presence (material and assignments)	4
Map content areas	Mapping and categorization of content areas, aiming for comprehensiveness	4
Local language	Content translation into local language	3
Peer review, editorial process	Peer review, editorial process	3
Navigable, searchable	Systematic characterization of resources for navigability and searchability	2
Networking of educators	Networking of educators, sharing best practice	2
Training of content creators	Training of content creators	2
Clarity of content	Clarity of content	2
Content integrated with trainee experience	Integration of content with trainee experience	2
Local content creators	Recruitment of content creators from the same context as learners or launch LMIC[b] platform	2
Technological advancement	General global technological advancement	2
Low bandwidth content	Use of low-bandwidth content where the internet is poor or expensive	2
Immediate feedback	Provision of immediate feedback to learner	1
Theme: platform managers		
Collaboration for awareness	Collaborate and partner with existing content providers or hosts to increase awareness	13
Tools to help learners find resources	Tools to help learners find resources (eg, automatically queued resources and custom search engines)	3
Open Access and Creative Commons	Availability of Open Access and Creative Commons resources	3
Funding and recognition for content creation	Funding and recognition for content creation	2
Tools to make content creation easier	Use of tools to make content creation easier	2
Free tools for hosting content	Use of free tools for hosting content	1
Existing ethical guidelines	Use of existing ethical guidelines	1

[a]FOAM: Free Open Access Medical Education.

[b]LMIC: low- and middle-income country.

Learners and Training Programs

Barriers

Most barriers under this theme related to learner engagement: the lack of an interactive learning culture conducive to self-directed e-learning, particularly in resource-limited settings [2,29,34,35,37]; a lack of trust in content or content creators [38,40,41]; and a general lack of learner motivation and adherence [23,29,34,35]. Practical barriers were a lack of learner digital literacy [2,23,34] and learners' limited available time due to competing priorities [2,34,51]. Barriers under this theme were particularly reported by studies in resource-limited contexts.

Enablers

Some of the barriers found can be expected to be partially addressed by global macrotrends, such as increasing learner familiarity with, and acceptance of, e-learning and interactive learning approaches [2,38,40,52]. Several enablers were reported, which may address challenges of learner trust and motivation—peer-to-peer recommendation of content [42,56], training bodies recommending specific content to their trainees [42], and the use of trusted curated compilations of resources [30,39,42,43,47,48,54]. Other enablers can be leveraged by training programs to increase engagement, such as the development of a formal engagement strategy [46]. External pressure, such as when completion of certain e-learning content is determined to be a mandatory part of a training program, with appropriate deadlines and reminders, was also reported as an enabler [2].

Content Designers and Creators

Barriers

Barriers reported relating to content creation and design included a lack of resource interactivity [23,30,32,35,50,53-55], resources that are difficult to find and navigate [31,35,40,42,44,48,50], and an overwhelming volume of content [33,38,42,43,48,56]. However, the major challenge under this theme—and the most cited barrier in this study—was a lack of quality control, which was identified in the majority of included studies (n=18, 53%) [33,35-39,41,42,44-46,48-51,54,55,57]. Other quality-related barriers reported were problems with quality evaluation tools [36,39,45,46,55], a lack of author subject area expertise [41], and dated content [21].

Incompleteness of content or lack of structure—where material does not appropriately cover all required learner knowledge areas or is not presented in a logical structure—was repeatedly reported [23,32,33,37-39,43,44,47,48,50,51,54,58]. Some topics appear to be covered in detail on multiple platforms, while other topics are seemingly absent. Grock et al [44] describe the "uneven distribution" of open access content as "holes in the FOAM." Content in some cases was also reported not to be at the appropriate level for target learners or not appropriate for the learners' context [23,28,33].

Finally, practical barriers found that can be taken into consideration by content designers and creators were learners' lack of access to adequate equipment and infrastructure such as computers, phones, and reliable internet connections [2,29,30,37,40,51,55,58] and lack of learner competence in the language in which content was provided [2,28,30,34,37].

Enablers

Many of the enablers reported under this theme can be considered general good practice in adult education, such as interactive learning approaches [2,23,31,32,34,43,50,53-56], clarity of content [23,29], the provision of immediate feedback to the learner [29], and student- or learner-centered design [23,29,31,34,51]. The "flipped classroom" was cited as an example of "an interactive learner-centric approach particularly well-suited to the needs of contemporary ... learners" [51]. Gamification was reported as another effective student-centered design approach, as it "represents a way to increase the attractiveness of learning content among students and foster their motivation to participate in the proposed activities" [34]. Other enablers centered on e-learning design, such as the use of an appropriate structure with learning objectives, multimedia, and the employment of an iterative design process [2,23,29,34,50,53,54]. Another reported enabler was the establishment of 3 forms of "presence": social presence (peers), instructor presence, and cognitive presence (material and assignments) [2,29,37,49].

Two enablers reported focused on the development of content creators: the networking and sharing of best practices among educators [31,35] and the training of content creators [34,35]. Bansal [35] proposes faculty development programs to "train a cohort of clinical educators who can drive the creation of FOAM resources." The final enabler under this theme was the systematic characterization of resources for navigability and searchability [32,53].

The most commonly reported enabler to address the issues of content quality was the use of objective, validated content quality evaluation tools to assess the quality of content before publication [2,33,37,38,45,47,48,50,53-57]. Examples given include the "Approved Instructional Resources" tool [45] and the revised "Medical Education Translational Resources: Impact and Quality" tool [59]. Other enablers addressing issues of content quality were the implementation of regular content review [2,28,47,51,53], content peer review as part of a transparent selection and evaluation process [38,53,55], and crowdsourced feedback [31,38,51,54].

Two enablers under this theme focused on ensuring that content was appropriate for the target learner's level and context: the recruitment of content creators from the same context as targeted learners [28,40] and the integration of learners' experience into content [23,29]. Integration of resources with established curricula [21,23,31,36,57] was reported as a means to ensure both content appropriateness and comprehensiveness. Mapping and categorizing content areas [32,38,53,54] were reported as a way to identify content area gaps and thus enable the production of more complete and comprehensive learning resources.

Where the internet connection of the target learner population is likely to be expensive or of poor quality, ensuring content is not bandwidth-intensive was an identified enabler [2,29]. In such contexts, Nieder et al [2] propose "[p]roviding access to

course media such as video content in lower resolution and downloading course materials for offline usage in places with a better connection." The global spread of technology and improvements in internet speed can also be expected to enable greater access over time [28,50]. Learner participation was reported to be facilitated by translation of content into local languages [2,28,34].

Platform Managers

Barriers

Barriers found, which can be addressed by platform managers, include learners' inability to access content due to requirements to register or be a member of an organization [2,31,36,49,53,55]. Lack of learner awareness of available resources [30,40,49] can also be addressed by platform managers.

A number of barriers to the long-term sustainability of open access platforms were reported—most commonly, the resources and efforts required to maintain and update content [21,23,28,31,35,36,43,47,49,51,52,55,58]. Lin et al [21] note that open access medical education platforms originated from "volunteers providing free education to all who wish to learn. This volunteerism comes at the expense of opportunity costs and may have been unsustainable for many sites that no longer exist." The direct costs of content development are also a notable barrier [21,23,29,50,52,55]. Barriers that were reported related to intellectual property [29,58], included questions over the legality of the common practice of reproducing content from journal papers [29]. Ethical concerns, such as the deliberate sharing of incorrect information, bullying on social learning spaces, and the unethical appropriation of material, were also raised [29,49,57].

Enablers

Collaboration between content providers and platforms was repeatedly reported as an enabler, in order to make resources available on highly visible platforms, thus addressing a lack of learner awareness of these resources [2,21,30,35,36,38,39,46,49,50,54,55,58]. Several relatively simple technological enablers were also found. Where cost is a barrier, the use of free tools [39], such as Google Drive for content hosting, was reported as an enabler. User-friendly content creation tools were reported to reduce the effort required to produce resources [31,46]. Incorporation of tools into platforms, such as custom search engines to help learners find resources [31,42,43], was proposed to address barriers around awareness, searchability, and navigability.

Financial support and academic recognition for content creation were seen to enable the long-term effort required of content creators [52,57]. The use of Creative Commons licenses to clarify the legal status of content was reported as an enabler to address intellectual property–related barriers [29,30,49]. Users are free to retain, reuse, revise, remix, and redistribute the content (the 5Rs) under Creative Commons licenses, which have a range of openness depending on how many of the 5Rs are allowed to the user. Mncube and Mthethwa [49] consider that "Once such [Open Access Educational Resource] common laws are well established in faculty ... collaboration ... will continue to grow unviolated." One study reported the use of existing ethical guidelines as an enabler [29].

Discussion

Principal Findings

As has already been seen in the specialties of emergency medicine and critical care [21], it seems likely that open access medical education resources in other areas and specialties are becoming increasingly consolidated in a smaller number of larger online platforms. Such compilations of open access medical resources have the potential to improve the learner experience by offering a "1-stop shop," where learners are confident that they can find easy-to-use, quality-assured, up-to-date, comprehensive learning resources appropriate for their context.

Our review finds numerous barriers reported to the design, production, and operation of such platforms. The literature also shows that there is much that open access content designers, authors, and platform administrators can do to address these barriers; and indeed, there is much that can be done by training programs and learners themselves. We can reasonably expect that some of these barriers will diminish in severity over time. Some of the practical barriers identified, particularly in resource-limited settings [2], will partially be addressed by improving internet connectivity, while growing learner familiarity with interactive online learning methodologies can be expected to partially address some of the cultural and motivational barriers.

The 3 most cited barriers in this review were a perceived lack of content quality control, incompleteness of content, and concerns that the demand on human and financial resources required to maintain and update content are unsustainable.

While informal peer and expert recommendations of resources may be helpful, neither learners nor experts are consistently able to make an accurate "gut feeling" appraisal of the quality of online educational resources [60]; therefore, informal recommendation of resources alone may not suffice as a quality control measure. Objective, validated content quality evaluation tools such as the "Approved Instructional Resources" tool [45] or the revised "Medical Education Translational Resources: Impact and Quality" tool [59] should be routinely used by content creators and open access platform curators.

Where e-learning content is targeted at students or trainees in formal training programs, such content should be integrated with learners' other educational activities, rather than existing apart from them. The connection between content and curricula should be made clear and explicit through a mapping of content to appropriate established curricula. Training programs should identify appropriate open access resources, which fulfill the requirements of their curricula and should guide their students and trainees toward them. The curation of content into platforms, and the linking of content and curricula, will make clear which training needs are met and which are not met by currently available open access content. Identification of content area gaps will reduce duplication of effort and allow "holes" [44] in

open access medical education content to be filled by appropriate content.

The barrier presented by the human and financial resources required to maintain and update content is the least amenable to the solutions found in this review. Enablers addressing the sustainability of human resources, such as paying content creators, may negatively impact the financial sustainability of such platforms. Cost and effort may be contained to some degree by the enablers identified in this review; however, creating, hosting, and updating high-quality content will continue to cost money and require significant effort. Hosting content on curated platforms, such as the United Nations Global Surgery Learning Hub [61] and OpenCriticalCare [62], which are free for both content providers and learners, may address some of the issues associated with long-term hosting of content as well as partially address issues of quality control and trust. Ultimately, the value of material and platforms will have to be acknowledged for the associated costs to be met.

Comparison With Prior Work

This review differs from prior published work by focusing on open access e-learning platforms compiling content from multiple sources, whereas previously published literature has predominantly focused on specific courses and cohorts. Many of the barriers and enablers identified relating to platforms have previously been found in studies of individual courses, and meta-analyses relating to e-learning in health sciences in general [23] and e-learning in medical education in LMICs [15].

These include learner motivation and familiarity with e-learning, incompleteness and inappropriateness of content, and challenges in maintaining and updating content. In LMICs, basic challenges in getting online were highlighted [15]. Enablers related to all of these barriers were similar to those found in this study. Some challenges related to courses are not applicable to platforms. Barteit et al [15] found a preponderance of pilot or small-scale e-learning interventions for resource-limited settings that never produced content at scale. De facto compilations of medical education contain significant volumes of content.

This study found the financial sustainability of open access medical education compilations, and the sustainability of the level of effort required, to be challenges with few straightforward solutions. This concern is echoed throughout the broader literature on open access medical education. Lee et al [52] calculated the median overall value of a FOAM website to be US $22,815 and concluded that there is “substantial value being generated from these resources and ... this should be recognized by academia.” Platform costs will either have to be met by funding from academic institutions and funding bodies or by charging fees—to content providers, to learners in high-income settings, to training programs, or for learners to access “premium” content. Lin et al [21] found that the majority of the 109 FOAM sites that they analyzed generated income, with 18% embedding advertisements; 27.5% asking for donations or payment for merchandise, continuing medical education credits, books, or web-based courses; and 44% being affiliated with a sponsoring institution, such as a professional society, hospital, or journal. Lee et al [52] draw parallels between the FOAM movement and the open access publication movement, noting that in making publications available open access, publishers shifted the cost from the content consumer to the content producer. They note that grant funding mechanisms exist to fund these publication costs and call for similar support for medical education content creation. Mncube and Mthethwa [49] quote an unnamed academic, “When we write and publish the research articles or book chapters we are incentivized, however in the development of [open access resources], there are no incentives.” Where it is not possible to fund content creators, and until more sustainable models are developed, greater acknowledgment and recognition of content creators and others involved in this work may be a simple way to help sustain their motivation.

Two important barriers found relating to compilations of medical education resources, that were either not discussed or not given prominence in the literature on individual courses, are issues of trust and language. It may simply be that analyses at a course level exclude potential learners who either do not trust the content or are not comfortable learning in the course language of instruction—they would never take the courses in the first place. We found that managers of such platforms aspiring to make content sourced from multiple different institutions available to a global audience must give much higher priority to issues of trust and language than content creators may have previously done. We found several means by which platform managers can build trust—most prominently, the transparent use of objective, validated content quality evaluation tools. Translation of content into appropriate languages was found to be a key enabler.

Recommendations for Future Research

In addition to mapping existing literature, future empirical research should include systematic surveys of open access platform websites and interviews with their developers to provide deeper insight into their design, governance, and real-world implementation. There is a notable lack of longitudinal research evaluating the lasting impact of open access medical education platforms. Additionally, limited evidence exists on the structured integration of these resources into formal medical training programs. Sustainable models—particularly those detailing financial and operational strategies for the long-term maintenance of such platforms—are also rarely published.

Implication of Findings

This review identifies from the literature actions that each stakeholder group can take to improve open access medical platforms and increase their impact. Recommendations are summarized in Table 4.

Table 4. Recommended actions for stakeholder groups.

Stakeholder group	Recommended actions
Learners	• Use trusted curated compilations of resources • Peer-to-peer recommendation of content
Training programs	• Recommend specific content on curated compilations of resources to learners • Require learner completion of certain content, with deadlines • Develop a formal learner engagement strategy
Content designers and creators	• Evaluate the quality of educational content using validated evaluation tools • Share best practices among educators and content creators • Recruit content creators from the same context as targeted learners and integrate learners' experience into content • Provide low-bandwidth and downloadable resources for learners with poor or expensive internet connectivity • Map and categorize new and existing content to ensure new content fills gaps rather than duplicates existing content • Integrate new resources into established curricula • Combine self-directed cognitive learning with peer interaction and instructor presence • Adhere to best practices in adult education, including interactive learning and learner-centered approaches, and the provision of immediate feedback • Translate content into appropriate languages
Platform managers	• Use Creative Commons licenses to clarify the legal status of content • Host content on open access platforms and use free tools to reduce costs • Enhance navigability and searchability with custom search tools and other tools • Formally recognize the contribution of content creators

Limitations

Only studies published in English were included, which may introduce language bias and limit the representation of perspectives from non-English–speaking regions. Furthermore, the majority of included studies originated from high-income countries, potentially narrowing the cultural and economic contexts considered. We recognize the possibility of funding bias influencing the evidence base. The exclusion of gray literature may also have led to the omission of relevant nonindexed reports or institutional documents. Changes in medical education technology are fast-paced, and the literature necessarily lags behind changes in learner behavior. Nevertheless, this review establishes a foundation for future research, implementation, and policy development in the field of open access medical education.

Conclusions

Open access medical education has the potential to add significant value to preservice and in-service medical education worldwide. However, numerous challenges are preventing open access medical education platforms from achieving their potential, particularly a lack of content quality control, incompleteness of content, and the challenge of sustaining the necessary human and financial resources.

Ultimately, if open access medical education is to achieve its potential, much greater coordination and collaboration on a global scale is required—between learners, educational institutions, content creators, and platform managers.

Authors' Contributions

All authors contributed to the design of the study. AAEA conducted the search, and AAEA and AB independently undertook each stage of the screening and extraction process, with discrepancies resolved by EPOF. All authors contributed to interpreting the data as well as drafting and reviewing the manuscript. All authors have approved the submitted manuscript and agree to be accountable for all aspects of the work.

Conflicts of Interest

None declared.

Abstract

Artificial intelligence (AI) has the potential to transform medical training through adaptive learning, immersive simulations, automated assessments, and data-driven insights, offering solutions to persistent issues such as high student-to-faculty ratios, overcrowded classrooms, and limited clinical exposure. Globally, many universities have already embedded AI literacy and competencies into undergraduate, postgraduate, and continuing education programs, while in Vietnam, the use of AI in medical education remains limited and fragmented. Most students have little formal exposure to AI, and empirical evidence on faculty or institutional readiness is scarce. Experiences from other countries, including Malaysia, Palestine, and Oman, demonstrate that incremental adoption and faculty development can facilitate cultural acceptance and curricular innovation, providing useful lessons for Vietnam. At the same time, significant barriers remain. These include inadequate infrastructure in provincial universities, low levels of AI literacy among both students and educators, underdeveloped regulatory and ethical frameworks, and resistance to pedagogical change. Cost-effectiveness and sustainability are additional concerns in a middle-income context, where upfront investments must be balanced against long-term benefits and equitable access. Advancing AI in Vietnamese medical education will therefore require a coordinated national strategy that prioritizes infrastructure, AI literacy, faculty development, quality assurance, and sustainable funding models, alongside ethical and legal safeguards. By addressing these key foundations, Vietnam can harness AI not only to modernize medical education but also to strengthen preparedness for a digitally enabled health workforce.

KEYWORDS

artificial intelligence; medical education; Vietnam; digital transformation; adaptive learning; virtual simulation; curriculum innovation; educational technology

Introduction

The rapid development of artificial intelligence (AI) technologies is transforming numerous industries, including the field of education. The last few years have witnessed significant potential for AI to enhance the way knowledge is delivered, tested, and learned at every level of education, from common learning spaces to highly technical fields such as medical training. AI applications in medical education range from personalized learning systems, automated evaluations, and virtual simulated patients to complex decision-support systems that enable clinical thinking and learning for diagnosis [1-3]. These developments align with broader patterns across the health care industry, where innovations backed by AI technology are increasingly being integrated into clinical practice workflows and diagnostic systems [4,5].

Globally, several countries possessing robust health and education systems have actively incorporated AI into their medicine curricula. These cross-disciplinary programs embed AI competence and proficiency within undergraduate, postgraduate, and continuing education courses [6,7]. It is seen through scoping reviews that learning enriched by AI can potentially maximize learning efficiency, clinical preparedness, and adaptability to real-world medical problems [8,9]. A significant case is that of the Icahn School of Medicine at Mount Sinai, which in 2025 announced a full roll-out of ChatGPT Edu, a partnership with OpenAI for use in advancing education, research, and innovation for its programs [10]. All of this can be enabled only through robust infrastructure, long-term funding, and an innovative culture that supports transformational curricula and technology infusion.

In comparison, Vietnamese medical training is confronted by unique context-related issues. The pedagogical model remains

strongly traditional, and hospital-based clinical attachments and didactic lectures dominate the learning environment. Limited digital infrastructure, uneven readiness among faculty members, and the shortage of national guidelines for integrating AI further limit innovation in teaching [11,12]. In addition, the disparity between AI development and pedagogical implementation is increasing across most low- and middle-income countries, and there are fears over learning inequity and readiness for the digital health workforce [13,14]. These inequalities explain the necessity to study the use, perception, and regulation of AI in Vietnamese medical education today.

Despite the significant focus on AI within international medical education, empirical research on preparedness, acceptance, and implementation of AI in the Vietnamese context is scarce. A study using a survey among pharmacy and medical students from the south region of Vietnam found that nearly all students had no idea what AI is and what it can do for health, while almost 80% thought it would be useful for their professional development [12]. There is a striking shortage when it comes to research on faculty members, institutional decision-makers, and policy-level interactions, but preparedness evaluations for AI within Vietnam's health care system have identified issues ranging from limited sociopolitical support to inadequate information infrastructure [15]. This lack of data makes it difficult for evidence-based planning and for congruence between technological progress and reality within education (Textbox 1). In addition, although the global discourse on AI in medical education is expanding rapidly, Vietnam has received little scholarly attention despite its unique challenges of limited infrastructure, high student-to-faculty ratios, and uneven policy development. This viewpoint aims to address this gap by synthesizing existing literature on the use of AI in medical education, with a specific focus on the opportunities and challenges of integrating AI into Vietnamese medical education. This is intended for medical educators, institutional leaders, and policymakers who are navigating digital transformation in health professions training. We suggest that AI could play a key role in solving persistent issues such as overcrowded classrooms, limited clinical training opportunities, and unequal access to learning materials. However, several barriers stand in the way, including underdeveloped infrastructure, a general lack of digital and AI literacy, unclear ethical and legal frameworks, and hesitation around changing traditional teaching methods. Drawing on global developments, current research, and our own professional experience, we believe Vietnam needs a strategic, inclusive plan to integrate AI. This should focus on upgrading infrastructure, equipping both teachers and students with the necessary skills, reforming curricula, and establishing national-level guidelines. With the right approach, AI could not only bring Vietnamese medical education into the digital age but also help build a future-ready health workforce.

Textbox 1. Gaps in the literature on artificial intelligence (AI) in medical education in Vietnam.

Although artificial intelligence (AI) is gaining momentum in global medical education, current literature reveals critical gaps in the Vietnamese context that hinder evidence-based planning and risk misalignment between technological advances and educational realities.

Lack of empirical research in medical education

- Most existing studies on AI adoption focus on general higher education institutions rather than health professional training [11,13].

Absence of national data on institutional readiness

- There is limited insight into how medical schools and policy stakeholders perceive or plan for AI integration [15,16].

Low AI literacy among health care students

- A cross-sectional study found that 92.2% of students in southern Vietnam had no understanding of AI in health care, and 70.6% had never received formal instruction on the topic [12].

Fragmented and small-scale initiatives

- Although programs such as the Fulbright-Google collaboration [17] show promise, they are isolated efforts and are not embedded in national medical curricula.

The gap between clinical AI use and educational application

- While AI is being introduced in Vietnamese health care [14], there is a lack of studies on its application in teaching, assessment, or simulation-based learning in medical education.

Characteristics of Medical Education in Vietnam

The Vietnamese system for training doctors has distinctive features at the structural and organizational level that are significantly different from high-income countries. There are about 30 universities across the country that offer undergraduate and postgraduate training for health sciences. A 6-year undergraduate program is typically completed by medical students to obtain a general medical doctor degree (MD, General Doctor).

Vietnamese teaching hospitals host, apart from undergraduate trainees, numerous other groups of learners simultaneously, including residents (Resident), master's students (Postgraduate student, Master), and candidates for Specialty Level I and II (Specialist Level I Doctor, Specialist Level II Doctor), all of whom require clinical experience in the same health care facilities.

This diversity and volume of learners place significant pressure on the teaching infrastructure. Hospital clinical sites are often stretched not only by patient care demands but also by educational requirements. The student-to-patient ratio is generally low, which reduces opportunities for hands-on practice, case-based discussions, and guided clinical reasoning [18].

Moreover, many faculty members manage multiple roles, including classroom instruction, clinical supervision, and full-time medical duties, which results in fragmented teaching time and limits the capacity for educational innovation [11,12].

Opportunities for AI in Vietnamese Medical Education

Lessons from global best practices highlight how AI can be adapted to resource-constrained settings similar to Vietnam. In Malaysia, pilot programs for AI literacy in medical schools have emphasized curriculum integration at the undergraduate level while addressing cultural resistance through faculty workshops [19]. A recent study conducted in Palestine reported high levels of AI adoption among medical students, with frequent use of tools such as ChatGPT (OpenAI) and virtual simulators. Students indicated that these technologies supported their academic performance and research productivity, particularly in tasks such as literature review and data analysis. Notably, students highlighted AI's usefulness in improving time management by automating repetitive academic tasks, thereby enhancing overall efficiency [20]. A study from Oman reported that medical students demonstrated a moderate level of readiness to adopt AI as they transitioned into their clinical training years. ChatGPT emerged as the most frequently used AI tool, and notable differences in attitudes were observed between students with higher technological proficiency and those with limited digital skills. The authors emphasized that medical schools should integrate AI into their curricula to better prepare students for future clinical practice [21]. These experiences demonstrate the value of incremental implementation, regional collaboration, and leveraging domestic innovation ecosystems. For Vietnam, adapting such strategies could mean initiating AI pilots at a small number of universities, gradually expanding to provincial schools, and fostering partnerships with both local startups and global technology firms. This phased approach would ensure that AI adoption is context-sensitive, financially feasible, and culturally acceptable.

Personalized Learning Experiences

AI facilitates the shift from 1-size-fits-all instruction to personalized teaching that adapts to the unique needs of each student. AI-powered adaptive learning systems continuously evaluate students' progress using diagnostic tests and real-time performance monitoring. These systems can then dynamically adjust how content is delivered, providing remedial modules for those who need extra help with specific topics or accelerating the pace for advanced learners [22-24].

In Vietnam, where medical schools often struggle with high student-to-teacher ratios, such systems can play a vital role in improving educational equity. For example, though not yet widely adopted, AI-based platforms have demonstrated how they can deliver tailored feedback and interactive learning content for medical students [1]. In a recent survey of health care students in Vietnam, over 80% said they were willing to use AI tools to aid their studies, yet more than 90% had never actually used such technologies [12].

In addition, AI can be a valuable asset for students learning in English by offering translation, summarizing complex medical texts, or providing culturally relevant explanations. Chatbots such as ChatGPT or the Medical Pathways Language Model can act as around-the-clock learning companions, helping students understand difficult topics, review for exams, or practice clinical thinking through interactive questions-and-answers simulations [25].

Enhanced Clinical Simulations

One of the most significant applications of AI in medical training is the use of clinical simulations combined with virtual reality, augmented reality, and natural language processing. These technologies can recreate high-stakes medical scenarios such as cardiac arrest, trauma response, or neonatal resuscitation, allowing students to make diagnostic and treatment decisions in a risk-free environment [26,27].

For example, AI-powered virtual patient platforms such as SimX (XR technology) and Body Interact (Take the Wind) offer students the opportunity to repeatedly practice, experience different case scenarios, and receive real-time feedback. These tools are designed to sharpen both psychomotor and cognitive skills, which are crucial for developing clinical competency [28,29]. In Vietnam, where access to real patient cases, particularly in rural training institutions, may be limited, such simulation-based learning can help fill crucial gaps in clinical exposure.

In addition, AI that uses the power of large language models (LLMs; advanced AI systems trained on vast amounts of text data, capable of generating human-like responses in natural language) can serve as a private coach to improve medical students' soft skills. For example, the Artificial Intelligence Medical History Evaluation Instrument (the University of Arizona), an AI coaching tool developed by the Arizona Simulation Technology and Education Center, has been designed to enhance the communication skills of medical students. This system analyzes data from medical interviews conducted between students and patients, offering comprehensive evaluations of their interpersonal communication and medical competency skills. Assessment and feedback are provided according to guidelines from various organizations, including the Liaison Committee on Medical Education, the American College of Surgeons, and the World Health Organization. Owing to its automated nature, this technology provides significant opportunities for personalized coaching and can transform medical education in terms of time efficiency and cost-effectiveness. This technology may also be applicable in terms of scalability and broader access, which can be adapted to various medical education settings, including those in low- and middle-income countries.

AI also makes it possible to adjust the complexity of simulations based on a student's performance. For instance, a student who successfully manages a simulated sepsis case might be presented with a more challenging case next time, one involving comorbid conditions or rare complications, following a mastery learning approach supported by AI [30].

Efficient Administrative Processes

AI's role in medical education goes beyond classroom instruction—it can also help resolve administrative challenges that are common in Vietnamese medical schools. For example, machine learning–based scheduling tools can streamline the creation of rotation timetables, classroom assignments, and faculty schedules. Software such as TimeTabler (October ReSolutions Limited) uses smart algorithms to handle logistical tasks that would otherwise demand extensive manual effort [31]. International experiences show that such systems can reduce scheduling conflicts dramatically and allow faculty to dedicate more time to teaching and mentoring.

AI also plays a role in assessment. It can be used to grade objective structured clinical examinations, multiple-choice questions (MCQs), and even written answers using natural language processing. Automated grading not only delivers faster feedback but also helps reduce human bias. Research shows that LLMs can support educators by generating standardized, objective structured clinical examination cases and evaluation rubrics. These AI tools can even benchmark student performance against expert evaluations [32,33]. In Vietnam, where faculty members often juggle teaching responsibilities across multiple institutions, such automation could reduce workload and improve consistency in student assessment.

Language processing capabilities allow AI tools to use LLMs to address issues related to medical education assessment. One particular domain that could significantly benefit from the application of LLM-based AI tools is the creation of MCQs for medical examinations. A multinational prospective study assessed the ability of ChatGPT to generate high-quality MCQs compared to university professors using standard medical textbooks [34]. The study showed that for the task of generating 50 MCQs for the graduate medical exam, ChatGPT took approximately 20 minutes, while professors took over 200 minutes. The analyses showed no significant differences in overall quality between MCQs generated by ChatGPT and by humans. This finding suggests that ChatGPT can produce MCQs of comparable quality to those generated by humans in a significantly shorter amount of time. It is important to note that since the publication of this study, more sophisticated LLM models with advanced reasoning capacity, including GPT-4 or GPT-5 (advanced LLMs developed by OpenAI), have been released by OpenAI, potentially outperforming the older models in such language processing tasks. Given that these models can be accessed via the application programming interface, tools that allow different software systems to communicate with each other—for example, enabling an educational platform to integrate AI functions—can automate this process without the need for manual input. Several tools using this approach have been developed, including Questgen (QuestgenAI Inc) or NoteGPT (NoteGPT AI Inc).

In Vietnam, where faculty members often juggle teaching responsibilities across various institutions or departments, automation like this can significantly lighten their load, giving them more time to focus on teaching and mentoring students.

In addition, predictive analytics powered by AI can help universities identify students who are at risk of failing based on their behavior and academic performance. This allows for timely intervention and support. Such tools are especially helpful in the competency-based education model that is gaining ground in Vietnamese medical training. International evidence supports the use of machine learning techniques such as k-nearest neighbors and exam performance predictors—to flag students who may need extra help [35,36]. In Vietnam, where competency-based education is being introduced, these systems could be integrated into student tracking to ensure timely support and reduce attrition. By combining automation with predictive tools, AI has the potential to not only ease administrative burdens but also strengthen educational outcomes through early intervention.

Data-Driven Decision-Making

AI can analyze large sets of educational data to support quality improvements in medical education. For instance, when integrated into learning management systems, AI can monitor things such as student engagement, quiz scores, and participation in discussion forums. This type of data can help educators identify which parts of the curriculum are not working well, pinpointing specific modules or concepts that consistently challenge students [37]. In other countries, AI-powered dashboards have been used to redesign underperforming modules, improve exam blueprints, and assess the impact of new teaching methods, demonstrating clear benefits for curriculum quality assurance [38,39].

At the broader institutional level, AI can aid in accreditation and quality assurance by generating detailed dashboards that track metrics such as student learning outcomes, faculty performance, and the success of graduates. These insights can help academic leaders—such as deans and curriculum planners—make well-informed decisions about curriculum updates, faculty development, and student support systems [40,41].

In Vietnam, where a national competency-based medical education framework is in development, AI could play a crucial role. It can help map student progress against national competency standards and produce standardized performance reports across various medical schools [12].

An additional opportunity emerges from Vietnam's health care digitization initiatives. With all hospitals nationwide mandated to implement electronic medical records by September 30, 2025 [42], medical schools will soon be connected to richer clinical data environments. This creates the possibility of linking students' performance in clinical rotations with electronic medical records-based outcomes, allowing education to be evaluated alongside real-world patient care. Such integration

could establish a feedback loop that improves both medical training and health care delivery.

Finally, AI-powered decision support systems can also assist policymakers by aggregating anonymized student and institutional data to forecast workforce needs. Predictive models could estimate shortages in specific specialties or geographic areas, ensuring that Vietnam's medical education system aligns more closely with national health priorities. In a context where disparities in health care access remain significant, the use of data-driven decision-making could guide not only academic reform but also broader strategies for building an equitable health workforce.

Challenges in Implementing AI in Vietnamese Medical Education

Table 1 summarizes the contrast between international adoption of AI in medical education and the Vietnamese context, highlighting the structural, educational, and policy gaps that shape the challenges discussed (Table 1).

Table . Comparison of artificial intelligence (AI) integration in medical education: international versus Vietnam.

Dimension	International context	Vietnamese context
Curriculum integration	Many universities embed AI[a] literacy and competencies into undergraduate, postgraduate, and continuing medical education programs [43].	No national AI curriculum, minimal exposure, and most students report no formal training in AI in health care [12].
Infrastructure	Robust digital platforms, simulation centers, and cloud-based tools are widely available, with strong institutional investment [29,43].	Limited infrastructure, particularly in provincial schools and outdated labs, and poor internet continue to hinder AI adoption [11,16].
Faculty readiness	Faculty development programs in AI pedagogy and interdisciplinary teaching are increasingly common [6].	Faculty often lack AI knowledge, have limited training opportunities, and have a heavy clinical workload that further limits innovation [12,14].
Policy and regulation	Clearer data protection and AI ethics frameworks in regions such as the European Union and the United States [44].	A national AI strategy exists, but there are no specific laws for AI in education or student data protection.
Student exposure	Widespread use of AI tools for adaptive learning, automated assessment, and clinical simulation [1,22-25].	Over 90% of health care students have never used AI in their studies, despite high interest [12].
Cultural acceptance	Increasingly normalized as part of digital transformation in education [45].	Skepticism and resistance among faculty and uneven acceptance across institutions.

[a]AI: artificial intelligence.

Limited Awareness and Understanding

A major obstacle to integrating AI effectively into Vietnamese medical education is the widespread lack of knowledge and basic understanding among both students and educators [12]. While discussions about AI in health care are growing globally, many medical trainees in Vietnam are still unfamiliar with its core concepts and practical applications. According to a 2023 cross-sectional study, 92.2% of health care students in southern Vietnam reported having no understanding of how AI works in health care, and 70.6% had never received any formal education on AI-related topics [12]. These figures highlight a significant educational gap and point to an urgent need to introduce AI literacy into the medical curriculum. The urgent call for this integration has also been sparked in Malaysia, a country located in the same geographic area as Vietnam, where unreadiness for AI has been reported widely among medical students [46].

Moreover, most medical schools in Vietnam still rely heavily on traditional, lecture-based teaching methods and have limited integration of digital tools. Without structured exposure to AI, whether through dedicated coursework, hands-on workshops, or interdisciplinary collaboration with departments such as data science, future health care professionals may lack the skills needed to use AI tools responsibly or interpret AI-generated clinical data. This lack of preparation not only hampers the adoption of AI in training but also raises long-term concerns about the quality of health care delivery as AI becomes increasingly embedded in global medical practice.

Infrastructural Constraints

The effective integration of AI in medical education relies heavily on a strong technological foundation. This includes dependable high-speed internet, access to cloud computing, up-to-date hardware, and specialized software. Unfortunately, many medical schools in Vietnam, especially those in rural areas or linked to lower-tier universities, face significant infrastructure challenges. Common issues such as limited budgets, outdated computer labs, and a lack of technical support continue to obstruct the adoption of AI-powered learning tools [11,15,16].

As of now, no medical university in Vietnam has officially developed or launched an AI-based curriculum tailored to medical training. The digital divide between urban and rural institutions further exacerbates the issue, highlighting both a lack of preparedness and a deep educational disparity.

Globally, research shows that while AI is making strides in medical education in well-funded regions, many low- and middle-income countries lag due to insufficient infrastructure, a shortage of trained faculty, and limited institutional readiness

[2,47]. These international gaps are mirrored within Vietnam, where centrally located universities may have the means and partnerships to explore AI, whereas many provincial medical schools simply lack the resources and expertise to do so.

Without unified national investment and clear policy direction to support digital transformation across all levels of medical education, AI advantages risk being confined to a few elite institutions, ultimately undermining efforts to build a fair and forward-looking health care workforce for the entire country.

Quality Assurance, Ethical, Legal, and Policy Challenges

Ensuring the quality, validity, and reliability of AI-assisted assessment is critical in medical education, where evaluation outcomes have direct implications for patient safety and professional competency [48]. Although AI shows promise in automating grading and generating exam content, risks remain regarding algorithmic bias, variability, and transparency [49]. To safeguard assessment integrity, AI-generated items and evaluations should undergo external expert review and be pilot-tested before use in high-stakes examinations. Institutions should adopt national or regional standards for AI-assisted evaluation, ensuring consistency across medical schools. Moreover, regular audits of AI performance against human benchmarks are needed to detect errors or unintended biases. Establishing clear oversight mechanisms will be essential for building trust in AI-enhanced assessments and protecting both educational and professional standards [50].

The use of AI in education also brings forward a range of ethical challenges, especially around data privacy, informed consent, fairness in algorithms, and transparency. Many AI systems rely on collecting and analyzing extensive data such as student performance, learning habits, and, in some cases, biometric or voice information. AI-powered proctoring tools used during online exams can record facial movements, keystrokes, and background activity. While these tools are meant to prevent cheating, universities have faced student protests and lawsuits due to concerns about surveillance and data misuse. Without strong legal or institutional safeguards, there is a real risk of similar issues in Vietnam, where institutional data governance remains underdeveloped and student privacy could easily be compromised [51].

A significant concern is algorithmic bias. If an AI system is trained on unrepresentative data or lacks clear decision-making criteria, it may unfairly evaluate students. This is especially troubling in high-pressure fields such as medical education, where skewed assessments could influence a student's confidence, academic progress, or even future career opportunities [2,52]. The lack of transparency in how these algorithms operate makes it even harder to hold them accountable.

As of 2024, Vietnam does not yet have a solid legal framework to govern the use of AI in higher education; it is important to situate this gap within the country's broader digital transformation and health policy agenda. In 2020, the government launched the National Digital Transformation Program to 2025 with orientation to 2030, which identifies health care and education as 2 priority sectors for digital innovation [53]. The program calls for the adoption of digital platforms, cloud-based services, and data-driven management tools in universities and hospitals, laying a foundation that could facilitate the integration of AI into medical training.

Similarly, the Ministry of Health has advanced health care digitization initiatives under the "Smart Health" and National Health Digital Transformation plans [54], focusing on electronic medical records, telemedicine, and health information systems. According to recent regulations, all hospitals nationwide are mandated to implement electronic medical records by September 30, 2025 [42]. While these initiatives primarily target clinical service delivery, they create data ecosystems and digital infrastructure that could be leveraged for AI-driven medical education, especially in areas such as simulation, case-based training, and competency tracking.

Although early-stage policies have been suggested under the national AI development strategy, no specific laws are in place to address data protection, algorithmic responsibility, or the ethical role of AI in classrooms [16]. This gap raises pressing concerns about how institutions and regulators should manage these technologies responsibly.

Finally, while AI can enhance efficiency and scale learning, it risks sidelining the personal, human aspects of medical training. Skills such as empathy, ethical judgment, and effective communication are vital in health care, and they develop best through real human interaction and mentorship. AI may support education, but it cannot replace the essential human touch in shaping compassionate medical professionals [1,55].

Cultural and Acceptance Issues

One of the key obstacles to integrating AI in Vietnam's medical education system is the cultural and institutional resistance to change. Many faculty members and administrators, having been trained in conventional teaching methods, may approach AI with skepticism or even see it as a threat to their professional roles. Concerns about job security, diminished academic authority, or simply a lack of familiarity with emerging technologies can fuel this reluctance [56,57].

These attitudes are deeply rooted in Vietnamese pedagogical traditions, which remain strongly influenced by Confucian values emphasizing hierarchy, respect for authority, and teacher-centered learning. The traditional lecture-based approach positions the teacher as the primary source of knowledge, while students are expected to learn through memorization and obedience. In this context, the idea of AI systems providing personalized tutoring or automated feedback may be perceived as undermining the authority of faculty or disrupting established classroom dynamics.

Similarly, the relationship between faculty and students in Vietnamese medical schools often emphasizes formality and deference, which may affect how students engage with AI-driven tools. While younger generations may be more open to experimentation, students might hesitate to adopt AI-based tutoring systems if they sense disapproval from faculty or if

doing so appears to challenge established norms of learning. Conversely, if faculty members actively endorse and model the use of AI, acceptance among students is likely to grow more rapidly.

Moreover, Vietnamese academic culture tends to value collective conformity over individual experimentation. Students often prioritize standardized examination performance, and learning strategies are adapted toward achieving success in high-stakes tests. Because AI tools often encourage exploratory, self-paced, and competency-based learning, there may be a mismatch between the innovative potential of AI and the exam-driven educational ethos. Unless AI is aligned with assessment systems and institutional incentives, it risks being perceived as peripheral or even irrelevant.

Addressing these cultural barriers requires meaningful investment in faculty development. Training programs that introduce educators to AI tools, illustrate their value in teaching, and offer hands-on learning opportunities can help build trust and competence. Promising signs of progress can be seen in local efforts such as Fulbright University's AI education grant and VinBrain's nationwide campaigns promoting AI in health care, both of which highlight the power of sustained institutional backing in shifting academic mindsets [17,58].

Leadership also plays a crucial role in fostering a culture of innovation. Universities need to actively support digital experimentation, offer incentives for early adopters, and ensure that AI initiatives align with broader goals such as competency-based education and health care system reform. Without genuine buy-in from faculty, there is a risk that AI will be viewed as a top-down mandate, poorly integrated into everyday teaching, and ultimately ineffective [2,24,59].

Cost-Effectiveness and Sustainability

Cost-effectiveness and sustainability are central concerns for Vietnam as a middle-income country [60-62]. While AI technologies promise long-term benefits, including reduced faculty workload, standardized assessments, and improved student retention, their implementation requires upfront investment in infrastructure, training, and software. To ensure sustainability, policymakers and universities must consider the return on investment and adopt funding models that extend beyond 1-time grants. Public-private partnerships, collaborations with technology companies, and integration with national digital transformation and health care digitization programs represent potential pathways for sustainable financing [62]. Without deliberate strategies, there is a risk that only urban and better-resourced institutions will benefit, thereby deepening existing inequities with respect to provincial universities. Embedding cost-effectiveness evaluations into policy design and monitoring will be essential to ensure scalability and equitable distribution of AI benefits across the entire medical education system.

Conclusion and Implications

Integrating AI into the Vietnamese medical education system offers a powerful opportunity to modernize how future health care professionals are trained. AI can individualize learning, simulate complex clinical scenarios, automate assessment, and guide responsive curriculum reform—advantages that are particularly relevant in Vietnam, where faculty shortages and unequal resource distribution persist—yet realizing these benefits requires more than enthusiasm. Low levels of AI literacy, uneven technological capacity, concerns about ethics and data protection, and resistance within academic culture remain significant barriers. The recommendations outlined in Textbox 2 provide a practical roadmap for short-, medium-, and long-term action. With deliberate planning, sustained investment, and national coordination, Vietnam can ensure that AI integration is not only feasible but also equitable and sustainable, ultimately strengthening the country's preparedness for a digitally enabled health workforce.

Textbox 2. Recommendations for the integration of artificial intelligence (AI) in Vietnamese medical education.

Short-term

- Introduce artificial intelligence (AI) literacy modules in undergraduate and postgraduate curricula, covering:
- Fundamentals of machine learning and large language models.
- Principles of data ethics, bias awareness, and privacy.
- Clinical applications of AI in diagnostics, simulation, and decision support.
- Require medical universities to conduct faculty development workshops on AI tools for teaching, simulation, and assessment.
- Pilot the use of AI-assisted exam generation and automated grading (eg, multiple-choice questions and objective structured clinical examination checklists) at selected universities.
- The responsible parties include individual universities, with oversight provided by the Ministry of Education and Training (MOET) and the Ministry of Health (MOH).

Medium-term

- Establish minimum infrastructure standards, including:
- Reliable high-speed internet access.
- Cloud-based learning management systems.
- Secure institutional data storage and access to national health data platforms.
- Develop national ethical guidelines for AI in education, coordinated by MOET and MOH, with input from medical universities, professional associations, and legal experts.
- Expand pilot projects to provincial universities, accompanied by rigorous outcome evaluations.
- The responsible parties include MOET, MOH, national medical councils, and professional associations.

Long-term

- Integrate AI literacy as a core requirement across all medical training programs nationwide.
- Mandate external quality assurance mechanisms for AI-generated educational content and assessments to ensure validity and reliability.
- Create a sustainable funding framework through public-private partnerships and government-supported digital transformation budgets.
- Align AI-based educational analytics with national health workforce planning systems, ensuring that training outputs meet the needs of the health care system.
- The responsible parties include MOET, MOH, the Ministry of Science and Technology, and national accreditation bodies.

The integration of AI has broad implications for policy, practice, and research. Policymakers must establish clear ethical and regulatory frameworks and invest in robust digital infrastructure to prevent widening inequities between urban and provincial institutions. For educators and universities, AI provides practical solutions to faculty shortages, overcrowded classrooms, and limited clinical exposure, yet these benefits can only be realized if faculty development and support systems are prioritized. For researchers, there is an urgent need for Vietnam-specific studies evaluating the effectiveness, acceptability, and long-term outcomes of AI-based educational tools. Interdisciplinary collaborations between medical and technical institutions will be crucial in generating locally relevant evidence.

Drawing from the recommendations outlined in this paper, Vietnam should prioritize: (1) including AI literacy modules in undergraduate and postgraduate curricula, (2) investing in IT infrastructure and cloud-based educational platforms, particularly in provincial schools, (3) conducting faculty development programs focused on digital teaching tools, (4) establishing ethical guidelines for AI use in education to protect student data and ensure fairness, and (5) promoting interdisciplinary collaboration between medical and technology faculties.

By addressing these policy, practice, and research priorities, Vietnam can ensure that AI adoption not only modernizes medical education but also contributes to a resilient, equitable, and future-ready health workforce.

Acknowledgments

During the preparation of this work, the authors used ChatGPT-4o to check and improve grammar and clarity during manuscript development. After using this tool, the authors reviewed and edited the content as needed and take full responsibility for the content of the publication.

Funding

No external financial support or grants were received for this work.

Authors' Contributions

TAN contributed to the conceptualization and methodology of the study, conducted the investigation, performed validation, and prepared the original draft of the manuscript. TBN contributed to conceptualization, methodology, investigation, and validation, in addition to participating in data collection. TBN also contributed to writing through original drafting, review, and editing of the manuscript. DCN, ADV, KLD, and NQL contributed to data collection and validation and assisted with the review and editing of the manuscript. DAN participated in data collection, validation, and manuscript review and editing and provided supervision throughout the project. DKN and VTH contributed to conceptualization, methodology, investigation, validation, and preparation of the original manuscript draft.

Abstract

The rapid transformation of the health care landscape requires physicians to not only be skilled clinically but also navigate and lead a highly dynamic, innovation-driven environment. This also provides an avenue for physicians to significantly enhance their ability to help their patients, through participation in health innovation projects. Despite this growing need and opportunity, few medical schools provide formal training in innovation and entrepreneurship (I&E). In this perspective, we examine the need for I&E education in medical curricula by exploring student interest, effective program models, and implementation strategies. To better understand medical student interest in innovation and willingness to participate in I&E programs during medical school, we surveyed 480 medical students at our institution, the Johns Hopkins University School of Medicine, and received 90 responses with a 19% response rate. We observed a strong interest in health care I&E, with 97% (87/90) of respondents valuing knowledge or experience in I&E and 63% (56/90) expressing intent to incorporate I&E into their careers. To assess the real-world impact of I&E education on medical professionals, we surveyed 12 alumni of the Johns Hopkins Center for Bioengineering Innovation and Design (CBID) Master's program who had also completed medical school. Graduates reported that their experiences cultivated transferable skills—design thinking, interdisciplinary collaboration, and leadership—that shaped their professional trajectories. We propose three models for incorporating I&E education into existing medical curricula—short-term workshops, one-year gap programs, and longitudinal tracks—and discuss their advantages and trade-offs. Early and structured exposure to I&E education in medical school empowers students to identify unmet clinical needs, collaborate across disciplines, and develop real-world solutions. As the pace of innovation continues to accelerate, integration of I&E education into medical curricula offers a timely opportunity for medical schools to cultivate physician leaders in this space.

KEYWORDS

health care innovation; medical education; curriculum development; bioengineering; leadership

Introduction

Medical students traditionally receive extensive training in biological sciences, clinical reasoning, and patient care, but minimal exposure to innovation methodologies, design thinking, and entrepreneurial concepts [1]. As the health care landscape undergoes unprecedented transformation through technological advances, changing information and data landscapes, and evolving patient expectations, traditional medical school curricula that primarily emphasize disease diagnosis and treatment protocols may no longer fully prepare physicians for the opportunities and challenges they will encounter [2,3]. As medical students, educators, and administrators, we believe that health care innovation and entrepreneurship (I&E) represents a critical area of education that should be integrated into modern medical school curricula. These concepts provide an important framework for how to identify real-world health care challenges, characterize these challenges in detail, and design effective solutions. They mix both theory and practice, spanning four essential domains: Medical, Business, Technical, and Entrepreneurial. From a medical student perspective, we uniquely recognize the critical gap between the rapidly evolving health care environment we are entering and the limited exposure to I&E concepts during medical education. Physicians are uniquely positioned to identify clinical problems worth solving, yet most lack the formal training to translate these insights into viable solutions, representing a missed opportunity to significantly expand their impact on the care of patients around the world.

Current Landscape and Needs

Although there has been increasing recognition of the importance of health care innovation, few medical schools offer structured I&E programs [4]. Examples include Harvard's Health Sciences and Technology (HST) program, Stanford's Biodesign Innovation coursework for medical students, University of Michigan's Biomedical Innovation & Entrepreneurship Certificate Program, George Washington's

Clinical Practice Innovation and Entrepreneurship Track, and at Johns Hopkins, the Center for Bioengineering Innovation & Design (CBID)'s one-year full time Master's program. Since its inception in 2009, 24 medical students and physicians have completed the CBID program [5].

A 2021 study found that only 15.2% (26/171) of American and Canadian allopathic medical schools offered I&E-oriented medical education programs [6]. Among these 28 programs, 57% (n=16) had been started within the past four years, 75% (n=21) required a selective application process, and 79% (n=22) required students to complete a capstone project [6]. The most common program structure is a four-year track or concentration (15/28, 54%) [6]. Other formats vary in duration, ranging from weeks-long courses to a five-year dual-degree program. Teaching strategies in these I&E programs include lecture series, progress meetings, problem-based learning, workshops, mentorship, and guest lectures.

Survey of Student Interest

Given this growing but still limited landscape of opportunities, we sought to assess medical student interest in health care I&E programs at our institution, the Johns Hopkins University School of Medicine. During the 2023 - 2024 academic year, we distributed an electronic survey via email to 480 students across all years and received 90 responses, an approximately 19% response rate. The survey assessed student perceptions of innovation importance and career intentions and was approved by the Johns Hopkins Medicine Institutional Review Board (ID: IRB00381640).

The results suggest strong interest among the student body in integrating health care I&E into medical education and a recognition of its importance. Most respondents (n=87, 97%) expressed that a physician's knowledge and experience with health care innovation was at least somewhat important, including 39 students (44.8%) who thought it was very important or essential. Additionally, 63% of students expressed that they were likely or very likely to incorporate health care innovation into their future practice. A total of 36% percent of students indicated that they were likely to devote more than one quarter of their future career time to health care innovation. Importantly, 43% of students reported that the availability of opportunities to learn about innovation was a positive factor in their choice of medical school (Table 1).

Table . Medical student survey.

Survey questions	Respondents, n (%)
How important is it for a physician to have knowledge about and experience with health care innovation?	
Not important	3 (3)
Somewhat important	48 (54)
Very important	37 (41)
Essential	2 (2)
Thinking about your vision for your medical career long term, what percentage of your time do you anticipate devoting to health care innovation?	
0% - 25%	58 (64)
25% - 50%	26 (29)
50% - 75%	4 (5)
75% - 100%	2 (2)
When you were applying to medical school, how did the availability of opportunities for exposure to healthcare innovation affect your choice of medical school?	
It was a negative factor	0 (0)
It was not a factor	51 (57)
It was a minor positive factor	21 (23)
It was a moderate positive factor	13 (14)
It was a major positive factor	5 (6)

We acknowledge several limitations of our student survey. The relatively low response rate may introduce selection bias, as students with a preexisting interest in I&E may have been more motivated to respond. Second, the survey reflects the perspectives of students at a single institution, and these findings may not be generalizable to other institutions. Nevertheless, with nearly all respondents considering familiarity with I&E somewhat important, this represents a sizable number of students, even factoring in the response rate.

Impact of Health Care Innovation and Entrepreneurship Training

Our institution offers a one-year immersive Master's degree program managed by CBID that provides a structured framework to allow students to study medical device innovation in a hands-on, team-based format, with attention to all four domains mentioned previously. To better understand the impact of early exposure to health care I&E, we distributed an electronic

survey via email to 12 medical school graduates who completed the program between 2018 and 2024.

Five graduates had completed the CBID program during medical school, and seven after medical school. The respondents' subsequent career paths demonstrate a strong commitment to I&E. Two practicing physicians currently dedicate 90% of their time to clinical practice and 10% to entrepreneurship, while ten current residents anticipate distributing their time across clinical practice (54%), research (19%), industry (9%), entrepreneurship (16%), and other roles (2%), including teaching programs like CBID (Table 2).

We also sought to assess the impact of skills that alumni had developed through the CBID program. When asked about which skills have been most applicable to their medical career, the most common responses were design thinking and ideation (n=11, 91.7%), leadership and team management (n=8, 67.7%), knowledge of health care markets (n=7, 58.3%), and interdisciplinary collaboration (n=6, 50%) (Table 2).

Table . CBID graduate survey.

Survey questions	Respondents
When did you complete the CBID program? n (%)	
During medical school	5 (42)
After medical school	7 (58)
How do you currently allocate your time to the following? n=2, (% of time)	
Clinical practice	90
Entrepreneurship	10
How do you hope to allocate your time to the following in your future career? n=10, (% of time)	
Clinical practice	54
Research	19
Entrepreneurship	16
Industry	9
Other	2
Which skills or experiences gained from CBID have been most applicable in your medical career? n=12, n (%)	
Design thinking and ideation	11 (92)
Leadership and team management	8 (68)
Knowledge of health care markets	7 (58)
Interdisciplinary collaboration	6 (50)
Project management	3 (25)
Other	1 (8)

[a]CBID: Center for Bioengineering Innovation and Design

Participants highlighted the program's transformative impact, with one stating, "The full CBID experience made a big difference in my career trajectory and the exposure alone to the space was invaluable as this is something most medical students do not have access to and gives a unique perspective on health care." Similarly, another student noted, "CBID offers a truly unique, collaborative, and hands-on experience that transformed my medical and surgical training. Participants learn to tackle clinical challenges comprehensively and without bias, enabling the development of clinically, commercially, and technically sound innovations." These findings suggest that structured I&E education through programs like CBID can equip students with skills that complement existing clinical training and experiences that potentially shape students' career trajectories.

In our opinion, design thinking skills acquired through such programs have the potential to augment a trainee's development across multiple aspects of medical practice and professional growth. Design thinking entails an organized, iterative process in which one repeatedly interrogates user needs, defines aspects of a problem, and explores potential solutions to address those aspects. This framework trains students to approach clinical scenarios with a structured, problem-solving mindset which can improve diagnostic reasoning and clinical judgment [7-9]. Moreover, exposure to design thinking can empower clinicians to reimagine their career trajectories and even contribute to innovations such as the development of new medical devices and therapies [10,11].

Interestingly, while 50% (6/12) of alumni identified interdisciplinary collaboration as valuable, it ranked lower than expected given the inherently collaborative nature of health care. In clinical practice, physicians routinely coordinate with a wide range of professionals and specialists from other disciplines. Likewise, successful physician innovators depend on interdisciplinary teams including engineers, entrepreneurs, and business professionals to translate ideas into viable solutions. Navigating this ecosystem is a critical "soft skill"

that I&E programs are uniquely positioned to cultivate through hands-on, team-based experiences. One possible explanation for these findings is that many medical students may have already developed a foundation of interdisciplinary skills by the time they joined the CBID program, which was applied to the innovation space with relative ease. Nonetheless, these findings do not detract the importance of supporting interdisciplinary collaboration through I&E curricula, as developing these skills early may better prepare future physicians to lead and thrive in complex health care environments.

Our alumni survey has limitations including a small sample size (n=12). Graduates of the CBID program are also likely to report that they plan to use this training in their future careers. However, our findings may actually underreport the true impact of such programs, as the long-term effects of such programs have not yet been fully realized. It may take time for graduates to assume leadership roles and make visible impacts in their respective fields.

Critical Timing and Developmental Considerations

In our opinion, exposure to health care I&E is important early in medical education. When students are exposed to I&E training before clinical routines are developed, they are more likely to look for opportunities for improvement over existing practices and have the tools to act effectively on these opportunities. This timing allows students to see clinical situations and identify clinical challenges through a critical lens. Rather than being solely acclimated to current standards, these students are more likely to question assumptions, recognize unmet needs, and envision improved solutions. As current students ourselves who are deeply involved in I&E programs at Johns Hopkins, we can attest to the ways in which these opportunities have complemented our development of clinical knowledge and helped us better tackle patient care obstacles.

Additionally, we believe that early exposure to health care I&E can help to cultivate physician leaders in the health care innovation space. This is evident in the current and anticipated future professional activities of the CBID alumni. While many respondents are still in residency training, most remain actively involved in I&E through various pursuits. Seven graduates serve as chief executive officers or cofounders of startups, while others mentor engineering students (n=1) or lead research labs (n=1). These career trajectories suggest that early engagement with innovation during medical education not only enhances students' ability to identify and solve complex clinical problems but also fosters leadership and sustained involvement in health care I&E.

Structural Considerations

We believe that the goal of a medical school I&E program should be to expose students to the principles of design thinking, to provide them with practical experience navigating the design process, and to enable them to become conversant with a wide range of experts in this field. By the end of the program, students should be equipped with the skills necessary to apply the design process to real-world clinical problems. While we are aware that not all physicians will be interested in pursuing a career in health care I&E, these skills are applicable to all aspects of problem-solving in medical practice and will help students build sufficient fluency in order to collaborate with peers in related fields [8,9]. There are several models for incorporating health care I&E training into medical education, each with its own advantages and disadvantages (Table 3).

Table . Structural models for innovation and entrepreneurship programs.

Model	Duration	Advantages	Disadvantages
Short-term programs	Weeks to months	Broad accessibility Easy curriculum integration Low time commitment	Limited hands-on experience Theoretical focus
Gap year programs	1 year	Comprehensive immersion Complete project cycles Dedicated focus time	Financial barriers Limited accessibility
Longitudinal tracks	4 years	Integrated learning Extended project development	Challenges for sustained engagement Requires curriculum flexibility Resource intensive

Short-Term Programs

Week- or month-long programs provide an excellent structure to introduce foundational I&E principles such as design thinking, problem identification, and prototyping to a broad range of students. Their shorter time commitment may be appealing to students who are interested but hesitant to dedicate significant time to I&E. Additionally, these programs are often easier to implement into the existing medical school curricula.

However, the limited duration may not provide students sufficient time for meaningful engagement in a hands-on project—an essential component for understanding the nuances of the design process. Without having practical experience, graduates of these curricula may only gain theoretical knowledge. Therefore, they may not be fully prepared to tackle and address more practical challenges that emerge along the journey of solving a clinical problem.

Gap Year Programs (Eg, One-Year Master's Degrees Such as the CBID Program)

Gap year programs provide comprehensive, hands-on experience working through the entire innovation process from identifying a clinical need to developing a prototype. By stepping away from traditional coursework and clerkships, students can fully immerse themselves in their projects without competing academic responsibilities, augmenting the learning experience.

However, financial or academic constraints may deter students from pursuing an additional year of education. Some students may be reluctant to delay their clinical training and career progression, while others interested in I&E may prefer earlier engagement rather than waiting several years to begin formal education.

Longitudinal Tracks (Eg, Integrated Four-Year Programs Alongside the MD Curriculum)

A four-year longitudinal track can seamlessly integrate innovation-focused classes alongside traditional medical curriculum, allowing students to receive both theoretical and practical exposure in innovation. By introducing I&E training at the beginning of medical school, students have more time for hands-on exposure allowing for deeper engagement in the project, time for iterative problem-solving, and a greater chance of seeing projects through to implementation. Additionally, the extended time frame allows students to develop meaningful relationships with mentors in both academia and industry. This structure enriches the learning experience and helps prepare students with the skills needed to succeed as future innovators.

However, sustained engagement over four years can be difficult especially as competing academic demands or student interest change. Furthermore, not all medical school curricula allot the time and flexibility necessary to incorporate this coursework. Additionally, implementing a longitudinal program requires substantial and ongoing faculty, mentorship, and institutional support to ensure strong educational quality across multiple years.

Challenges and Implementation Considerations

There are several challenges to implementing innovation-focused programs within a medical school curriculum. Notably, the highly structured and densely packed schedule of the medical school curriculum may leave limited room for additional courses or activities. However, the I&E program's duration and content can be tailored around the existing schedule. Many medical schools allocate decided time for optional independent scholarly activities and research [6]. Portions of this time can be allotted to core classes in the I&E track or independent work. In the clinical years, students often have the option to take research electives, which can also provide additional time to engage with the I&E curriculum.

A phased implementation approach may help effectively introduce a health care I&E track, especially in institutions with limited resources. By initially offering short elective courses that require minimal infrastructure, institutions can assess student engagement and interest [12]. For example, during the 2024 - 2025 academic year, we designed and led a three-week long elective course for first year medical students focused on teaching the principles of the design process and applying them to simple real-world problems. Fifteen (out of 120) first-year medical students registered for and then completed the course, reflecting high student interest. As faculty observe the value students place on I&E training, they may become more receptive to integrating these concepts into the broader curriculum. The positive outcomes from a pilot program can also build a compelling case for increased institutional support and may also help create a collaborative environment in which faculty and administration can collectively support the evolution of the medical curriculum.

Another challenge for the implementation of a health care I&E program is securing sustainable funding. One strategy is to pursue external funding sources dedicated to improving medical education. For example, the American Medical Association's ChangeMedEd initiative offers Innovation Grants to support transformation educational projects. Another option is forming partnerships with health care organizations and technology companies. For example, collaborations with venture capital or medical device companies can provide students with projects to address real-world clinical needs. This offers students practical experience while also advancing the partners' objectives. These partnerships also provide students with expertise and mentorship. In fact, the aforementioned CBID program successfully uses such a partnership model for many of the project opportunities offered to their students. In addition, at Johns Hopkins, pre- and postdoctoral training grants focused on health care I&E have provided support for some medical students and residents in pursuing yearlong Masters programs and projects.

Future Directions and Expected Trends

We anticipate that interest in I&E education among medical students will continue to increase. First, growing student awareness of the importance of health care I&E is evident in our survey findings, where 43% of students considered innovation opportunities when choosing their medical school. Second, external forces, including health care system pressures, technological advancement, and changing care delivery models create increasing demand for physician innovators. Third, the increase in dual-degree and specialized programs reflects students' desire to differentiate themselves for residency applications and career development [4,6]. Notably, 57% of the 28 identified programs were launched within the past four years, underscoring the recent surge in innovation-focused medical education.

Future studies should be conducted to further understand the role of I&E education in medical curricula. These studies should

be larger and involve geographically diverse institutions across different tiers and program structures to validate the observations from our study. Additionally, longitudinal studies with larger cohorts that follow students for multiple years through medical training and into their careers will be important to capture the full effect of structured I&E training on career trajectories and professional contributions in health care.

Conclusion

As medicine evolves at an ever-accelerating pace, it is increasingly important for the next generation of physicians to have a proper foundation in clinical problem solving and develop the design thinking principles and effective problem-solving skills that will allow them to integrate emerging technologies into their solutions and contribute to the creation new ones. Early exposure to health care I&E allows students to nurture both of these aspects of their academic development simultaneously, augmenting the quality of their overall training and promoting their ability to serve as physician leaders of health care I&E in the future. Our findings suggest substantial interest in I&E training among medical students at our institution, consistent with national trends, and we expect this trend to increase rather than diminish. Therefore, following in the footsteps of prior successfully implemented programs, we encourage all medical schools to investigate ways in which they can integrate I&E programs into their curriculum. These efforts will better prepare students to collaborate across disciplines and lead future innovation initiatives that will ultimately improve the care of the patients they will serve.

Abstract

Generative artificial intelligence (GenAI) presents novel approaches to enhance motivation, curriculum structure and development, and learning and retrieval processes for both learners and instructors. Though a focus for this emerging technology is academic misconduct, we sought to leverage GenAI in curriculum structure to facilitate educational outcomes. For instructors, GenAI offers new opportunities in course design and management while reducing time requirements to evaluate outcomes and personalizing learner feedback. These include innovative instructional designs such as flipped classrooms and gamification, enriching teaching methodologies with focused and interactive approaches, and team-based exercise development among others. For learners, GenAI offers unprecedented self-directed learning opportunities, improved cognitive engagement, and effective retrieval practices, leading to enhanced autonomy, motivation, and knowledge retention. Though empowering, this evolving landscape has integration challenges and ethical considerations, including accuracy, technological evolution, loss of learner's voice, and socioeconomic disparities. Our experience demonstrates that the responsible application of GenAI's in educational settings will revolutionize learning practices, making education more accessible and tailored, producing positive motivational outcomes for both learners and instructors. Thus, we argue that leveraging GenAI in educational settings will improve outcomes with implications extending from primary through higher and continuing education paradigms.

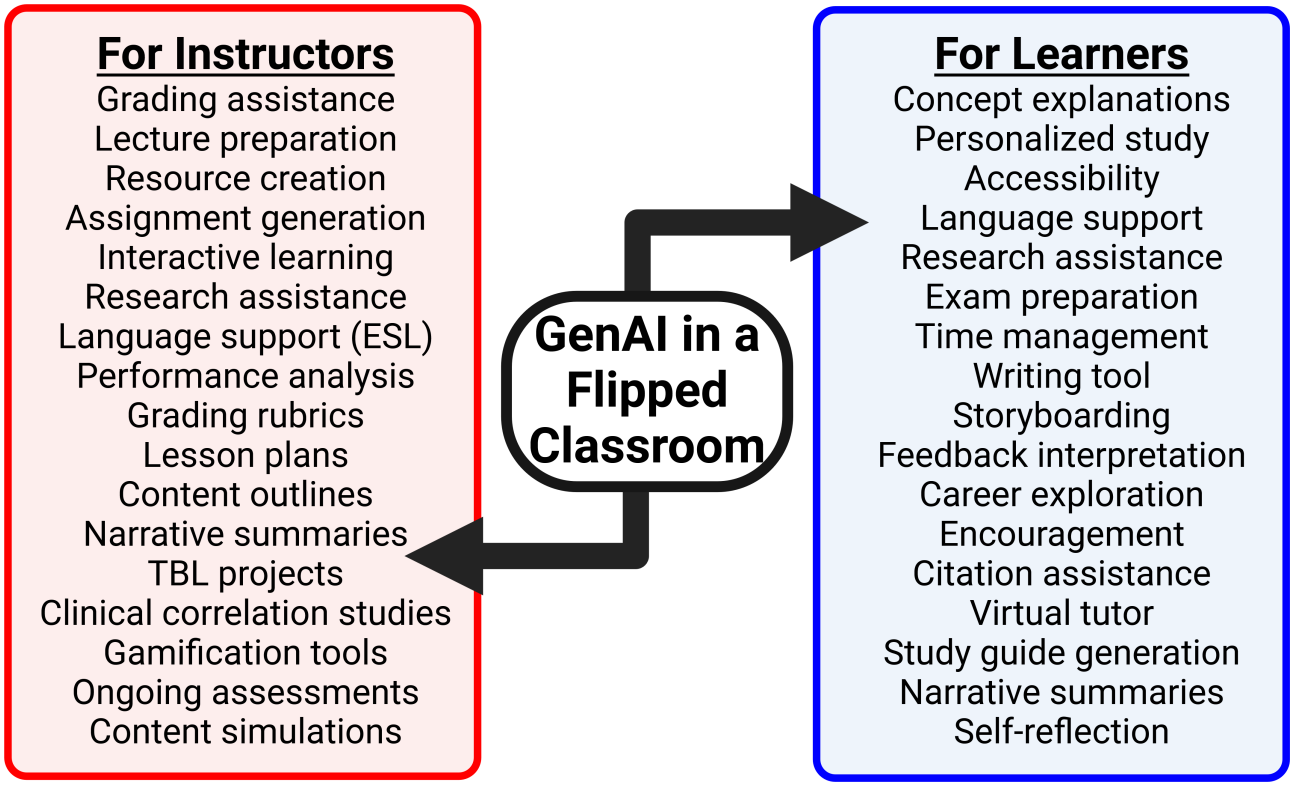
Introduction

Generative artificial intelligence (GenAI) is impacting educational spaces in ways that few technologies have since the personal computer and calculator [1-3]. Though GenAI is not a new concept, its inroads into education and pedagogy started in earnest following the release of "ChatGPT" (November 30, 2022). We observed learners using ChatGPT within weeks of its release. GenAI continues to rapidly evolve with new "GPTs," models, websites, application programming interfaces, and GenAI-enabled hardware [3-6]. GenAI is now "mainstream" with low activation barriers for use. This new reality is sending shockwaves through educational institutions and districts, including higher and clinical education. Learners, instructors, and administration work to understand and define implications while either leveraging or obstructing GenAI implementation. Indeed, banning and blocking GenAI use in some educational settings remains with no clear consensus on what role GenAI can, or should, play going forward. With this rapidly evolving space, it's challenging to differentiate inflated expectations and hype from productivity and enlightenment, to borrow from the Gartner Hype Cycle. One could argue that the GenAI "peak of inflated expectations" has yet to be reached. However, the new reality in clinical and higher education is one where GenAI will play a role going forward, both within classrooms and clinical practice [3,6-8]. What that looks like remains variable and will change depending on the knowledge of those involved, personal perspectives on GenAI, learner and programmatic needs, and accreditation standards and expectations. Our immediate approach was to embrace GenAI, like ChatGPT and other tools as they have come online (eg, Claude, Bard, and CoPilot), as a new tool to facilitate learning, retrieval, and motivation in a higher education, clinically focused, instructional environment. The rationale is that modern GenAI can generate diverse outputs (eg, text, images, videos, and language) derived from data-centric training sets [9] using narrative style prompts or data inputs (eg, content outlines, documents, PDFs, and images). Thus, there is a pragmatic reality that new GenAI tools have a

low activation barrier for use while being capable of generating high-quality output focused on user needs. It's evident that modern GenAIs ability to generate extensive, coherent, responses is fundamental to increasing engagement, communication, and motivation in educational settings. Though not seamless, especially when considering potential for malfeasance or hallucinations [10], GenAI can integrate throughout curricula to reduce overhead and improve outcomes (Figure 1). This integration fosters environments that inspire and empower learners, promote motivation and collaboration, and facilitates the creation of dynamic and individualized curricula.

Figure 1. Generative artificial intelligence application in a flipped classroom model enhances both learner (blue) and instructor (red) experiences. Shown are examples of generative artificial intelligence benefit and impact within respective domains. Bidirectional arrows indicate reciprocal enhancement of generative artificial intelligence applications, demonstrating improvements in instructor-driven activities inherently enrich learner experience, thereby reinforcing a flipped classroom learning environment. GenAI: generative artificial intelligence.



The objective of this viewpoint is to advance a positive perspective on leveraging GenAI tools in modern medical education environments while presenting examples and methods tested in our hands since ChatGPT's initial release. This viewpoint is presented from both learner (Mrs Monzon) and instructor (Dr Hays) perspectives as, in our experience, both offer unique opportunities on GenAI use. Learners are focused on knowledge acquisition and retrieval from an individualized perspective. Not all learners have the same motivation, hidden curriculum, previous knowledge, and experience, or ability to learn and retain learning objectives defined by instructors. Likewise, instructors are unable to individualize curricula across multiple learners or sections while ensuring productive exposure to core learning objectives defined by accreditation and program standards. It's a conundrum of modern higher education, learners seeking individualized instruction amidst information overload while instructors are bandwidth-limited and hamstrung by program and accreditation demands. GenAI tools will directly impact this reality in a positive manner and empower both learners and instructors. The current challenge is what does that look like? How can GenAI be integrated into learning environments to facilitate learning and retrieval, drive motivation, and improve outcomes while avoiding pitfalls such as loss of voice, data ownership and use, academic misconduct or malfeasance, and incorrect information? This future must balance innovation and GenAI integration with established guidelines, integrity and safety guardrails, and equity. By presenting a nuanced perspective of the interplay between GenAI and learning theories from both learner and instructor perspectives, this viewpoint intends to inform GenAI integration that is inclusive, forward-thinking, and collaborative while not ignoring tangible GenAI benefits for all stakeholders in the learning ecosystem. Integration should not overshadow essential human elements of teaching and learning but rather complement and enhance both, thereby creating a dynamic and inclusive educational environment that is responsive. Finally, we argue that GenAI should not be ignored but embraced. It's imperative that learners are exposed to new technologies that will increasingly impact workforce dynamics going forward. Instructors are innovators and our learners are digital natives surrounded by AI technologies. We implemented and evolved methods described in this viewpoint within graduate (PhD and MS), clinical (dietetics and RD), and undergraduate curricula. Leveraging GenAI in courses does require initial effort, yet subsequent improvements in effort needed, instructional quality, and learner feedback justify the initial cost. GenAI has proven, in our hands, to positively impact every pedagogical niche. It should be noted that we acknowledge significant ethical

concerns regarding GenAI use in educational settings. This has been covered extensively elsewhere [10,11] and the current viewpoint starts with the perspective that GenAI can, and should, play a role in educational settings.

Learner Perspective

Technology is a powerful means to facilitate collaboration between learners and instructors. Learning management systems (eg, Canvas or D2L) are an example of this point, leveraging technology to facilitate learning and retention. In this sense, bringing GenAI into classroom settings is an evolutionary step with clear emerging data that it enhances learner engagement, motivation, and personalized learning in a self-directed manner. The pragmatic meaning is that interactive collaboration can be extended from instructor-learner or learner-learner to include learner-GenAI where the scope and implementation of learner-GenAI interactions is defined by tools being used, prompt design (Figure 2), and personalized needs (Figures 1 and 3). This approach fosters learner motivation as a key driver for positive outcomes [12]. In addition, learning is more effective when it's relevant, engaging, and contextualized to real-life scenarios (eg, team-based learning or clinical applications) in accordance with adult learning theory. Cognitive load is reached when germane, intrinsic, and extraneous factors become unmanageable [13]. Incorporating GenAI into the educational framework can simplify the intrinsic load, reduce the extraneous load and in turn maximize the germane load. This is consistent with our observations using GenAI to foster collaborative interactions in clinical courses. To maintain learner motivation, one must account for both intrinsic and extrinsic factors [13]. Intrinsic factors include self-efficacy, self-determination, curiosity, cognitive engagement, emotional well-being, professional well-being, and innate interest in the material presented. Extrinsic factors include pedagogical approach, peer interactions, assessment methods, learning environment, curriculum design, and quality and scope of feedback (both peers and instructors). A unique aspect to the learner-GenAI interaction is that it impacts both intrinsic and extrinsic motivational elements for learners. For instance, GenAI can be implemented as a personal tutor or study partner that encourages conversations and positive feedback in a low activation barrier environment (eg, compared with instructor office hours). Engaging GenAI "chatbots" like ChatGPT can also be conversational for learners, like interacting with a human counterpart (see "Current Limitations and Future Hurdles" section below). Thus, leveraging the learner-GenAI interaction provides agency to learners which increases autonomy and motivation [14].

Figure 2. Prompt design. General overview for developing prompts with clearly defined role (red), bounds (green), and input (blue). Each component is essential for effective generative artificial intelligence use toward minimizing refinement while helping ensure output is optimized toward specific needs.

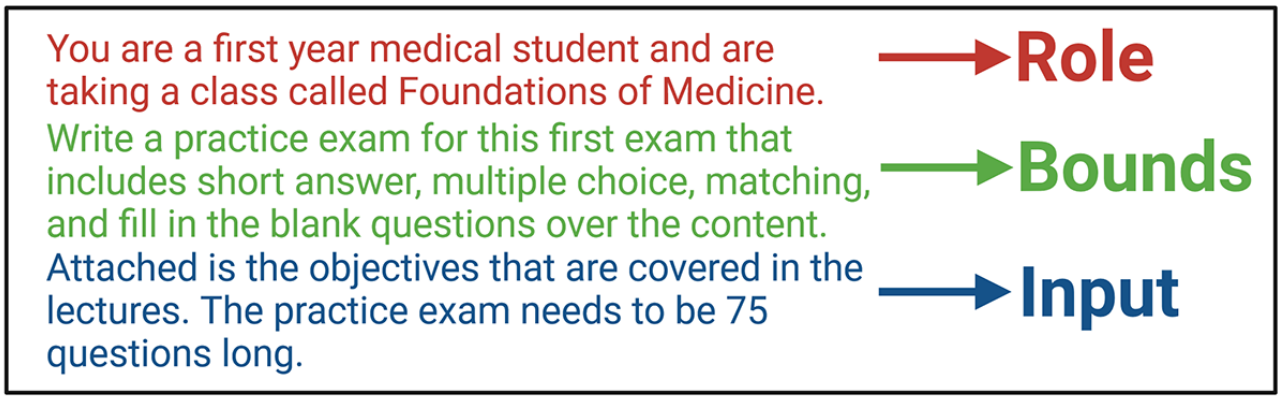


Figure 3. Example learner prompts for leveraging generatice artificial intelligence. Three example learner input prompts are shown (blue box) with representative ChatGPT (accessed on December 10, 2024) output (black box) for the top prompt (black arrow). In these instances, the resultant output can change significantly with minor changes in the input prompt provided. This is also true when using the same input prompt across different generatice artificial intelligence tools. Thus, specificity and clear instructions are key to effect desired output.

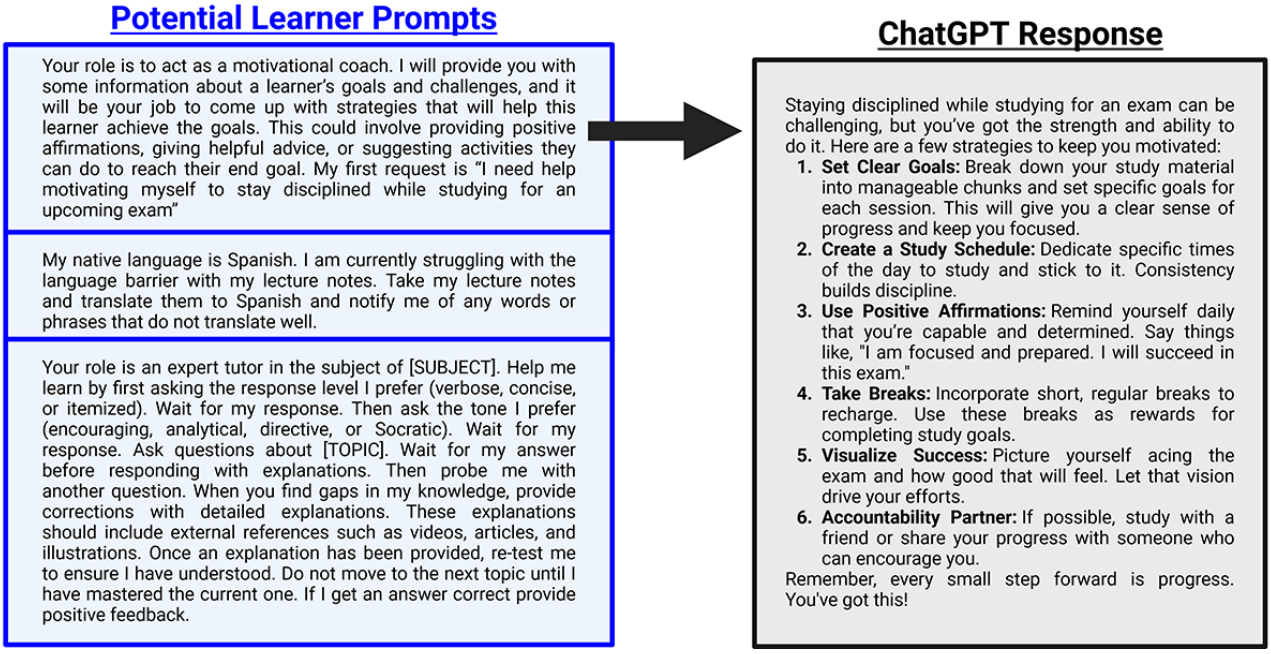


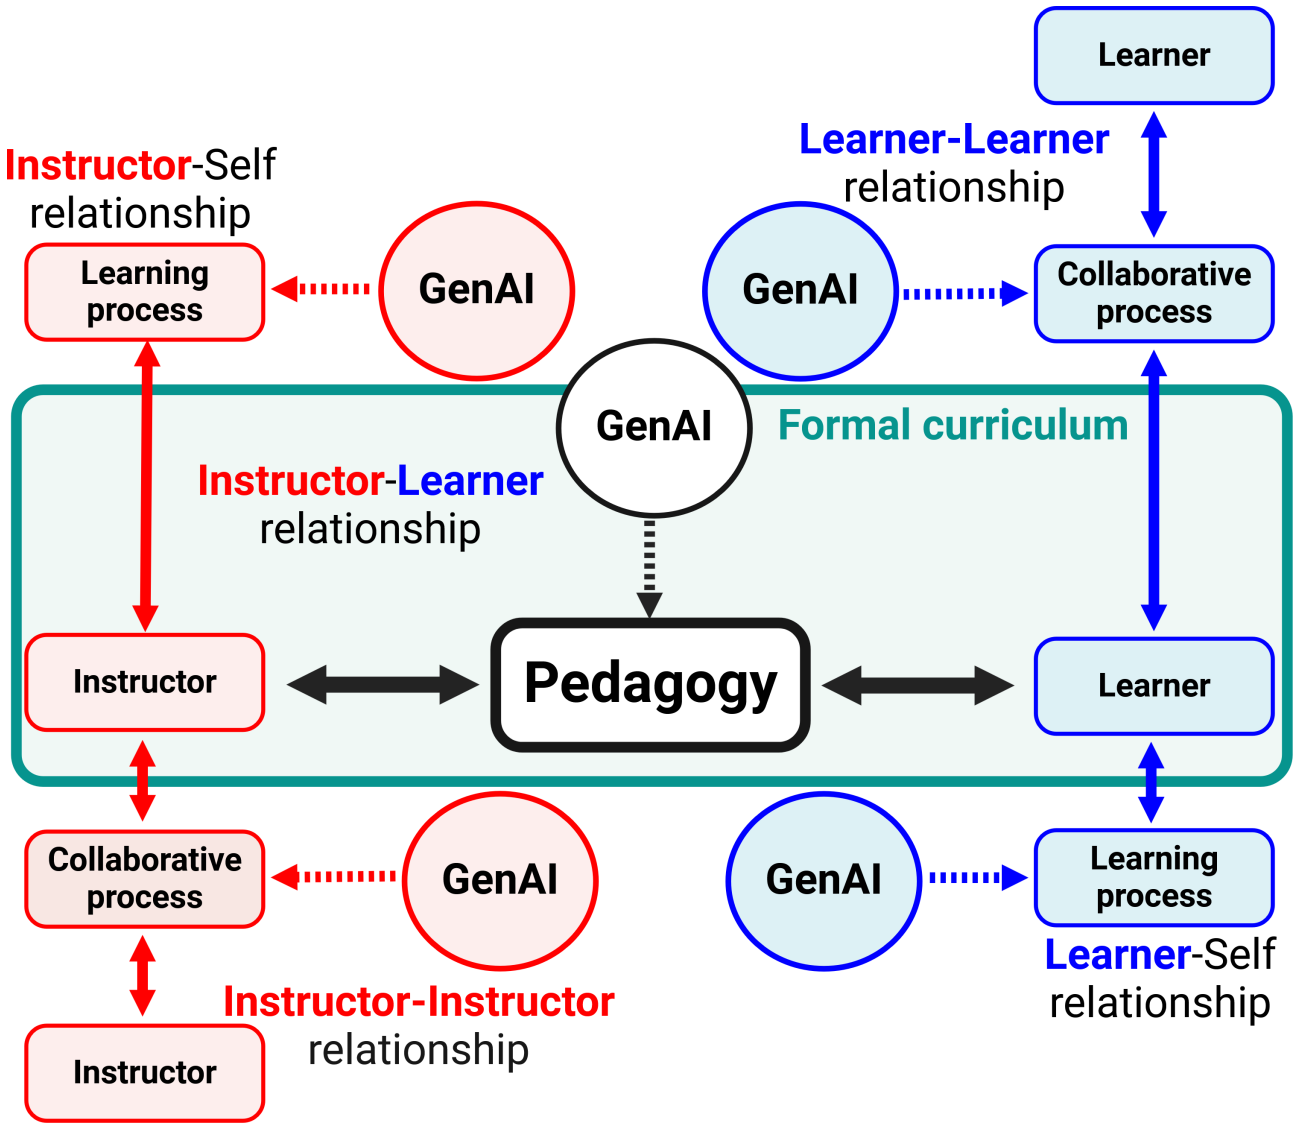
Beyond motivation, retrieval practice is an essential component for learner ownership over new material and, for example, applying knowledge in a clinical setting where integration and rapid access is often required [13]. Indeed, learned information is rapidly forgotten without reinforcement [15]. This is a core consideration of the "Desirable Difficulties" theory by Bjork and Bjork [15] suggesting that one should introduce challenges (eg, spacing or testing effects and varied practice) to enhance long-term memory retention of new information. Thus, retrieval practice requires active effort by learners to bolster information recall. This active engagement promotes deeper processing and understanding to facilitate ownership. A common example of retrieval practice in medical learner training is leveraging the Socratic method in clinical rounds, case discussions, simulations, journal clubs, team-based learning, and even mortality and morbidity conferences. In these scenarios, clinicians are pushed to understand, integrate, and verbalize knowledge under immediate critique and assessment. This moves beyond simple passive recall or reading to test true understanding and identify areas where learners assume ownership of knowledge but fail accurate retrieval or application [16]. In simplistic terms, retrieval practice is a common element to most curricula through formative (common in direct clinical training) and summative (common in formalized classroom instruction) assessments. Incorporating learner-GenAI methods into the curriculum provides a dynamic, ongoing, personalized, and iterative method to facilitate retrieval practice for learners outside of formal, instructor-based, course design. The learner-GenAI axis is instructor-independent in this instance. GenAI can generate adaptive quizzes and assessments while customizing difficulty level and content based on learner proficiency (eg, Figure 3). As learners progress and improve in retrieval practice, GenAI can dynamically adjust question complexity, ensuring continued adaptive learning. These tools analyze users learning patterns, preferences, performance data, and needs to personalize content. In this instance, GenAI recommends specific retrieval or practice exercises and intervals to drive memory consolidation. Learner-GenAI natural language interactions can efficiently manage spaced repetition schedules based upon individual learning patterns and needs to adapt timing and frequency of review sessions, ensuring learners revisit information at optimal intervals for memory retention. Finally, it's important for instructors to consider that learners do not enter courses on equitable footing in knowing how to access, use, and leverage GenAI tools. Initial training with pragmatic examples, discussion of prompt engineering, setting up accounts if needed, and reviewing available tools and associated strengths and weaknesses is strongly advised for courses that allow GenAI use.

Instructor Perspective

Instructors, faculty, and programs within higher education and clinical training settings are primary determinants of motivational factors for learners [12-14]. These include accreditation and departmental oversight (meaning "static" curriculum), designing and structuring assessment, determining feedback mechanisms, managing learning environment, defining expectations, and even implementing recognition and reward systems for positive outcomes or performance. Thus, in our experience, learner motivation is impacted in significant ways before the first day of class. With this backdrop in place, what role can GenAI play in higher education and clinical training from the instructors' perspective? This question has interesting parallels to the "great calculator debate." These include questions of access and equity, learners using these tools outside class regardless of policies set by schools and instructors, learners not gaining essential skills, or knowledge, through their use, modifications required for existing curricula with a major

shift away from algorithms and "rules" toward meaning, concepts, and applications, and ability to trust accuracy of answers produced from novel technologies. Yet, even with the rapidly evolving current landscape surrounding GenAI, we posit that GenAI has significant benefits for instructors. Thus, the instructors' role in harnessing GenAI as an educational tool is multifaceted and includes instructional design, creating dynamic learning content, and even streamlining administrative tasks (Figures 1 and 4), all of which are predicated on training and learning about a rapidly evolving field with new tools appearing almost daily.

Figure 4. Role of generative artificial intelligence in educational relationships and processes. Generative artificial intelligence intersects with and supports relational dynamics between instructors (red) and learners (blue). Four primary interactions are shown, instructor-self, instructor-learner, learner-self, and learner-learner, where generative artificial intelligence serves as a pivotal tool for enhancing learning processes. Generative artificial intelligence's contribution to the pedagogical framework is central, mediating and enriching explicit curriculum delivery and assimilation. Bidirectional arrows between actors and generative artificial intelligence signify a feedback loop allowing for continuous improvement of educational strategies. It underscores generative artificial intelligence's potential to facilitate collaborative processes as well as promoting self-directed learning and peer-to-peer engagement. GenAI: generative artificial intelligence.



GenAI integration by instructors can lower activation barriers to create dynamic, engaging, personalized, and efficient learning environments that optimize learner outcomes (inclusive of motivation and retrieval). We approach this using a flipped classroom (Figure 1), content gamification, streamlined workflows, team-based learning, knowledge gap analysis, and consistent feedback using "exit tickets," all facilitated using GenAI tools. The concept of classroom "flipping" has gained attention in recent years as an approach to instructional delivery. Flipping involves inverting traditional curriculum structure with learners acquiring, or at least engaging, new content outside of structured class time and using active learning methods during class to reinforce, expand upon, and use retrieval practice to reinforce and learn content [17]. All of which is instructor-guided as part of the instructor-learner core axis (Figure 4) [18]. If done well, this approach allows instructors to focus on providing targeted and personalized feedback, requires higher-order critical assembly and thinking skills, and facilitates meaningful discussion or reinforcement during class time for learners. Core tenants of this approach are engaging motivation for learners and expanded retrieval practice outside of high-stress graded assessments like quizzes or exams. Though

our experience with the above approach involves class sizes ranging from 5‐40 learners, others have successfully implemented flipped classroom methods with more than 200‐300 learners [19]. Great examples of this dynamic approach are “metabolic melodies” in which the instructor, Dr Kevin Ahern from Oregon State University, uses complex biochemistry content to generate songs set to popular music such as “Yellow Submarine” by the Beatles. In this instance, Dr Ahern is extremely creative and a musician with an affinity for the Beatles. GenAI empowers instructors, even those lacking creative brilliance, to turn complex content into interactive and dynamic content such as games, clinical case scenarios, creative narratives, or even music and images. Thus, leveraging GenAI in a flipped classroom environment can reduce instructor workload while improving learning outcomes.

Gamification of course content is one mechanism toward merging GenAI tools with positive learner outcomes. GenAI can quickly generate games (eg, Kahoot!, bingo, Jeopardy!, crossword puzzles, or quiz show questions) using content outlines, slides, or even lecture as input (eg, Figure 5). Games are a low stress means of retrieval practice while promoting an interactive and engaged classroom experience [20]. GenAI can also generate complex clinical practice scenarios with rich hypothetical patient details. These scenarios require learners to use critical thinking and diverse knowledge outputs in a similar method to group-based socratic questioning used in medical education. One area we have had great success in using GenAI is developing gap analysis surveys for learners to assess knowledge levels upon course entry, midcourse for progression, and end of course for effectiveness relative to course objectives. GenAI can quickly generate gap assessments using course learning objectives, prerequisite course content outlines and turnkey instructor needs to provide immediate input on needed content modifications when introducing new content. This is an effective approach to identify knowledge gaps or needs that an instructor may assume are covered in prior courses, or were covered but not retained. Finally, GenAI can be leveraged to streamline workflows before, during, and after content delivery. This includes using templates to generate individualized self-assessment tools for learners, providing narrative feedback for learners on correct and incorrect responses, turning content outlines into focused assessments, integrating lecture modalities under core and redundant learning objectives, and statistical analysis on batched learner responses to identify learning gaps post-content delivery (Figures 1 and 6) [21]. Thus, improving learner outcomes using GenAI tools shows significant promise even with clear limitations, discussed below, and rapidly evolving tools. A central theme for instructors when considering GenAI integration into preplanning, execution, and postanalysis is to balance promoting motivation with opportunities for knowledge retrieval. Course guidelines and instructor expectations must be very clearly defined as to acceptable GenAI use during a given course. This is important considering the current environment where broad institutional or district policies may be lacking, or nonexistent, and variability in what is acceptable between different instructors and courses. Effective communication and clear policies and procedures remain the most important means to avoid academic misconduct or malfeasance. Adapting retrieval strategies to accommodate different learning styles, while ensuring inclusive and personalized learning experiences, is important yet challenging to implement in practice. GenAI holds promise for instructors as these tools provide opportunities to reduce activation barriers (eg, time constraints) toward delivering more effective content and meaningful assessments.

Figure 5. Example instructor prompts for leveraging generative artificial intelligence. Three example instructor input prompts are shown (red box) with representative ChatGPT (accessed on December 10, 2024) output (black box) for the middle prompt (black arrow). A key aspect for instructors is to clearly define the level of instruction being provided, type of learner being instructed, with narrowly defined content scope relative to learning objectives. The latter can be accomplished by inputting content outlines, lecture slides, or narrative summaries.

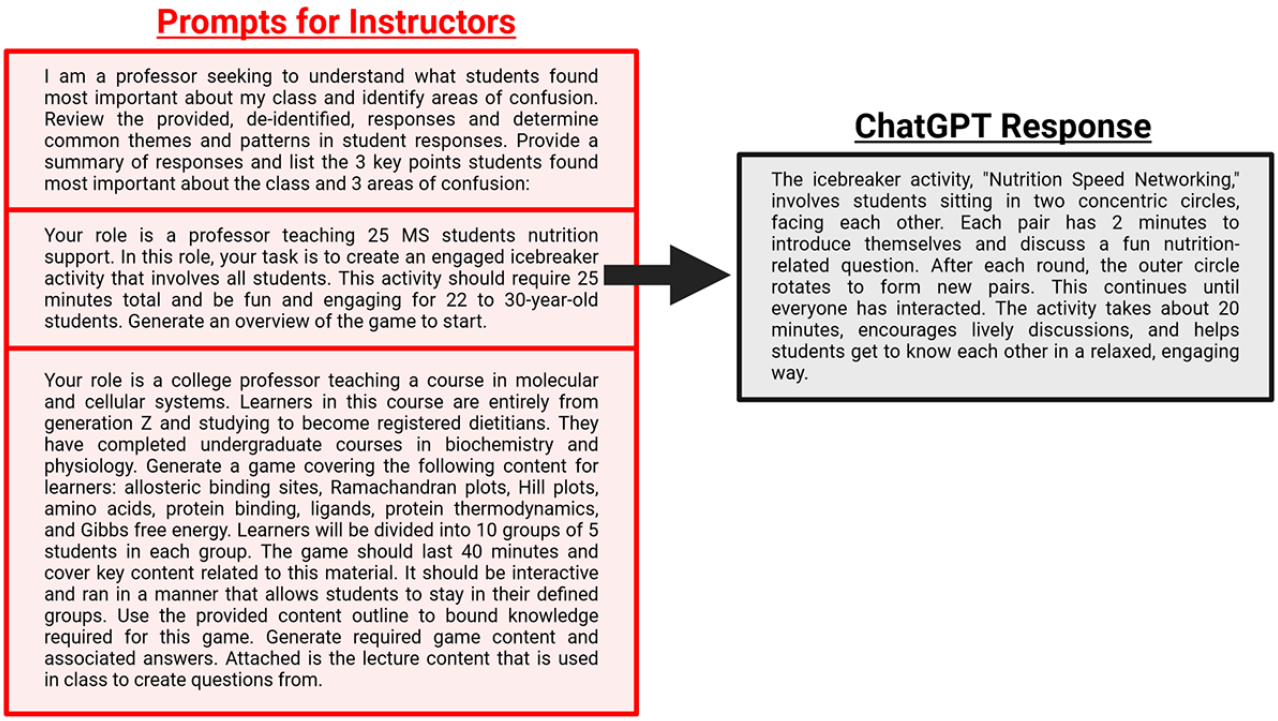


Figure 6. Generative artificial intelligence integration across assessment types. Generative artificial intelligence use across assessment modalities is shown. In formative assessment, generative artificial intelligence aids in creating interactive content and personalized feedback mechanisms. For summative assessment, generative artificial intelligence capabilities extend to evaluating overall learning achievements and generating comprehensive exams. Normative assessment with generative artificial intelligence focuses on establishing benchmarks and evaluating learning outcomes against standards, while diagnostic assessment leverages generative artificial intelligence for early detection of learning gaps and customization of learning experiences. The central position of "Assessment with GAI" emphasizes its role as a centralized tool, facilitating a comprehensive and integrated approach to educational assessment. GenAI: generative artificial intelligence.

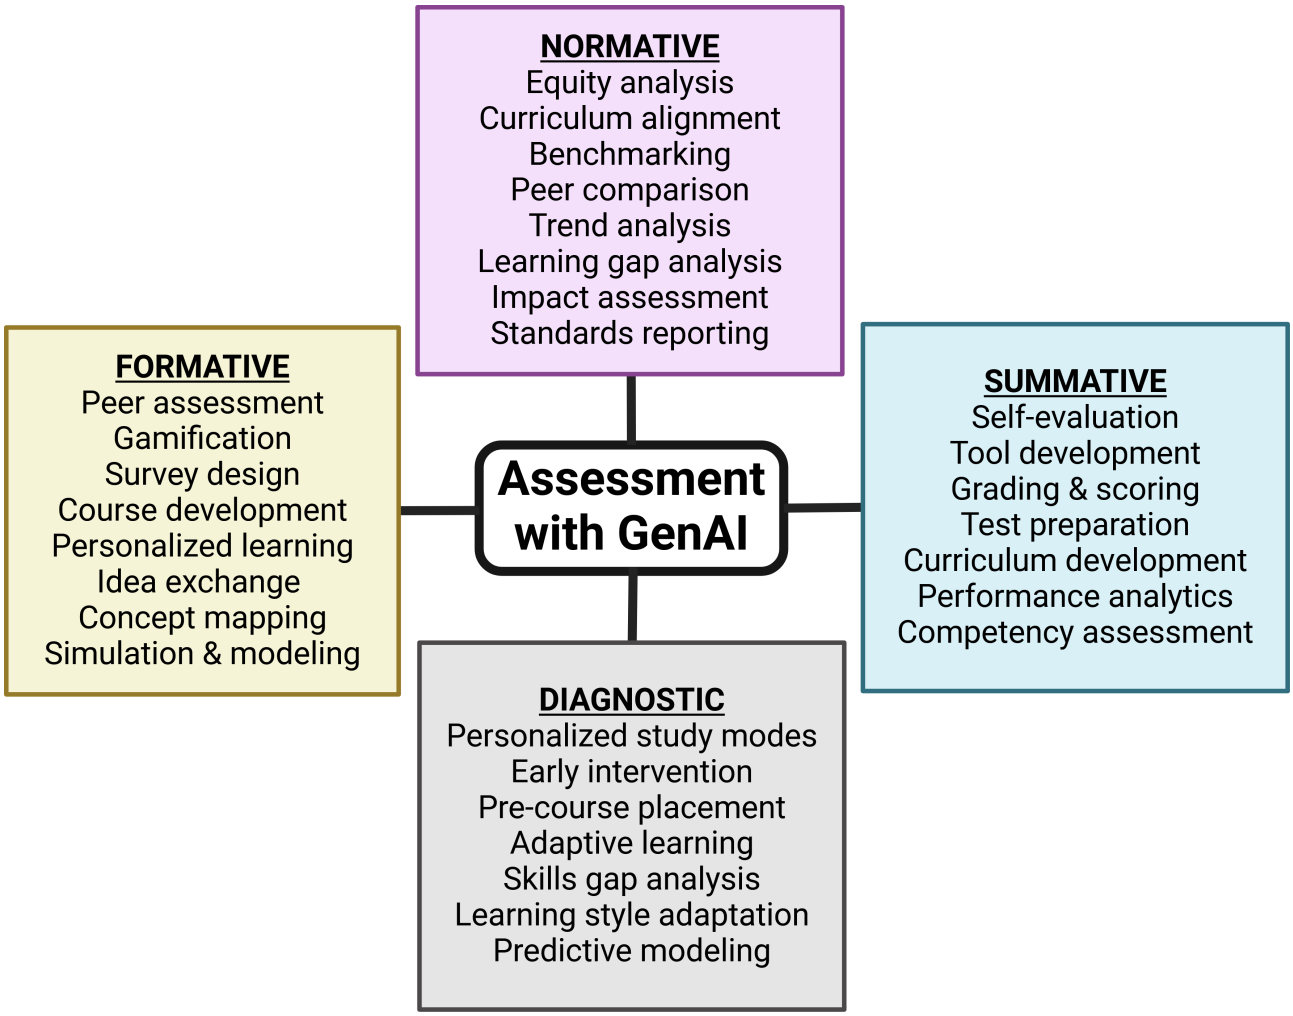

Current Limitations and Future Hurdles

Embracing GenAI tools holds promise for both learners and instructors, yet significant hurdles remain, and user caution is warranted in a rapidly evolving environment of GenAI capabilities, tools, ethics, and acceptable use policies and procedures. Accuracy of GenAI output is a critical aspect that requires careful consideration and diligence, especially when used as a training tool for future clinicians and scientists. LLMs are trained by large datasets and leverage analytics to produce predictions, not logic-derived integrations linking informed input to informed output [22]. Thus, a randomness can exist between prompt design and output obtained. Learners and instructors must both carefully assess and evaluate output from GenAI tools to detect "hallucinations" (ie, incorrect GenAI output that presents as correct). Outside of local application programming interface iterations, general releases of these GenAI models are trained on large datasets that may include unvalidated data from the internet. Thus, even if effort is made to include reliable and authoritative sources, these large training datasets may contain misinformation, biases, or outdated information from uncurated data. We have observed this on several occasions when implementing GenAI as an educational tool, where output sounds entirely factual and even referenced only to be completely incorrect with nonexistent references (this improved substantially in GPT-4o and Claude-3.5 Sonnet, accessed on April 11, 2024). As of this submission, caution is still warranted even with significant improvements in model quality. One effective strategy to minimize accuracy issues is uploading content, such as lecture outlines or even slides, and designing focused prompts working from provided content. If possible, use an institutionally firewalled GenAI tool where content is not shared beyond immediate use. This works well to develop focused learner assessments. This leads to another limitation and hurdle: the rapid pace of GenAI tool development, improvement, and deployment has created an environment where time-limited instructors and digital native learners are increasingly overwhelmed with determining best practices, tools, methods, or even workflows. We have responded to this reality by developing open training courses (eg, on Canvas Learning Management System from Instructure) with frequent

updates and ongoing informational seminars, often targeting instructors, to raise awareness of AI changes as they relate to clinical practice and pedagogy. While this rapidly evolving landscape of tools and capabilities is a challenge, it's also an opportunity to leverage new features and expand impact.

In addition, a caveat to implementing "chatbot" style GenAI like ChatGPT in educational frameworks is the input prompt. The relationship between input prompt and output produced is so integrated that "prompt engineering" is a growing career emerging alongside GenAI [23]. Prompt engineering is the careful construction of input prompts or instructions for GenAI models to influence content, style, voice, depth, and even accuracy of resultant output. How input prompts are constructed is a primary determinant of what models produce, even down to small changes like omitting single words, changing adverbs, or using commas versus numbers for a list [24]. These small changes can produce vastly different results with biased, misleading, or inaccurate information [24]. Truly effective prompts are often complex and descriptive, striking a balance between specificity and openness [25]. Meaning, a prompt that is too specific may limit the ability to generate diverse or creative responses, and a prompt that is too open-ended may result in ambiguous or irrelevant output. The approach we use is constructing "Role+ Bounds+Inputs" style input prompts. In this formula, "Role" involves assigning the chatbot a specific job or identity for the analysis (eg, college professor teaching a specific course and learner type), "Bounds" will establish limitations and constraints for model operation (eg, academic context, subject matter, and level of expected answer), and "Inputs" includes relevant contextual information (eg, content outlines, rubrics, or slide summaries). Using a structured prompt guides GenAI models to produce more focused, accurate, and relevant responses. In addition, one can use a scaffolding approach with iterative prompts building toward a common theme or objective. The complexities of prompt engineering have been discussed elsewhere and leveraging the resources provides a deeper discussion of the benefits of a productive prompt while leveraging GenAI [26,27].

GenAI tools such as ChatGPT are proving transformative, impactful, and hold immense potential for enhancing the educational experience for both learners and instructors. Yet, this new reality is problematic considering the lack of transparency on training data content; ethical and socioeconomic implications; quality control and model accuracy; and the potential to perpetuate bias, loss of voice, and agency for both learners and instructors [21]. Learners should be empowered to make informed decisions regarding their participation in GenAI-related or driven activities, and instructors should encourage learners to ask questions, express concerns, and participate in shaping ethical guidelines related to GenAI use in curricula [11,21]. Furthermore, instructors and administrators have an expectation to proactively define clear policies and procedures for GenAI use in educational settings that provide flexibility for both learners and instructors. A major benefit to GenAI use in educational settings is its collaborative potential to rapidly generate personalized and dynamic content, yet this requires equity in understanding and use. Considering GenAI's rapid evolution, this equity has always been absent in courses we have started since ChatGPT was released in November 2022. It's incumbent on instructors to ensure learners are familiar with GenAI tools being used and available. Data-driven insights from GenAI analytics enable instructors to provide targeted support to individual learners as skills develop and courses progress. This can facilitate multimodal learning experiences, incorporating various media formats such as videos, audio, and interactive simulations mentioned above. Significant hurdles remain regarding GenAI use in higher education. These include data ownership and privacy, output accuracy, linking learner needs with instructor resources, and ensuring sufficient training to avoid equity and GenAI skills gaps when being used. Academic institutions are increasingly looking at internal, data-protected and firewalled, GenAI resources (eg, Microsoft CoPilot) yet there remain limited options for analyzing course content and metrics. Finally, ethical concerns associated with leveraging GenAI by both learners and instructors is a major (probably primary at most institutions) topic of discussion.

Conclusions

Our experiences in leveraging GenAI across 5 academic semesters have, overall, been very positive. This implementation is from the perspective of informing and training both learners and instructors; establishing clear policies and procedures relating to academic misconduct at the department, college, and institutional levels; ensuring equity and ability in use; and constant vigilance regarding content accuracy and limitations. LLMs and GenAI have evolved through decades of iterative research across multiple disciplines including statistics, mathematics, and computer science data science [28]. They are not new technologies. Development of the transformer architecture in 2017 was a key transition point for the emergence of current "chatbots" gaining momentum in popular media and use [29]. This technology continues to evolve with diffusion, attention mechanism variants, and retrieval-enhanced transformer mechanisms being new examples of how GenAI technology is rapidly evolving [30]. Through leveraging large datasets with high-demand computational needs, current GenAI models show significant promise. The important point being, these models (eg, ChatGPT or Claude) excel at pattern recognition yet struggle with defining logical connections between training data and outputs produced ("reasoning"). This is an important caveat for application in higher educational settings focused on critical thinking, developing advanced knowledge and skills within specific disciplines, clinical training, and scientific discovery. As such, it's essential for instructors, administrators, policymakers, institutions, districts, and learners to collaborate and communicate toward what this future will look like as GenAI models evolve. Through this collaboration, GenAI use in educational settings can be leveraged while minimizing negative aspects like potential misconduct, data privacy, algorithmic bias, accuracy, and equity concerns. We argue that GenAI can play a valuable role in higher education settings to improve learner motivation and knowledge retrieval while facilitating workflows and content generation for instructors. This viewpoint explores GenAI's potential as an educational tool including alignment with learning theories (eg, behaviorism and cognitive load theory),

implications for learners and instructors (eg, flipped classrooms and self-directed assessments), responsible implementation (eg, bias and equity), and evolving challenges (eg, hallucinations and misconduct).

Acknowledgments

The authors would like to extend appreciation to professional and graduate students from the Department of Nutritional Sciences and College of Medicine Graduate Program in Biological Sciences for providing feedback and insights during spring and fall 2023 courses as we developed material presented.

Abstract

In the first decade of this century, physicians maintained considerable professional autonomy, enabling discretionary evaluation and implementation of new technologies according to individual practice requirements. The past decade, however, has witnessed significant restructuring of medical practice patterns in the United States, with most physicians transitioning to employed status. Concurrently, technological advances and other incentives drove the implementation of electronic systems into the clinic, which these physicians were compelled to integrate. Health care practitioners have now been introduced to applications based on large language models, largely driven by artificial intelligence (AI) developers as well as established electronic health record vendors eager to incorporate these innovations. Although generative AI assistance promises enhanced clinical efficiency and diagnostic precision, its rapid advancement may potentially redefine clinical provider roles and transform workflows, as it has already altered expectations of physician productivity, as well as introduced unprecedented liability considerations. Recognition of the input of physicians and other clinical stakeholders in this nascent stage of AI integration is essential. This requires a more comprehensive understanding of AI as a sophisticated clinical tool. Accordingly, we advocate for its systematic incorporation into standard medical curricula.

KEYWORDS

clinical medicine; artificial intelligence; large language models; decision support; AI; LLM; AI in medicine

Introduction

Artificial intelligence (AI) has demonstrated long-standing potential to fundamentally transform health care delivery. Prior to the emergence of large language models (LLMs) in the modern era, the implementation and advancement of AI applications were predominantly concentrated in domains such as diagnostic imaging and predictive analytics. These early efforts endeavored to provide decision support for clinicians in critical clinical contexts, such as sepsis identification and management. These implementations were not patient-facing, and these benefits were generally perceived as natural extensions of broader technological progress.

In contrast, today's interactive chat apps, showcasing advances in LLMs, are able to simulate sentient conversational speech, which has prompted a reconceptualization of AI capabilities. The proficiency of these systems to rapidly process and summarize relevant information from a vast collection of stored knowledge has sparked debates as to the potential of these models to exceed human cognitive performance in tasks requiring sophisticated clinical decision-making and interpretative analysis [1].

Heralded for its transformative potential, AI in medicine has promised to enhance administrative efficiency through the automation of repetitive and time-intensive processes, support doctors through improved diagnostic accuracy, meticulously reduce iatrogenic errors, facilitate personalized medicine tailored to individual patient characteristics, and enable clinicians to navigate the continually expanding corpus of medical research advances and evolving practice guidelines [2,3]. However, earlier initiatives to integrate AI into health care frameworks saw limited adoption, as clinicians remained unconvinced as to the technology's capacity to add substantive value in the clinical setting [4-6]. Technological constraints in computer vision and natural language processing impeded widespread clinical adoption of nascent AI applications, while evolving regulatory frameworks constituted significant barriers to commercialization [5].

Another significant factor impacting the trajectory of health care AI implementation was a shift in professional autonomy. Prior to the preceding decade, the medical profession within the United States operated with greater practitioner independence. Physicians unfamiliar with AI technology, or unconvinced of its practical advantages, had little incentive to incorporate the new technology into their workflow [7]. Notably, they were able to determine for themselves when and how best to invest in and implement AI into their medical practice. The contemporary practice landscape has since undergone significant transformation, as the majority of physicians have transitioned from autonomous ownership to employment relationships with

hospitals or other corporate health care systems [8]. This structural shift has profound implications for the implementation and governance of AI technologies in clinical settings, as employed health care professionals, unable to keep pace with these developments, risk marginalization as key stakeholders [9]. Their essential perspectives may be overlooked in critical decisions that will shape clinical workflows, promote work-life balance, and address professional burnout, ultimately redefining their intrinsic role in the health care system [10].

What Practicing Physicians Need to Understand Regarding the Role of LLMs

In the past year, multiple reports have highlighted the remarkable achievements of LLMs on medical knowledge tasks, often claiming accuracy near 100%, which surpasses human capability [11]. The benchmark testing panels used to evaluate these models have included datasets of clinical vignettes, urgent care encounters, and medical licensing or board exam datasets [12]. Such impressive results, widely publicized in both the general and industry media, have significantly influenced perceptions of medical AI capabilities compared with human practitioners [13].

The inadequacy of standard LLM evaluation metrics as grounds for physician workforce reduction has been comprehensively examined previously [14-18]. For example, the performance of medical LLMs is still dependent on the provision of pertinent clinical history information and salient features of the physical examination, and it is still not clear that this critical initial step in successfully identifying the nature of a medical condition can be adequately performed by an LLM. Automated techniques to acquire the clinical history by requiring that the user select from a predetermined menu of symptoms and descriptors may fail to capture nuanced empathetic human interaction, such as a sense of advocacy, caring, comfort, and dedication that emerges during genuine patient-provider encounters [19,20].

Although LLMs can demonstrate proficiency in tasks involving logic, reasoning, and assimilating large volumes of structured data, these models still lack essential clinical skills such as observation of a patient's demeanor, interpretation of nuanced nonverbal clues, and establishing rapport—competencies instinctively performed by a seasoned physician. Such limitations in basic sensorimotor and perceptual processing represent a manifestation of Moravec's paradox, a theoretical conundrum that poses formidable challenges to researchers investigating generative AI [21]. Simulated expressions of empathy and clinical judgment can still be perceived as superficial and scripted, precisely because their responses rely on predicted or pretrained responses, rather than authentic and experiential understanding of a patient's lived reality.

Limitations of LLM Capabilities

Physicians should understand that inference on LLMs is highly dependent on the data on which they have been trained. Details on specific dataset selection for model pretraining are proprietary knowledge, but many have been trained on datasets such as PubMed Central, MIMIC-III clinical notes, sanitized data from electronic health record interactions, and clinical practice guidelines [22,23]. These models undergo further fine-tuning on additional medical knowledge datasets as well as physician-patient dialog datasets [24]. As with any commercial deployments, medical LLMs must adhere to "continuous integration/continuous deployment" principles in machine learning operations, with monitoring to assure that the application dataset does not drift too far from the training dataset and that regular maintenance fine-tuning and dataset updating are performed [25].

Physicians should also be aware that LLMs, functioning as statistical pattern generators rather than verified information arbiters, generate outputs based on probabilistic distributions within their training data rather than through systematic verification of factual accuracy. Hallucinations remain problematic, afflicting even the latest reasoning models [26,27]. These confabulatory responses can be difficult for the clinician user to detect, creating a risk for their use in the clinic. Compounding this issue, it has been noted that references cited by LLMs to support their claims may themselves be hallucinatory [28].

Bayesian inference plays a significant role in the clinical application of LLMs in medical decision support. Despite having been trained on extensive medical corpora encompassing comprehensive clinicopathological knowledge, these models may exhibit deficiencies in appropriately weighting disease prevalence. The adage "when you hear hoofbeats, think horses, not zebras," reflects the experience of physicians that more common etiologies may present atypically and should still be prioritized. Current LLMs may still struggle in providing reasonable estimates of pretest disease probability, a skill that physicians acquire after years of clinical experience [29]. As a consequence, LLMs may disproportionately elevate rare conditions with close symptom concordance over more common diseases with partial clinical alignment [30]. LLMs may also fail to understand that the diagnostic process is dynamic and iterative, requiring ongoing refinement in response to emerging patient data revealed in subsequent encounters.

The Importance of Prompting

The role of system prompt customization in the efficacy of the physician-LLM interaction has been largely unexplored. Physicians may find benefit in interacting with an LLM that behaves like a trusted colleague, rather than a chatbot. Being able to manage the tone of an LLM might encourage a more exploratory and conversational interaction that lowers anxiety and stress, rather than isolated zero-shot querying as with a search engine. Strategic modifications to the system prompt can significantly influence model output, potentially resulting in divergent clinical management recommendations [31]. A demonstration of the efficacy of engineered prompting is the use of Medprompt and AutoMedPrompt, which invoke advanced techniques, such as chain-of-thought reasoning, *k*-nearest-neighbor–selected few-shot prompting, ensemble voting, and textual gradients, to extract high performance from generalist foundation models in standardized question-answer benchmarks, surpassing that of specialist models [32,33]. These

prompt enhancement techniques can yield impressive scores on multiple-choice question-answer datasets, such as MedQA-USMLE or PubMedQA. However, it is important to recognize that zero-shot (unassisted) performance on unstructured input is the more clinically relevant paradigm, an area where there is a comparative paucity of empirical performance data. A comprehensive study of various open-source models, including several that were fine-tuned on medical corpora, demonstrated that 1- to 3-shot prompting was requisite for optimal clinical language comprehension. The investigators concluded that while LLMs demonstrate proficiency in exam-style question-answer tasks with provided options, they exhibit significant limitations in open-ended scenarios [34].

Public LLMs typically restrict access to system prompting, but domain-specific consultative LLMs should offer this as a customization option. Currently, certain industry stakeholders regard proficiency in prompt engineering as "simply an expected skill," exemplifying a troublesome paradigm in which the vast majority of physicians, inadequately trained in this regard, are dependent on software developers to craft tools that physicians poorly understand [35]. Physicians should seek training to develop expertise in crafting suitable prompts to obtain the most relevant and suitably formatted information, while minimizing the likelihood of hallucinatory outputs [36,37].

LLM Performance Compared With Physician Performance

In addition to reports describing expert-level performance in question-answer multiple-choice testing, LLMs have been touted as being superior in the generation of differential diagnoses when presented with clinical vignettes [38]. These capabilities may stem from the models' capacity to recall factual information from their training corpora, rather than from any inherent ability to synthesize insight from a panoply of clinical indicators, as with human clinical reasoning [38]. For example, the performance of GPT-4 in identifying the diagnosis of published internal medicine cases was significantly decreased when challenged with unpublished clinical vignettes [39].

A recent systematic review and meta-analysis encompassing 83 studies across diverse models (including GPT-4, GPT-4o, PaLM2, and Perplexity, as well as open-source models fine-tuned in the medical domain) found that the pooled accuracy of the generative AI models was 52.1%, demonstrating no overall advantage over physician performance. The models were tested against a variety of clinical vignette datasets, as well as challenges posed in prominent medical journals. Notably, the performance of expert physicians was 15.8% higher, while nonexpert (resident) physicians maintained a marginal 0.6% advantage over LLMs [40].

A counterpoint to these observations, in a commentary highlighting 6 selected studies that examined the effectiveness of LLMs as diagnostic adjuncts, concluded that LLM assistance failed to enhance clinicians' diagnostic accuracy, with the models purportedly demonstrating superior performance on various assessment metrics [41]. We concur with the contention that claims of physician inferiority in these studies remain inconclusive, given methodological limitations, including an insufficient number of valid datapoints for robust comparison [42]. Nevertheless, it is readily apparent that physicians unaccustomed to AI-augmented workflows found LLM assistance unhelpful or counterproductive, especially when resolving discordant or ambiguous model outputs, which consumed valuable clinical time [43].

Physicians should also be cognizant of special legal ramifications regarding the use of AI for clinical decision support. The use of LLMs in patient care potentially exposes a clinician to novel vulnerabilities, broadly including model overreliance, inadequate appreciation of performance limitations, informed consent challenges, and potential bias with ethical ramifications [44,45]. These risks highlight the need for the robust regulatory oversight of LLM-based technology [46]. In litigation, physicians have been required to demonstrate adherence to a reasonable standard of care; however, these norms may evolve in response to transformative technologies [47]. In the event of an adverse outcome, physicians also risk penalization by juries whether or not an AI recommendation is accepted or overruled [48,49]. A rigorous discussion of the legal ramifications of using AI in clinical decision-making is beyond the scope of this viewpoint, but in light of the above considerations, the most prudent use of medical AI may be to confirm an existing medical decision, rather than as a means to augment care [50].

The Need for Active Physician Involvement in Shaping the Future of Generative AI in Health Care

Machine learning and generative AI will undoubtedly catalyze remarkable advancements in health care delivery, especially in clinic settings. These technological advances will undoubtedly exert differential impacts across medical specialties as advances in machine learning are increasingly leveraged to assist in image-processing tasks; however, they are unlikely to wholly replace the clinical expertise of physicians [51]. Indeed, Geoffrey Hinton, the "godfather of AI," was notoriously inaccurate as to his predictions regarding the demise of diagnostic radiology as a career [52]. We feel that health care providers will continue to play essential roles and that AI technology has the potential to augment the capabilities of physicians, nurses, pharmacists, and clinical researchers through the identification of more effective therapeutics and facilitation of novel technological innovations.

We also wish to emphasize, however, that the notion that a physician empowered by AI may outperform a doctor without this advantage may obscure deeper issues [53]. Near-term enhancements in AI-driven productivity gains may ultimately lead to its commoditization and may not necessarily translate to increased compensation, decreased burnout, or even job security [54]. In the early stages, physicians may even see an increased demand for their services (Jevons paradox) [55]; however, some warn that the augmentation or empowered role of health care providers may ultimately lead to a restructuring

of the health care system. Patient intake and flow structures may be eventually redirected to meet the needs of third parties, such as insurers or hospital administrators, to prioritize revenue cycle management, or even to interface with other AI systems, such as those that seek to leverage actionable insights from outcomes data to guide evidence-based treatment recommendations. The adaptation of AI integration may reconfigure key decision-making in health care systems away from the employed physician to those whose priorities put greater weight on economic or political factors.

Physician input remains critically important in this process, especially in the transformative stages of AI integration into the clinic. We posit that the aforementioned structural shift in the physician employment landscape has significantly attenuated their influence as essential stakeholders and arbiters regarding technological implementation decisions [56]. Clinical practitioners should avoid defaulting to passive acceptance as institutionally procured software systems integrate AI technologies into their established clinical workflows.

Generative AI applications in medicine are still early in development, necessitating an approach that balances technological promotion with the practice-refined workflow of the clinical diagnostic process. The complexities of medical decision-making transcend simplistic evaluation through multiple-choice question-answering from medical datasets. Concern has already been raised that AI-based applications are being adopted too rapidly by hospitals eager to offer the latest in technological innovation, but without the necessary continuous oversight. Relying on the Food and Drug Administration to develop and regulate safeguards is not feasible [57]. A different approach, centered on the physician and accommodating the workflow requirements of the practitioner, will better foster physician-AI synergy [58,59]. Achieving this will require that physicians develop a deeper understanding of the workings of AI technology, comparable to their understanding of more traditional medical tools (Figure 1). We advocate for research initiatives exploring optimal physician-AI collaboration, potentially including practitioner proficiency in customizing LLM tools to address specific needs. Physicians with such expertise will be better able to advise regulatory bodies on establishing appropriate guardrails against potentially deleterious applications, privacy violations, and the perpetuation of bias and misinformation in health care contexts [60].

Furthermore, clinicians who are well-versed in the limitations of LLMs and related AI applications can provide essential expertise in medicolegal proceedings involving adverse clinical outcomes associated with AI utilization. Enhanced training in AI methodologies will equip physicians to critically evaluate medical research, which increasingly applies advanced data analytics in clinical settings. Such training will also enable physicians to contribute experiential insights and conduct rigorous critiques of machine learning applications designed to enhance predictive analytics. Actualization of these objectives necessitates comprehensive integration of AI education within the pathways of standard medical curricula [60].

Proposals for Physician Engagement in AI

As AI increasingly transforms health care delivery, physicians must proactively expand their expertise to include the following principles, ensuring responsible and effective integration of these technologies into clinical practice:

- Physicians should have some understanding of how deep learning models are trained and be aware of factors that can impact accuracy, such as dataset bias, covariate shift, out-of-distribution generalization, and concept drift.

- Physicians should understand how deep learning models are evaluated and, when possible, demand from software vendors the provenance of the datasets used for model training as well as performance metrics before they are introduced into the clinic.
- Physicians should understand the mechanism underlying LLMs; their intrinsic limitations and vulnerabilities; the impact of prompt engineering on output quality; and how to reduce hallucinatory behavior. Physicians should understand how to evaluate the capabilities of LLM models, as well as whether the information they generate will be exported and used for training purposes. Physicians should understand the ramifications of ambient LLM listening, for example, the custody and retention issues regarding the source recordings generated by AI scribes. These issues pertain to data privacy and confidentiality.
- Physicians should understand the potential ethical concerns intrinsic to how LLMs are trained, so as to minimize their perpetuation.
- Physicians should understand the legal ramifications of using LLMs as clinical diagnostic support. Physicians should recognize that medical LLMs function best when used adjunctively to validate evidence-based practice, rather than to generate novel treatments or be allowed to operate autonomously.
- Physicians should understand how privacy and confidentiality may be breached by incautious use of public LLM models.
- Physicians should develop sufficient understanding of clinical AI to be able to critique commercial software.
- Physicians should be able to educate and help train ancillary health care staff as to the proper use of AI technology, as well as to instill confidence in patients that such technology will be responsibly deployed.
- There should be greater physician participation in the development, validation, and implementation of clinical AI systems, tailored to local deployments.
- Physicians should collaborate with clinical informaticians throughout clinical AI implementation to ensure regulatory preparedness and compliance.

By embracing these essential AI competencies, physicians can maintain their central role in patient care while leveraging this technology to enhance clinical outcomes and preserve the integrity of the medical profession.

Abstract

The integration of digital health and informatics competencies into health care education in Canada is essential for preparing a workforce capable of leveraging health care technologies to enhance care delivery and patient outcomes. Despite significant advancements, the current educational landscape in digital health remains inconsistent, characterized by fragmented curricula and uneven competency attainment. Addressing these gaps requires an innovative reframing of digital health competencies guided by a robust, outcomes-oriented framework. These authors propose the Quintuple Aim as an effective framework for outlining and organizing digital health and informatics competencies, focusing simultaneously on improving patient experience, enhancing population health, reducing health care costs, improving health care provider experience, and advancing health equity. Each dimension of the Quintuple Aim provides a critical lens for identifying, prioritizing, and contextualizing core competencies. Within the "patient experience" aim, competencies prioritize patient-centered technology use, including digital literacy, privacy awareness, and the ability to empower patients through technology. "Healthcare provider experience" competencies prioritize usability, workflow integration, and strategies to mitigate technology-related burnout. Under "population health," competencies emphasize data-driven decision-making, analytics, and health informatics to support effective public health interventions. Competencies associated with "cost reduction" focus on operational efficiency, resource optimization, and economic evaluation of digital health solutions. Finally, "health equity" competencies emphasize inclusivity, cultural safety, and the elimination of digital divides, ensuring equitable access to digital health technologies. Potential assessment strategies aligned with each competency area are highlighted, emphasizing formative and summative evaluations that include simulation-based assessments, real-world technology integration projects, and reflective practice portfolios. By applying the Quintuple Aim as a guiding structure, digital health education can achieve greater standardization, clarity, and alignment with health care system needs, while simultaneously allowing for tailored adaptations responsive to specific regional and institutional priorities. This paper introduces the Quintuple Aim as a guiding framework to comprehensively identify and organize core digital health and informatics competencies for health professional education.

KEYWORDS

digital health; health informatics; competency-based education; Quintuple Aim

Introduction

The rapid advancement of digital health technologies necessitates a health care workforce equipped with the requisite knowledge, skills, and abilities to effectively integrate and use these technologies [1-3]. Educating the Canadian health care workforce in digital health is essential to enhance patient care and safety, improve health care accessibility, and ensure the sustainability of health care systems. The International Council of Nurses, the World Health Organization (WHO), and the Organisation for Economic Co-operation and Development (OECD) emphasize the importance of digital literacy for health care providers to effectively leverage technology and adapt to evolving health care challenges [4-7]. Despite the increasing importance of digital health and health informatics, there is a significant gap in the number of educational programs offered across Canada that prepare health care professionals for these challenges [2,8].

There is a recognized and acute need for more digital health professionals who bring informatics knowledge, digital health understanding, and data analytics skills to health care settings

[2,5,8-12]. Terms essential to this discussion include digital health, health informatics, and competency. Digital Health refers to the use of technologies for improving the health and well-being of people at individual and population levels, as well as enhancing the care of patients through intelligent processing of clinical and genetic data and leveraging digital health technologies and services to transform care delivery [5,7,13,14]. The Canadian Institutes of Health Research cite Canada Health Infoway's definition of Digital Health as "the use of information technology or electronic communication tools, services and processes to deliver health care services or to facilitate better health" [15]. Health Informatics is a focused area within digital health and is defined by the American Medical Informatics Association as "the science of how to use data, information and knowledge to improve human health and the delivery of health care services" [16]. A competency refers to defined knowledge, skills, and qualities expected to competently carry out a function [17]. In the context of health care, the term competency is defined as "an observable ability of a health professional, integrating multiple components such as knowledge, skills and attitudes" [18]. Informatics competencies are integral to the broader concept of digital health and should be integrated into an educational digital health program [1,2,8]. For the purposes of this paper, digital health is used as an umbrella term that includes health informatics competencies alongside broader digital technologies and services that enhance health system performance. These competencies are designed for health care professionals seeking digital health education to develop the knowledge and skills necessary for effectively integrating digital technologies into health care practice.

Current State of Digital Health Education

Despite multiple organizations highlighting the need for the health care workforce to acquire and maintain the knowledge and skills to navigate technologically advancing health care systems [2,5,9-12], current Canadian postsecondary educational programs often lack the comprehensive curriculum, faculty expertise, and resources necessary to equip graduates with these competencies [2,8]. This gap between the evolving digital health landscape and the preparedness of health care professionals can potentially lead to inefficiencies, reduced quality of care, increased clinician workload, and missed opportunities for innovation within health care settings [9,10].

If the gap in digital health education remains unresolved, the health care workforce will continue to struggle with the integration and use of digital health technologies, which are increasingly vital for modern health care delivery. The International Council of Nurses highlights that digital health is integral to enhancing care quality and patient outcomes, making it essential for nurses to be proficient in these technologies [5]. The WHO also stresses that a well-prepared workforce is crucial to achieving the full potential of digital health innovations globally [7]. Without adequate education, the health care sector risks failing to capitalize on digital evolutions as noted by Socha-Dietrich [6], whose OECD report emphasizes the importance of empowering health care professionals to adapt to these advancements. Furthermore, the 2023 Canadian Survey of Nurses by Canada Health Infoway reveals that gaps in digital health proficiency can directly impact the quality of care provided [19].

Prioritizing Digital Health and Informatics Competencies

Digital health technologies are transforming health care delivery, requiring a shift in education to equip health care professionals with essential digital health and informatics competencies. Effective digital health educational programs typically include components such as data analytics, health information system interoperability, privacy and ethical considerations, and health informatics theory [20]. These curricula also emphasize skills such as leadership, communication, project management, and change management, all of which are critical in implementing and managing digital health initiatives [21]. Studies have shown that graduates of digital health programs often demonstrate improved competencies in using digital health technologies, which translates to better patient outcomes and more efficient health care delivery [10,20-22].

The Quintuple Aim as a Framework

The Quintuple Aim is a framework for health care improvement that aims to make health care more equitable, effective, and efficient [23]. In the evolving landscape of health care, the integration of digital health and informatics competencies plays a critical role in achieving the goals outlined in the Quintuple Aim: enhancing patient experience, improving care team well-being, reducing costs, advancing population health, and promoting health equity [23,24]. These competencies empower providers to harness technology and data-driven insights, ultimately enhancing patient care and health outcomes. By aligning digital health and informatics competencies with the Quintuple Aim, health care professionals can better navigate and contribute to a system that prioritizes both efficiency and equity.

Many researchers and organizations have compiled lists of informatics competencies for health care professionals in various roles in the health care system [20-22,25-29,30,31]. In addition, several researchers have developed frameworks to guide the organization, prioritization, and context of the competencies [21,22,32-36]. These authors suggest organizing and combining these competencies into the 5 categories outlined in the Quintuple Aim (patient experience, provider experience, reduced cost, population health, and health equity). This competency framework supports clinicians, health care administrators, informatics specialists, and other professionals preparing for roles in digital health. These competencies are not only confined to single objectives but intersect across multiple areas of the Quintuple Aim. As health care systems increasingly adopt advanced digital solutions, it becomes evident that these competencies do not function in isolation; rather, they create synergies that benefit both individual and population-level outcomes. Understanding these overlaps is essential for designing education programs and initiatives that prepare health care providers to meet the complex and interconnected needs of today's health care environments. Table 1 maps each of the

Quintuple Aims to digital health competencies as well as potential assessment strategies.

Table . Mapping digital health competencies to the Quintuple Aim Framework.

Quintuple Aim and competency	Assessment strategies
Patient experience	
Integrating digital health technologies into care	Practical simulations, case studies, and reflective assignments around patient management, communication, and decision-making, ethical, privacy, and interoperability concerns.
Applying and understanding user-centered design	Project-based evaluations to design, test, and refine digital health solutions based on patient needs, usability, and accessibility.
Patient-centered digital literacy and virtual care skills	Role play scenarios and patient simulations to communicate via digital platform and ensure patients can navigate virtual care services.
Ethical practice	Case-based discussions, ethical dilemma scenarios, and reflective essays around privacy, data security, informed consent, and responsible use of technology.
Communication skills	Virtual patient consultations and collaborative team simulations to explain digital health tools, address patient concerns, and facilitate effective communication through digital platforms.
Genomics competencies	Case studies, quizzes, or practical exercises to interpret genetic data, apply genomic information in clinical decision-making, and use digital tools for personalized patient care.
Provider experience	
Interoperability principles	Scenario-based assignments and systems integration projects to navigate and connect various digital health platforms, ensuring seamless data exchange and collaboration across health care settings.
User-centered design and workflow optimization	Hands-on projects to design digital health solutions that prioritize user experience, streamline clinical processes, and demonstrate the ability to enhance efficiency and usability within health care environments.
Critical thinking and evaluation	Analytical case studies to critically assess the effectiveness of digital health tools, identify potential areas for improvement, and evaluate their impact on patient care and health care workflows.
Clinical decision support and evidence-based practice	Simulations and practical examinations to use digital tools to make data-driven decisions, incorporate the latest clinical guidelines, and evaluate the outcomes of their decisions in patient care scenarios.
Reduced cost	
Efficient use of digital health technologies	Real-world simulations and timed exercises to quickly and accurately navigate digital health systems, manage patient data, and complete tasks with minimal errors and maximum efficiency.
Cybersecurity, privacy, and ethical use of digital health technologies	Written examinations, case studies, and scenario-based discussions to test knowledge of data protection laws, ethical guidelines, and strategies for safeguarding patient information in digital health environments.
Digital health ecosystems and interoperability	Group projects to analyze and design solutions that demonstrate how different digital health platforms work together.
Data analysis	Data-driven case studies and analytical projects to interpret health care data, identify trends, and make recommendations.
Population health	
Data management and analysis	Projects to analyze large data sets to identify trends and evaluate strategies.
Adaptability to emerging technologies	Hands-on exercises and simulations to learn and integrate new tools into clinical practice.
Leadership, change management, and project management skills	Team-based projects to plan, execute, and evaluate implementation of digital health solutions.
Health equity	
Addressing digital health disparities	Case studies and community-based projects to identify barriers to digital health access, propose strategies for increasing inclusivity, and evaluate the impact of their solutions on underserved populations.

Quintuple Aim and competency	Assessment strategies
Health data access	Practical exercises and written assignments to analyze the ethical, legal, and technical aspects of accessing and sharing health data, ensuring compliance with regulations while considering patient privacy and data security.
Indigenous data sovereignty	Case studies and reflective essays that analyze the importance of respecting Indigenous peoples' control over their health data, explore ethical considerations, and demonstrate how to apply culturally appropriate practices in digital health.
Health literacy and patient education	Role-playing exercises and patient simulation scenarios to effectively communicate digital health information, assess patient comprehension, and tailor education to diverse literacy levels and needs.

Patient Experience

Overview

The patient experience category of the Quintuple Aim focuses on improving the quality, accessibility, and personalization of care to enhance patient satisfaction and outcomes. Digital health technologies play a crucial role in advancing this goal by enabling virtual care, mobile health apps, wearable devices, and patient portals that facilitate seamless communication between patients and providers. These tools empower individuals to actively engage in their care, access real-time health information, and receive timely interventions, ultimately leading to more patient-centered, efficient, and responsive health care experiences.

Integrating Digital Health Technologies Into Care

The ability to effectively translate digital health knowledge and theory into practical applications within patient care settings is essential to enhancing the patient experience with digital health technologies. Health care students should be supported in developing proficiency in using digital health technologies and applications for patient care, identifying appropriate patient education materials, and acting as advocates for system users [2,37]. Competencies in using electronic health records for comprehensive documentation, effective communication among care providers, and making evidence-informed decisions are needed in today's health care workforce [4,5,28]. Health care students should be adept at leveraging virtual care platforms for remote consultations and patient monitoring, expanding access to care and addressing health care disparities [10,25,26]. In addition, understanding how digital tools can enhance patient engagement and empower individuals to actively participate in their care and self-management of chronic conditions is essential [11]. Understanding the functionalities and interconnectedness of health information systems, virtual care platforms, mobile health apps, and emerging technologies like artificial intelligence (AI) and robotics is fundamental [1,3,38-40]. Furthermore, understanding the capabilities and limitations of these technologies is essential for their appropriate and effective application in providing quality patient care. If digital health technologies are not effectively integrated into patient care, patients may face reduced access to timely information, fragmented communication with providers, and lower engagement in their own health management, ultimately compromising their overall health care experience. The competency of integrating digital health technologies into care could be assessed through practical simulations, case studies, and reflective assignments that evaluate health care students' competency in using digital tools for patient management, communication, and decision-making, while also considering their understanding of ethical, privacy, and interoperability concerns (Table 1).

Applying and Understanding User-Centered Design

Informatics competencies that enhance patient-centered care focus on human-centered design, usability principles, and patient engagement strategies within digital health solutions. Students should learn to critique digital health technologies, such as patient portals, telehealth and virtual care systems, and mobile health apps, to ensure they are user-friendly, accessible, and culturally sensitive [41,42]. Training in health literacy principles and user-centered design methodologies can foster empathy by deepening health care students' understanding of patient needs, ensuring that digital health solutions are accessible, inclusive, and tailored to diverse populations. If health care professionals understand and apply user-centered design, it will make it easier for patients to navigate and engage with health technologies, ultimately leading to improved patient satisfaction [43]. If user-centered design is not applied when integrating digital health technologies, patients may struggle with inaccessible, confusing, or nonintuitive systems, leading to frustration, decreased engagement, and potential disparities in health care access and outcomes. Health care students' abilities to apply and understand user-centered design in relation to digital health technologies could be assessed through project-based evaluations where students design, test, and refine digital health solutions, considering patient needs, usability, and accessibility to ensure the technology meets the diverse requirements of end users (Table 1).

Patient-Centered Digital Literacy and Virtual Care Skills

For patients and caregivers, digital health literacy is crucial for understanding and managing their own health conditions. With the advent of virtual care, online patient portals, and mobile health apps, patients are increasingly expected to engage with digital platforms [44]. The increased adoption of virtual care, accelerated by the COVID-19 pandemic, underscores the need for health care professionals to be proficient in patient-centered digital literacy [45,46]. This includes using virtual care platforms and mobile health apps effectively to engage with patients

remotely [47]. Health care professionals are often required to support patients in using digital health technologies to manage their health [2,48]. Patient-centered digital literacy and virtual care competencies are particularly important as virtual care has become a staple in health care delivery, requiring providers to ensure equitable access and appropriate care via digital means [42,45,46,49]. A lack of digital health literacy can lead to misunderstandings, nonadherence to treatment plans, and ultimately poorer health outcomes [50]. Competencies in patient-centered digital literacy and virtual care skills could be assessed through role-playing scenarios, patient simulations, and assessments that measure health care students' ability to effectively communicate with patients via digital platforms, educate them about digital tools, and ensure patients can navigate virtual care services with confidence and ease (Table 1).

Ethical Practice

Ethical training on the appropriate use of digital tools is necessary to navigate complex privacy issues and ensuring health care professionals are equipped with these skills fosters secure and ethical practices in digital health environments [27,51]. In addition, competencies in data privacy, confidentiality, and security are essential, as safeguarding patient data contributes to clinicians' confidence and comfort in using digital health systems, thereby supporting a safer work environment [52]. Furthermore, integrating ethical frameworks into digital health education can help health care professionals recognize and address biases, promote equitable access to technology, and uphold patient autonomy in an increasingly digital health care landscape. If ethical practices are not incorporated into digital health education, there is a risk of compromising patient privacy, consent, and autonomy, which can undermine trust in health care systems and negatively impact patient experiences [52]. Ethical practice competencies may be assessed through case-based discussions, ethical dilemma scenarios, and reflective essays that evaluate health care students' understanding of privacy, data security, informed consent, and the responsible use of technology in patient care (Table 1).

Communication Skills

Strong communication skills are critical for the effective use of digital health technologies to interact with patients, explain complex information, and provide clear instructions [51]. For instance, explaining the use of health information technologies, providing educational resources on conditions, treatments, procedures, or guiding patients on using digital health apps requires excellent communication skills. Health care professionals must also be trained in communication competencies, such as digital compassion and patient advocacy, so as to better facilitate positive experiences for patients [20,21,53,54]. These competencies are particularly crucial in virtual care, where fostering patient trust and engagement without face-to-face interaction demands a specialized skill set [45,46]. If communication skills are not incorporated into digital health education, patients may experience a lack of emotional connection with health care providers, leading to diminished patient satisfaction and outcomes. Communication skills may be assessed through interactive exercises, such as virtual patient consultations or collaborative team simulations, where health care students are evaluated on their ability to clearly explain digital health tools, address patient concerns, and facilitate effective communication through digital platforms (Table 1).

Genomics Competencies

Genomic competencies empower health care providers to deliver more precise and personalized care, identifying genetic factors that influence disease risk, medication responses, and treatment options [41]. By integrating genomic data into clinical decision-making, practitioners can tailor interventions to each patient's unique genetic profile, potentially improving the efficacy of treatments and reducing adverse reactions to medications [41,55,56]. As genomic technology continues to evolve, training in this area not only supports patient outcomes but also contributes to more efficient, cost-effective, and equitable health care by reducing trial-and-error in treatments and focusing on individualized approaches [55-58]. Without adequate training in genomics, health care professionals may struggle to interpret complex genetic data, limiting their ability to leverage these advancements in clinical practice and potentially widening disparities in access to precision medicine. Genomics competencies may be assessed through case studies, quizzes, and practical exercises that test health care students' ability to interpret genetic data, apply genomic information in clinical decision-making, and use digital tools for personalized patient care (Table 1).

Provider Experience

Overview

The provider experience category of the Quintuple Aim emphasizes the well-being, satisfaction, and efficiency of health care professionals, recognizing that a supported workforce is essential for high-quality patient care. Digital health technologies contribute to this goal by streamlining workflows, reducing administrative burdens, and enhancing communication through electronic health records, clinical decision support systems, and telehealth platforms. These tools can help mitigate burnout by improving efficiency, reducing repetitive tasks, and allowing providers to focus more on patient care. When effectively integrated, digital health solutions potentially foster a more sustainable and rewarding work environment for health care professionals.

Interoperability Principles

Understanding interoperability standards to facilitate enhanced care coordination can help leverage the full potential of digital health technologies [9]. This encompasses an understanding of interoperability and data standards, enabling the seamless exchange of health information between different systems and care settings [59]. As scopes of practice shift and we are faced with workforce shortages and the emergence of new roles, having access to comparable, sharable data derived from the use of clinical data standards has the potential to provide support for human resource and health policy decisions at local, regional, and national levels [60,61]. As we plan for a future where AI is foundational to facilitate evidence-informed decision-making, it is vital that we have standardized clinical data to inform care

decisions and resource allocation. If interoperability principles are not incorporated into digital health education, health care providers may face fragmented systems, difficulty accessing patient information across platforms, and increased administrative burden, all of which can hinder clinical decision-making and job satisfaction [52]. Health care students' understanding and use of interoperability principles could be assessed through scenario-based assignments and system integration projects where they demonstrate their ability to navigate and connect various digital health platforms, ensuring seamless data exchange and collaboration across health care settings (Table 1).

User-Centered Design and Workflow Optimization

Designing user-friendly digital health systems that minimize cognitive load and enhance workflow efficiency can significantly improve provider well-being [34]. Digital health education programs should include principles of human-computer interaction, usability testing, and ergonomics to ensure systems are intuitive and supportive of provider workflows [4,5,28,34]. Digital health systems generate numerous alerts and notifications, potentially contributing to provider burnout. Training can address strategies for managing alert fatigue, including customization, prioritization, and effective communication protocols to minimize unnecessary interruptions and streamline information flow [62].

Key competencies also include ergonomics, cognitive load theory, and human factors in technology design. These informatics skills empower health care providers to design and implement systems that minimize administrative burden, optimize usability, and reduce unnecessary interruptions during clinical workflows [63]. For example, well-designed electronic health record interfaces that prioritize intuitive navigation and minimize excessive documentation can significantly reduce cognitive overload, allowing providers to focus more on direct patient care.

Training in workflow optimization and data automation is also vital, as these competencies enable professionals to implement time-saving measures within electronic health record systems and other digital health tools. Reducing the time spent on repetitive or low-value tasks allows clinicians to dedicate more time to patient care, which can enhance job satisfaction and reduce burnout [63]. In addition, an understanding of implementation science, which guides the successful integration of new technologies into health care systems, may help optimize workflow by identifying barriers to technology adoption, refining processes to enhance efficiency, and ensuring digital tools seamlessly integrate into clinical practice [10]. If user-centered design and workflow optimization are not incorporated into digital health education, health care providers may encounter inefficient, cumbersome systems that increase cognitive load, disrupt clinical workflows, and contribute to burnout and frustration. User-centered design and workflow optimization could be assessed through hands-on projects where health care students design digital health solutions that prioritize user experience, streamline clinical processes, and demonstrate the ability to enhance efficiency and usability within health care environments (Table 1).

Critical Thinking and Evaluation

The rapid evolution of the digital health landscape necessitates the ability to critically evaluate new tools, discern their potential benefits and limitations, and assess their impact on health care delivery and outcomes [48,64]. This competency involves building a strong theoretical understanding of health informatics, staying abreast of emerging technologies, recognizing their strengths and weaknesses, and developing the ability to translate data and research findings into evidence-informed practices. A strong understanding of data science and bioinformatics can further enhance the ability to critically analyze health data and contribute to the development of novel digital health solutions [42]. If critical thinking and evaluation are not incorporated into digital health education, health care providers may struggle to assess the effectiveness of digital tools, leading to suboptimal decision-making, reduced confidence in technology, and potential negative impacts on patient care. Critical thinking and evaluation skills could be assessed through analytical case studies, where health care students critically assess the effectiveness of digital health tools, identify potential areas for improvement, and evaluate their impact on patient care and health care workflows (Table 1).

Clinical Decision Support and Evidence-Based Practice

Digital technologies that enhance evidence-informed practice, such as clinical decision support systems, are becoming central to health care delivery. Educating clinicians on the use and optimization of these tools helps improve diagnostic accuracy, decision-making, and treatment planning [20]. Furthermore, familiarity with decision support technologies enables health care professionals to access real-time evidence, which is crucial for safe, high-quality care [20]. Failing to advance the use of clinical decision support and evidence-based practice using digital technologies may lead to outdated treatments, increased medical errors, and missed opportunities for improving patient outcomes through data-driven insights. Clinical decision support and evidence-based practice skills may be assessed through simulations or practical examinations where health care students use digital tools to make data-driven decisions, incorporate the latest clinical guidelines, and evaluate the outcomes of their decisions in patient care scenarios (Table 1).

Reduced Cost

Overview

The reduced costs category of the Quintuple Aim focuses on lowering health care expenses while maintaining or improving the quality of care. Digital health technologies contribute significantly to cost reduction by streamlining administrative tasks, reducing hospital readmissions, and enabling remote monitoring through telehealth and mHealth apps. By automating routine processes, improving care coordination, and providing patients with more proactive management of chronic conditions, these technologies can minimize the need for costly in-person visits and prevent unnecessary hospitalizations. Ultimately, the integration of digital tools could create a more efficient and financially sustainable health care system.

Efficient Use of Digital Health Technologies

Proficiency in using electronic health records to streamline documentation, reduce redundancy, and improve care coordination can lead to significant cost savings. Training should go beyond basic data entry and focus on leveraging decision support systems, expert systems, and other features to optimize clinical workflows and resource usage [37,48]. Telehealth adoption is rapidly increasing, offering cost-effective virtual care delivery models. Digital health education programs should incorporate telehealth and virtual care training, equipping providers with the skills to conduct virtual visits, remotely monitor patients, and use virtual care platforms effectively [2,45-47]. To help empower informatics professionals to advocate for cost-effective technology adoption and usage, they should also be aware of the economic implications of digital health technologies, including cost-benefit analysis, return on investment, and value-based health care models [34]. If the efficient use of digital health technologies is not incorporated into digital health education, health care systems may face increased operational costs due to inefficiencies, higher rates of preventable hospitalizations, and missed opportunities for cost-saving innovations such as telehealth and automation. Efficient use of digital health technologies could be assessed through timed exercises or real-world simulations where health care students demonstrate their ability to quickly and accurately navigate digital health systems, manage patient data, and complete tasks with minimal errors and maximum efficiency (Table 1).

Cybersecurity, Privacy, and Ethical Use of Digital Health Technologies

With the growing reliance on digital tools comes the increased risk of data breaches and cyberattacks. Competency in cybersecurity, including understanding data protection principles and mitigating security risks, is essential for maintaining patient trust and ensuring the safety of health information systems [65]. Cybersecurity, privacy, and ethical use of digital health technologies reduce health care costs by safeguarding sensitive information, preventing data breaches, and ensuring trust in digital systems. Effective cybersecurity measures prevent costly breaches that can lead to financial penalties, legal liabilities, and expensive recovery processes [65]. In addition, ethical use of digital health technologies ensures transparency, fostering patient trust, which encourages technology adoption and self-management [27]. If cybersecurity, privacy, and the ethical use of digital health technologies are not incorporated into digital health education, health care systems may face costly data breaches, legal penalties, and loss of patient trust, ultimately leading to increased financial and reputational risks. Cybersecurity, privacy, and the ethical use of digital health technologies may be assessed through written examinations, case studies, or scenario-based discussions that test health care students' knowledge of data protection laws, ethical guidelines, and strategies for safeguarding patient information in digital health environments (Table 1).

Digital Health Ecosystems and Interoperability

Promoting interoperability and connected care in health care reduces costs by improving coordination and access to complete patient information, which decreases unnecessary tests, procedures, and medication errors [52]. These systems streamline administrative tasks, lowering overhead, and support value-based care models focused on quality outcomes. In addition, by enabling population health management and enhancing patient engagement, interoperability fosters preventive care and self-management, further lowering expenditures associated with chronic conditions and emergency care. Overall, interoperability creates a more efficient, cohesive, and cost-effective health care environment [52,66]. If digital health ecosystems and interoperability are not incorporated into digital health education, health care organizations may incur higher costs due to redundant testing, inefficiencies in data sharing, and fragmented care coordination, leading to suboptimal resource use. Health care students' understanding of digital health ecosystems and interoperability could be assessed through group projects where they analyze and design solutions that demonstrate how different digital health platforms can communicate and work together to improve patient care and health care outcomes (Table 1).

Data Analysis

The reduction of health care costs can be achieved through the application of informatics competencies such as data analysis. Cost analysis skills help professionals make data-informed decisions that balance cost and quality in patient care, while health economics education emphasizes understanding economic drivers within health care [34]. Cost-benefit analysis tools within digital health platforms allow for optimized resource allocation and reduced waste, ultimately reducing costs while maintaining quality. Through these competencies, digital health practitioners can advocate for financial strategies that lower costs without compromising care quality. If data analysis is not incorporated into digital health education, health care systems may struggle to identify cost-saving opportunities, leading to inefficient resource allocation, increased waste, and missed chances for data-driven decision-making that could enhance financial sustainability. The data analysis competency may be assessed through data-driven case studies or analytical projects where health care students interpret health care data, identify trends, and make evidence-based recommendations for improving patient outcomes or optimizing health care processes (Table 1).

Population Health

Overview

The population health category of the Quintuple Aim focuses on improving health outcomes across communities by addressing preventive care, chronic disease management, and health disparities. Digital health technologies support this goal by enabling large-scale data collection, predictive analytics, and remote monitoring, allowing health care providers to identify trends, allocate resources efficiently, and implement targeted interventions. Tools such as electronic health records, virtual care platforms, and mobile health apps enhance access to care, especially for underserved populations, while data-driven insights help inform public health strategies. By leveraging digital health, health care systems can promote proactive,

equitable, and efficient approaches to population health management.

Data Management and Analysis

To improve population health, health care professionals must be skilled in using data analytics to assess and address health trends and disparities. Health informatics education programs should thus prioritize competencies in population health informatics, which includes training in data collection, analysis, and interpretation related to population health metrics [20,21]. In addition, familiarity with tools for epidemiological analysis and population health management, including geospatial mapping and predictive analytics, can equip graduates with the knowledge to identify at-risk populations and forecast public health trends [21,25].

Understanding social determinants of health and leveraging big data are also central to enhancing population health, as they enable health care providers to integrate nonclinical factors impacting patient outcomes into their care approaches [42,49]. Analysis of social, behavioral, and environmental determinants of health supports the delivery of personalized care. The ability to collect, store, manage, analyze, and interpret health data is indispensable in the digital health era.

This competency also encompasses data literacy and the ability to critically appraise data quality and reliability [59]. Students should develop proficiency in basic statistics, data visualization techniques, and gain an understanding of data governance and privacy principles, which are particularly critical given the sensitive nature of health information and the need to maintain patient confidentiality [28,34]. As digital health technologies become increasingly sophisticated in capturing social, behavioral, and environmental determinants of health, health care professionals must be able to analyze and use this data to deliver personalized and holistic care, as well as appreciate the extent that digital health technologies impact the planet [2,67-69]. If data management and analysis are not incorporated into digital health education, health care systems may struggle to track disease patterns, allocate resources effectively, and develop targeted public health interventions, ultimately hindering efforts to improve population health outcomes. Health care students' understanding of data management and analysis in relation to digital health and population health could be assessed through projects where they analyze large datasets to identify health trends, evaluate interventions, and propose strategies for improving population health outcomes using digital tools and evidence-based insights (Table 1).

Adaptability to Emerging Technologies

AI is being increasingly used to enhance population health strategies through predictive analytics. Health care leaders must stay abreast of emerging technologies such as AI, robotics, and big data analytics [21,40,70]. AI marks a pivotal advancement in the digital transformation of health care, and traditional health care education and training often do not sufficiently address the digital competencies required for its effective use [40]. To ensure the safe and efficient adoption of AI, health care professionals need foundational knowledge in machine learning and neural networks, skills for critical evaluation of datasets, and the ability to integrate AI into clinical workflows while managing bias and ensuring smooth human-machine interaction in clinical settings. Furthermore, an understanding of the legal and ethical implications of digital health and the broader impact of AI adoption is essential [3,12,33,39,49,70]. If adaptability to emerging technologies is not incorporated into digital health education, health care systems may fall behind in implementing innovative solutions, limiting their ability to address evolving public health challenges and widening disparities in access to effective care. Adaptability to emerging technologies may be assessed through hands-on exercises or simulations where health care students are tasked with quickly learning and integrating new digital health tools into clinical practice, demonstrating flexibility and problem-solving skills in response to evolving health care technologies (Table 1).

Leadership, Change Management, and Project Management Skills

Health care professionals should be equipped to champion digital health transformation and spearhead initiatives that promote the adoption and integration of digital technologies within health care organizations and systems [27,42,59]. This competency includes a grasp of change management principles, enabling graduates to navigate the complexities and challenges associated with implementing new technologies and workflows [20,21]. Proficiency in project management is also vital, ensuring the organized planning, execution, and evaluation of digital health initiatives [20,21]. If leadership, change management, and project management skills are not incorporated into digital health education, health care organizations may struggle to implement and scale digital health initiatives effectively, leading to fragmented care, inefficient resource use, and missed opportunities to improve health outcomes. Leadership, change management, and project management skills in relation to digital health could be assessed through team-based projects where health care students plan, execute, and evaluate the implementation of digital health solutions, demonstrating their ability to lead, manage stakeholder expectations, and navigate challenges in health care technology integration (Table 1).

Health Equity

Overview

The health equity category of the Quintuple Aim focuses on reducing disparities in health care access, quality, and outcomes across diverse populations. Digital health technologies support this goal by expanding access to care through telemedicine, mobile health apps, and remote monitoring, particularly for underserved and rural communities. In addition, data analytics and AI can help identify health disparities, enabling targeted interventions and resource allocation. However, to fully realize these benefits, digital health solutions must be designed with inclusivity in mind, ensuring accessibility for individuals with varying levels of digital literacy, socioeconomic backgrounds, and health care needs.

Addressing Digital Health Disparities

Digital health interventions must be designed to avoid widening existing health inequities. Training should highlight the role of social determinants and the need for equitable technology use, as well as the role that data standards play in ensuring clinical documentation accurately reflects representation of social determinants of health [58]. Culturally sensitive and accessible digital tools are essential, and education programs must stress the importance of cultural considerations to ensure fair access [42,45,49]. Health care professionals also need advocacy skills for the ethical deployment of digital health solutions to prevent these technologies from exacerbating disparities [37]. If addressing digital health disparities is not incorporated into digital health education, existing health care inequities may worsen, as underserved populations could face barriers to accessing digital tools, leading to gaps in care and poorer health outcomes. Health care students' ability to address digital health disparities may be assessed through case studies or community-based projects where they identify barriers to digital health access, propose strategies for increasing inclusivity, and evaluate the impact of their solutions on underserved populations (Table 1).

Health Data Access

Limited access to personal health data leads to fragmented care, delays in diagnosis, and increased health care costs [52,66]. Ensuring patients have control over their health data is vital for improving outcomes, especially for marginalized communities [42,71]. Limited access disproportionately affects vulnerable groups, reinforcing health disparities and increasing the economic burden on both individuals and the health care system. Equitable access to health data is crucial for high-quality care and patient autonomy [42,66]. Importantly, "health data access" encompasses both individual-level access, where patients control, view, and share their personal health records, and population-level access, where aggregated data systems support public health surveillance, population health planning, and policy development. Competent digital health professionals must understand and ethically navigate both dimensions to effectively address inequities and improve community health outcomes [72]. If health data access is not incorporated into digital health education, marginalized communities may face continued barriers to care, as health care providers could lack the tools and knowledge to leverage data effectively, exacerbating disparities in health outcomes and access to services. Understanding of health data access could be assessed through practical exercises or written assignments where health care students analyze the ethical, legal, and technical aspects of accessing and sharing health data, ensuring compliance with regulations while considering patient privacy and data security (Table 1).

Indigenous Data Sovereignty

Understanding Indigenous Data Sovereignty helps professionals create data systems respectful of Indigenous cultural and ethical values. Principles like OCAP (Ownership, Control, Access, Possession) emphasize self-determination, advocating for ethical guidelines that honor Indigenous perspectives on health data [73,74]. Indigenous community involvement in research phases is essential to uphold ethical standards and enhance trust and relevancy in findings [75]. However, the scope of Indigenous Data Sovereignty extends beyond research. It must also be applied to public health surveillance, health system planning, and digital infrastructures to ensure that data about Indigenous populations is governed in ways that align with Indigenous laws, protocols, and priorities aligned with specific Nations. Indigenous communities should have equitable access to their own data to support local decision-making, health planning, and service delivery. Embedding Indigenous data governance at community, institutional, and policy levels enables Indigenous-led responses to health challenges and advances broader goals of health equity and reconciliation [76]. If Indigenous data sovereignty is not incorporated into digital health education, there is a risk of exploiting or misusing Indigenous health data without proper consent or oversight, potentially undermining trust and perpetuating historical injustices in health care. Health care students' understanding of Indigenous data sovereignty may be assessed through case studies or reflective essays where they analyze the importance of respecting Indigenous peoples' control over their health data, explore ethical considerations, and demonstrate how to apply culturally appropriate practices in digital health initiatives (Table 1).

Health Literacy and Patient Education

Digital health literacy is vital for patients, caregivers, and health care professionals alike. Patients need digital health literacy to manage their care effectively. Providers, leaders, and researchers must understand and use digital tools, as literacy across these groups supports quality care, informed decision-making, and research innovation. Digital health literacy fosters improved understanding, adherence, and outcomes across the health care system [50]. If health literacy and patient education are not incorporated into digital health education, patients may struggle to understand and effectively use digital health tools, exacerbating health disparities and hindering efforts to promote equitable access to care and tailor education to diverse literacy levels and needs. Health literacy and patient education in relation to digital health could be assessed through role-playing exercises or patient simulation scenarios where health care students demonstrate their ability to effectively communicate digital health information, assess patient comprehension, and tailor education to diverse literacy levels and needs (Table 1).

Integrated Digital Health Competencies for the Quintuple Aim

Digital health competencies, such as interoperability, data literacy, and person-centered care principles, overlap across the 5 domains of the Quintuple Aim, enhancing both patient and provider experiences. These competencies promote equitable patient-centered care by improving access, streamlining care processes, and supporting population health efforts. A comprehensive approach to digital health education enables health care professionals to meet the diverse, interconnected demands of modern health care, supporting both individual and population-level outcomes. Failing to create a comprehensive approach to digital health education in relation to the Quintuple Aim could lead to fragmented health care delivery, where

inefficiencies persist, patient experiences, health outcomes remain unequal, and costs rise, ultimately hindering the achievement of improved health for all.

Standardized Yet Customizable Digital Health Education

Standardized informatics competency-based curricula, as described by organizations such as the Canadian Association of Schools of Nursing, the International Medical Informatics Association and the American Medical Informatics Association, provide a crucial foundation for health informatics education [20,21,77]. However, the health care landscape varies significantly across regions, influenced by factors like technological infrastructure, health care systems, cultural norms, and local health priorities. These differences require that standardized curricula also provide additional opportunities for curricula customization, versatility, and variety of delivery methods [78-80], bridging academic learning and real-world application, and aligning curricula with evolving health care demands [20,78].

To align with the Quintuple Aim framework, educational delivery strategies should intentionally match the competency emphasis to each aim. For instance, competencies that address the “Improving Population Health” aim should be emphasized in programs targeting public health professionals, while “Reducing Costs” and “Enhancing Efficiency” may be prioritized in executive and administrative education. This alignment ensures that the education of health care professionals is not only technically robust but also strategically positioned to support each domain of the Quintuple Aim.

The integration of case-based learning (CBL) with competency-based education potentially offers an effective pedagogical strategy, especially in digital health education, where learners need to master both theoretical concepts and practical skills in an ever-evolving field. CBL engages students with practical scenarios that simulate real-world challenges, encouraging critical thinking, collaborative problem-solving, and decision-making. In complex and rapidly evolving environments like health care, competency-based education can provide context-rich scenarios that mimic real-life challenges, while CBE ensures that students meet predefined learning outcomes essential for professional competence [78-81].

Achieving a balance between standardized and customized education could also involve adopting a modular approach. Core competencies can be standardized across programs, while additional modules can be tailored to meet local needs. For instance, health care educational programs can integrate standardized content on digital ethics and health data infrastructure but offer elective modules or microcredentials on specific areas such as local legislative and regulatory policies, electronic health records design, or virtual care workflows relevant to regional health care priorities [80]. Digital competencies are also not uniformly applicable across all health professions. Direct care providers, such as nurses, physicians, and allied health professionals, require competencies focused on clinical decision support, patient communication, and digital documentation. Health administrators need competencies focused on systems-level data analytics, resource management, and technology implementation. Public health practitioners, in contrast, may require competencies related to population surveillance, data ethics, and cross-sectoral data integration. These variations highlight the need for educational frameworks that are both discipline-sensitive and practice-informed, ensuring that digital health education is relevant to specific roles while maintaining shared foundational competencies.

Collaborations between academia and industry can ensure that curricula stay relevant. Industry insights help shape competencies that meet real-world demands, while partnerships provide students with practical experiences through internships and projects. This alignment fosters a skilled workforce ready to integrate digital health technologies effectively [34,40].

Together with maintaining strong academic and health care system partnerships, a hybrid approach, combining core standardization with customization through CBL and modular content delivery, potentially offers a sustainable model for developing digital health curricula that align with both global standards and local needs, and ensures health care professionals are prepared to navigate the complexities of digital health care, ultimately contributing to more effective, equitable, and patient-centered care delivery.

Conclusion

The development of a standardized digital health curriculum that integrates both core competencies and context-specific customization is essential for equipping health care professionals to thrive in a rapidly evolving technological landscape. As health care systems increasingly rely on digital health technologies to enhance patient care and improve outcomes, health care professionals should at minimum be competent in skills such as data management, interoperability, digital literacy, and virtual care delivery. Standardization ensures consistency and fosters interprofessional collaboration, while context-specific case studies and modular customization enable education programs to address specific health care priorities, such as rural health care or emerging technologies. Achieving a balance between these approaches will ensure that digital health education remains relevant, responsive, and capable of meeting both global standards and local needs. Ultimately, a digitally competent workforce will be crucial to advancing health care delivery, supporting innovation, and achieving sustainable health outcomes in individuals, communities, and populations.

Abstract

This paper aims to describe the cocreation and development processes of an educational ecosystem-centered Bachelor's degree in Digital Health and Biomedical Innovation (SauD InoB). This program is shaped by a multidisciplinary, intersectoral, and collaborative framework, involving more than 60 organizations in teaching activities, internship supervision, or hosting, most of which collaborated in needs assessment, curriculum development, and public promotion of the degree. In the context of health care digital transformation, this comprehensive Bachelor's degree will respond to unmet demands of the labor market by training students with technological, research, and management skills, as well as with basic clinical and biomedical concepts. Graduates will become transdisciplinary, creative professionals capable of understanding and integrating different "languages," reasoning, clinical processes, and scenarios.

Introduction

Biomedical innovation may be defined as the process of creation and application of scientific and technological knowledge to improve health care and promote health and well-being [1]. It includes developing therapeutic and diagnostic health technologies, biotechnology, precision medicine, drug discovery, or health care digitalization [2], which may encompass developing and using technologies such as health information systems, artificial intelligence, and advanced health data analytics [3,4].

To address global health challenges, imposed by aging demographics and sustainability of health and care systems, biomedical innovation is expected to integrate digital health [1], which plays an increasingly important role in the organization and management of health systems and institutions, health research, and health interventions [5]. However, biomedical innovation and digital transformation processes are frequently long, costly, risky, and challenging [2], involving changes in management dynamics [6,7] of complex project ecologies in which knowledge creation, flow, and outputs depend on the communication between multidisciplinary areas and sectors of activity [1]. Such a demanding context is further rendered more complex by management challenges, such as interoperability problems, data security concerns, ethical and legal aspects, low digital and scientific literacy among patients [6], resistance to change [7], or a recognizably insufficient health professionals' workforce, simultaneously trained in digital health and biomedical innovation areas [8-10].

Overcoming these challenges and promoting successful change dynamics depends on multiple factors, namely a bold vision shared with different actors, engagement with the society

through the involvement of various stakeholders, infrastructures, or the involvement of professionals with technical and scientific expertise, capable of adjusting the changes of management processes to contextual and cultural specificities [6] and to create synergies between different disciplinary areas and sectors of activity.

Identifying the unmet need for these professionals led to the creation of an innovative and comprehensive Bachelor's degree in Digital Health and Biomedical Innovation (SauD InoB) at the University of Porto, one of the largest Portuguese universities.

In Portugal, the BSc degree leads to the degree of "licenciado," corresponding to the level 6 of the National Qualifications Framework and European Qualifications Framework. A BSc degree may range from 180 to 240 European Credit Transfer and Accumulation System credits (ECTS) and last from 6 to 8 curricular semesters [11].

The BSc degree was structured according to the requirements and milestones of the Portuguese Agency for Assessment and Accreditation of Higher Education (A3ES) and grounded on the first steps of Kern's approach to curriculum development: (1) identification and characterization of a problem, (2) identification of training needs, (3) definition of goals and objectives, and (4) definition of educational strategies [12]. This process comprised innovative aspects, engaging from the outset on a comprehensive and collaborative educational ecosystem–centered approach focused on the enhancement of students' experiences and outcomes and on the strengthening of their contributions to society through the development of creativity and innovation capacity [13].

The BSc degree was created within an educational ecosystem, involving academic, research, health care, business, and society (eg, patients' associations). An educational ecosystem refers to the interconnected network of factors and processes that influence students' learning and development. Just like a natural ecosystem where different elements, such as air, water, plants, and animals, interact to create a balanced environment, an educational ecosystem consists of various components that work together to shape the learning experience [14-16]. According to Bronfenbrenner's Ecological Systems Theory, learning and development are influenced by factors, processes, and actors situated in different contexts, some of them more directly involved in the learning process, such as family, teachers, higher education institutions, or internship sites (microsystem), others situated in a broader context, such as the course regulations (macrosystem), or the economic situation and cultural values that may influence learning (exosystem). Furthermore, learning may also be influenced by the interactions between contexts, for example, between the universities and industry (mesosystem) and by the dimension of time, for instance, by the effects of the technological development (chronosystem) [17].

Like natural ecosystems, educational ecosystems involve disturbances that may challenge their balance and require resilience, flexibility, and responsiveness to the needs and characteristics of different contexts and actors [14]. The concept of ecological university seems to entail this notion of disturbance and adaptive management. With the development of knowledge societies, higher education institutions no longer occupy a hegemonic position in the creation and legitimization of knowledge, and the actions of the individual and collective knowledge creators, users, legitimizers, and beneficiaries are informed by a widening diversity of perspectives and voices (eg, companies also have their own laboratories). In this context, higher education institutions must be able to interact with other contexts or ecological zones (eg, industry, patient associations, and government) with different rhythms, interests, epistemologies, and perspectives [18-20], but also to cross boundaries and build bridges between those contexts, not only to maintain their legitimacy, but also to be able to contribute to the health and functionality of the ecosystem [14].

Some authors concluded that the involvement of diverse stakeholders may promote an alignment with the needs of patients [21] or with the specific needs of diverse populations [22] and foster creativity, entrepreneurship, and innovation [13,23]. Curriculum development processes in transdisciplinary areas involving multidisciplinary and multisectoral teams tend to be complex processes in which tensions can arise, for example, related to different interests and rules [15]. Nevertheless, research on ecosystem-based curriculum development is still scarce, leaving the actors involved in these processes without a consistent theoretical basis to support their practices and decisions.

This viewpoint aims to contribute to the knowledge about curriculum development by describing the educational ecosystem–centered, multidisciplinary, and multisectoral cocreation and development process of the SauD Inob BSc degree, from needs assessment and curriculum design to the public promotion of the degree, aiming to attract its first group of students and the results of the first edition of the degree application.

The Educational Ecosystem

The creation of this BSc involved 3 faculties within 1 university, the collaboration of 3 polytechnic institutions, and partnerships with more than 60 organizations, including hospitals and other health care providers, pharmaceutical and health technologies companies, research and governmental institutions, and patients' associations. Cocreation processes involved more than 130 contributors, including faculty, researchers, master's and PhD students and graduates in health, health informatics and data science, professionals working in diverse functional areas and sectors of activity, and managers and policy makers. The recruitment of students and alumni was strategically carried out in relevant master's and doctoral programs, with some focus on digital health and biomedical innovation (medical informatics, clinical and health services research, and health data science), ensuring a highly relevant and involved participant base. Besides contributing to the BSc degree through involvement in teaching and internship supervision or hosting internships, most partners and collaborators were also integrated into needs assessment and curriculum development.

A list of the partners involved in the course is listed in [24].

The Need for a BSc Degree in Digital Health and Biomedical Innovation

Needs assessment was based on a narrative literature review, document analysis, and meetings with the stakeholders integrated into the educational ecosystem. Individual meetings with partner representatives were carried out to discuss their perspectives on the interplay between labor market needs and the curriculum of SauD InoB and to establish a collaborative commitment. The curriculum was also presented and discussed in the first meeting of partners of the BSc degree in Digital Health and Biomedical Innovation in September 2023.

A literature review revealed a compelling but still unmet need to develop digital health and biomedical innovation skills and knowledge among the different professional groups involved in health care provision [8-10,25]. This need has been enhanced by a remarkable acceleration of the development of information and communication technologies, with repercussions for the adoption of electronic health records, the development of apps for monitoring chronic diseases, or advances in data analysis [3,4]. This unmet need motivated the introduction of digital health and biomedical innovation contents in the curricula of health and information technologies degree-awarding courses, the development of continuous education courses in biomedical and health informatics [26], and the creation of a few degree-awarding courses, in digital health and biomedical innovation [27-31], such as the BSc in Digital Health (Politechnic Institute of Porto, Portugal), the BSc in Digital Technologies and Health (University Institute of Lisbon, Portugal) [27], the Master's Degree in Digital Health (Deggendorf Institute of Technology, Germany) [28], or the Master's Degree in Digitalization in the Health Sector (University of Oslo, Norway) [31]. Nevertheless, the stakeholders involved in SauD InoB creation considered that the training offered in these areas is still insufficient to overcome the challenges of this fast-paced development context, namely in the North of Portugal.

The stakeholders identified the need to develop new professional profiles of transdisciplinary health care professionals who may establish bridges between different disciplinary or professional areas, academic and research cultures, knowledge, languages, and epistemologies. Graduates from SauD InoB are expected to be able to hold careers in (1) data analytics and artificial intelligence in health, (2) biomedical and clinical research, (3) health information systems and telemedicine, and (4) health consulting and management, innovation management, and other health-related areas. The labor market for these professionals may include digital technology and health informatics, pharmaceutical, medical device, and biotechnology companies, hospitals and health care institutions, research and development organizations (biomedical and clinical research laboratories, academia, research and development service companies, and consulting firms), and health policy and regulatory organizations.

Aims and Learning Outcomes of SauD InoB

SauD InoB aims at training health professionals capable of (1) understanding concepts and "languages" in human biology, clinical medicine, and health care services and (2) mastering skills in health information systems, programming, data science, and research methodology. Therefore, these professionals will be able to identify, develop, and solve the main problems associated with health care services and with their digital transformation, offering them practical solutions that bridge different fields.

Upon completion of the study cycle, graduates should be able to apply critical knowledge about (1) human biology; (2) the pathophysiological basis of health and disease, different types of diseases, diagnostic tests, and therapeutic interventions; (3) clinical language and reasoning; (4) mathematics and statistics; (5) informatics, computing, and programming; (6) organization, pathways, and processes of health care provision in multiple contexts; (7) health care management and innovation; and (8) ethical, regulatory and security, data privacy in digital health, and health innovation processes. They should also be able to participate in the development, design and implementation, or management of databases, health care research and innovation projects, digital health systems and strategies, and apply data science approaches in health (processing, statistical analysis, and presentation of data).

SauD InoB goes beyond developing specific digital health and biomedical innovation competencies. It aims to create a new professional identity, which is defined as the individual sense of identification with a (new) profession and a sense of belonging to a community of professionals sharing specific knowledge, competencies, values, activities, and norms [32]. This is a distinctive characteristic of SauD InoB derived from being a BSc and not a subsequent degree, in which students' professional identities are more likely to be influenced by the roles and competencies that characterize the professional or disciplinary area of their initial academic training [32].

Further information on the objectives, expected learning outcomes, and competencies of SauD InoB can be found on the course web page [33].

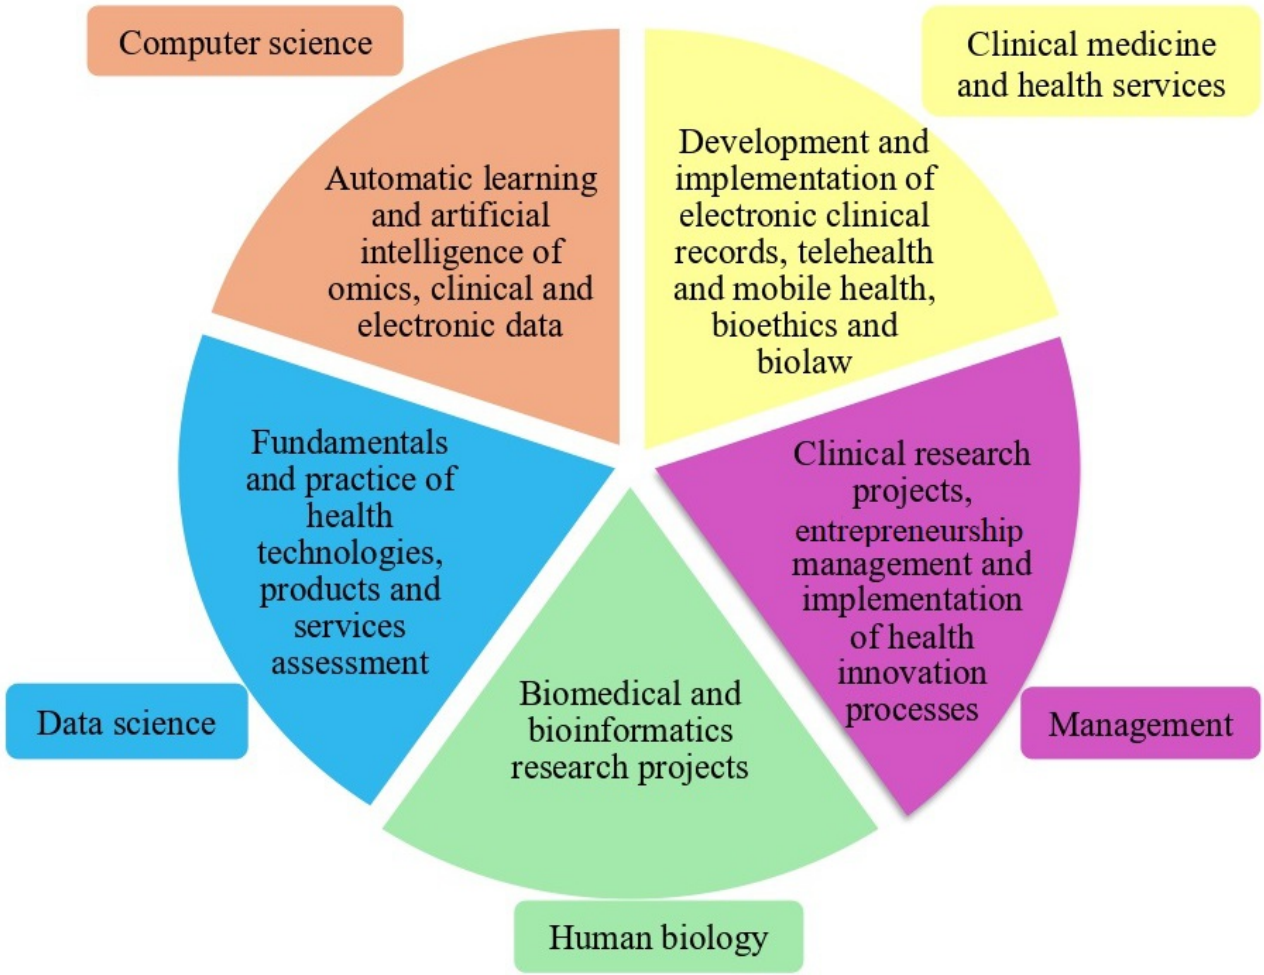
Curriculum and Teaching and Learning Methods

SauD InoB comprises 6 academic semesters and 180 ECTS, integrating standardized and pluralized curricular components [34]. ECTS are units of learning based on learning outcomes and their associated workload and were defined to promote transparency and mobility within the European Higher Education Area.

Multimedia Appendix 1 lists the curricular structure of SauD InoB. The first 4 semesters (120 ECTS) constitute a common core, including a set of curricular units that all students must complete.

These 120 ECTS are divided into the areas of Computer Science (29 ECTS), Data Science (26 ECTS), Human Biology (26 ECTS), Clinical Medicine and Health Services (25 ECTS), and Management (11 ECTS). Elective units correspond to 3 more ECTS. Figure 1 shows the fundamental areas of SauD InoB.

Figure 1. Fundamental areas of SauD InoB and main topics addressed by each area.



In the last 2 semesters (60 ECTS), students must choose 1 of 4 branches, each of them with a stronger focus in 1 of the fundamental areas of SauD InoB: (1) Data Analytics and Artificial Intelligence is more focused on Data Science, (2) Health Information Systems and Telemedicine is more focused on Computer Science, (3) Clinical Research and Health Innovation Management is more focused on Clinical Medicine and Health Services, and (4) Biomedical Research and Bioinformatics is more focused on topics related to Human Biology. The creation of these branches was aligned not only with the fundamental scientific areas of the course but also with the professional profiles defined earlier by the educational ecosystem stakeholders. Each branch comprises 3 internship curricular units in the first semester and a project curricular unit in the second semester, in addition to a set of core and elective curricular units related to the subject.

Thus, the course enables an early differentiation in these profiles while providing introductory training in the different areas of knowledge, even in the third year, which confers a valuable competitive advantage for the labor market and responds to a pressing need in the health sector for professionals who have an overview of the sector and can build bridges between different professions and areas of knowledge.

The BSc includes theoretical, theoretical-practical, laboratory practice, and seminar classes, in which active teaching-learning methods, which promote interactions, will be privileged (eg, discussion of fictitious or real case studies, problem- or project-based learning, and flipped classroom). All branches include a project curricular unit in collaboration with one of the partners. Professional practice will be promoted through short-term observation and immersion activities and 3 internships in different areas in the third year. Despite its transdisciplinary approach, as health care processes are the central focus of SauD InoB, all branches include an internship in clinical medicine and health services.

Horizontal and vertical articulations will be promoted, for example, through use cases discussion, assignments involving various curricular units, simulation of patients' pathway in the health care services, and assignments fostering progressively complex, transdisciplinary, and critical approaches.

Teaching and learning activities will be supported by education technologies (eg, e-learning platforms and medical simulation devices).

Preliminary Assessment, Accreditation, and Funding of Saud InoB

The creation of new cycles of studies in Portugal requires a preliminary assessment and accreditation process [35,36], comprising the digital submission of a detailed proposal. After a preliminary analysis of compliance with national regulations and quality guidelines, the proposal is assessed by an external assessment commission. Besides assessing the written proposal, the commission conducts site visits and consultations and issues an evaluation report, which is the basis for the accreditation decision. More detailed information about accreditation can be found on the A3ES website [35].

The process of cocreating this BSc degree began in August 2021 and entailed the elaboration of a brief and an extended creation and accreditation proposal. The proposals were approved by the Pedagogical and Scientific Councils of the faculties involved in the cycle of studies and by the dean and senate of the university and were submitted to A3ES approval in February 2022.

In March 2023, the A3ES External Assessment Commission, including 3 external experts, issued a preliminary assessment report, which configured a peer review process comprising advice on the curriculum design and other suggestions for optimizing the BSc degree (eg, changes in the name of the BSc degree and a decrease in the number of branches, requiring changes to the curricular structure and to the syllabi of some curricular units). The commission included an international bioinformatician with expertise in genome analysis, systems biology, and computational tools for biomedical research; a professor of pharmacology and medical doctor with a strong background in biomedical sciences and medical education; and a digital health and health care management expert, with leadership experience in eHealth systems and medical informatics.

The task force incorporated most of the suggestions in a final proposal, and in May of 2023, SauD InoB was approved. The conclusions of the final assessment report asserted that “this training offer is not only pertinent and very innovative, but also of the highest quality and demand. The professionals it will train will make an unrivaled contribution to biomedical innovation structuring” [37].

The assessment reports can be found at the A3ES website. More information about the composition of the External Assessment Commission can be found in its final report [38].

The first edition of the cycle of studies was held in the 2024-2025 school year.

This cycle of studies was also included in the application of the University of Porto to the funds of Portugal’s Recovery and Resilience Plan, a plan integrated into NextGenerationEU [39], aiming to restore sustained economic growth in the postpandemic period and to respond to the challenges of the dual climate and digital transition [40].

Public Promotion of SauD InoB

Public promotion of SauD InoB emphasized that the new course aimed to promote health innovation in Portugal by creating professionals with skills suited to the current and future needs of the health care market. Prospective students were invited to deepen their knowledge of human biology, experience the daily work of health care services alongside doctors and health professionals, develop programming skills, and gain expertise in cutting-edge methods for analyzing biological or clinical data.

In structural terms, a plan was defined to publicize the new degree in May 2023 (soon after the course was approved by A3ES). Public promotion of SauD InoB included posts in social media, institutional newsletter and webpage, news media publications, direct marketing actions (eg, email, SMS, course, and flyer), distribution of course gifts, dissemination of the course in academic institutional events, education fairs and targeted events, activities and presentations in high schools, and a newsletter (SauD InoB News).

Multimedia Appendix 2 shows the strategic plan for the promotion of SauD InoB.

Results of the Competition for Accessing the First Edition of SauD InoB

Admission to first cycles of studies in Portuguese public higher education institutions is limited to a maximum number of placements (numerus clausus) and requires an application through an annual competition held by the Directorate-General for Higher Education under the general regime, special conditions (eg, top-level athletes and permanent staff of the Portuguese Armed Forces), or special competitions (eg, applicants older than 23 years or holders of a previous BSc degree) [11]. The admission process under the general regime is based on a weighted average of internal high school and national exams (entry score), ranging between 0 and 200 points. Some courses may also require the fulfillment of specific prerequisites, such as physical or functional aptitude tests. In the first edition of SauD InoB, 40 vacancies were opened for the first phase: 35 for the general regime, one under special conditions (for top athletes), and 4 for a special competition (holders of a previous BSc degree).

SauD InoB received 284 applications for the general competition, of which 83 were first option (candidates may apply for up to 6 cycles of studies, indicating their order of preference). The entry scores of the admitted applicants ranged between 179 and 199, placing SauD InoB as the 27th (out of 1119) cycle of studies with the highest entry score in the country, and 36 of the admitted applicants chose the course as their first option.

Considering the special competition for holders of a previous BSc degree, SauD InoB received 14 applications and filled all

4 vacancies. Results from the competition under special conditions were not available when this article was written.

Final Remarks and Future Work

This paper describes the cocreation and the development process of a BSc degree in Digital Health and Biomedical Innovation, intricately developed within an educational multidisciplinary and multisectoral ecosystem, aiming to train transdisciplinary, highly skilled, and creative professionals able to respond to the needs and challenges of the health care sector in the context of fast-paced innovation and digital transformation. Besides following the requirements and milestones for the creation and accreditation of cycles of studies as determined by A3ES, this creation process was based on Kern's approach to curriculum development [12] and grounded on the concept of ecological university [18-20].

This ecosystem-centered cocreation of a bachelor's degree enabled the team to learn a few lessons, which may be helpful for other researchers and curriculum developers:

1. The integration of diverse stakeholders in the cocreation process seems to have fostered the development of a more adapted curriculum, flexible and responsive to the needs of diverse employers and to the needs of the users of the services that will be delivered by the professionals trained by Saud InoB;
2. The results of the competition for accessing the first edition of SauD InoB and subsequent admission of students with high classifications confirmed the relevance of this BSc course. Furthermore, the vacancies under special conditions and the special competition may increase the diversity of students and contribute to the democratization of access to SauD InoB;
3. More research is needed on curriculum development methods.

Further work will be needed to monitor the implementation of SauD InoB and promote continuous adaptation of the education processes to the needs of students and other actors. This involves pursuing collaboration with its current partners, namely through regular partner meetings, widening community involvement by joining new partners, and designing tools and strategies to involve students (and, in the future, graduates) in the processes of continuous assessment and improvement of SauD InoB. Course assessment will be pursued through meetings with faculty and students' representatives. The University of Porto also assesses all the courses through pedagogical questionnaires from the students. Furthermore, all the degree-awarding courses in Portugal are periodically assessed by A3ES.

This work may contribute to the knowledge about processes involved in creating new cycles of studies and informing academics and other stakeholders on the practices involved in such processes. Moreover, and even if the first edition of SauD InoB is still taking its first steps, this cocreation process and educational ecosystem–centered approach may be already considered a successful experience of productive interactions [41], which questions (even if not in an uncritical way) [18] a discourse of higher education in crisis [42,43] and reflects higher education's more than ever active role in promoting bridges between different actors who, in a knowledge society, join forces to promote the improvement of societies and the well-being of the population.

Acknowledgments

The authors would like to acknowledge the support and contributions to the creation of the Bachelor's degree in Digital Health and Biomedical Innovation (Saud InoB) from the Academic Management and Communication Management Units of the Faculty of Medicine of the University of Porto (FMUP), the Communication and Image Service of the University of Porto, the CHAIR in Onco-Innovation of FMUP, and all the partners (Parceiros [24]) and faculty (Docentes da Licenciatura SauD InoB [44]) of Saud InoB.

Abstract

The integration of large language models into medical education has significantly increased, providing valuable assistance in single-turn, isolated educational tasks. However, their utility remains limited in complex, iterative instructional workflows characteristic of clinical education. Single-prompt AI chatbots lack the necessary contextual awareness and iterative capability required for nuanced educational tasks. This Viewpoint paper argues for a shift from conventional chatbot paradigms toward a modular, multistep artificial intelligence (AI) agent framework that aligns closely with the pedagogical needs of medical educators. We propose a modular framework composed of specialized AI agents, each responsible for distinct instructional subtasks. Furthermore, these agents operate within clearly defined boundaries and are equipped with tools and resources to accomplish their tasks and ensure pedagogical continuity and coherence. Specialized agents enhance accuracy by using models optimally tailored to specific cognitive tasks, increasing the quality of outputs compared to single-model workflows. Using a clinical scenario design as an illustrative example, we demonstrate how task specialization, iterative feedback, and tool integration in an agent-based pipeline can mirror expert-driven educational processes. The framework maintains a human-in-the-loop structure, with educators reviewing and refining each output before progression, ensuring pedagogical integrity, flexibility, and transparency. Our proposed shift toward modular AI agents offers significant promise for enhancing educational workflows by delegating routine tasks to specialized systems. We encourage educators to explore how these emerging AI ecosystems could transform medical education.

(JMIR Med Educ 2025;11:e76661) doi:10.2196/76661

KEYWORDS

artificial intelligence; agents; pedagogy; large language models; instructional design

Introduction

The use of large language models (LLMs), such as ChatGPT, has surged in medical education, largely due to their capacity to generate answers, summaries, or clinical scenarios on demand [1]. While these tools offer convenience, most implementations remain confined to single-turn interactions with minimal contextual awareness [2]. As such, they are ill-suited to the inherently complex, multistep processes that define both clinical reasoning and medical education instructional design.

Medical education is neither linear nor static. Learners must navigate evolving information, engage in iterative reflection, and integrate feedback across diverse domains. Educators, likewise, must design learning experiences that are both structured and flexible, adapting in real time to learner needs and contextual constraints. In this Viewpoint article, we argue that advancing the role of artificial intelligence (AI) in this domain requires a conceptual and architectural shift—from chatbots to modular agents.

Elements of the proposed multistep modular agent framework are already in pilot use at our institution. For example, a history-taking application uses an agentic patient alongside companion agents that surface summaries and nudge questions when learners stall. Similar workflows have been trialed for scenario design and rubric authoring across both undergraduate and postgraduate medical education settings. We hope this Viewpoint will be useful for educators and support staff (eg, instructional designers) who are seeking structured, pedagogically aligned ways to integrate AI into their teaching and assessment practices.

Why Single-Prompt AI Chatbots Fall Short in Complex Educational Workflows

LLMs have demonstrated strong performance in generating simulated patient responses, drafting multiple-choice questions with plausible distractors, and providing clear, conversational explanations to learners, making them valuable for isolated, language-driven tasks in medical education [1,3,4]. These interactions, however, remain fundamentally static and

transactional. The AI responds once to a prompt, with limited contextual memory and no intrinsic understanding of how its output fits into a broader pedagogical framework. This architecture is not suited to the realities of medical education, which demand systems that can manage evolving learner inputs, sustain contextual awareness, and scaffold multiple interconnected subtasks. Rather than seeking access to models' internal "reasoning," we emphasize transparent, reviewable intermediate artifacts. For example, tables of objectives, draft scenarios, and rubric levels. These should be open to educator review at frequently defined checkpoints.

Medical educational workflows combine structure with adaptability. On one hand, structured elements such as predefined curricula, learning objectives, and assessment frameworks provide learners with a clear roadmap [5]. These components are essential for building knowledge systematically, maintaining consistency across training programs, and aligning educational outcomes with professional standards [6]. At the same time, medical education demands flexibility. Learners must continuously adapt their understanding in response to new information, clinical contexts, and feedback [7]. This dynamic process mirrors the realities of clinical practice, where patient presentations are often unpredictable, and decisions evolve as new data emerge [8].

For instance, designing a simulation scenario or a performance rubric involves more than a single step [9]. It requires iterative alignment with learning objectives, incorporation of cultural and contextual considerations, and ongoing refinement based on feedback. These are complex and adaptive processes rather than linear tasks. Relying on a single, comprehensive prompt to guide such development can result in superficial or inconsistent outputs [2]. It also places an unrealistic expectation on the prompt designer to capture all instructional nuances at once.

Modular AI Agent Framework: A Pedagogically Aligned Alternative

To address the limitations of single-dimension chatbot systems in educational design, we propose a shift in consideration to a modular, multistep AI agent framework. An agent is a specialized AI process that operates with explicit goals, constraints, contextual inputs [10,11], and error-handling capacity. This contrasts with simple chained prompts, which merely sequence tasks without structured autonomy or memory (Table 1). Agents can operate in parallel as well as sequentially, whereas chained prompts are inherently linear.

Table . Comparison of key features of chatbots and multiagent frameworks [10,11].

Dimension	Chatbots (single or chained prompts)	Modular multiagent frameworks
Transparency	Outputs are all-in-one; intermediate reasoning often hidden	Intermediate artifacts (objectives, drafts, rubrics) explicit and reviewable
Model specialization	One model handles all subtasks; prompt engineering is the only lever	Each agent can call the model or tool best suited for its subtask
Error localization	Errors propagate; difficult to isolate or correct	Errors traceable to specific agents; easier to isolate and correct
Evaluation	Only final output assessable	Stepwise evaluation at each checkpoint
Cost	Lower per run but may require multiple retries	Higher per run (multiple agents) but more efficient for complex workflows
Pedagogical fit	Possible with skilled prompt design and oversight, but constrained by single system prompt	Agents can be designed to map systematically onto instructional frameworks
Instructional scope	Constrained by single system prompt (eg, 8000 characters in customGPT as of September 2025); must pack all instructions into one prompt; success depends on model's ability to follow and prioritize prompts	Each agent only receives the instructions it needs for its task, reducing ambiguity and improving compliance
Scalability	Harder to adapt; changing prompts may affect entire workflow	Extensible; new agents can be added or replaced independently
Workflow structure	Sequential, linear	Supports both series (one task after another) and parallel (simultaneous subtasks) workflows

Rather than tasking a single agent with the entire instructional-design workflow, responsibilities are distributed across a pipeline of specialized agents, each optimized for its step [10,11]. These agents can invoke function calls or other tool integrations so that every agent not only reasons in natural language but also acts with the precise utilities needed to fulfill its mandate.

An *AI agentic framework* can model the expert-led, multistep process educators use in scenario design by integrating task specialization, interactive user feedback, and tool integration. Each specialized agent hands its output to the next, preserving logical and pedagogical continuity while an overarching orchestrator agent monitors the entire pipeline, coordinates handoffs, and can route back to the relevant specialist agent for further iteration when needed [12]. This intuitive structure supports extensibility through tool integration and scalability

by allowing agents to be refined, replaced, or expanded based on evolving needs. In other words, pedagogy comes first: agents map intuitively onto how we already teach and assess. MEDCO (Medical Education Copilots), for example, optimizes learner-and-agent dialogue in simulated encounters [13]. In comparison, our educator-in-the-loop approach focuses sequentially on the lesson design objectives, story, tasks, and marking guide. Each draft is reviewed and approved before moving on. This enables educators to remain central to the process, reviewing and approving outputs at each stage to safeguard pedagogical integrity and contextual relevance.

An Example in Scenario Design

We present an example of a modular AI agentic framework that offers a structured yet flexible approach to developing clinical communication scenarios. This design allows the system to emulate the collaborative workflow of a multidisciplinary education team including educators, instructional designers, content experts, and assessment specialists by assigning each phase of scenario construction to an agent optimized for that purpose.

This example system is composed of 7 AI agents, each operating within clearly defined instructional boundaries. Other than the orchestrating agent, 6 other agents function sequentially, handing off their outputs to the next agent in the pipeline to ensure continuity, coherence, and pedagogical alignment. Each agent is responsible for a specific task that reflects real-world instructional design practices, where complex deliverables are broken into manageable, interdependent stages.

The orchestrating agent oversees the entire workflow, ensuring that each specialized agent performs its task effectively and that the outputs are cohesive and aligned with the pedagogical goals. The orchestrating agent can return generated outputs from specific agents for further iteration if required.

The scenario overview agent initiates the workflow by generating a scenario title and a structured table of learning or assessment objectives. Educators are prompted to review and refine objectives before proceeding.

The storyline agent builds on the approved objectives by producing 3 patient storylines. Each includes narrative elements, such as patient background, emotional and physical concerns, hidden agendas, and sociocultural context, with explicit localisation to the Singaporean setting.

The candidate instructions agent crafts clear, structured learner instructions, including task descriptions and background details.

The surrogate patient script agent generates a detailed script to guide the simulated patient's behavior. It incorporates behavioral cues, emotional tone, and plausible responses to candidate questions. The agent can retrieve example scripts via file searches and invoke web tools to integrate culturally relevant details.

The scoring rubric agent allows users to define their own rubric, including domains of competence and marking scales. Users can construct a table of performance criteria that aligns with the scenario's learning objectives. The rubric incorporates score levels, descriptive anchors, and exemplar behaviors. Additionally, tool-calling and web search functionality enable the retrieval of validated rubrics to ensure alignment with existing assessment frameworks.

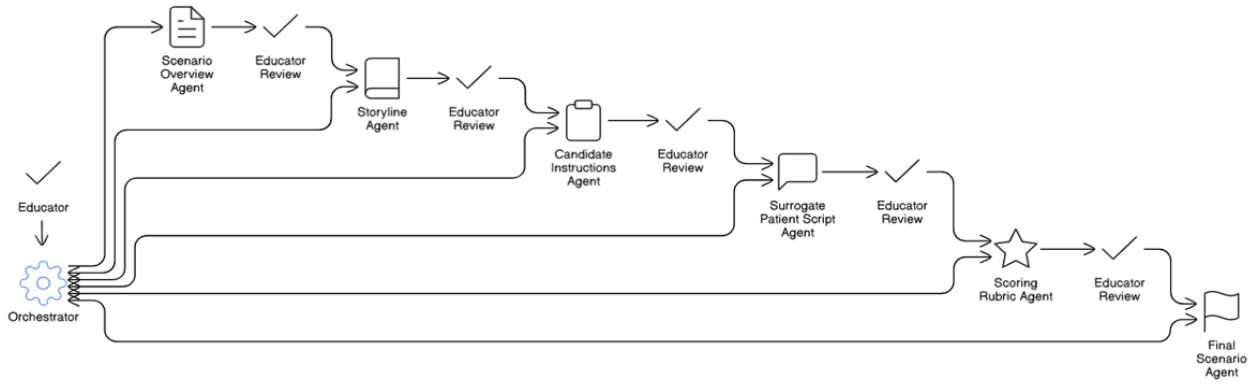
The final scenario agent compiles all approved components into a cohesive scenario document. It ensures consistency in formatting, terminology, and contextual accuracy, preparing the scenario for direct use or further adaptation by educators.

Figure 1 illustrates the 7-agent pipeline with educator checkpoints and the orchestrating agent. Each handoff (represented by arrows) is schema-checked; the educator can approve or request revision before progression.

In agent-based generative workflows, the concept of a discrete "error" is less relevant than in traditional rule-based systems. Output quality is influenced by multiple factors: the specificity and clarity of user prompts, the depth of reasoning elicited by the design structure, and the availability of exemplars or templates that guide generation. Agentic frameworks allow for improved output quality, as each agent is specifically trained and instructed to perform a certain task and provided with the necessary tools to execute it effectively. Specific model types can also be selected to best fit the nature of the task, for example, reasoning, long-context, tool-use, and vision tasks. The modular framework uses these elements to produce educational artifacts that are functional, pedagogically sound, and contextually sensitive.

By breaking down the scenario design process into agent-specific tasks, the system supports a structured and transparent development process.

Figure 1. Seven-agent pipeline for scenario design with educator checkpoints. The orchestrating agent routes tasks, monitors quality, and reruns only failing steps; educators review intermediate artifacts at each gate.



Educational Theory Alignment and Pedagogical Implications

Drawing from instructional design theory, each agent's role mirrors existing teaching and assessment practices—from objective setting to content creation to assessment alignment [14]. It also resonates with complexity theory in education, which acknowledges the nonlinear, adaptive, and emergent nature of curriculum design [8]. By assigning each AI agent a tailored reasoning strategy, such as generative models for creative storytelling or deterministic models for rubric precision, we preserve pedagogical coherence while leveraging the strengths of LLMs in context-specific ways. Moreover, the use of AI agents to build culturally localized cases (eg, context-specific language patient scripts) demonstrates how modularity can enable personalization without compromising scalability. The overall system thus acts not as a content generator, but as a structured collaborator in instructional design.

Human-in-the-Loop: Safeguarding Pedagogical Quality and Trust

Central to our framework is the conviction that AI agents must augment—not replace—human educators. Every stage of the agentic pipeline therefore includes a mandatory checkpoint where educators review, revise, and approve an agent's output before it is handed to the next specialist agent. Only when the reviewer is satisfied, and no further iterations are requested, does the workflow advance.

This checkpoint design yields 3 advantages. First, pedagogical assurance: continuous expert oversight guarantees that scenarios remain faithful to institutional standards, educator requirements, learner needs, and real-world clinical practice. Second, iterative flexibility: at any time, users can return to an earlier step, reopen an agent's draft, and trigger additional refinement cycles. This bidirectional flow prevents "lock-in" to premature decisions and supports rapid improvement when curricular goals evolve. Third, transparency and trust: because every AI-generated artifact is treated as a draft, it remains open to critique rather than being accepted as a "black box" verdict. Educators retain clear visibility into the rationale behind each decision. This collaborative, human-guided process reflects traditional instructional design workflows, ensuring that final materials are shaped by pedagogical judgment rather than relying solely on algorithmic output.

To provide readers with a familiar curricular reference point, we align the proposed agentic pipeline with Kern's [15] 6 steps of curriculum development. This alignment is not intended as a prescriptive template, but rather as an interpretive framework that illustrates how agent outputs and educator checkpoints correspond to established stages of curriculum design. In doing so, Kern's [15] model provides conceptual coherence, while the agentic workflow demonstrates a practical means of operationalizing each step. Table 2 summarizes this mapping.

This approach reflects the collaborative nature of instructional design, where materials are developed through iterative review and decisions are guided by pedagogical judgment rather than algorithmic output alone.

Table . Agent-to-pedagogy mapping: how each agent (and the educator) contributes across Kern's steps 1 - 6.

Kern's 6 steps	Agent and educator roles
Step 1: problem identification and general needs assessment	Scenario overview agent frames the educational problem and proposes objectives; orchestrator agent ensures consistency. Educator reviews problem framing and refines objectives.
Step 2: targeted needs assessment	Scenario overview agent structures learner-specific needs. Educator validates alignment with learner context and institutional requirements before progression.
Step 3: goals and objectives	Storyline agent translates objectives into case narratives with sociocultural context. Educator evaluates relevance, realism, and coherence of the narratives.
Step 4: educational strategies	Candidate instructions agent defines learner tasks; surrogate patient script agent operationalizes the interaction; storyline agent scaffolds narrative complexity. Educator provides iterative feedback, ensuring strategies remain pedagogically sound.
Step 5: implementation	Scoring rubric agent designs criteria for performance; final scenario agent compiles all components; orchestrator agent ensures alignment. Educator approves rubrics, validates final scenario quality, and ensures usability.
Step 6: evaluation and feedback	Scoring rubric agent embeds standards and feedback anchors; orchestrator agent supports routing to the educator for revision. Educator delivers final judgments, integrates feedback, and ensures final product is satisfactory.

Practical Considerations

Some may argue that carefully engineered single-prompt workflows within a large language model (eg, customGPTs), can produce comparable results. Yet empirical data show that single-prompt workflows still trail agentic teams in diagnostic accuracy and bias mitigation [16-18].

Agent modularity also offers benefits that chained prompts find difficult to replicate. First, it allows the educator end user to assign each subtask to the foundation model best suited to the cognitive demands of the task. For example, a reasoning-optimized model can be used for diagnostic planning, a vision-capable model for image annotation, and a fast, low-cost model for rubric scoring.

Second, specialized agents can issue narrowly focused tool or function calls, which helps ensure stricter compliance with domain-specific instructions. An analogy illustrates this: asking a single writer to produce an entire clinical simulation, including learning objectives, patient script, scoring rubric, and feedback, in one attempt is less reliable than assigning each section to professionals who have the right expertise and references. Modularity gives an AI pipeline that same division of labor advantage.

Third, modularity localizes failure and simplifies evaluations. Breaking the workflow into a series of small, purpose-built agents lets educators spot problems exactly where they occur, verify the quality of each step in isolation, and rerun or update only the affected agent without disturbing the rest of the pipeline.

While the modular-agent approach offers clear advantages, it is not without trade-offs. Stitching together multiple agents raises implementation complexity, especially in low-resource or nontechnical settings. Here, "vibe coding," a visual and block-based approach to wiring agents, tool calls, and routing rules, is helping to lower the barrier for educators who do not have coding experience [19]. Vibe coding allows educators to create educational apps by instructing AI in natural language. Any educator who hopes to pivot toward AI-augmented end-to-end educational workflows must begin with careful process decomposition. The instructional journey should be mapped into discrete steps, with the cognitive and technical requirements of each step clearly specified [20,21]. There are several practical implementation choices to consider. The input and output schemas between agents are standardized at each step with simple templates to ensure minimum quality standards. Educators are provided with "prompt cards" documenting instructions, data sources, tools, and approvals, with any changes logged for accountability. All drafts are automatically logged with source, model, prompt card, and a summary that enables traceability. Clear acceptance criteria guide fallback or rollback when a step underperforms, allowing repair or educator-initiated rewrites without restarting the pipeline. Versioning and update policies are also in place. Runs typically complete within minutes, with token use and costs managed by combining efficient models for routine steps with reasoning models for critical alignment.

Limitations

This Viewpoint advances a conceptual and architectural position supported by early pilot deployments; however, we have not yet conducted prospective controlled studies to compare modular multiagent pipelines with single-step chatbots in terms of their impact on learner outcomes.

Conclusion: Rethinking AI's Role in Medical Education Together

Moving beyond chatbot paradigms opens new possibilities for the use of AI in medical education. Modular, agent-based

systems can mirror the sophistication of human instructional design, support iterative feedback loops, and preserve important contextual nuance. Their true value lies not in replacing educator labor, but in amplifying educator intent. Realizing this potential requires investment in systems that prioritize transparency, alignment, and human AI collaboration.

One promising step is the shift toward purpose-built agent ecosystems. Rather than relying on single-prompt chatbots, educators can begin by decomposing the instructional process, mapping each step, and identifying where a specialized agent, equipped with the appropriate model, data access, and tool-calling privileges, might help relieve cognitive load or automate repetitive tasks. Delegating routine activities to autonomous agents allows human experts to reclaim valuable time for higher-order mentoring, empathy, and creative pedagogy. Embracing this agentic mindset can help AI feel less like a black box chatbot and more like a transparent, collaborative partner that transforms tedious processes into opportunities for deeper learning and innovation.

We invite educators who are curious and committed to innovation to join us in exploring and shaping these agentic ecosystems together.

Acknowledgments

The authors acknowledge the use of ChatGPT with GPT-4o and GPT-5 (OpenAI) in the editorial refinement of this manuscript. These tools were used exclusively to improve clarity of sentence structure and address grammatical nuances. The authors did not use generative AI for ideation, conceptual development, or drafting of content. At all stages, the authors' critical judgment and scholarly voice were preserved. All outputs were independently reviewed, revised, and verified to ensure scholarly integrity and intellectual authorship. There is no funder involvement in this Viewpoint.

Abstract

The release of GPT-4 Omni (GPT-4o), an advanced multimodal generative artificial intelligence (AI) model, generated substantial enthusiasm in the field of higher education. However, one year later, medical education continues to face significant challenges, demonstrating the need to move from initial experimentation with the integration of multimodal AIs in medical education toward meaningful integration. In this Viewpoint, we argue that GPT-4o's true value lies not in novelty, but in its potential to enhance training in communication skills, clinical reasoning, and procedural skills by offering real-time simulations and adaptive learning experiences using text, audio, and visual inputs in a safe, immersive, and cost-effective environment. We explore how this innovation has made it possible to address key medical educational challenges by simulating realistic patient interactions, offering personalized feedback, and reducing educator workloads and costs, where traditional teaching methods struggle to replicate the complexity and dynamism of real-world clinical scenarios. However, we also address the critical challenges of this approach, including data accuracy, bias, and ethical decision-making. Rather than seeing GPT-4o as a replacement, we propose its use as a strategic supplement, scaffolded into curriculum frameworks and evaluated through ongoing research. As the focus shifts from AI novelty to sustainable implementation, we call on educators, policymakers, and curriculum designers to establish governance mechanisms, pilot evaluation strategies, and develop faculty training. The future of AI in medical education depends not on the next breakthrough, but on how we integrate today's tools with intention and rigor.

(JMIR Med Educ 2025;11:e79309) doi:10.2196/79309

KEYWORDS

multimodal generative pretraining transformers; GPT-4o; artificial intelligence; interactive learning; medical education

Introduction

The impact of artificial intelligence (AI) within health care continues to expand, ranging from diagnostic imaging to medical training [1]. Its integration into medical education offers promising solutions to numerous challenges, particularly the need for substantial resources to effectively train students in competencies like communication, clinical reasoning, and procedural skills. AI tools offer scalable, low-resource alternatives that can help bridge these gaps.

In 2024, OpenAI released GPT-4 Omni (GPT-4o), a multimodal model combining text, image, and audio processing. Unlike text-only systems, GPT-4o supports more dynamic interactions, such as engaging in real-time, human-like conversations, interpreting visual content, and performing realistic voice-based simulations. GPT-4o received widespread attention within medical education due to its multimodal capabilities enabling realistic simulations that extend to procedural skill assessment and interactive case analyses. Early demonstrations highlight GPT-4o's ability to simulate patient interactions [2], visually identify medications [3], and undertake medical examinations with higher accuracy than GPT-4 and GPT-3.5 [4,5].

However, one year after its release, there is clearly a slow pace of adoption and implementation remains limited [6]. Although some institutions have experimented with GPT-4o integration [7] and others analyzed medical students' attitudes toward this integration [8], sustained adoption within formal curricula has lagged.

This Viewpoint highlights how GPT-4o shows promise as a relevant tool to enhance medical education and address many of its challenges, despite the initial hype fading. We examine its strengths in simulating patient interactions, increasing equity due to low-resource deployment, and reducing educator workload. We also address concerns including accuracy, bias, ethical reasoning, and digital access. Our aim is not to present GPT-4o as a cure-all, but to advocate for a structured, research-informed pathway for integrating such tools meaningfully into medical training. Although this discussion

focuses on general medical education, specific considerations for dental medicine and other health disciplines warrant future exploration.

Educational Challenges Addressed by GPT-4o

Here are some of the educational challenges addressed by GPT-4o:

1. Communication skills: Developing interpersonal communication is vital for effective clinical practice. Traditional role-playing methods, reliant on patients or actors, are resource-intensive and challenging to standardize and scale. GPT-4o–generated virtual patients simulate diverse and adaptive interactions, fostering essential skills such as delivering bad news and providing culturally sensitive care. By creating realistic, immersive environments, GPT-4o aligns with situated learning theory, enabling learners to acquire practical skills in context.
2. Clinical reasoning: Diagnostic and intervention decision-making requires iterative exposure to varied scenarios. Static case-based learning often fails to engage learners dynamically. GPT-4o generates interactive, context-rich cases tailored to learner actions, promoting experiential learning [9] and hypotheticodeductive reasoning [10]. Feedback is immediate and adaptive, allowing users to refine diagnostic strategies in real time. These features advance cognitive load management, enhancing learning efficiency.
3. Essay-based assessments: Essay writing fosters critical thinking and provides a platform for expressing individual ideas. Despite these benefits, educators often avoid using essay writing due to the time required for grading. GPT-4o automates the assessment of essay responses, providing detailed feedback on reasoning, structure, and language [11]. This automation reduces educator workloads, encourages higher-order assessments, and supports personalized student development. However, overreliance on automated grading may overlook nuanced clinical reasoning or professional reflection, underscoring the need for educator oversight [12] Additionally, some research suggests that students may perceive AI-generated feedback as impersonal, leading to reduced engagement or trust [11].
4. Procedural skills: Skill acquisition in procedures relies on hands-on practice, detailed feedback, and in-person, one-on-one observation and assessment. GPT-4o's ability to produce realistic simulations and analyze video inputs offers scalable solutions for performance evaluation. Future integration with augmented reality and virtual reality technologies could facilitate immersive training experiences, replicating clinical environments for enhanced procedural competence. However, the concept of fidelity, including how realistic and believable simulations appear to learners, is critical. Low-fidelity simulations risk invoking the "uncanny valley" effect, where interactions feel unnatural and may reduce engagement [13].

Potential Benefits

For Learners

GPT-4o supports ongoing skill development by offering, personalized instant performance evaluation and feedback. Due to its realistic clinical simulations, students are exposed to a wide range of medical cases and can practice clinical reasoning in a realistic and practical way. Learners can practice breaking bad news to virtual patients, interpret multimodal data such as radiological images or heart sounds, and receive adaptive feedback tailored to their level. As a result, students can develop their confidence in a secure, flexible, and nonjudgmental learning environment.

For Educators

GPT-4o helps ease the workload by performing time-consuming tasks such as writing patient scenarios, setting assessments, marking essays, and providing personalized feedback on student performance. This gives educators more time to focus on tasks such as student support and course development. Additionally, seeing as GPT-4o is already pretrained, there is no need for heavy investment in custom AI tools, making it easier and quicker for institutions to adopt. Nevertheless, institutions should address faculty resistance by providing hands-on workshops, co-designing AI use cases with educators, and sharing evidence from pilot studies to build confidence in its implementation.

Global Accessibility

Due to GPT-4o being cloud-based, it does not require costly infrastructure, making it accessible to both learners and educators in low-resource settings. This helps democratize medical education and training and results in a more even distribution of health care expertise globally [14].

Challenges and Considerations

Although AI holds promise in medical education, there are also some challenges and considerations:

1. Accuracy: AI programs like GPT-4o may generate errors or "hallucinations" [15]. To overcome this, the output of such tools requires continuous supervision and validation to ensure their reliability.
2. Data privacy: To uphold confidentiality and ethical standards, learner performance data must be protected. This may be achieved through the adoption of strict data security measures by educational establishments. However, implementing strict data security is complex, requiring closed systems, robust encryption, and governance frameworks. There are trade-offs between using real learner data, which raises confidentiality concerns, and synthetic data, which may lack realism.
3. Bias: Training data biases associated with gender, ethnicity, or socioeconomic status may influence AI outputs. As a result, initiatives to reduce these biases are essential, especially since AI tools are being used more and more to deliver and filter health care information, where transparency and trust are essential [16]. Emerging frameworks like Fairlearn and AI Fairness 360 offer tools

to audit and mitigate bias in AI systems, supporting fairer educational outcomes [17].

4. Ethics and professionalism: Although GPT-4o performs very well in simulations, professionalism or complex ethical reasoning may be more challenging for it [12]. These limitations highlight the importance of human oversight and complementary teaching methods.
5. Access: Despite its general affordability, access to GPT-4o still depends on a stable internet connection, potentially limiting its reach in underserved regions with poor connectivity [18]. Addressing this challenge requires exploring offline or low-bandwidth alternatives to ensure a broader reach.

Next Steps

Emerging empirical studies are beginning to validate GPT-4o's role in medical education. For example, a pilot by Öncü et al [2] used GPT-4o as a virtual standardized patient to simulate complex communication and crisis scenarios, demonstrating high learner engagement and feasibility in training clinical reasoning. Bicknell et al [19] evaluated GPT-4o across 4 national licensing exams, where it achieved a 90.4% accuracy rate, surpassing GPT-4 and average medical student performance. Similarly, Zhong et al [20] benchmarked GPT-4o for rare disease diagnosis using multilingual clinical data, with the model achieving the highest diagnostic accuracy among tested large language models. These studies reinforce the potential of GPT-4o to enhance assessment, simulation, and clinical education, while also underscoring the need for rigorous longitudinal evaluation frameworks.

Future research should assess how effectively GPT-4o enhances learner competencies like critical thinking, decision-making, and procedural skills. Evaluation frameworks should include multimodal fidelity measures, learner satisfaction, performance metrics, and longitudinal tracking of outcomes such as clinical preparedness. These metrics will help assess the educational impact of GPT-4o in realistic, complex learning environments. Additionally, GPT-4o could support interprofessional education by simulating collaborative scenarios between medical, nursing, and dental students. Such integration may enhance communication, teamwork, and understanding across health disciplines, particularly in complex patient care settings.

To further expand its uses, GPT's multimodal capabilities could be extended to interpret video and audio data, such as echo scans and heart sounds. To guarantee that implementation is ethical, scalable, and in line with curriculum objectives, cooperation between AI developers, educators, and legislators is equally vital. Addressing challenges such as accuracy, bias, and accessibility challenges will ensure equitable benefits for all learners. Even though GPT-4o is a significant step forward, its use in medical education should be guided by research and specific learning aims. To offer useful assistance for adoption, we propose a set of initial steps for institutions to implement GPT-4o (Textbox 1).

Textbox 1. Recommendations for institutions considering GPT-4o integration.

1. Begin with a small-scale pilot project focusing on a single competency (eg, communication).
2. Provide prompt engineering training for faculty members.
3. Develop ethical guidelines for student use.
4. Incorporate artificial intelligence literacy into medical curricula.
5. Collaborate with technology experts to conduct longitudinal assessments of performance.
6. Design simulated scenarios that support interprofessional education (eg, medical, dental, and nursing collaboration).
7. Address faculty concerns through workshops, co-designed implementation strategies, and sharing evidence from early adopters.

Conclusion

The integration of GPT-4o into medical education represents a promising shift. It not only tackles long-standing challenges by offering scalable, immersive training solutions, but its multimodal nature also results in it offering advantages over prior models in certain contexts. Consequently, both educators and learners globally stand to benefit as access to quality education becomes more equitable. However, for this integration to be effective, medical institutions must move past experimentation through pilot studies and toward embedding into formal curricula. Finally, GPT-4o must not be viewed as a quick fix but rather as a tool that demands thoughtful design, evaluation, and governance, and its integration should be guided by rigorous research, ethical considerations, and faculty collaboration.

Abstract

The increasing use of generative large language models (LLMs) necessitates a fundamental reevaluation of traditional didactic lectures in medical education, particularly within psychiatry. The specialty's inherent diagnostic ambiguity, biopsychosocial complexity, and reliance on nuanced interpersonal skills demand an educational model that transcends mere information transfer, focusing instead on cultivating sophisticated clinical reasoning. This viewpoint argues for a shift from passive knowledge transmission to active, facilitated development of higher-order thinking, aligning with the Bloom taxonomy. We describe four core propositions: (1) shifting foundational knowledge acquisition to faculty-curated asynchronous artificial intelligence (AI)–assisted micromodules; (2) transforming synchronous time into "Ambiguity Seminars" for discussing nuanced cases, biopsychosocial formulation, and ethical dilemmas, leveraging faculty expertise in guiding reasoning; (3) integrating live LLM critical interaction drills to develop prompt engineering skills and critical appraisal of AI outputs; and (4) realigning assessment methods (eg, objective structured clinical examinations [OSCEs], reflective writing) to evaluate clinical reasoning and integrative skills rather than rote recall. Successful implementation requires comprehensive faculty development, explicit institutional investment, and a phased approach that addresses scalability across varying resource settings. This reimagined approach aims to cultivate clinical wisdom, equipping psychiatric trainees with adaptive reasoning frameworks essential for excellence in an AI-mediated future.

KEYWORDS

large language models; medical education; didactic lecture; artificial intelligence; educational technology

Introduction

The advent of powerful, publicly accessible large language models (LLMs) like ChatGPT marks an inflection point for medical education. Specifically, these tools are driving a shift from information scarcity to abundance, which directly challenges the traditional role of the didactic lecture as the main medium of information transfer. Consequently, the widespread adoption of these tools necessitates a fundamental rethinking of this lecture model. The necessity to evolve beyond traditional

didactics is amplified in psychiatry, a specialty with inherent diagnostic ambiguity, profound biopsychosocial complexity, and a fundamental reliance on nuanced interpersonal competencies and the interpretation of subjective human experience. These defining features demand an educational model that transcends mere information, one that actively cultivates the sophisticated clinical reasoning and integrative skills essential for practice. Such a model aligns with established pedagogical frameworks like the Bloom taxonomy, aiming to engage trainees across a spectrum of cognitive processes, from foundational understanding to higher-order thinking and complex problem-solving. Consequently, we argue that psychiatric didactic time must pivot from passive knowledge transmission toward an active, facilitated development of clinical reasoning, with faculty evolving from information repositories ("sage on the stage") [1] into catalysts for critical thinking and contextualization. This proposed evolution aligns with the core tenets of competency-based medical education, which prioritizes the demonstration of integrated professional capabilities over time-based training and simple knowledge acquisition [2]. It is a direct application of the call to cultivate "adaptive expertise," the ability to flexibly and innovatively apply deep conceptual knowledge to novel problems, which stands in contrast to the routine expertise fostered by traditional didacticism [3]. This viewpoint outlines four core propositions for this necessary transformation.

Psychiatry's inherent complexity imposes a high intrinsic cognitive load, yet traditional lectures often increase extraneous load through passive delivery, hindering deep processing and schema learning [4]. Seeking greater efficiency, trainees increasingly forgo these sessions. This mismatch contributes significantly to declining attendance as trainees prioritize the flexibility of alternative resources [5]. Beyond attendance effects, meta-analyses indicate that active learning consistently improves achievement and reduces failure compared with traditional lectures [6], with flipped designs in medical education showing measurable gains when preclass work is structured and accountability is built in [7].

The Shifting Landscape: AI's Impact on Medical Education and Psychiatry's Unique Needs

The widespread availability of LLMs for educational purposes [8-10] drastically accelerates this trend by collapsing traditional knowledge asymmetries. However, alongside potential benefits, the unguided use of these tools necessitates critical artificial intelligence (AI) literacy due to inherent risks of these systems, mainly around inaccuracies and "hallucinations" [10-15] as well as the potential propagation of embedded societal biases [16-18]. Additionally, the risk of automation bias influencing clinical judgment [13], coupled with outputs often lacking the critical nuance essential for psychiatric practice [10,15,16], further underscores current AI limitations. Effectively navigating this landscape demands not only critical evaluation skills but also proficiency in prompt engineering [14,19]. Current didactic structures, largely reliant on outdated lecture formats, are ill-equipped for this complex new reality, failing to prepare trainees for an information environment increasingly mediated by AI. This challenge is not unique to the AI era; for decades, educational theorists have argued for the necessity of active learning methodologies to move beyond the passivity of the lecture format and better cultivate the complex reasoning skills required for professional practice [1]. This aligns with meta-analytic evidence from health profession education and the broader higher education literature showing flipped/active approaches outperform lecture-based formats [6,7].

Beyond general AI challenges, psychiatric education faces unique demands. Diagnosis relies on subjective interpretation and negotiated constructs, not definitive tests, with evolving models adding complexity. Effective practice requires sophisticated biopsychosocial formulation, integrating diverse data (biology, psychology, narrative, and social context), which is a reasoning skill poorly served by simple fact delivery. Current LLMs struggle with the nuance, empathy, subjectivity, and deep biopsychosocial integration vital for psychiatry [15,16,20]. Given that navigating uncertainty and ambiguity are core competencies, psychiatric education must prioritize cultivating robust clinical reasoning, metacognition, and critical thinking to develop "clinical wisdom" over mere recall [1,4].

Developing such clinical wisdom demands a pedagogical evolution. Because LLMs reduce the challenge of accessing factual knowledge, faculties' comparative advantage shifts to fostering higher-order cognitive skills such as critical thinking, contextual reasoning, and the synthesis of information, evolving their role from primary knowledge sources to catalysts for these deeper learning processes. The following propositions operationalize this shift.

Core Propositions for Reimagining Psychiatric Didactics

First, the acquisition of foundational knowledge, corresponding to initial cognitive levels in the Bloom taxonomy such as "Remembering and Understanding," shifts to faculty-curated AI micromodules. These short asynchronous resources, perhaps AI-drafted [15,19,20] but rigorously vetted for accuracy/nuance [10,14-16], free synchronous time and reduce extraneous cognitive load [21,22]. This vetting process would involve cross-referencing AI-generated content against established clinical guidelines and seminal texts, scrutinizing for embedded biases [16-18], verifying the authenticity of citations [11], and ensuring the material aligns with local practice standards and the appropriate learner level.

Second, synchronous time becomes an "Ambiguity Seminar," where psychiatric complexity is addressed directly. Faculty use nuanced vignettes to teach how to reason, framing the clinical problem and uncertainties first, rather than delivering more facts [1]. To achieve this, faculty would use techniques such as Socratic questioning to probe assumptions and guide hypothesis generation ("What evidence supports that diagnosis over others?"). They would also focus on metacognitive modeling, verbalizing their own reasoning process when faced with uncertainty ("Here is why I am prioritizing this intervention, despite these conflicting data points...") to demonstrate how

experts navigate ambiguity, thereby shifting the focus from finding a single correct answer to developing a robust and defensible reasoning process. While AI may help draft initial cases [18], instructors refine them toward situations in which diagnoses straddle categories and pharmacological guideline algorithms do not neatly apply. Learners then generate competing hypotheses with confirming and disconfirming data, craft a succinct biopsychosocial formulation, and propose a first-line plan that goes beyond the textbook, stating trade-offs and safety contingencies in the patient's context. LLMs can be used as a sounding board, but outputs are treated as claims to be tested; their breakdowns become teachable moments about limits and bias. The aim is disciplined, creative problem-solving, yielding brief original formulations and plans that learners can defend aloud.

Third, seminars integrate live LLM critical interaction drills. Trainees query an LLM with case questions, then critique the output: checking accuracy, bias, relevance, and citations. This requires prompt engineering instruction [14,19,20]. Engaging in such exercises helps trainees develop sound habits for evaluating information, improves their AI literacy, and equips them to counter automation bias [13]. Prompting students to critique LLM responses encourages them to use the AI as a sounding board to refine their own clinical judgment; this process also lessens the risk of AI-driven inaccuracies and develops crucial practical abilities.

Finally, to ensure learning objectives are met, assessment must be realigned with reasoning skills, moving beyond recall. While the Bloom taxonomy can delineate how AI might assist with foundational knowledge tasks, evaluation must focus on higher-order thinking that is inherently resistant to artificial augmentation. Specifically, objective structured clinical examinations (OSCEs) should be designed to assess not just the analysis of complex information but also the trainee's real-time interpersonal skills and their ability to adapt to unexpected information from a standardized patient. To ensure integrity, these OSCEs must be conducted in proctored environments where the use of external AI tools is prohibited. Similarly, reflective writing assignments can be made more robust by requiring trainees to integrate highly specific, personal patient interactions—details an AI could not fabricate—or by using in-class timed "reflection stems" that demand immediate synthesis of a shared experience. A mandatory oral defense of these reflections then becomes a nonnegotiable component to validate the authenticity of the reasoning and personal insights presented. These methods, by directly targeting the upper echelons of the Bloom taxonomy and evaluating skills requiring embodied clinical presence and personal experience, offer a more authentic assessment of the competencies that current AI systems struggle to replicate.

A Framework for Implementation: Addressing Practical Challenges

We proposed a pragmatic blueprint that flips factual acquisition to curated micromodules, reclaims synchronous time for faculty-facilitated ambiguity seminars, and integrates AI-critical drills, with assessments aligned to higher-order clinical reasoning. This section aims to translate that design into an implementable institutional plan while acknowledging costs and constraints.

Translating these propositions from theory into practice requires a pragmatic strategy that directly addresses the significant challenges of institutional inertia, resource allocation, and faculty development. A successful rollout is not merely a technical task but a complex exercise in change management. The most significant barrier is often faculty resistance, which may stem from the substantial workload of curriculum redesign and a perceived evaluation of traditional lecturing expertise. Consequently, this change must be framed as an elevation of the faculty role, shifting members from information transmitters to expert guides who model and cultivate complex clinical reasoning. We acknowledge that this viewpoint presents a theoretical framework and that its efficacy has yet to be established through empirical research; its primary goal is to provide a road map for such investigation.

To manage this transition, a dedicated faculty development program is essential, requiring protected (and renumerated) time for hands-on training in advanced Socratic facilitation for the ambiguity seminars, critical AI literacy for appraising model outputs, and the skills for curriculum cocreation. Furthermore, this educational model is not resource-neutral and requires explicit institutional investment. Success is contingent on access to a stable and user-friendly learning management system; privacy-compliant AI platforms; and most critically, formally protected faculty time. This work cannot be an unfunded mandate added to existing clinical and academic responsibilities. To centralize and sustain the effort, programs might consider creating a dedicated role, such as a clinical AI education lead. Recognizing that institutional capacities vary widely, this framework is designed to be scalable. High-resource programs might implement the full model, while lower-resource settings can adopt a "low-fidelity" version using freely available language models and multi-institutional consortia for open-access materials. Crucially, this scalability must extend to individual trainees to ensure equitable participation. Programs should provide accessible, screen reader–friendly materials and use privacy-compliant AI platforms, offering device support or non-LLM analytic pathways where live access is infeasible. By embedding these accessibility measures, the core principles of flipping the classroom and focusing synchronous time on facilitated reasoning can be maintained inclusively across all settings.

Central to this framework is a commitment to educational equity. The integration of AI tools risks exacerbating existing disparities related to socioeconomic status, disability, or access to technology. Therefore, programs must actively ensure equitable implementation. This includes providing institutional access, where possible, to privacy-compliant AI platforms to avoid financial barriers for trainees; offering device support; and ensuring all digital materials are fully accessible and screen reader–friendly. Furthermore, the development of "non-LLM analytic pathways" is crucial; these are alternative assignments that achieve the same core learning objectives of critical reasoning and evidence appraisal but do not require live AI

interaction, ensuring that technological barriers do not impede a trainee's educational progress.

Finally, a phased 3-year timeline can make this significant reform manageable. Year one would focus on a pilot within a single teaching block to establish the proof of concept and gather feasibility data. Year two would involve expansion and refinement, using pilot data to roll the model out to other blocks. Year three would target full integration and sustainability, making the model standard practice and shifting research toward longitudinal multisite evaluation to assess broader generalizability.

Beyond implementation, systematic and rigorous evaluation is essential. Pilot studies should assess primary outcomes (OSCEs for formulation/reasoning/appraisal, reflective writing) and secondary measures, including engagement versus historical data [5], ambiguity tolerance, and satisfaction [1]. Process evaluation and qualitative focus groups should explore reasoning, AI trust, and cognitive load [4]. Future research needs longitudinal tracking, cost-utility analysis, AI comparisons, and scalability assessments, prioritizing methodological rigor [9,14] to address gaps in psychiatric AI education research [15,16].

Conclusion

This reimagined approach aims to redefine psychiatric education for a new era defined by the widespread availability of knowledge through LLMs. Faculty should pivot from primarily dispensing facts toward cultivating clinical wisdom, defined as sound judgment under uncertainty. Accordingly, this viewpoint proposes retiring lectures focused on the transfer of facts in favor of curated micromodules, thereby reclaiming synchronous time for facilitated reasoning seminars that incorporate critical AI interaction. We hope programs pilot this model (or similar ones), focusing didactic time on core competencies like biopsychosocial formulation and ethical deliberation. Equipping trainees to interrogate machines, not just query them, requires moving beyond outdated methods. In an AI-mediated future, the cultivation of adaptive reasoning frameworks will be fundamental to clinical excellence.

Abstract

Background: The integration of artificial intelligence (AI) and machine learning (ML) into biomedical research requires a workforce fluent in both computational methods and clinical applications. Structured, interdisciplinary training opportunities remain limited, creating a gap between data scientists and clinicians. The National Institutes of Health's Bridge to Artificial Intelligence (Bridge2AI) initiative launched the Artificial Intelligence–Ready and Exploratory Atlas for Diabetes Insights (AI-READI) data generation project to address this gap. AI-READI is creating a multimodal, FAIR (findable, accessible, interoperable, and reusable) dataset—including ophthalmic imaging, physiologic measurements, wearable sensor data, and survey responses—from approximately 4000 participants with or at risk for type 2 diabetes. In parallel, AI-READI established a year-long mentored research program that begins with a 2-week immersive summer bootcamp to provide foundational AI/ML skills grounded in domain-relevant biomedical data.

Objective: To describe the design, iterative refinement, and outcomes of the AI-READI Bootcamp, and to share lessons for creating future multidisciplinary AI/ML training programs in biomedical research.

Methods: Held annually at the University of California San Diego, the bootcamp combines 80 hours of lectures, coding sessions, and small-group mentorship. Year 1 introduced Python programming, classical ML techniques (eg, logistic regression, convolutional neural networks), and data science methods, such as principal component analysis and clustering, using public datasets. In Year 2, the curriculum was refined based on structured participant feedback—reducing cohort size to increase individualized mentorship, integrating the AI-READI dataset (including retinal images and structured clinical variables), and adding modules on large language models and FAIR data principles. Participant characteristics and satisfaction were assessed through standardized pre- and postbootcamp surveys, and qualitative feedback was analyzed thematically by independent coders.

Results: Seventeen participants attended Year 1 and 7 attended Year 2, with an instructor-to-student ratio of approximately 1:2 in the latter. Across both years, postbootcamp evaluations indicated high satisfaction, with Year 2 participants reporting improved experiences due to smaller cohorts, earlier integration of the AI-READI dataset, and greater emphasis on applied learning. In Year 2, mean scores for instructor effectiveness, staff support, and overall enjoyment were perfect (5.00/5.00). Qualitative feedback emphasized the value of working with domain-relevant, multimodal datasets; the benefits of peer collaboration; and the applicability of skills to structured research projects during the subsequent internship year.

Conclusions: The AI-READI Bootcamp illustrates how feedback-driven, multidisciplinary training embedded within a longitudinal mentored research program can bridge technical and clinical expertise in biomedical AI. Core elements—diverse trainee cohorts, applied learning with biomedical datasets, and sustained mentorship—offer a replicable model for preparing health professionals for the evolving AI/ML landscape. Future iterations will incorporate additional prebootcamp onboarding modules, objective skill assessments, and long-term tracking of research engagement and productivity.

Introduction

Artificial intelligence (AI) has demonstrated transformative potential in health care, with deep learning algorithms now able to screen for diabetic retinopathy from fundus photographs and predict patient-specific glycemic fluctuations [1] at performance levels comparable to expert clinicians. However, despite these advances, a persistent gap remains between model developers and clinical end users.

Clinicians often lack formal training in AI and machine learning (ML) or data science. Only about 28% of published AI/ML model development studies include clinician involvement, and their contributions are frequently limited [2]. Likewise, in the United Kingdom, just 13.8% of trainee physicians reported feeling adequately prepared for the integration of AI into clinical practice [3]. Conversely, engineers and computer scientists are rarely trained in the clinical, regulatory, or ethical complexities of health care delivery. This persistent disconnect constrains interdisciplinary collaboration, limits translational impact, and risks generating AI systems that perform poorly in real-world clinical settings [4-6].

Recognizing these interdisciplinary and workforce gaps, the National Institutes of Health (NIH) launched the Bridge to Artificial Intelligence (Bridge2AI) initiative in 2022 to promote the creation of FAIR (findable, accessible, interoperable, and reusable) multimodal datasets while advancing coordinated skills and workforce development [7]. Among its flagship data generation projects (DGPs), the Artificial Intelligence–Ready and Exploratory Atlas for Diabetes Insights (AI-READI) is curating a comprehensive dataset integrating ophthalmic imaging, physiologic measurements, wearable sensor data, and survey responses from approximately 4000 individuals with or at risk for type 2 diabetes [8,9].

Beyond data generation, AI-READI integrates a 3-phase educational framework within the Bridge2AI ecosystem (Figure 1). This framework recruits multidisciplinary trainees, delivers an intensive 2-week AI/ML bootcamp, and transitions participants into a year-long mentored research internship. Together, these stages provide a continuum of learning that couples foundational instruction with sustained, project-based engagement, directly aligned with the consortium's goal of building a diverse and AI-ready biomedical workforce.

Although a growing number of AI training programs exist—from massive open online courses to short-term institutional electives—many rely on generic or narrowly scoped datasets, offer limited interdisciplinary interaction, or lack sustained mentorship [10-12]. In contrast, the AI-READI Bootcamp was intentionally developed for trainees from diverse disciplines to collaborate on structured, domain-relevant biomedical datasets that reflect the complexity of real-world research. Led by faculty with experience in NIH- and National Science Foundation–funded training initiatives, the curriculum integrates seminars in ML, statistics, and responsible AI with notebook-based coding laboratories anchored in the AI-READI dataset.

Each cohort (Year 1=2023; Year 2=2024) was independently developed and iteratively refined in response to structured participant feedback. This feedback-driven design aligns with broader trends in AI education emphasizing modular content, scaffolded mentorship, and interdisciplinary collaboration [11-13].

This manuscript details the design and iteration of the AI-READI Bootcamp, summarizes participant characteristics and evaluation outcomes, and distills key lessons for institutions aiming to build inclusive, practice-oriented AI training programs in health care.

Methods

Ethical Considerations

This study involved the evaluation of an educational training program and analysis of aggregated, deidentified survey and program evaluation data collected as part of routine program assessment. In accordance with institutional and US federal guidelines (45 CFR §46) [14], formal institutional review board review was not required, as the project constituted educational program evaluation with minimal risk to participants and did not involve the collection of identifiable private information. Participation in surveys and program evaluations was voluntary. Participants were informed that their responses could be used for research and dissemination purposes and that participation or nonparticipation would not affect their standing in the program. Completion of the surveys was considered to imply informed consent. All data were analyzed in a deidentified and aggregated manner. No direct identifiers were collected or retained. Data were stored on secure, access-controlled institutional systems, and only study personnel had access to the data. Privacy and confidentiality were maintained throughout the study. Participants did not receive financial compensation for survey participation beyond the educational benefits associated with participation in the AI-READI Bootcamp.

AI-READI Intern Recruitment and Bootcamp Participant Selection

Participants for the year-long AI-READI internship program were recruited from diverse academic and professional backgrounds, including computer science, engineering, medicine, public health, nursing, pharmacy, and allied health fields. Selection prioritized quantitative aptitude, scientific curiosity, and interdisciplinary interest rather than prior coding experience. Coursework in calculus, linear algebra, or statistics was preferred but not required for eligibility. Recruitment strategies included an informational brochure on the AI-READI website; dissemination through faculty web pages, journals, mailing lists, and social media; and outreach by alumni, mentors, and current trainees through word-of-mouth engagement.

Applicants completed an online application comprising educational history, research experience, a 750-word personal statement, and one faculty recommendation. Reviewers scored submissions on a 1 - 5 scale across 4 domains: academic achievement, technical skills, research experience, and strength of recommendation. Top-ranked candidates received AI-READI–funded internship positions (6 in Year 1; 5 in Year 2), while additional high-scoring applicants were invited to participate in the bootcamp as unfunded trainees (11 in Year 1; 2 in Year 2).

Bootcamp Structure and Educational Objectives

The AI-READI Bootcamp is a 2-week immersive, in-person educational program hosted annually at the University of California San Diego. It functioned as both the foundational training phase and the launchpad for the year-long mentored research internship. The curriculum emphasized collaborative, application-oriented learning tailored to participants' diverse disciplinary backgrounds and varying levels of technical preparedness.

Educational objectives were to (1) develop proficiency in core programming workflows using Python, Jupyter Notebooks, and GitHub; (2) introduce foundational principles of AI/ML, including supervised and unsupervised learning; (3) provide hands-on experience through structured coding laboratories using multimodal, domain-relevant biomedical data; (4) promote reproducible and ethical research practices; and (5) foster interdisciplinary collaboration, critical thinking, and cohort cohesion.

The curriculum intentionally targeted multiple domains of Bloom's taxonomy [15], integrating didactic instruction to build knowledge (cognitive), using applied coding to develop technical skills (psychomotor), and facilitating ethics discussions to promote responsible AI use (affective).

Participants completed approximately 80 hours of lectures, coding tutorials, and small-group mentorship sessions. Dormitory housing facilitated peer learning, collaborative debugging, and informal knowledge exchange. Instruction was led by a multidisciplinary faculty team spanning computer science, data science, medicine, public health, and ethics. Curriculum content was refined iteratively between cohorts in response to postbootcamp feedback (see Results).

Participant Characteristics and Baseline Data Collection

Before the bootcamp, all participants completed a standardized intake form capturing demographic and educational information, including age, gender, highest degree attained, primary discipline, prior experience with programming languages (eg, Python, R, SQL), and self-reported exposure to AI/ML. These responses informed real-time instructional adjustments and enabled instructors to tailor laboratory groupings, pacing, and mentorship to each cohort's skill profile.

Postbootcamp Survey and Feedback Analysis

After completing the bootcamp, participants were invited to complete an anonymous evaluation survey assessing instructional quality and overall experience.

- Quantitative items: 7 core statements rated on a 5-point Likert scale (1=strongly disagree; 5=strongly agree) evaluated lecture usefulness, facility quality, instructor effectiveness, alignment with expectations, staff support, organizational quality, and overall enjoyment.
- Qualitative items: open-ended prompts solicited feedback on the most and least valuable components, suggested improvements, and logistical factors such as scheduling, pacing, and housing.

Quantitative data were summarized using descriptive statistics. Qualitative responses underwent independent dual-coder thematic analysis; discrepancies were resolved through discussion. Resulting insights informed iterative refinements to curriculum structure, pacing, and instructional methods between program years.

Results

Participant Characteristics

A total of 17 trainees participated in Year 1 and 7 in Year 2 of the AI-READI Bootcamp. As summarized in Table 1, participants came from varied academic and professional backgrounds, including ophthalmology, public health, pharmacology, neuroscience, engineering, and computer science. Educational attainment and programming experience also varied substantially, reflecting the program's deliberate design to attract learners with strong quantitative potential regardless of prior coding experience.

Table . Participant characteristics of bootcamp cohorts.

Characteristic	Year 1 (n=17)	Year 2 (n=7)
Age (years), mean (SD)	33 (3.4)	32 (9.5)
Race, n (%)		
Asian	8 (47.1)	3 (42.9)
African American	3 (17.6)	2 (28.6)
White	4 (23.5)	1 (14.3)
Other	2 (11.8)	0 (0)
Sex, n (%)		
Male	9 (52.9)	2 (28.6)
Female	8 (47.1)	5 (71.4)
Highest degree, n (%)		
PhD or MD	15 (88.2)	4 (57.1)
MA, MS, or MPH	2 (11.8)	1 (14.3)
BA or BS	0 (0)	2 (28.6)
Funding, n (%)		
AI-READI–funded[a]	6 (35.3)	5 (71.4)
Non-AI-READI–funded	11 (64.7)	2 (28.6)
Disciplinary background, n (%)		
Ophthalmology	12 (70.6)	1 (14.3)
Public Health	1 (5.9)	1 (14.3)
Pharmacology	1 (5.9)	1 (14.3)

Survey Feedback and Satisfaction Outcomes

Postbootcamp surveys were completed by 13 of 17 (76%) participants in Year 1 and 4 of 7 (57%) in Year 2. Across both cohorts, quantitative ratings were high, with notable improvements in Year 2 (Table 2). Year 2 participants assigned mean scores of 5.00 in 3 categories—instructor effectiveness, staff support, and overall enjoyment—while all other domains, including lecture usefulness, organizational quality, and facility adequacy, averaged between 4.50 and 4.75. No item received a mean rating below 4.0.

Qualitative feedback from Year 1 highlighted several key areas for improvement. Participants valued the conceptual depth of lectures but desired greater emphasis on applied content aligned with their upcoming research projects. Some noted that the larger cohort size made coding laboratories challenging to manage and recommended smaller groups to support individualized troubleshooting. Hands-on laboratories and mentorship—both from faculty and peers—were consistently described as the most valuable program components. Participants also emphasized the benefits of shared housing and peer interaction in fostering collaboration and community.

Table . Postbootcamp evaluation: comparison of Year 1 and Year 2.

Item	Year 1 (n=13)	Year 2 (n=4)
	Average (SD; range)	Average (SD; range)
The lectures were helpful to my learning and development	4.46 (1.05; 2.00-5.00)	4.75 (0.50; 4.00-5.00)
The bootcamp facility was in an accessible location and adequate	4.46 (1.00; 2.00-5.00)	4.75 (0.50; 4.00-5.00)
The instructors helped me understand the subject matter	4.31 (1.11; 1.00-5.00)	5.00 (0.00; 5.00-5.00)
The bootcamp met my educational needs and expectations	4.31 (1.07; 1.00-5.00)	4.75 (0.50; 4.00-5.00)
I had adequate support from the program staff and faculty	4.46 (1.20; 1.00-5.00)	5.00 (0.00; 5.00-5.00)
The bootcamp was well organized	4.23 (1.24; 1.00-5.00)	4.50 (0.58; 4.00-5.00)
I enjoyed the bootcamp overall	4.46 (1.00; 2.00-5.00)	5.00 (0.00; 5.00-5.00)

The redesigned Year 2 curriculum addressed many of these concerns. Participants emphasized the benefits of earlier integration of the AI-READI dataset, closer alignment between instructional content and research projects, and strengthened peer collaboration. Several respondents noted that receiving materials and agendas in advance would have enhanced preparation for more technical sessions. Overall, Year 2 participants described the bootcamp as a strong foundation for subsequent research activities, increasing both confidence and competence.

Together, these findings validate the bootcamp's iterative design and demonstrate that refinements in Year 2 enhanced the learning experience while preserving core strengths in applied instruction, mentorship, and interdisciplinary collaboration.

Curriculum Iteration and Structure

The curriculum was iteratively refined between Year 1 and Year 2 based on participant feedback and faculty debriefings. Year 1 focused on establishing foundations in Python workflows, core ML algorithms, and introductory discussions on ethics and bias. In Year 2, the instructional team implemented several structural and pedagogical updates to enhance applied learning and mentorship. The cohort size was reduced to achieve an approximately 1:2 faculty-to-student ratio, and modules on Git/GitHub version control and environment setup were moved earlier to reinforce reproducibility. Structured, domain-relevant data from the AI-READI project—including retinal images and clinical variables—were integrated throughout the curriculum, allowing trainees to engage directly with multimodal biomedical data that mirrored the complexity of biomedical research workflows.

Additional modules were introduced in Year 2 to align with evolving learner needs and faculty expertise. Mini-seminars on FAIR data principles, AI-READI schema design, and agile project management helped participants navigate the practical aspects of large-scale dataset curation. A dedicated half-day session on large language models introduced transformer architectures and encouraged discussion of the opportunities and limitations of generative AI in health care. The Year 2 capstone project centered on fine-tuning RETFound, a retina-specific foundation model for institutional classification of retinal images, fostering critical reflection on domain generalizability and algorithmic bias.

Tables 3-5 summarize the curriculum's progression from foundational programming to applied AI/ML methods, highlighting key updates, instructional content, and the shift toward hands-on, clinically relevant learning experiences.

Table . Summary of curriculum refinements between Year 1 and Year 2 of the AI-READI[a] Bootcamp.

Dimension	Year 1 focus	Year 2 iteration and rationale
Programming foundations	Introduction to Python and Jupyter via guided exercises	Added pandas and real-world data operations to support independent analysis
Tools and environment	Introduced GitHub and IDEs[b] for version control	Moved earlier to establish reproducibility from the start
Machine learning concepts	Covered regression, SoftMax, convolutional neural networks, and backpropagation	Added large language models and expanded gradient descent laboratories
Data science techniques	Applied principal component analysis, K-means, and spectral clustering to face images	Expanded to exploratory data analysis, digital signal processing, and feature extraction
Applied learning	Face clustering and glucose modeling laboratories	Shifted to retinal image analysis using the AI-READI dataset
Ethics and fairness	Discussed racial bias in pain expression	Broadened to data pitfalls and fairness across AI[c] pipelines
Clinical integration	Minimal use of clinical data	Incorporated AI-READI clinical variables and retinal images
Student engagement	Lunch talks and informal discussions	Added structured mini-seminars and interactive sessions for peer learning

[c]AI: artificial intelligence.

Table . Year 1 AI-READI[a] Bootcamp curriculum.

Day	Session topics	Format
1	Bootcamp orientation; introduction to Python, Jupyter notebooks	Lecture + hands-on laboratories
2	Python, IDEs[b], Jupyter workflows	Lecture + coding practice
3	Introduction to machine learning, perceptrons, gradient descent; logistic and SoftMax regression	Lecture + laboratories
4	Backpropagation, deep learning fundamentals; representation learning	Lecture + laboratories + discussion
5	Convolutional neural networks	Lecture + laboratories
6	GitHub version control; introduction to pandas	Lecture + coding
7	Linear algebra review; regression models; regression laboratories	Lecture + regression laboratories
8	Principal component analysis, face laboratories, K-means, spectral clustering	Lecture + laboratories
9	Clustering laboratories; discussion on racial bias in data; pitfalls in data science	Lecture + laboratories + ethics discussion
10	Digital signal processing; glucose laboratories; closing reflections	Lecture + laboratories + closing

[a]AI-READI: Artificial Intelligence–Ready and Exploratory Atlas for Diabetes Insights.

[b]IDE: integrated development environment.

Table . Year 2 AI-READI[a] Bootcamp curriculum.

Day	Session topics	Format
1	Introduction to Python, Jupyter, IDEs[b]; GitHub version control	Lecture + hands-on laboratories
2	Python pandas, joining datasets, exploratory data analysis	Lecture + coding exercises
3	Correlations, health sheet overview, data visualization	Lecture + laboratories
4	Digital signal processing, feature extraction, basic image processing	Lecture + laboratories
5	Linear algebra, regression models (linear, nonlinear, ridge, lasso)	Lecture + regression laboratories
6	Principal component analysis (PCA), image alignment, introduction to clustering	Lecture + PCA laboratories
7	Clustering (K-means), pitfalls in data science	Lecture + laboratories + discussion
8	Machine learning introduction, perceptrons, logistic/SoftMax regression	Lecture + gradient descent laboratories
9	Backpropagation, deep learning, representation learning, machine learning best practices	Lecture + eigenface laboratories
10	Convolutional neural networks, introduction to large language models	Lecture + coding demos

Discussion

Principal Results and Learner Outcomes

Quantitative and qualitative outcomes demonstrate that the AI-READI Bootcamp effectively delivered foundational AI/ML education to multidisciplinary biomedical trainees, yielding consistently high satisfaction and confidence across 2 consecutive years. In Year 2, mean postbootcamp ratings improved across all domains—from 4.23 - 4.46 (Year 1: n=13) to 4.50-5.00 (Year 2: n=4)—with 3 categories (instructor effectiveness, staff support, and overall enjoyment) achieving perfect 5.00 scores. These findings align with Kirkpatrick's training evaluation model (Levels 1 and 2 outcomes), reflecting strong learner satisfaction and perceived knowledge gains, while qualitative feedback suggested enhanced confidence and readiness for independent research (Level 3 outcome).

Bridging Disciplinary Divides in AI/ML Education

As AI continues to transform biomedical research and clinical practice, a persistent skills gap remains between data scientists and clinicians [16-18]. Engineers may lack clinical context, whereas physicians often have limited exposure to algorithmic reasoning and data analytics—constraints that can hinder translational innovation and collaboration.

The AI-READI Bootcamp was intentionally designed to bridge this divide by uniting trainees from medicine, neuroscience, computer science, public health, and pharmacology under a shared mentorship model spanning technical and clinical faculty. This approach reflects best practices identified in recent AI curriculum review [5,11,12] and parallels pedagogical strategies in health professions education—such as interprofessional and team-based learning—that foster cross-disciplinary problem-solving and shared understanding [19].

Building Engagement Through Iterative Refinement

Iterative curriculum refinement was central to sustaining engagement and relevance. Key adjustments between Year 1 and Year 2—including smaller cohort size, earlier integration of AI-READI datasets, and increased time for small-group coding—were guided directly by participant feedback. Year 2 trainees highlighted the benefits of multimodal biomedical data, individualized mentorship, and peer collaboration as core strengths.

Anchoring abstract AI/ML concepts in domain-specific datasets proved particularly effective. By analyzing fundus photographs and structured clinical variables from the AI-READI dataset, participants investigated issues such as site-level variability and domain shift, deepening their understanding of real-world data challenges. This experiential approach aligns with educational frameworks emphasizing authentic data environments and iterative feedback [20], supporting evidence that short-format programs can achieve substantial impact when paired with applied learning and sustained mentorship.

Situating the Bootcamp in the National AI Training Ecosystem

The AI-READI Bootcamp contributes to a growing ecosystem of NIH-supported initiatives advancing the biomedical AI/ML workforce. Within the Bridge2AI program, AI-READI complements other DGPs—including VOICE, which hosts AI summer schools and hackathons on precision public health, and CHoRUS, which provides continuing medical

education–accredited clinical AI workshops on dataset curation, pair programming, and mentored laboratories [9].

Beyond Bridge2AI, the AIM-AHEAD Consortium extends these efforts through part-time fellowships, faculty development programs, and mentored research opportunities aimed at graduate students, health care professionals, and community partners [21]. Parallel innovations are emerging at the institutional level: Stanford University engages students in interdisciplinary teams applying ML to clinical challenges; the Duke Institute for Health Innovation pairs medical trainees with data scientists; and programs at the University of Florida and Carle Illinois College of Medicine integrate clinician-engineer coteaching models. Collectively, these efforts underscore the increasing national and institutional commitment to embedding AI within health professions education, though many remain short-term or elective in scope.

Distinctive Features and Broader Applicability

Although numerous national initiatives—such as AIM-AHEAD, VOICE, and CHoRUS—have expanded AI/ML education through workshops and fellowships, the AI-READI Bootcamp occupies a distinctive niche within this ecosystem. By embedding a 2-week immersive experience within a year-long mentored research internship, it integrates foundational instruction with sustained, project-based engagement. In addition to mastering core AI/ML methods and completing mentored research projects, participants contribute to consortium-wide Bridge2AI initiatives focused on data standardization, FAIR and ethical data practices, biorepository optimization, and workforce development. This multifaceted structure positions the AI-READI Bootcamp as both a pilot and a scalable framework for cultivating interdisciplinary expertise in biomedical AI.

Lessons Learned and Recommendations

Our experience designing and refining the AI-READI Bootcamp suggests several important lessons for future initiatives. Modular, scaffolded content enables learners with varying backgrounds to progress in parallel. The use of curated, domain-relevant datasets grounds abstract concepts in applied contexts, fostering deeper engagement. Participants valued the theoretical framing but reported that they learned most effectively through practical, hands-on components, suggesting future bootcamps should emphasize applied coding while keeping lectures concise and focused.

Equally important are the program's structural features. Maintaining a low faculty-to-student ratio supports real-time troubleshooting and individualized feedback. Embedding bootcamps into longitudinal research structures promotes meaningful skill transfer and project ownership. Structured and informal peer support—through shared housing, collaborative debugging, and group presentations—strengthens technical skills, enhances problem-solving, and builds lasting professional networks. These practices align with curriculum frameworks emphasizing structure, assessment, real-world alignment, and longitudinal mentorship [5,10-12].

Scalability, Replication, and Sustainability

The AI-READI Bootcamp model was intentionally designed for scalability and replication through a modular curriculum organized into discrete instructional units. In alignment with FAIR and open science principles, all lectures, laboratories, and onboarding materials are publicly available on GitHub, enabling other institutions to adapt content to their own technical and educational contexts. The program's structure, which pairs short-term immersive instruction with a longitudinal mentored research experience, offers a reproducible framework that can be integrated into diverse training pipelines, including graduate education, residency programs, and interdisciplinary research initiatives. The AI-READI model also promotes long-term sustainability through its open educational resources within the Bridge2AI consortium, embedded mentorship networks, and continued dissemination of curricular updates and trainee outcomes across the Bridge2AI community.

Limitations and Future Directions

This study is limited by the absence of standardized, performance-based assessments, which are necessary to measure knowledge retention and applied competency. Postbootcamp evaluations for both years relied on self-reported survey data, which are subject to response and recall bias and may not directly reflect objective skill acquisition. In addition, the study is limited by its single-site implementation and small sample size (Year 1: n=17; Year 2: n=7), which may affect generalizability. The Year 2 postbootcamp ratings, while high, are based on only 4 respondents.

To address these gaps, future iterations will incorporate pre- and postbootcamp knowledge assessments and coding exercises aligned with Kirkpatrick Level 2 outcomes to objectively measure learning gains. Longitudinal tracking of trainee outputs such as publications, presentations, and continued engagement in AI-related research will further assess sustained impact. Broader dissemination of the curriculum and collaboration across Bridge2AI partner DGPs may also enhance reproducibility and external validation of outcomes. We also plan to strengthen prebootcamp onboarding (Table 6) through structured preassessment materials, curated readings, and practice exercises to improve baseline preparedness and maximize in-person learning.

Through these refinements, the AI-READI Bootcamp aims to evolve from a formative, single-site pilot to a scalable, high-impact model for interdisciplinary AI/ML education in biomedicine. To promote transparency and adoption, all bootcamp materials, readings, and onboarding instructions are openly available via the AI-READI Bootcamp GitHub repository (Table 6).

Acknowledgments

We thank the faculty instructors, teaching assistants, and administrative staff at University of California San Diego for their invaluable contributions to the planning and delivery of the Artificial Intelligence–Ready and Exploratory Atlas for Diabetes Insights (AI-READI) Bootcamp. We also thank the AI-READI interns for their active participation and constructive feedback, which directly informed improvements to the Year 2 curriculum.

Funding

This work was supported by the National Institutes of Health (NIH) through the Bridge2AI program (award OT2OD032644). The views expressed in this manuscript are those of the authors and do not necessarily represent the official views of the NIH. AM received additional individual support from the SHISEIKAI Scholarship Fund to Study Abroad.

Data Availability

The postbootcamp evaluation data (quantitative survey responses and deidentified qualitative feedback) are not publicly available to preserve participant confidentiality but are available from the corresponding author upon reasonable request.

Abstract

Background: Project ECHO (Extension for Community Health Outcomes) is an innovative program that uses videoconferencing technology to connect health care providers with experts. The model has been successful in reaching health care providers in rural and underserved areas and positively impacting clinical practice. ECHO Idaho, a replication partner, has developed programming that has increased knowledge and confidence of health care professionals throughout the state of Idaho, United States. Although the ECHO model has a demonstrated ability to recruit, educate, and train health care providers, barriers to attending Project ECHO continuing education (CE) programs remain. The asynchronous nature of podcasts could be used as an innovative medium to help address barriers to CE access that health care professionals face. The ECHO Idaho "Something for the Pain" podcast was developed to increase CE accessibility to rural and frontier providers, while upscaling their knowledge of and competence to treat and assess substance use disorders, pain, and behavioral health conditions.

Objective: This paper describes the creation and preliminary assessment of the ECHO Idaho "Something for the Pain" podcast.

Methods: Podcast episodes consisted of interviews with individuals as well as didactic lectures. Audio from these recordings were edited for content and length and then professionally reviewed by subject matter experts (eg, featured episode speakers). Target audiences consisted of health care providers and community members interested in behavioral health and substance use disorders. Metrics on podcast listeners were assessed using SoundCloud's RSS feed, continuing education survey completion, and iECHO.

Results: The ECHO Idaho "Something for the Pain" podcast's inaugural season comprised 14 episodes with 626 minutes of CE material. The podcast series received a total of 2441 listens from individuals in 14 different cities across Idaho, and 63 health care providers listened and claimed CE credits. The largest professional group was social workers (n=22; 35%).

Conclusions: We provide preliminary evidence that podcasts can be used to provide health care providers with opportunities to access CE material. Health care providers listened to and claimed CE credits from the ECHO Idaho "Something for the Pain" podcast. Project ECHO programs should consider creating podcasts as an additional platform for disseminating ECHO material.

Introduction

Project ECHO (Extension for Community Health Outcomes), founded by the University of New Mexico, provides accessible education and specialty training to rural and underserved professionals through an all-teach, all-learn model that uses interactive video conferencing (ie, Zoom technology) [1]. In 2018, through a collaboration between the University of Idaho WWAMI (Washington, Wyoming, Alaska, Montana, Idaho) Regional Medical Education Program and the Idaho Department of Health and Welfare Statewide Healthcare Innovation Plan, ECHO Idaho became the only Project ECHO replication partner in the state of Idaho [2]. Since 2018, ECHO Idaho has provided rural and underserved communities with educational opportunities and cultivated a community of health care professional learners across the state. Researchers assessing the Project ECHO model have found that attendees increase their

knowledge, clinical skills, and confidence, thus increasing the quality of care for patients in rural and underserved communities [1-10]. Health care professionals participating in the ECHO Idaho series have similarly reported increases in both their knowledge and in their confidence to provide specialty care for their patients [2,11].

Despite the myriad documented benefits of the Project ECHO model, challenges relevant to maximizing attendance and increasing overall reach of the program (eg, recruiting participants from rural areas) still exist [2-4,12]. For example, scheduling conflicts and time constraints have been reported as barriers to attending ECHO sessions [5,10,13]. Although some hubs have modified the ECHO model (eg, changed session lengths), no conclusive changes have been recommended and minimal research has been conducted to assess how modifications to the model could positively impact and enhance provider training [10,13]. Other models of continuing education (CE) (eg, e-learning) have been reported to be effective in changing knowledge, self-efficacy, and skills [14]. However, the effect of such models on professional and clinical practice, as well as patient outcomes, remains largely unknown.

Thus, exploring and researching novel or innovative platforms to disseminate information and increase clinical skills for health care providers, while subsequently decreasing potential barriers to attendance, are necessary. One proposed approach is the use of a podcast platform to deliver Project ECHO materials. A podcast may be an effective, interactive, and cost-efficient way to deliver Project ECHO programming while addressing some barriers reported by participants. For example, the asynchronous nature of podcasts would allow providers the flexibility to engage with the material on their own time, and to pause and resume listening when needed. Research has reported that podcasts can be an impactful model to train and enhance professional development [15-17]. Additionally, due to the COVID-19 pandemic dramatically changing the landscape of health care and education [18], the use of podcasts to deliver medical education curricula has increased [19-22]. Researchers have found podcasts increase participant knowledge and self-efficacy while also indirectly impacting professional and clinical practice [19-22]; however, the full scope of the impact of educational podcasts remains unknown [16].

To test the efficacy of the podcast model for delivering medical education, ECHO Idaho developed the "Something for the Pain" podcast, with support from the Idaho WWAMI Medical Education Program and in partnership with the Valley County Opioid Response Project [23]. The podcast was meant to increase CE accessibility for rural and frontier providers, while upscaling their knowledge of and competence to treat and assess behavioral health conditions. The purpose of this paper was to present the development and implementation process of the ECHO Idaho "Something for the Pain" podcast's inaugural season, as well as to discuss the preliminary findings regarding the reach of the podcast, lessons learned, and proposed future uses of this innovative platform.

Methods

Program Development and Implementation

Program Description

Due to the increased need for more specialty training related to behavioral health, opioids, pain, and substance use disorder (SUD), in 2021, the ECHO Idaho "Something for the Pain" podcast was developed as an innovative approach to disseminate ECHO Idaho materials. The inaugural season contained 14 episodes that presented best-practices and resources for behavioral health, opioid use disorder, and SUD prevention, treatment, and recovery specific to Idaho. The podcast was free to access, and eligible providers were able to obtain no-cost CE credits for listening to an episode.

Episode Development

The ECHO model learning framework typically includes two sections: (1) didactic lectures and (2) a case-based presentation and discussion. To mirror the framework of the ECHO model, the 14 podcast episodes were primarily broken down into two parts: (1) interviews with individuals and (2) didactic presentations. The interviews were with health care professionals and community members who had first-hand experience and knowledge of evidence-based practices and resources pertinent to the Idaho context. The didactic presentations were taken from previously recorded ECHO Idaho sessions across 4 series (ie, Behavioral Health in Primary Care; Opioids, Pain and Substance Use Disorders; Counseling Techniques for Substance Use Disorders; and Viral Hepatitis and Liver Care). Audio from these recordings were edited for content and length and then professionally reviewed by subject matter experts. The subject matter experts also assisted with generating CE-eligible episode assessment questions that could be used to gauge audience engagement.

Audience Recruitment

The primary intended audience for the podcast was health care providers and community members with an interest in SUD and behavioral health. Initial recruitment occurred by using ECHO Idaho's network of prior ECHO Idaho session attendees, which, at the time of the first episode's release in May 2021, consisted of approximately 3000 diverse Idaho health care professionals (eg, those who held an MD/DO, PA, NP, MCSW, or LCPC). Members of the ECHO Idaho staff invited participants from the pre-existing ECHO network to listen to the podcast as an additional means of earning CE credit at their convenience. Additionally, ECHO staff developed a targeted marketing campaign that involved personal and bulk emails, newsletter announcements, weekly announcements, paid advertisements, social media posts, print bulk postcard mailings, as well as advertising on other podcast programs. The podcast was housed on SoundCloud, which increased its accessibility through user search engines and algorithms.

Podcast Data Metrics

Listener engagement was tracked using SoundCloud's RSS feed. The feed provided click metrics (ie, how many listens occurred) for each podcast episode consumed within a specified

timeframe. Eeds, an electronic CE management system, was used to track CE credits claimed following episode and assessment completion. Additionally, to gain insight into listener experience, participants were required to answer a user experience question in Eeds. Lastly, individuals interested in listening to the podcast could register on the ECHO Idaho website. Registration information collected included demographic questions like profession, credentials, primary practice location, sex, and age. iECHO, a web-based proprietary program and management software database, was used to manage participant demographic data (ECHO Institute, University of New Mexico) entered on the registration form.

Data Analysis

Data were exported from Eeds and iECHO and a descriptive statistical analysis was performed using SPSS, version 28 (IBM Corp).

Ethical Considerations

The project was certified as exempt (protocol #23‐150) by the Institutional Review Board at the University of Idaho. Data were deidentified for the purposes of analysis, and informed consent was obtained from all participants prior to their involvement in the study.

Results

RSS Feed

The first season of the ECHO Idaho “Something for the Pain” podcast included 14 episodes (released May 2021 to June 2022); 13 episodes were related to perinatal SUD, and 1 bonus episode gave a brief history of Project ECHO and Vandal Theory (Table 1). The average length of an episode was 45 (SD 11.9) minutes and the average number of listens per episode was 188 (SD 46.5) (Table 1). The season provided a total of 626 minutes of CE material available for perpetual access. The podcast was released on the streaming platforms SoundCloud, Apple Podcasts, Google Podcasts, Spotify, Sticher, and iHeartRadio. As of April 19, 2023, the initial season of the podcast had garnered over 2000 listeners from various parts of the United States, with most of the listeners based in Idaho.

Table . Information on each episode including release date, title, length, and total listens of each episode.

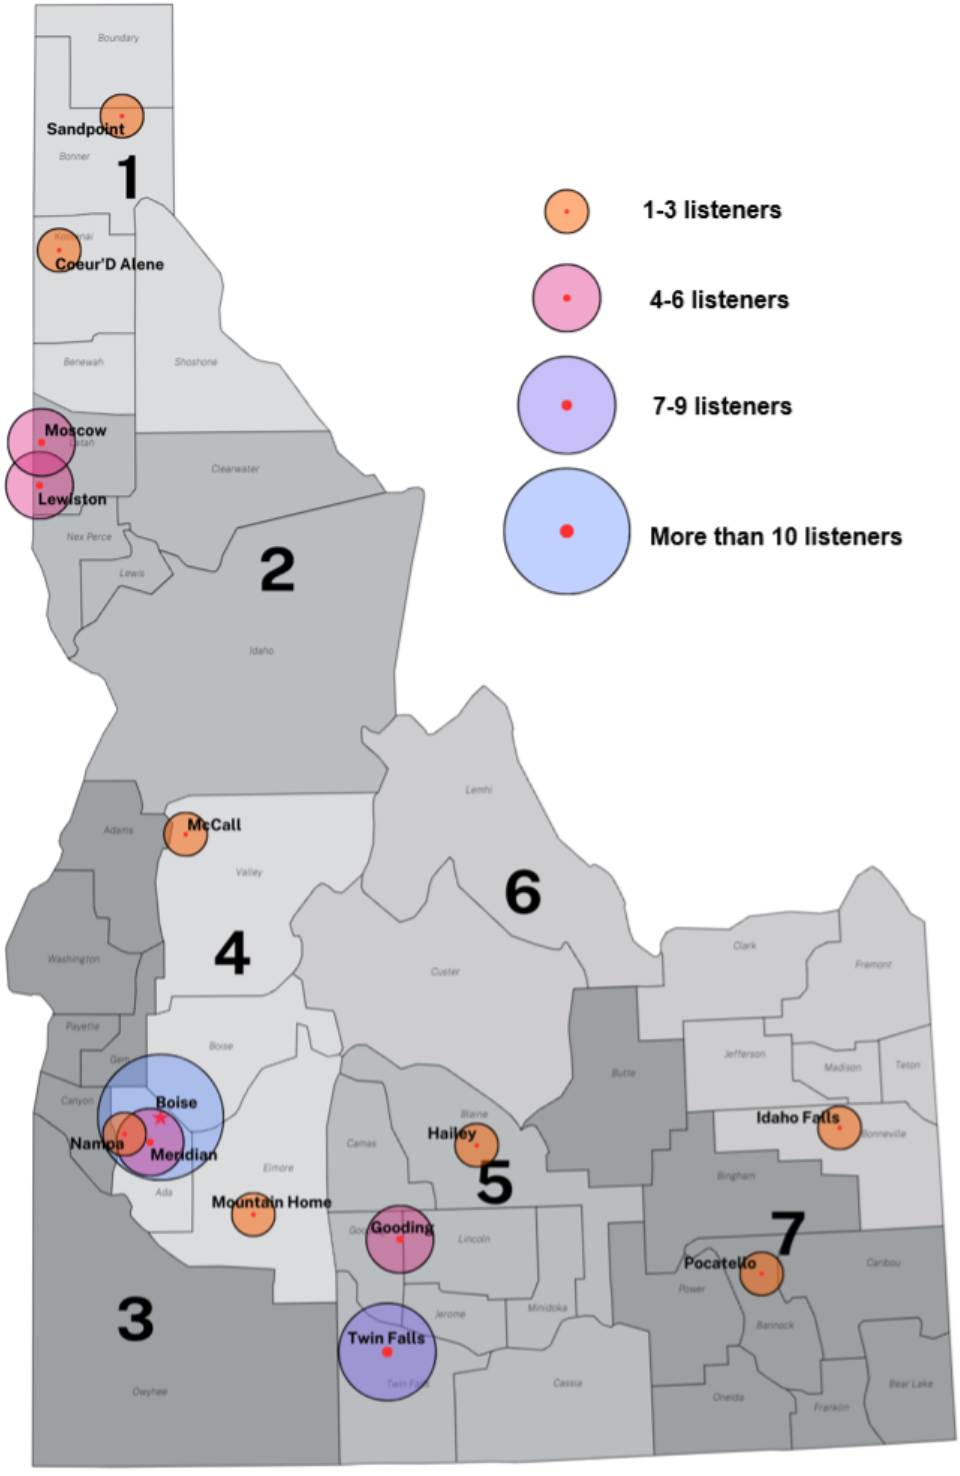
Release date	Episode	Length (minutes)	Listens
5/11/2021	Episode 1: Framework for Addiction as Disease (feat. Craig Lodis, PhD)	31	286
5/17/2021	Episode 2: State of Substance Use in Idaho (feat. Amy Jeppesen, LCSW, ACADC)	47	212
6/3/2021	Bonus Episode: Project ECHO Origin Story & The Vandal Theory (feat. Sanjeev Arora, MD)	37	N/A[a]
7/1/2021	Episode 3: De-escalation Techniques and the Valley County Court Services' Diversion Program (feat. Abby Abbondondalo and Skip Clapp)	45	159
7/11/2021	Episode 4: Harm Reduction and Valley County's Opioid Response Project (feat. Brenda Hoyt, NP, Courtney Boyce and Shelly Hitt)	47	165
7/23/2021	Episode 5: Motivational Interviewing and Donnelly's The Change Clinic (feat. Deb Thomas and Barbara Norton)	60	191
8/9/2021	Episode 6: LaDessa Foster Talks Levels of Care in Substance Use Disorder Treatment (feat. LaDessa Foster)	32	164
8/23/2021	Episode 7: Monica Forbes Talks SMART Recovery, Stigma and Reentering Society Post-Incarceration (feat. Monica Forbes)	35	178
9/1/2021	Episode 8: Marjorie, Wilson Talks Idaho's Syringe Service Programs (feat. Marjorie, Wilson and Ian Trosoyer, DNP)	51	185
9/13/2021	Episode 9: LaDessa Foster Talks Managing Clinical Services for Patients and Providers (feat. LaDessa Foster)	30	274
3/2/2022	Episode 10: Lindsay Brown Talks Peer Recovery Supports (feat. Lindsay Brown)	55	168
3/25/2022	Episode 11: Talking Telehealth in SUD Care | McCall Mobile Medicine (feat. Drew Holliday, MSW)	45	188
5/4/2022	Episode 12: Deborah Seltzer Talks Coding and Billing for Substance Use Disorders (feat. Deborah Seltzer)	51	122
6/13/2022	Episode 13: SUD Treatment for Justice-Involved Patients | Day One Program (feat. Radha Sadacharan, MD, MPH and Rebecca Lee)	60	149

[a]Not available.

CE Credit

A total of 63 unique health care professionals representing 14 distinct cities and spanning all 7 public health districts within the state of Idaho, as well as out-of-state listeners, claimed CE credit for season 1 of the podcast (Figure 1). The podcast drew a diverse array of professionals from various disciplines, with social workers being the most widely represented group among those who claimed CE credits (Multimedia Appendix 1). Three questions were generated for each of the 13 episodes eligible for CE credits. The average percentage of correct answers for all episodes was 83% (SD 11.6%) (Multimedia Appendix 2), thus providing preliminary evidence related to audience engagement and potential impact on learning outcomes.

Figure 1. Health care professionals claiming continuing education credits from the ECHO Idaho "Something for the Pain" podcast within the state of Idaho. Values 1-7 represent Idaho's 7 public health districts (map adapted from MapChart).



Discussion

Principal Findings

ECHO Idaho's "Something for the Pain" podcast included 14 episodes providing best practices and resources for behavioral health, opioid use disorder, and SUD prevention, treatment, and recovery specific to Idaho. The podcast included interviews with health care professionals and community members who had first-hand experience and knowledge of evidence-based practices, as well as didactic presentations taken from previously recorded ECHO Idaho sessions. Audience recruitment primarily focused on health care providers and community members interested in the behavioral health and SUD field. Metrics such as click metrics, CE credits, and user experience questions were used to track listener engagement. Data collected from Eeds and iECHO systems were analyzed using SPSS, providing a descriptive statistical analysis.

The ECHO Idaho podcast effectively engaged a diverse group of health care professionals throughout Idaho, demonstrating the utility of podcasts as a versatile tool for professional development and outreach. This highlights the possibility of leveraging podcasts to not only provide CE but also to serve as a means of attracting more health care professionals to Project ECHO sessions. The widespread accessibility of podcasts suggests their potential as a potent recruitment tool for future Project ECHO initiatives.

This report presents a preliminary assessment of an innovative platform to engage with health care professionals, as well as community members, by providing insightful information and professional development material via the medium of podcasts.

Limitations

Although the initial season of the podcast engaged with diverse health care providers across the state, the podcast's impact on clinical practice remains unknown. Previous literature has suggested internet-based continuing medical education can increase knowledge, change physician behavior, and indirectly impact clinical practice [16,24]. Therefore, future research should collect feedback from nonlisteners and previous listeners to understand their preferences for this innovative platform as well as assess the direct impact of podcast-based CE on listeners' knowledge and professional and clinical practice through quantitative and qualitative analyses.

Additionally, although several data analytics methods were used, some challenges remain. The RSS data records clicks (ie, listens) on each episode, but there is no way to track how long someone listened or if they completed the full episode. Therefore, interpretation of those data points should be made with caution. Similarly, due to data constraints, it is difficult to assess the benefits of the ECHO podcast compared to the more traditional ECHO program model. As a result, we were unable to fully evaluate the podcast's impact, particularly in terms of reach, impact on learning outcomes, and its influence on clinical practice. Future research should focus on assessing these variables, as they are crucial for understanding the effectiveness of this type of CE material. Lastly, the effectiveness of our recruitment strategies remains undetermined. Future research should prioritize evaluating these strategies to optimize the return on investment and enhance the overall impact of the podcast.

Lessons Learned

Overall, the goal of the podcast was to provide clinicians across the state with an easily accessible CE program. We learned that podcasts could be used to engage Idaho health care providers and provide access to CE opportunities. Although we provide evidence of successfully reaching listeners, a robust marketing campaign was not used. Furthermore, the topics were selected by a team of subject matter experts without input from listeners or previous ECHO Idaho attendees. In the future, assessing additional indicators (eg, listener preferences related to episode length, topic selection, impact on clinical practice, perceived barriers to listening to podcasts) could ensure that new podcast series and episodes meet the needs of current and potential listeners.

Conclusions

The ECHO Idaho "Something for the Pain" podcast was developed as a new and innovative way of providing CE for health care providers. We provide evidence that this approach was successful in its efforts to engage a sizable audience of listeners who claimed CE credits for participation. The podcast had listeners from diverse health care professions representing cities from across Idaho and the United States. Future research efforts should include the collection of additional information such as listener preferences, knowledge change, professional and clinical impact, and patient outcomes to guide the implementation of Project ECHO information into an effective CE podcast format.

Acknowledgments

ECHO (Extension for Community Health Outcomes) Idaho's "Something for the Pain" (episodes 1-13) podcast was created by ECHO Idaho and the University of Idaho, supported by the WWAMI Medical Education Program, in partnership with the Valley County Opioid Response Project. ECHO Idaho's "Something for the Pain" (episodes 1-13) podcast was made possible by a grant from the US Department of Health and Human Services Health Resources and Services Administration (HRSA; grant GA1RH39585). Its contents are solely the responsibility of the authors and do not necessarily represent the official views of Central District Health or HRSA. The authors would like to thank Samuel Steffen for his work with podcast development and implementation.

Authors' Contributions

RW was involved in the concept and design, data analysis, data interpretation, manuscript writing, and approval of the final manuscript. MPC was involved in the concept and design, data interpretation, manuscript writing, and approval of the final manuscript. JDM, SMD, and RTB were involved in the concept and design, manuscript writing, and approval of the final manuscript. All authors agreed to be accountable for all aspects of the work.

Abstract

Despite the exposure of cardiothoracic anesthesiology trainees to patients with cardiac implantable electronic devices (CIEDs), there is a paucity of formal curricula on this subject. Major impediments to educating cardiothoracic anesthesiology trainees on CIEDs include busy clinical schedules, short staffing, inconsistent trainees' exposure to CIEDs, multiplicity of vendors, and a "millennial" mentality of the new generation of learners. As a result, cardiothoracic anesthesiology trainees graduating from their residency and fellowship programs may lack the competency to manage patients with CIEDs. Herein, we report our systematic approach to designing, validating, mapping, evaluating, and delivering a CIED curriculum on the first mobile app of its kind on this subject. Development of the CIED curriculum proceeded through the Kern 6-step approach of problem identification, determining and prioritizing content, writing goals and objectives, selecting instructional strategies, implementation of the material, and evaluation and applications of lessons learned. This was followed by the delivery of the curriculum in the form of a user-study app and administrator-type app with functionalities in the assessment of the learners' gains, experience, and satisfaction as well as the administrator's capability to update the educational content based on the feedback of the learners and the emerging technology. As such, the CIED app allows asynchronous learning at the pace of the learners and allows, through a multiplicity of educational materials, the ability to digest this complex and understudied subject. We report on the pilot phase of the project. We benefit from the experience of a multidisciplinary team of anesthesiologists, computer scientists, and educators in accomplishing this project.

Introduction

Cardiac implantable electronic devices (CIEDs) are electronic devices placed in patients experiencing permanent life-threatening arrhythmias. They include pacemakers, implantable cardioverter-defibrillators (ICD), and cardiac resynchronization therapies (CRT). The number of CIEDs implanted is increasing rapidly worldwide [1]. Due to increased longevity and technological advancement, the number of patients with CIEDs undergoing surgical procedures is steadily increasing [2]. With a growing sophistication of the technology and the potential for preventable adverse events related to CIED dysfunctionality in the perioperative period [3], there is a need for anesthesiology trainees to gain the knowledge and skills necessary to manage CIEDs perioperatively [4].

Despite an increased exposure of anesthesiology trainees to patients with CIEDs, and the availability of anesthesiology-led CIED services [5], there have not been formal curricula to educate trainees on this complex subject. Furthermore, busy clinical schedules, staff shortages, relatively short duration of the cardiothoracic rotation, the unpredicted and inconsistent exposure of trainees to patients with CIEDs, and the "millennial" mentality of the current generation of learners [6], all have challenged synchronous teaching and learning modalities. As

a consequence, currently graduating anesthesiology trainees may lack the competency needed to manage patients with CIEDs in their future careers.

Mobile learning (m-learning) is a learning mode that uses a mobile device or tablet. It allows self-directed asynchronous learning at the pace of the learner and hence frees the learner of time and physical constraints. M-learning was shown to be associated with higher learning gains compared with conventional learning in a multitude of medical specialty education [7-10]. At the time of writing this study, there are only 4 programs in the country where CIEDs are perioperatively managed by anesthesiologists with inconsistencies in the educational methodologies delivered to the trainees on this subject.

To remedy the current gap, we describe in this tutorial the systematic process of development and delivery of a high-quality CIED educational curriculum through a mobile app platform. This manuscript should be of interest to anesthesiology educators seeking to incorporate new competencies and rubrics related to CIED into residency training programs.

Methods

Development of High-Quality CIED Educational Curriculum

Using the Kern 6-step approach to curriculum development [11], we created goals, learning objectives, instructional content, and pre and postassessments to be delivered via m-learning, and user feedback regarding CIEDs. The Kern framework for curriculum development has been applied for training across multiple medical specialties [12-14]. The authors expanded the 6 steps by including an expert review of the instructional objectives.

Due to the perioperative nature of CIEDs, the curriculum focuses on knowledge and skills within the Accredited Council of Graduate Medical Education (ACGME) domain of Patient Care.

The basic process of curriculum development in medical education has been outlined [12-14] as consisting of the following steps:

1. Problem identification
2. Determining and prioritizing content (focusing on the needs assessment).
3. Writing goals and objectives.
4. Selecting instructional strategies.
5. Implementation of the curriculum.

Evaluation and application of lessons learned.

Problem Identification

Several intersecting challenges motivated the development of a curriculum for CIED management. As indicated earlier, technological advances and increased life expectancy have resulted in a steady increase in the number of CIEDs implanted annually [2]. Similarly, there has been an increase in the number of patients with CIEDs undergoing surgical procedures. Due to the rates of postoperative CIED-related complications, CIED-related deaths, and hospital readmissions related to CIEDs, there is a specific need for training in the knowledge and skills needed to manage CIEDs in the perioperative period. Cardiothoracic anesthesiology trainees are extensively exposed to patients with CIEDs during their training. Training ranges from a month-long rotation in the cardiac operating rooms and cardiac surgical intensive care units as an elective or core rotation during residency to a 12-month dedicated accredited clinical fellowship. Despite evidence that the initiation of perioperative anesthesiology-based CIED service is associated with better patient outcomes [5,15-17], there are no standardized published training curricula regarding CIEDs for cardiothoracic anesthesiology trainees. While these conditions highlight the general need for a curriculum focused on CIED interrogation for cardiothoracic anesthesiology trainees and fellows, a specific problem prompted the efforts of this project. A problem involving case delays of procedures on patients with CIEDs due to the show of device representatives and cardiology fellows and the occurrence of multiple preventable patient safety events due to perioperative CIED malfunctions triggered our institution to seek the initiation of an anesthesiologists-led CIED service. A dual-trained cardiothoracic and critical care anesthesiologist with expertise and training in CIED management (AZ) championed this quality and safety initiative. The implementation of an anesthesiologist-led CIED service created an in-parallel need to train anesthesiology trainees with a similar scope of practice to sustain the service. This need was based on an average number of 400 patients with CIED undergoing cardiac and noncardiac procedures at our institution per year. We reasoned that the rising use and exposure to CIED, the complexities of perioperative management of these devices, and the clear gap resulting from the absence of a standard methodology for educating cardiothoracic anesthesiology trainees all justify the design and delivery of a high-quality CIED curriculum for these trainees.

Determining and Prioritizing Content (Needs Assessment)

We conducted a needs assessment to assess the current status of CIED education to cardiothoracic anesthesiology trainees in our institution and nationwide and determine potential areas for improvement. Our needs assessment focused on 3 aspects. First, scanning the literature and anesthesiology program websites on published educational material on CIEDs for trainees. Second, we conducted a survey via Qualtrics to cardiothoracic anesthesiology trainees at our institution and at the Ochsner Clinic. The survey included questions about the level of training, the form of CIED didactics, the fallbacks of the current teaching, and what the trainees would like to see in a CIED curriculum. The third aspect of the needs assessment was in the form of in-person informal interviews with residents and cardiothoracic anesthesia trainees at our institution. Interviewees were asked open-ended questions about the current teaching of CIEDs at our institution and areas for improvement. A total of 6 interviews were conducted, 10 - 15 minutes each, with 2 trainees at a time. The interviews took place during breaks from working hours in the anesthesia lounge. The PI took notes and observed the reactions of the interviewees during the interviews. The PI then presented the results of the needs assessment to the Cardiothoracic Fellowship Program Director and the Residency

Program Director at our institution. The results of the needs assessment are summarized in Textbox 1.

Textbox 1.

The results of our needs assessment are summarized as follows:

- At the time of writing, there were 4 institutions that deliver formal cardiac implantable electronic device (CIED) didactics to cardiothoracic anesthesia trainees and fellows.
- Didactics are in the form of website videos (2 institutions) and scheduled lectures (3 institutions).
- Didactic materials were in the form of textbooks, review articles, and on-site workshops at national societal meetings on a yearly basis.
- Most of the didactics are directed to the simpler programming of temporary epicardial pacers that are placed intraoperatively. As a consequence, there is no formal interrogation of these devices [18].
- Trainees at our institution had not received instructional material about CIEDs before the interviews and survey dates.
- Lecture-based training was the predominant instructional approach trainees experienced and was also the least desirable.
- Approximately one-third of trainees rated app-based instruction as their first or second choice of instructional method (hands-on was the most desirable approach).
- Almost three-fourths of respondents indicated that they would prefer a self-paced e-learning system for learning about CIEDs.

The collective results of our needs assessment led us to reason a need to test the design, development, and delivery of a formal comprehensive CIED curriculum to our cardiothoracic anesthesia trainees that adapts to their time constraints.

Conceptual Framework

Conceptual frameworks represent ways of thinking about a problem and responding to the complexity of an educational phenomenon. Adding a conceptual framework to best practice approaches such as the Kern 6 step-approach for curriculum design helps construct goals and objectives. Furthermore, this integration helps select the educational intervention to achieve the educational goals and objectives and determine the evaluative methodology of the educational intervention, which will eventually determine the outcomes to be assessed and the evaluative strategy to determine the success of these outcomes [19]. Overall, both best practice and conceptual framework contribute to the rigor of educational scholarship.

Around 2 theories contributed to the design and development of the CIED curriculum, based on the needs assessment. The self-regulated framework, attributed to Zimmerman and Schunk, entails that learners plan, monitor, and evaluate their own learning to achieve their goals [20]. The self-regulated theory is applicable to the busy schedule of cardiothoracic anesthesiology trainees that interferes with synchronous learning, and importantly, to the maturity level of trainees at this stage of their career. The self-regulated theory thus calls for the design of an asynchronous learning method in the form of m-learning. The self-regulated framework was used to formulate the research question: whether an app-delivered CIED curriculum is a suitable delivery method for cardiothoracic anesthesiology trainees.

The Kolb experiential learning cycle that describes the 4-stage learning cycle in the form of concrete experience, reflective observation, abstract conceptualization, and active experimentation is another framework that influenced the design of the practical modules of the curriculum [21]. The framework guided the formulating of the research question: whether video recording of the interrogation and programming procedures of CIEDs by vendor will allow trainees to gain the skills needed to perform these procedures through Kolb stage of reflective observation?

Establishing Goals and Objectives

Based on a review of textbooks and consultation with colleagues, the first author developed an initial draft of seventeen major goals and associated instructional objectives (5 - 15 objectives for each goal). Overall, curricular goals focused on knowledge, psychomotor skills, and attitudes of the learners and were tailored in a stepwise fashion from acquiring foundational knowledge to applying this knowledge to acquiring the skills in managing CIEDs. For example, the curriculum progresses from understanding and recognizing electrocardiographic patterns of pertinent tachyarrhythmias and bradyarrhythmias to understanding the basics of CIED indications, structure, and function of CIEDs, to recognizing pacer rhythms and understanding the 4 basic parameters used in interrogating and programming CIEDs on different vendors. The final modules of the curriculum are in the form of recorded videos of the performance of device interrogation and programming on the 4 contemporary device vendors. Assessment of the psychomotor skills of the trainees will be in the form of a video recording of the trainee conducting the 4 steps of device programming and interrogations in the form of (1) identification of the vendor, (2) identification of the device, (3) assessment of pacing dependency, and (4) performance of battery and leads functionality in the form of battery longevity, leads impedances, and sensing amplitude and capture threshold. An assessment rubric was created to grade the performer's skill (Multimedia Appendix 1).

Following the development of 17 goals and objectives associated with such goals, we sought to evaluate the proposed goals and objectives by surveying a group of 17 CIED subject matter experts (SME) on whether (1) the objectives are critical or important to CA learners, (2) the instructional objectives fit the learning goals, and (3) whether the objectives as written were clear. After the initial development of the goals and objectives,

the process to evaluate the objectives was similar to methods used by a previous medical curriculum validation process used in obstetrics in Canada [22].

The curriculum validation process involved the identification of a national panel of experts in curricula relating to CIEDs. The definition of expertise of an expert was based on the qualifications: board certification in Cardiology, Electrophysiology, and equivalent certification in CIEDs with greater than 5 years of experience, and an expertise in medical curricular design.

Each panelist received an online survey (Qualtrics) which presented the 17 major learning goals of the curriculum and the instructional objectives for each goal (5 - 15 objectives per goal). Respondents were asked to rate the importance of each instructional objective (not important, important, and essential), the fit of the objective to the learning goal (does not fit and aligns), and the clarity of the objective (unclear or ambiguous and clear).

Ethical Considerations

The study was approved by the University of Alabama Institutional Review Board (IRB00012550) and adheres to the applicable CONSORT (Consolidated Standards of Reporting Trials) guidelines. The requirement for patient consent was waived.

Results

Response to Validation of Goals and Objectives

A total of 17 SMEs responded to the Qualtrics survey. The results of the validation survey are in the process of publication elsewhere. In brief, all objectives were rated as important or essential by 80% or more of the 17 raters, several goals had fewer than 70% of objectives rated as essential by 73% or more of the experts, with 6 goals having no objective that was rated as “essential” by more than 73% of experts. A goal of understanding the unique features of individual CIED vendors received the lowest rating given that this subject was not pertinent to cardiothoracic anesthesiologists.

In response to SMEs’ response, we have kept objectives that were either essential or important to greater than 75% of the raters and removed the objectives that were considered important by less than 75% of raters. Furthermore, goals whose objectives were considered important by less than 75% of the raters were removed.

The modified curriculum was then named “Anesthesiology Prospective-basic Curriculum” (Textbox 2).

Textbox 2. Basic cardiac implantable electronic device (CIED) curriculum: anesthesiology perspective

- Module 1: Basic cardiac electrophysiology
  - 1A. Basics of surface electrocardiogram
  - 1B. Heart blocks
  - 1C. Pertinent tachyarrhythmias
- Module 2: Indications of pacemakers, implantable cardioverter defibrillators (ICDs), and cardiac resynchronization therapies (CRTs)
  - 2A. Permanent pacemaker (PPM) indications
  - 2B. ICD indications
  - 2C. CRT indications
- Module 3: Anatomy of pacemakers
  - 3A. Generators
  - 3B. Leads
- Module 4: Pacemaker modes and codes
  - 4A. Generic pacemaker codes and modes
  - 4B. Ventricle paced, Ventricle sensed, Inhibited response (VVI) pacing as an example of single chamber pacing
  - 4C. Dual chamber paced, Dual chamber sensed, Dual response (DDD) pacing as an example of dual chamber pacing
- Module 5: Anatomy of ICDs
- Module 6: Operation of ICDs
  - 6A. ICD recognition of arrhythmias
  - 6B. ICD treatment of arrhythmias
- Module 7: Guidelines for perioperative management of CIEDs
- Module 8: Magnet behavior
- Module 9: Programming and interrogation of CIEDs
- Module 10: University of Alabama (UAB) Anesthesia Clinical Protocol of Perioperative CIED Management

Selection of Instructional Modality and Strategies

One focus of this curriculum development project was the commitment to delivering instructional content and resources, assessment, and program evaluation (eg, usage, acceptability, and satisfaction) of the curriculum via an updatable, accessible, asynchronous electronic platform. An m-learning platform for delivering the curriculum was considered essential for accommodating the constraints experienced by cardiothoracic anesthesiology trainees. Delivering the curriculum via modular delivery of content provides a flexible, self-paced, competency-focused approach to instruction and assessment.

In order to develop the m-learning platform within a structure that would be manageable to learners, the retained goals and objectives were distributed among 11 modules and submodules. The use of modules is a common structure for m-learning platforms [23,24]. Curricular mapping between goals, objectives, the instructional resources associated with each objective, and the assessment for each objective was created for all goals and objectives within the curriculum (Table 1).

Table . Instructional map for module 1A, 1B, and 1C

Module	Goals	Objective	Instruction	Assessment
1A	• Understand basics of heart rhythm formation and propagation • Establish a foundation for recognizing paced rhythms	• Differentiate between pacemaker and myocardial cells • Differentiate the action potential for both pacemaker and myocardial cells • Understand the ionic basis responsible for different phases of action potentials • Recognize and define refractory periods on an action potential	• Text • Differentiate between pacemaker cells and myocardial cells	Written quiz with visuals
1B	• Understand basics of electrocardiogram depiction • Understand the various types of heart block	• Determine heart rates on EKG by at least 2 methods • Identify the axis on surface EKG • Identify different types and levels of heart block on surface EKG	• Visuals • Text	Written quiz with visuals

1C	• Recognize the different types of supraventricular tachycardias
	• Understand the differences between ventricular and supraventricular tachycardias
		• Describe EKG patterns of SVT
		  • Determine electrocardiogram pattern of atrial fibrillation
		  • Describe electrocardiogram patterns of AVRNTa
		  • Describe electrocardiogram patterns of atrial tachycardias
		  • Describe electrocardiogram pattern of atrial flutter
		• Recognize EKG pattern of VT
		  • Monomorphic
		  • Polymorphic
		  • VF
		  • Accelerated idioventricular rhythm
		• Understand common SA node abnormalities
		• Describe wide complex SVT
		• Differentiate wide complex SVT from VT
			• Visuals
			• Text
				Written quiz with visuals

Assessment materials were developed in the form of pre and postinstructional quizzes. Postinstructional quizzes were slightly different in order and content from prequizzes. The rationale for this difference is to assess trainees' incremental learning gains after reading the modular instructional material and to assess whether the postquiz responses were due to knowledge acquisition versus memorization of prequiz grading of wrong answers. A minimum passing score of 80% was used as the criterion for passing any quiz. Quizzes consisted of both multiple-choice questions (MCQ) and open-ended questions. The former were created to assess knowledge, comprehension, and simple applications, while the latter were created to assess

a deeper level of learning and ability to explain the reasoning behind the responses [25]. Grading of open-ended questions was performed by the instructor, while grading for MCQs was performed automatically. Quizzes could be taken indefinitely until passing scores are achieved. Assessment for modules that covered skills was in the form of virtual actual device interrogations. This was in the form of performing 4 basic steps: identification of CIED vendor, determination of the type of CIED, determination of pacer dependency, and determination of device functionality in terms of battery longevity, leads' function in terms of sensing and capture thresholds, and leads' impedances. Programming entailed adjusting the device settings to suit the site of the surgical procedure and the use of electrosurgical interference, applying a magnet when indicated, and disabling tachycardia therapy in patients with implantable cardioverter defibrillators. Device restoration included restoring of basic settings of the device after the completion of the procedure and enabling tachycardia therapies for ICDs. The interrogations, programming, and restoration were performed under the supervision of the PI on the protocol.

The CIED curriculum underwent an instructional and content validity assessment as a final evaluation step. The instructional validity is aimed at engaging a cohort of SEM to judge whether the instructional content and resources within the app provide a valid representation of each instructional objective. The content validity assessment tested whether the pre-post quizzes were adequately informed by the instructional content and resources linked to the objective. The rationale for engaging SMEs on instructional and content validity is to consolidate the validation of the alignment of goals to objectives. Engagement was in the form of the Qualtrics survey sent to the same SMEs who were provided with the assessment and instructional and assessment material via email. Both the instructional and content validity assessment provided validation of the curricular map in the form of alignment of goals to objectives and to instructional material to assessment. This validation process is conceptually distinct from the assessment of learners' satisfaction of the curricular content, which is in the form of a short survey embedded at the end of each module. The validation process in this form is consistent with the Accreditation Council of Graduate Medical Education (ACGME) [26-28] (Table 2).

Table . Alignment of curricular contents with Accreditation Council of Graduate Medical Education core competencies.

ACGME[a] core competency	Corresponding curricular material to achieve competency
Patient care: "To demonstrate compassionate, appropriate, and effective care for patients, including the ability to perform comprehensive history and physical examinations, formulate diagnostic plans, and coordinate patient care."	History and physical examination of the patient to determine pertinent information about the CIED[b] (indications, type, vendor, previous interrogation reports).
Medical Knowledge: "To possess a strong foundation of biomedical knowledge and the ability to apply it to patient care, staying current with evolving medical knowledge."	Instructional material in the form of module narrative, constantly updated narratives in response to new guidelines and latest technology (leadless pacemakers and subcutaneous ICDs)[c], library of updated articles
Practice-based learning: "to investigate and evaluate their own care, appraise scientific evidence, and continuously improve their practice through self-evaluation and lifelong learning."	Unlimited attempts at solving the quizzes, interactive platform between the user study app and the admin app to allow interactive feedback from instructor to learner on performance
Interpersonal and communication skills: "to effectively communicate with patients, families, and other healthcare professionals, building strong relationships and fostering trust."	Adequate documentation of the interrogation and programming procedure, communication with surgical and EP services on device malfunction issues in need of intervention.
Professionalism: "To demonstrate ethical conduct, respect for colleagues, and a commitment to patient well-being, upholding the highest standards of professional behavior."	Competency adequately emphasized throughout the instructional material and skill assessment of the curriculum.
Systems-based practice: "To understand and navigate healthcare systems, working effectively within teams and advocating for patients' needs within the context of the healthcare system."	Detailed instruction on navigating EMRs[d], checklists on consulting other services and contacting device reps for vendor-specific issues.

[a]ACGME: Accreditation Council of Graduate Medical Education.

[b]CIED: cardiac implantable electronic devices.

[c]ICD: implantable cardioverters defibrillators.

[d]EMR: electronic medical records.

Delivery of the Curriculum

Pilot Phase

We developed a de novo cloud-based system for the project. The CIED app (and the accompanying admin grading app) has 2 components: the mobile and web front-end, and the cloud-based back-end (Figure 1).

Figure 1. Screenshots of the cardiac implantable electronic device app.

Front-end

The CIED app and the admin grading app are developed using Ionic (OutSystems), a cross-platform mobile app framework. This allows consistent functionality and user experience across iOS and Android devices. It also allows deploying a web app, which can be accessed from mobile phones or tablets as well as desktop web browsers.

Back-end

The back-end of this system is built using the Google Cloud. More specifically, we host the back-end computing, database, and analytics services based on the Google Firebase engine. We used the Google Cloud Firestore database to store the course modules, quiz questions, and per-user data such as grades. We used Firebase's authentication engine to register and manage users.

Analytics

For detailed user analytics, we used Google Firebase Analytics engine. It provided us with details on how the users interacted with the system and viewed different modules and videos. The per-user data on grades and quiz attempts provides us with information on the quiz attempts and performance. We collected pre and postlesson quizzes to compare performance before and after each lesson.

The evaluation of the educational material will occur in three phases. First, performance analytics will be performed, which will quantify the learning gain after compared to before taking the quizzes. Second, web analytics will determine the time taken by trainees in studying and answering the quizzes. Through this evaluation, the level of complexity of the material will be evaluated. Third, usability analytics will assess the learners' satisfaction with the curricular content and app usability.

A total of 2 distinct applications were created; the User Study App, empowering cardiothoracic anesthesiology trainees to enhance their knowledge, and the Admin Grading App, streamlining quiz management and assessment. The successful integration of these apps creates a cohesive ecosystem that fosters growth, engagement, and continuous improvement within the anesthesiology community. Both apps are compatible with Android and iOS platforms.

User Study App

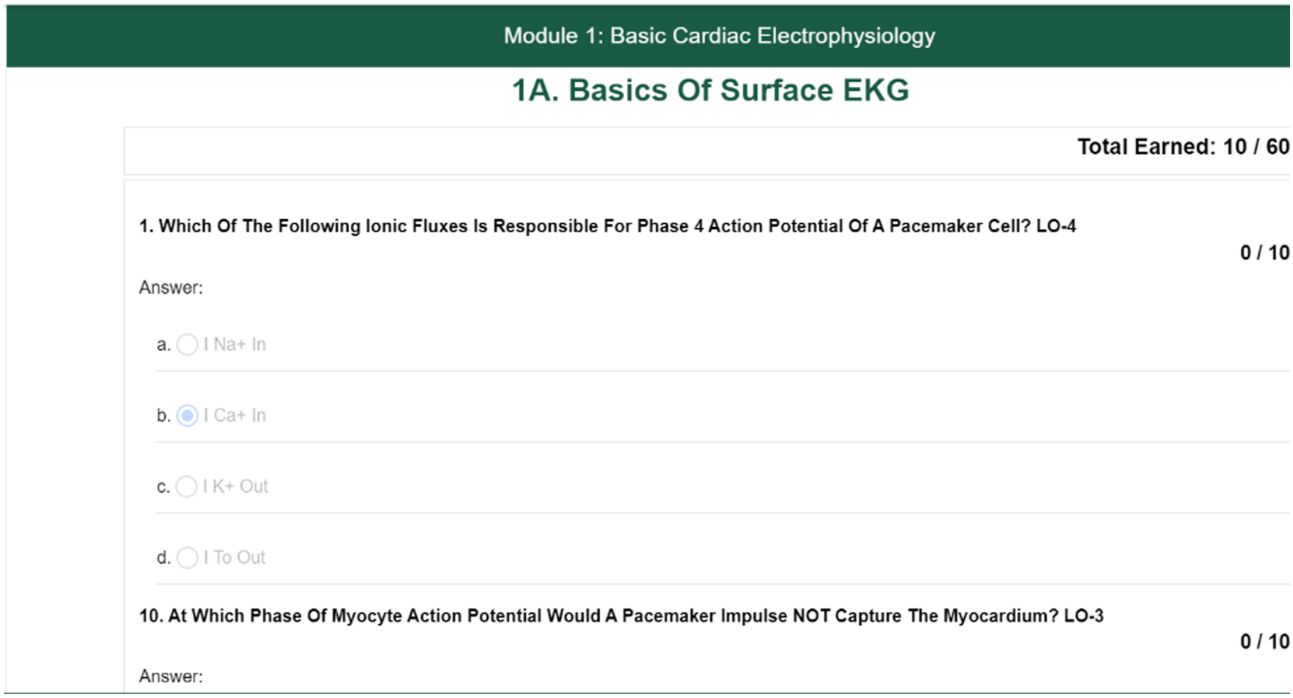
This app is a knowledge hub catering to anesthesiology practitioners' learning needs. It offers a collection of study materials, interactive resources, and self-assessment tools to foster professional growth. For usability testing, we are using the AttrakDiff test (https://www.attrakdiff.de/index-en.html). AttrakDiff is a standardized test designed to evaluate the user's experience. It is widely used to assess the attractiveness of a product in terms of usability and appearance.

The User Study App is integrated with the prequiz condition (Figure 2).

Prequiz Requirement

Users must complete a prequiz assessment before gaining access to study materials.

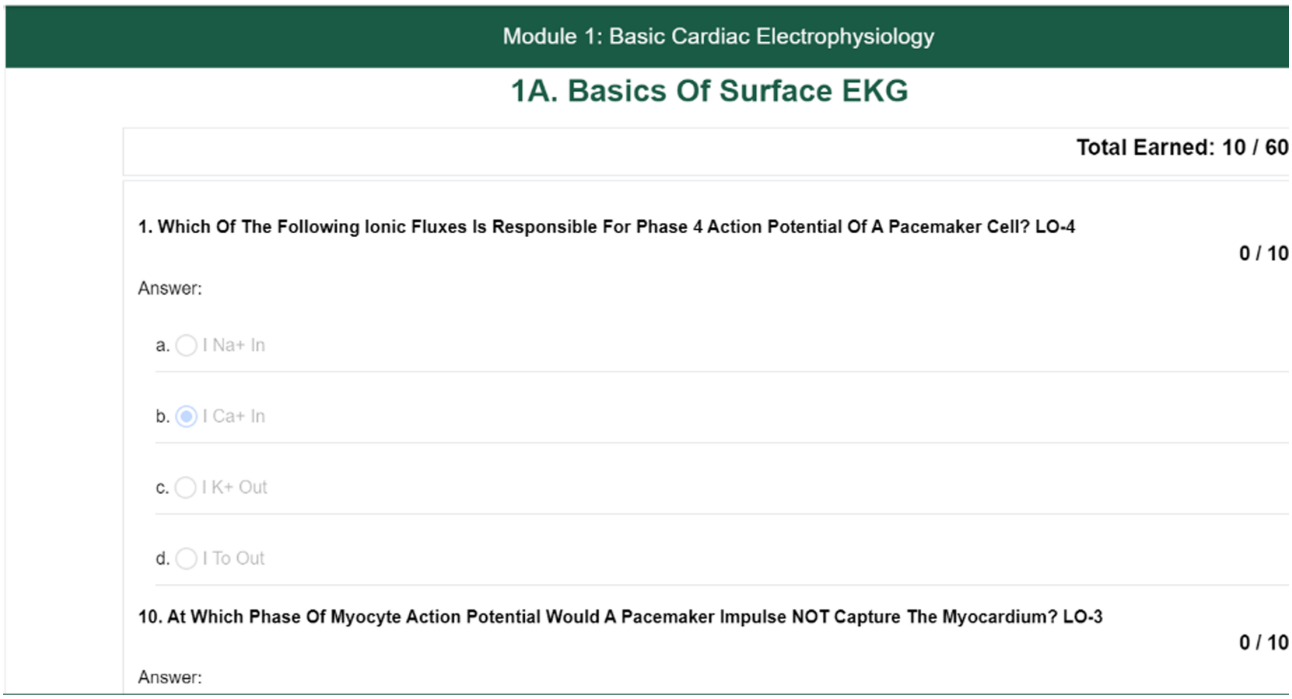
Figure 2. Screenshot of a modular instruction material-user app.



Study Materials

This includes a library of articles, multimedia content, and case studies tailored to various anesthesiology topics and expertise levels (Figure 3).

Figure 3. Screenshot of a quiz on a modular instruction material.



Interactive Quizzes

Quizzes were designed to complement the study materials and reinforce learning objectives.

Progress Tracking

Personalized user dashboards displaying prequiz scores and study progress, aiding in self-assessment and goal setting.

Learners' Satisfaction Surveys

Surveys on the learning experience of trainees were embedded at the end of each module. The surveys assess learners' views on the clarity of the educational material, alignment of the educational objectives to goals and to the instructional and assessment material, what areas need further instruction and what technical issues arose during the navigating the module (Figure 4).

Figure 4. Screenshot of the Qualtrics survey embedded at the end of each instructional module.

Admin Grading App

The Admin Grading App equips administrators with powerful tools to manage quiz content and evaluate user performance. Key features are given below.

Admin Dashboard

This is a secure login portal providing access to quiz management, user profiles, and analytics.

Quiz Creation

This is a user-friendly interface allowing administrators to create and customize quizzes, tailoring them to specific learning objectives.

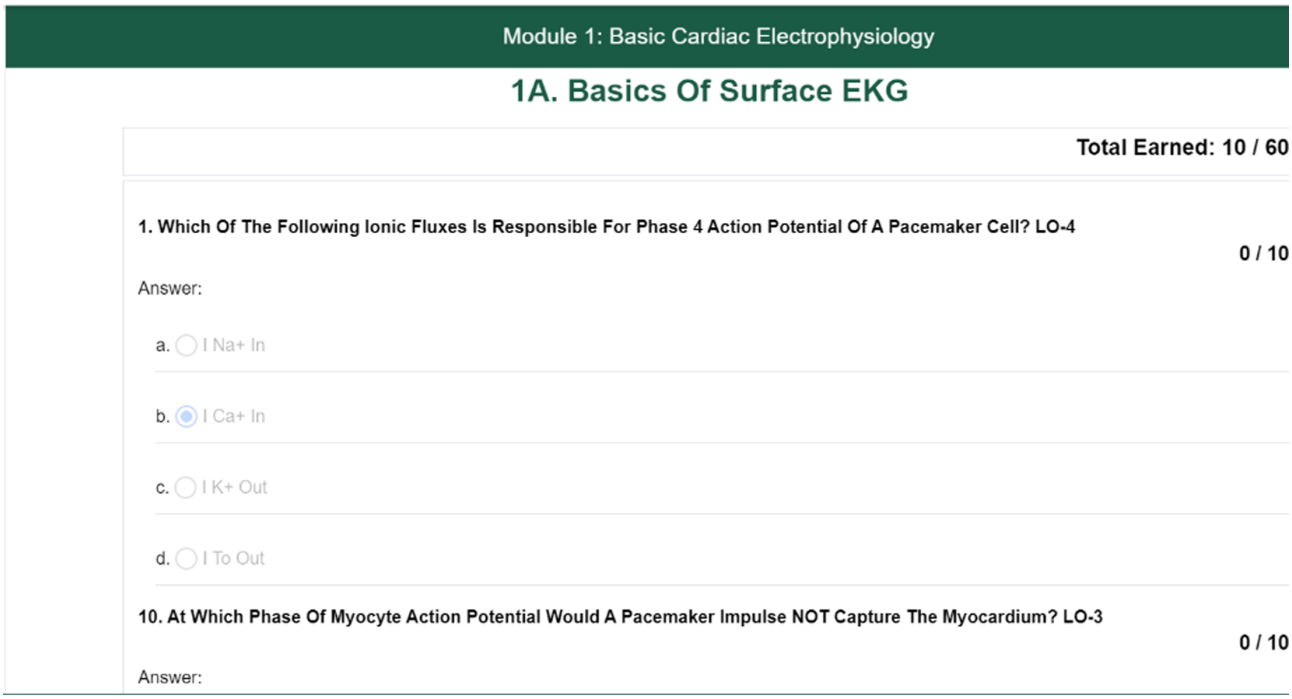
User Management

This includes comprehensive user profiles and progress reports, assisting administrators in understanding individual learning trajectories.

Grading Interface

This was a grading system enabling assessment of quiz responses (Figure 5).

Figure 5. A screenshot of grading of a quiz-administrative app.



Analytics and Reporting

Data visualization tools providing insights into overall user performance, popular study topics, and areas needing further emphasis.

Integration and Security Measures: Fostering a Cohesive Ecosystem

The integration of the User Study and Admin Grading Apps is facilitated through shared databases, ensuring data synchronization and consistency. Security measures, including strong encryption and authentication protocols, safeguard sensitive user information and preserve the platform's integrity.

Discussion

Principal Findings

This manuscript describes the process of designing, developing, and app delivering a comprehensive CIED curriculum for cardiothoracic anesthesiology trainees. This project has engaged an interdisciplinary team of cardiologists, electrophysiologists, technologists, computer scientists, and medical education. With the delivery of the curriculum, the investigators are in the process of collecting data on the platform implementation; user perceptions of usability, perceived effectiveness in promoting learning, and satisfaction with all components of the app; psychometrics of the learning assessments, and analysis of learning within each module.

While there are no previous studies on this subject to compare our work to, our mobile app goes in line with other studies that used mobile apps for educating anesthesiology trainees. Marty et al [29] designed a mobile app to facilitate programmatic assessment of anesthesiology trainees and tested its performance in five teaching institutions. The app provided insightful information about feedback completion times and documentation of learning goals. Monroe et al [30] implemented a mobile app for anesthesiology trainees rotating through a pediatric rotation in an academic institution. Similarly, Herbstreit et al [31] created a mobile platform formed of several department-specific apps and qualitatively demonstrated high satisfaction rates with the mobile learning content and pace. Compared with the above-mentioned studies, we have followed formal steps of creating a curriculum, consulted nationwide SMEs, and developed a curricular map that aligns instructional material

and assessment to goals and objectives. Distinctively, our admin app uses web, performance, and usability analytics, which are either not covered or partially covered in other studies.

The project represents a collaborative effort between multiple teams to enhance trainees' educational experience. As such, it extends the boundaries of cardiac anesthesiology, adding the new dimension of electrophysiology. Furthermore, this project represents a remarkable link between quality improvement, patient safety, and medical education. The effective implementation of our project is in line with similar improved outcomes with enhanced multidisciplinary team buildings and dynamics [32-34]. On the other hand, the program encountered some challenges before its successful implementation. First, the diversity in the learners' training levels, including second-year rotating residents and cardiothoracic fellows, posed a challenge in the selection of instructional material. Second, the process of curricular instructional and assessment validation was more of a laborious process for SMEs due to the lengthiness of the material. Third, the choice of the instructional material was more of a challenge for basic learners given the density of the subject. This has led us to a multiple iterative process to adjust the curriculum to conform to the needs of a basic anesthesiology learner.

It is important to recognize some of the limitations of our project. At the time of writing of this manuscript, the project remains descriptive. We are currently collecting data on the learning gain and usability of the app. Therefore, the process of curricular refinement remains an iterative process. There is relatively a few number of SMEs recruited for the validation process of the curriculum. At the time of this recruitment, the curriculum remains in the initial stages and is subject to more iterations when more feedback is received from trainees. At such a point, more SMEs will be recruited on further refinements of the curriculum. Ideally, validation of curricular mapping should occur in a single step. In our case, given the lengthiness of the content, the process of curricular validation proceeded through validation of alignment of learning goals and objectives, followed by the instructional content and assessment validation. Furthermore, our SMEs were not confined to those with backgrounds in anesthesiology. While this may be regarded as a limitation, the diversity of SMEs' backgrounds allows more robustness of the curriculum.

Conclusions

The CIED app is a novel application-delivered curriculum on a complex and understudied subject in anesthesiology training. The curriculum adheres to conventional steps of curricular design. The m-delivery of the curriculum and the functionality of the app in the evaluation of the learners' performance and satisfaction responds well to the challenges that face trainees in achieving synchronous learning and engages them in the learning and evaluation processes. As we continue to enhance and expand the CIED app, we envision its instrumental role in elevating the quality of anesthesiology practice worldwide, ultimately benefiting patient outcomes and health care excellence.

Abstract

Opportunities to learn ultrasound-guided/assisted (USGA) neuraxial techniques for pediatric patients are limited, given the inherent high stakes and small margin of error in this population. Simulation is especially valuable in pediatrics because it enhances competency and efficiency, without added risk, when learning new skills, specifically those seen with ultrasound-guided regional anesthetic techniques. However, access to simulation opportunities involving the use of phantom models in medical education is limited due to excessive costs. We describe a process for producing ultrasound phantoms by using synthetic ballistic gelatin; these ultrasound phantoms can be used for simulation and are affordable, reproducible, and indefinitely shelf stable. The ultrasound images produced by these phantoms are comparable to those obtained from a real pediatric patient, including the sacral anatomy necessary for caudal epidural blocks, as validated by practicing pediatric anesthesiologists. Phantom models offer a more cost-effective alternative to commercially prepared phantoms, thereby expanding access to realistic simulations for neuraxial ultrasound in pediatric medical education, without the prohibitively high expense.

Introduction

Opportunities to learn ultrasound-guided/assisted (USGA) neuraxial techniques for pediatric patients are limited, given the inherent high stakes and small margin of error in this population. Simulation is a valuable and effective method for learners—whether used by trainees or experienced clinicians—to enhance their competency, efficiency, and confidence in performing regional anesthetic and neuraxial techniques [1-4]. Ultrasound enhances safety, decreases complications, and improves the efficacy and accuracy of neuraxial blockade in pediatric patients from preterm to adolescence [5-12]. The utility of ultrasound is even more apparent in syndromic children with unusual anatomy, patients who comprise a large subset of the pediatric population that presents for surgery at a young age [13]. Honing pediatric patient–related ultrasound skills in a simulation setting is an ideal scenario for learning without risk. Unfortunately, educational curricula and teaching models lag behind recent advancements in simulation.

Despite efforts to create affordable and reproducible ultrasound phantoms, many lack a realistic appearance, and most are not indefinitely, if at all, shelf stable or portable because they are made of water, agar, gelatin, or other substances or are derived porcine models [3,4,14,15]. The cost of manufactured models that offer all these features can be prohibitively expensive, amounting to several thousand dollars, and these models may generate an inferior simulation experience [14]. Limited access to high-fidelity ultrasound phantoms significantly restricts opportunities for learners to take advantage of low-stakes simulation training and necessitates practicing on live patients, including infants and children, to learn valuable skills—a method with varying degrees of success and much higher stakes. There is a dearth of literature describing spine phantoms that are made with the necessary anatomy to teach pediatric trainees how to use ultrasound to approach the caudal epidural space. We describe a method for creating a realistic, affordable, reproducible, and shelf-stable spine phantom model that allows for the demonstration of key ultrasound images of the spine and caudal anatomy that are required to perform USGA neuraxial techniques on pediatric patients. Furthermore, the synthetic ballistic gelatin used to produce the phantom model can be reclaimed and reused to make “fresh” models for an indefinite

period of time, allowing for multiple practice sessions without additional costs.

Methods

Overview

We present a tutorial describing the construction of an ultrasound phantom of the spine, based on similar previous descriptions [16]. Notably however, our model includes both lumbar anatomy and sacral anatomy, which are lacking in previously published iterations but are essential for learning pediatric-specific neuraxial sonoanatomy. Additionally, we completely submerged our spine model in ballistics gel, creating stable, flat surfaces surrounding the spine to facilitate scanning the model in multiple orientations, which simulates the use of ultrasound for prone, lateral, and sitting positions. Further, an anonymous survey was sent to 10 practicing attending pediatric anesthesiologists to evaluate the similarity between the ultrasound images generated from the phantom and images from a real patient. Three ultrasound views were evaluated for likeness and accuracy on a 5-point Likert scale.

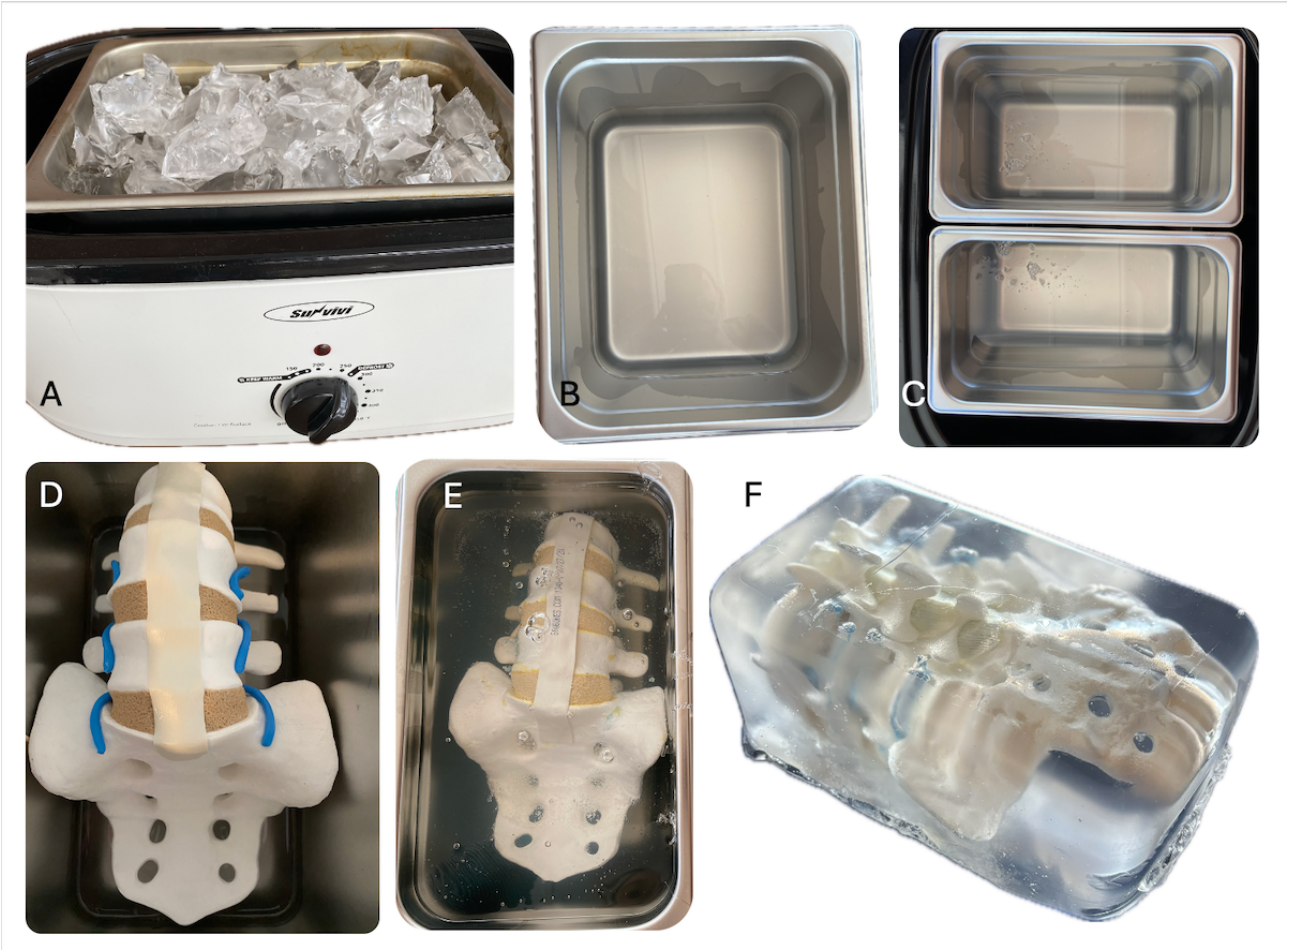
How to Create a Phantom Model

The following stepwise process can be used to create a spine phantom:

- Step 1: Preheat a portable oven to 250-270 °F (121-132 °C). A portable oven is preferable, as it can be used outside to prevent inhalation of the unpleasant smell from melting gel. It is critical to review the manufacturer's guidelines; ensure that the ballistics gel is always melted in well-ventilated areas; and ensure that caution is used to avoid overheating the gel, as it could light on fire.
- Step 2: Cut or tear ballistics gel into smaller pieces for melting.
- Step 3: Place the gel into an oven-safe pan (either a mold pan or an extra container), with the goal of melting the gel to create a 1- to 3-inch gel layer at the bottom of the pan.
  - This layer mimics the soft tissue covering the spinous processes. Add more gel to create a thicker layer, if desiring to create a model with greater depth to the epidural space.
  - Generally, it is preferable to melt the gel in an extra oven-safe container and pour it into a mold pan for each subsequent step; however, for the first layer, the gel can preferentially be melted directly in the mold pan.
- Step 4: Melt the gel in the oven until all bubbles are gone. This step takes about 2 to 4 hours, depending upon the amount of gel melted. It is critical to minimize bubbles in this layer, as this is the surface that will be scanned with ultrasound.
- Step 5: Allow the bubble-free layer to cool significantly (approximately 30-60 min). Then, place the spine model into the pan, with spinous processes facing down toward the bottom of pan and touching the gel, and press it very gently into the gel. Hold or secure the spine model in place until the gel sets and the model is not moving in the pan (10-20 min).
  - During the first cooling period, the gel should be cool enough to touch and be starting to firm up, with some resistance to pressure from a fingertip, but it should be soft enough to envelop the tips of the spine model's spinous processes.
  - If free-pouring gel into a mold pan (rather than melting gel directly in it, as is preferable), aim to pour toward one side/corner of the pan to minimize air bubbles. A ladle can be used to pour gel into the mold pan, again aiming to pour into one side/corner of the pan (rather than fanning) to minimize bubbles.
  - If many large bubbles are present, consider placing the mold pan back into the oven and cooking further until bubbles are gone (a few small bubbles are generally not problematic).
  - Hot gel will soften the spine model and result in curved spinous processes. Therefore, press only hard enough on the model to make slight contact between the tips of spinous processes and the gel; this contact secures the model to hold it in place in future steps.
- Step 6: Allow gel in mold pan (containing 1- to 3-inch gel layer) and spine model to cool completely.
- Step 7: Once cool, pour more melted gel (see step 3 for melting instructions) into the mold pan until the spine model is completely covered.
  - Pour quickly and to one corner or side at the coccyx-end of the model.
  - Bubbles in this step are not as concerning because this surface will be placed facing down and will not be scanned.
  - Bubbles will continue to rise to the top for several minutes as the gel cools; large bubbles can be popped/opened to create a flatter surface on this side of the phantom, though it is not necessary to do so.
- Step 8: Allow the mold pan (which should now contain the gel-covered spine model) to cool completely, preferably overnight, until the gel is solid.
- Step 9: Remove phantom from pan, using firm but gentle traction on the gel.
  - It may help to run an offset spatula (or another flat, thin tool, such as a butter knife) along the edges of the phantom and pan to help separate the phantom from the mold pan.
  - Once loosened, it can be helpful to stand the pan upright on the short side and slide fingers between the gel and pan as deep as possible to fully free the top side of the gel. Then, firmly push down, while continuously pulling out, on the gel until it releases from the pan.
- Step 10: Store phantom at room temperature, with spinous process side up. To clean, use water and a lint-free towel.

Figure 1 shows correlated pictures of the stepwise process and final phantom model.

Figure 1. Stages of phantom production, with A to C showing steps 1 to 4, D showing steps 5 and 6, E showing steps 7 and 8, and F showing step 9. (A): Cut gel in an extra container placed inside a portable oven set to 270 °F (132 °C). (B): Melted, bubble-free gel in the extra container. (C): Two mold pans. (D): Spine model, with anterior side up, placed in cooled, bubble-free layer. (E): Spine model submerged completely in gel and cooled. (F): Completed spine phantom that has cooled completely and has been removed from the mold pan.



Materials

Multiple options exist for the materials that are used to create a phantom model for practicing neuraxial ultrasound skills. Table 1 outlines those used by the authors, along with purchase sites and prices. Each phantom is composed of a spine model embedded in ballistics gel. Additional necessary items are reusable for multiple production cycles. Supplies include an oven that can sustain 250-270 °F (121-132 °C; US $119 for a portable oven), an oven-safe mold (US $9), and an extra oven-safe container (US $11). Optional items include a ladle or another heatproof tool for scooping melted gel. The ladle can be useful for more precision in transferring the gel into the pan. It does potentially create more bubbles than pouring directly; however, bubbles are mitigated by placing the pan back into the oven. The ladle is also useful for ensuring that the anterior side of the model is completely covered with gel and that any bubbles remaining on the anterior side do not interfere with ultrasound scanning. Furthermore, because the spine model is completely submerged in ballistics gel, an offset spatula may be helpful for loosening and releasing the phantom from its mold.

Table . List of materials, where to purchase, costs, and notes on pertinent information.

Item and description		Purchase site	Cost	Notes
Oven (portable)				
	"Sunvivi 22-Quart Roaster Oven"	Amazon.com (ASIN[a]: B07K25WBZ4)	US $119	Any oven that can sustain 250 - 270 °F (121-132 °C).
Ballistics gel				
	"10% FBI Gel Block"	Clearballistics.com (SKU[b]: 852844007000)	US $76 + shipping	Makes ≥4 phantoms.
Spine model				
	"Spine, Lumbar Vertebrae with Nerve Roots and Ligamenta Flava, L3-Sacrum, Solid Foam"	Sawbones.com (SKU: 1340-1)	US $161 + shipping	Preferred.
	"Medical Human Lumbar Spine Demonstration Model Anatomical Model Lumbar Vertebrae Sacrum & Coccyx, with Herniation Disc,for Science Classroom Study Display Teaching Medical Model 15 Inch Hight"	Amazon.com (ASIN: B074JCS4SC)	US $34	Less expensive. Requires removal of some vertebrae to fit recommended oven-safe mold. Alternative option is 3D printed model.
Oven-safe mold				
	"1/4 size 6" Deep Steam Table Pan"	Webstaurantstore.com (item number: 4070469	US $9	Any oven-safe receptacle that is similar in size to spine model. Can be purchased from local restaurant supply store.
Extra oven-safe container				
	"1/2 Size 6" Deep Steam Table Pan"	Webstaurantstore.com (item number: 4070269)	US $11	Used to melt bigger volume of gel.
Gel dye				
	"Tone dye"	Humimic Medical [17]	US $35	Used to opacify gel; comes in a variety of skin tone colors.

[a]Amazon Standard Identification Number.

[b]Stock keeping unit.

Cost

The cost for our preferred spine model is approximately US $161, but a more cost-effective version with fewer vertebrae can be purchased for US $34. The more expensive model is preferred due to the ease of placement in the mold, image quality on ultrasound scans, and representation of more neuraxial structures (spinal nerves and ligamentum flavum). Newer 3D printing technology allows for the printing of customizable and cost-effective pediatric spine models that could alternatively be used in our phantom. Ballistics gel priced at US $76 allows for the production of 4 or more phantoms. The additional items previously mentioned can amount to a cost between US $139 and US $150.

Results

There are 6 views that are critical to performing USGA neuraxial procedures; each is easily obtained from the ultrasound phantom:

- Parasagittal views (Figure 2): transverse process ("trident" sign), articular process ("camel hump" sign), and oblique interlaminar ("horse head" or "sawtooth" sign) views
- Transverse midline views (Figure 3): spinous process, interspinous process/interlaminar ("bat" or "flying bat" sign), and sacral cornua ("frog" or "frog eye" sign) views

Figure 2. Parasagittal images from phantom (**A, B, and C**), with probe placement relevant to bony anatomy and ultrasound indicator oriented cephalad, and patient (**D**), with ultrasound indicator oriented caudad. (A): Parasagittal TP view ("trident" sign). (B): Parasagittal AP view ("camel hump" sign; dashed blue line shows "camel hump" outline). (C): Parasagittal oblique interlaminar view ("horse head" or "sawtooth" sign; blue line shows "horse head" outline) in phantom. (D): Parasagittal oblique interlaminar view in patient. AC: anterior complex (interface of anterior dura and vertebral body); AP: articular process; ESM: erector spinae muscle; L: lamina; LF: ligamentum flavum; PC: posterior complex (interface of ligamentum flavum and posterior dura); TP: transverse process.

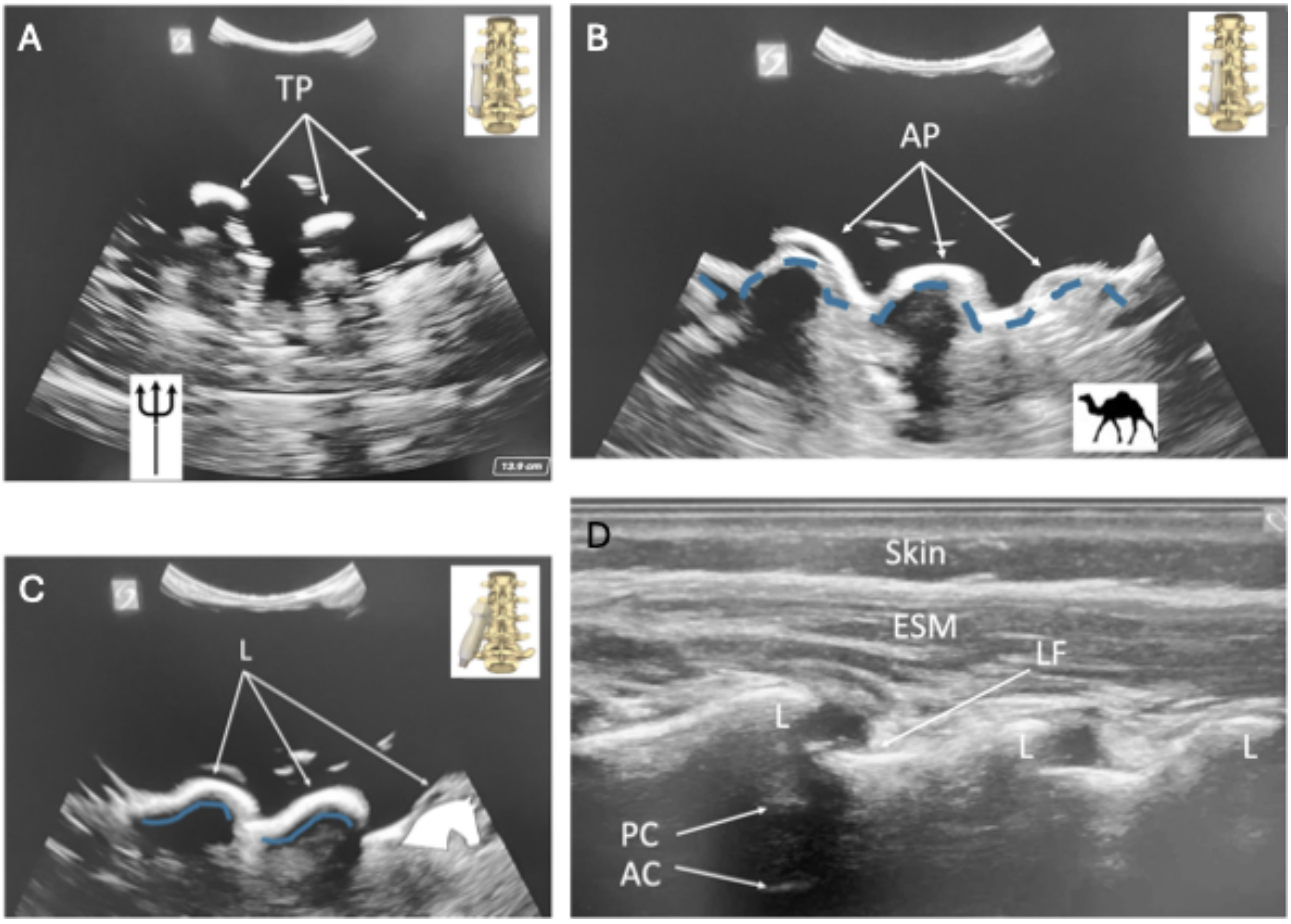


Figure 3. Transverse images from phantom (**A, B, and D**), with probe placement relevant to bony anatomy, and patient (**C and E**); ultrasound probe indicator is oriented left in all images. (A): Transverse midline SP view from phantom. (B): Transverse interspinous (interlaminar) view ("bat" or "bat wing" sign; dotted line shows "bat wing" outline) from phantom. (C) Transverse interspinous (interlaminar) view from patient. (D): Transverse SC view ("frog" or "frog eye" sign) from phantom. (E): Transverse SC view from patient. AP: articular process; ITS: intrathecal space; L: lamina; LF: ligamentum flavum; LF+D: ligamentum flavum+dura (ie, posterior complex); PD: posterior dura; S: sacrum; SC: sacral cornua; SCL: sacrococcygeal ligament; SH: sacral hiatus; SP: spinous process; TP: transverse process; VB: vertebral body.

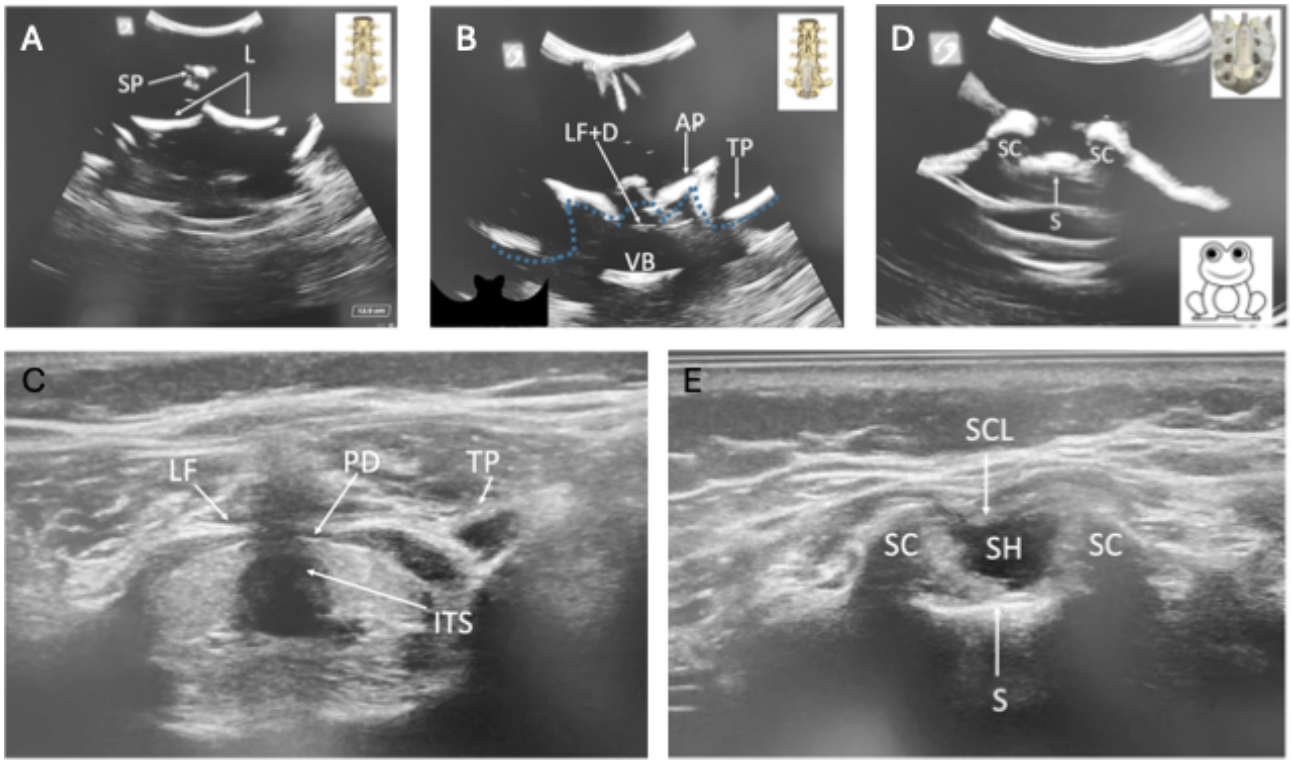

Each of these views is demonstrated in Figures 2 and 3, with an additional image of the ultrasound probe placement in relation to the bony landmarks of the lumbosacral spine and patient sonoanatomy, where available. Several spine images from a 6-month-old male infant (written consent obtained from parent) are shown (Figures 2D, 3C, and 3E) beside the phantom images for comparison. Because the spine model lacks certain elements, not all structures appear on the phantom scan, and some cannot be obtained.

Phantom images were evaluated for likeness and accuracy via comparison to actual patient images by 10 practicing attending anesthesiologists. Each image was graded on a 5-point Likert scale for how similar it appeared to the actual patient image. All 10 respondents agreed or strongly agreed that the transverse sacral cornua view ("frog" sign) and parasagittal oblique interlaminar view ("horse head" sign) were similar to those of real patients. Of the 10 respondents, 8 agreed or strongly agreed that the transverse interspinous view ("bat wing" sign) was similar between the phantom and real patient images, 1 respondent was neutral, and 1 respondent somewhat disagreed.

Discussion

Unlike previous phantoms described by Morrow et al [16], Mashari et al [14], and others, our spine phantom generates ultrasound images and views that closely replicate the sonoanatomy of a pediatric patient (Figures 2D, 3C, and 3E). A key advancement in our design is the incorporation of the sacrum and sacral hiatus—critical structures needed for visualizing the caudal space, which is a technique that is often used in accessing the neuraxis in pediatric patients. Furthermore, by fully submersing the spine model in ballistics gel, our phantom offers superior stability during scanning and allows for repositioning to simulate sitting, lateral, and prone patient orientations. The enhanced design ensures a more realistic training experience, thereby helping practitioners develop the precise skills necessary for pediatric neuraxial techniques.

Practicing pediatric anesthesiologists overall found our phantom's ultrasound images comparable to ultrasound images of real pediatric anatomy, particularly for the transverse sacral cornua ("frog" sign) and parasagittal oblique interlaminar ("horse head" sign) views. However, while responses for the transverse interspinous (interlaminar) view ("bat wing" sign) were generally positive, some noted minor discrepancies between the phantom images and those of real patients. Given that the phantom lacked several ligaments and the spinal canal seen in real patients, this feedback provides an opportunity for improvement in future phantom models, which could be addressed by the techniques described by Morrow et al [16] (spinal canal) and Mashari et al [14] (ligaments).

Ultrasound has been used to identify anatomical landmarks for epidural or spinal neuraxial procedures and to identify placement of catheters that are inserted in the caudal space and threaded to the lumbar or thoracic space in pediatric patients [5,6,9-12]. The creation of ultrasound phantoms, as described in this paper, can increase access to ultrasound simulation and enhance opportunities for learning critical procedural skills in a

low-stakes environment [1-4,14,16]. To meet these needs, we created a phantom that is indefinitely shelf stable, reproducible, and cost-effective (approximately US $92 to US $219 per phantom, including the materials listed plus the reusable materials). By modifying the previous technique described by Morrow et al [16], our phantom was specifically designed to image the sacral cornua and to easily scan in the prone or lateral positions, which are essential features for training anesthesia clinicians in pediatric neuraxial sonoanatomy.

The use of spine phantoms was previously limited by their costs; however, budget-friendly spine phantoms created with readily available materials produce a realistic feel when palpating for anatomic landmarks [14] and generate many of the views required to perform neuraxial USGA procedures [14,16]. These phantoms also replicate sonoanatomy with high fidelity, as demonstrated by Mashari et al [14], who actually found that their low-cost model resulted in superior fidelity for ultrasound imaging when compared to an expensive, commercially available task trainer.

There are some limitations to the phantom described herein, of which many can be attributed to the absence of more complex anatomical structures. Although some views and sonoanatomy cannot be identified without these structures, easy solutions are available if needed. For example, our model has a fused sacrum, as is common in adults; therefore, scanning of the sacrum in the sagittal plane—a useful technique for performing in-plane USGA caudal epidural blocks in infants and children—is futile. This problem can be relieved by obtaining an anatomically correct spine model that is reflective of infants or young children, either through purchase or through 3D printing [14,18]. Models of pediatric spines with both normal anatomy and abnormal anatomy could be made via 3D printing, enhancing the pediatric-specific simulation experience; however, access can be limited and may be costly when considering the initial monetary investment in a 3D printer.

The phantom described also lacks contents of the spinal canal, rendering it inadequate for simulating access to the intrathecal space for spinal blockade. Inserting fluid-filled tubing into the empty spinal canal (a technique described by Morrow et al [16]) prior to pouring melted gel on the model could provide a potential solution. However, while this added feature can present itself as another useful learning tool, we found that needling the phantom degrades the image quality over time and should be considered when deciding whether to include a spinal canal in future models. Other potential options for making a more complete model include adding a ligamentum flavum by using silicone paste [14]. This technique may be useful for creating a sacrococcygeal ligament, which is an important landmark when performing USGA caudal blocks while using the transverse sacral cornua view (“frog” sign).

Of further note, we chose to use clear ballistics gel for our phantoms, since it allows for the direct visualization of spine model structures, which can be very helpful for early learners but is not realistic or comparable to scanning live patients. Products used to opacify the gel can be purchased on the internet (Table 1) if a more realistic option is desired.

Future directions for the use of our spine phantom model center on teaching critical skills and assessing knowledge of and comfort with high-stakes procedures in novice trainees. Further evaluation of our phantom should focus on the effectiveness of the phantom as a teaching tool.

By constructing a reproducible, affordable, and shelf-stable spine phantom that can be scanned to generate images and sonoanatomy of the infant and child neuraxis, trainees can be provided with a low-stakes environment in which they can learn how to perform high-stakes regional anesthesia blocks. By addressing the limitations of previous models, our phantom provides an affordable, high-fidelity tool that enhances access to realistic neuraxial ultrasound training for pediatric trainees.

Acknowledgments

Funding for the materials used to create the phantoms was provided by the University of Colorado Department of Anesthesiology. The funder was not involved in the study design; in the collection, analysis, and interpretation of the data; in the writing of the report; or in the decision to submit the paper for publication.

Abstract

Background: Medical education can be challenging for students as they must manage vast amounts of complex information. Traditional mnemonic resources often follow a standardized approach, which may not accommodate diverse learning styles.

Objective: This tutorial presents a student-developed approach to creating personalized multimodal mnemonics (PMMs) using artifical intelligence tools.

Methods: This tutorial demonstrates a structured implementation process using ChatGPT (GPT-4 model) for text mnemonic generation and DALL-E 3 for visual mnemonic creation. We detail the prompt engineering framework, including zero-shot, few-shot, and chain-of-thought prompting techniques. The process involves (1) template development, (2) refinement, (3) personalization, (4) mnemonic specification, and (5) quality control. The implementation time typically ranges from 2 to 5 minutes per concept, with 1 to 3 iterations needed for optimal results.

Results: Through systematic testing across 6 medical concepts, the implementation process achieved an initial success rate of 85%, improving to 95% after refinement. Key challenges included maintaining medical accuracy (addressed through specific terminology in prompts), ensuring visual clarity (improved through anatomical detail specifications), and achieving integration of text and visuals (resolved through structured review protocols). This tutorial provides practical templates, troubleshooting strategies, and quality control measures to address common implementation challenges.

Conclusions: This tutorial offers medical students a practical framework for creating personalized learning tools using artificial intelligence. By following the detailed prompt engineering process and quality control measures, students can efficiently generate customized mnemonics while avoiding common pitfalls. The approach emphasizes human oversight and iterative refinement to ensure medical accuracy and educational value. The elimination of the need for developing separate databases of mnemonics streamlines the learning process.

Introduction

Problem Statement

Medical education presents students with the challenge of managing vast amounts of complex information. Mnemonics, memory techniques using associations and patterns, have demonstrated efficacy in improving the encoding and retrieval of medical knowledge [1]. These aids enhance learning and recall by transforming information into more memorable formats through elaborative encoding, retrieval cues, and imagery [2]. However, traditional standardized approaches often fail to accommodate diverse learning preferences, necessitating flexible applications that cater to individual needs.

Theoretical Framework

Paivio's dual-coding theory provides the theoretical foundation for this tutorial, supporting the integration of multimodal tools in education. By encoding both verbal and visual information through separate but interconnected pathways, students' understanding of academic vocabulary can be enhanced [3]. This theory underpins the potential effectiveness of multimodal mnemonics in medical education, particularly when combined

with personalization. Research indicates that personalized mnemonic techniques yield superior recall performance compared to standard strategies, with students using self-generated mnemonics demonstrating better performance on recall tasks [4,5].

Current State of Artificial Intelligence in Medical Education

Recent advances in generative artificial intelligence (AI) technologies have created new opportunities for personalized learning aid creation [6]. AI tools such as ChatGPT and DALL-E have demonstrated proficiency in generating creative and personalized content [7]. ChatGPT, a large language model, uses natural language processing to understand context and generate human-like text responses [8]. It can create diverse textual outputs, including various types of mnemonics. DALL-E, on the other hand, is an AI model designed to generate images from textual descriptions [9]. However, most AI applications in medical education currently focus on data analysis and pattern recognition rather than creative content generation for learning support [10].

Tutorial Aims and Target Audience

This tutorial aims to provide medical students with practical guidance for creating personalized multimodal mnemonics (PMMs) using AI tools. Through a systematic approach, we detail the step-by-step process of generating text and visual mnemonics using ChatGPT and DALL-E, incorporating templates and examples for effective prompt engineering. The tutorial shares strategies for personalizing mnemonics based on individual learning preferences while addressing common challenges and their solutions in AI-assisted mnemonic creation.

The primary audience includes medical students seeking to enhance their learning through personalized AI-assisted mnemonics. Secondary audiences include medical educators interested in implementing these tools in their teaching practice and students in other health care fields who can adapt these methods to their specific needs. By following this tutorial, readers will learn to create personalized learning aids that combine text and visual elements, potentially improving their ability to retain and recall complex medical information. The approach emphasizes practical implementation while maintaining academic rigor, making it accessible to both novice and experienced users of AI tools in educational settings.

Methods

PMMs: Tool Selection and Rationale

This tutorial uses ChatGPT and DALL-E 3 as the primary AI tools for creating PMMs. ChatGPT (GPT-4 model) was selected for text mnemonic generation due to its advanced natural language processing capabilities and ability to generate diverse textual outputs [11]. DALL-E 3 was chosen for visual mnemonic creation based on its proficiency in generating detailed, concept-relevant images from textual descriptions [12]. These tools were selected for their complementary strengths in producing textual and visual content, respectively, allowing for the creation of comprehensive, multimodal mnemonics. Both tools are accessible through OpenAI's platform, with ChatGPT available through both free and paid subscriptions, and DALL-E 3 using a credit-based system.

Configuration Settings and Access

For optimal results in medical mnemonic generation, we recommend using ChatGPT's GPT-4 model with a temperature setting of 0.7, which provides an effective balance between creativity and accuracy in medical content generation. For DALL-E 3, the high-quality setting ensures maximum detail and clarity in visual representations. While both tools offer free tiers, a professional subscription is recommended for consistent access to the latest model versions and enhanced capabilities.

Prompt Engineering Framework and Quality Assessment

The implementation of PMMs requires a systematic approach to prompt engineering and quality assessment. The process begins with zero-shot learning, where we provide clear instructions without examples, allowing the AI to generate mnemonics based purely on prompt structure. When initial results require refinement, we implement few-shot learning by providing 1 to 2 successful examples to guide the AI. For complex medical concepts, we use chain-of-thought prompting to break down the mnemonic creation process into logical steps.

Zero-shot prompting (providing direct instructions without examples) allows the AI to generate outputs based on its pretrained knowledge [13]. For example, a simple prompt like "Create a memorable mnemonic for the Krebs cycle intermediates" tests the AI's baseline capabilities without additional guidance.

Few-shot prompting (including 1 to 2 successful examples before the target prompt) helps guide the AI by demonstrating desired outputs [13,14]. For example, showing a successful biochemical pathway mnemonic before requesting one for the Krebs cycle improves output quality by providing clear examples of the expected format and style.

Chain-of-thought prompting breaks complex tasks into logical steps, improving accuracy through structured reasoning [15]. For example, "First, list intermediates. Then, identify key features. Finally, create a mnemonic." This systematic approach helps ensure comprehensive and accurate outputs, particularly for complex medical concepts.

The implementation followed a five-stage iterative process: (1) template development, in which adaptable prompt templates for text and visual mnemonics are created; (2) refinement, which optimizes prompts through testing of various structures and keywords; (3) personalization, which integrates learning preferences and personal associations and adds options for imagery, humor, and clinical relevance [16]; (4) mnemonic specification, in which prompts for various mnemonic types (acronyms, phrases, rhymes) are created, with corresponding visual representations; and (5), quality control, which is based on peer-to-peer review discussions.

The mnemonics generated through this process were evaluated in peer-to-peer discussions among student authors, facilitated and guided by mentors. This iterative feedback process, integral to quality control, not only ensured medical accuracy and

educational value by leveraging student insights and expert guidance, but also trained students to critically assess the quality, accuracy, and effectiveness of AI-generated content. Identified inaccuracies or areas for improvement directly informed subsequent prompt adjustments.

The medical concepts used in this study were carefully selected from ongoing medical courses, ensuring immediate relevance to current learning needs. This selection process focused on identifying complex topics that students found challenging to memorize while ensuring diverse representation of medical subjects and validation against standard medical resources.

For text mnemonic generation, we developed a basic template structure that incorporates medical accuracy, memorability, and personalization elements: "Create a memorable [mnemonic type] for [medical concept]. Focus on [key aspects]. Make it [characteristics: funny/clinical/etc]. Include [specific elements] that relate to [learning context]."

For visual mnemonic creation, the template emphasizes clarity and medical accuracy: "Generate a [style] image depicting [mnemonic content] for [medical concept]. Emphasize [key visual elements]. Ensure medical accuracy and clarity." These templates serve as starting points and can be customized based on individual learning preferences and specific medical concepts.

Common Challenges and Solutions

Through our implementation process, we identified several common challenges. Inaccurate medical terminology can be addressed by including specific medical terms in prompts. Unclear visual representations are improved by specifying anatomical or clinical details. When mnemonics become overly complex, requesting step-by-step breakdowns helps maintain clarity and usability. These solutions emerged from practical experience and continue to evolve as we refine the process.

Ethical Considerations

This educational methodology development did not require formal ethical review as it did not involve human subjects research, collected no personal data, and used only publicly available AI tools as part of regular educational activities.

Results

The implementation of PMMs using AI tools demonstrated both potential and limitations across a range of medical concepts. Through systematic testing and refinement, we identified key performance metrics, quality assessment outcomes, and practical implementation challenges.

Generation Performance

The PMM generation process exhibited consistent performance characteristics. Text mnemonic generation via ChatGPT consistently required 2 to 3 minutes per concept. Generating corresponding visual mnemonics with DALL-E 3 required 3 to 5 minutes per concept. Reaching a satisfactory mnemonic typically involved 1 to 3 iterative attempts. The initial success rate, defined as achieving acceptable output on the first attempt, was 85%. After applying quality control and refinement procedures, this success rate increased to 95%. These data suggest that generating PMMs is feasible within a reasonable timeframe, particularly when incorporating iterative refinement.

Quality Assessment and Examples

Table 1 presents 6 examples of AI-generated PMMs, illustrating the range of mnemonic types generated and highlighting observed successes and areas for improvement. The table includes the target medical concept, the text mnemonic generated by ChatGPT, the visual prompt provided to DALL-E 3, the resulting visual mnemonic, and specific limitations encountered.

Through systematic documentation of the implementation process, we observed that achieving satisfactory results typically required 1 to 3 iterations per concept. Initial attempts often needed refinement in areas such as the precision of medical terminology, visual clarity, or text-image alignment. The examples in Table 1 showcase both successful implementations and instances where refinement was necessary, providing practical insights for users of this tutorial.

The development of a mnemonic for bacterial cell wall antibiotics serves as a representative example. The initial AI-generated mnemonic incorrectly used the term "harbipenems" instead of "carbapenems." This error, corrected in subsequent iterations, demonstrates the need for human validation, specifically by the medical student or a medical professional. Other examples in Table 1 illustrate the variety of generated mnemonic types, including acronyms, rhymes, and short phrases, paired with their visual counterparts. While generally effective, some visual mnemonics presented challenges in terms of clarity, anatomical accuracy, and alignment with the corresponding text mnemonic.

Table . Artifical intelligence (AI)–generated personalized multimodal mnemonics.

Medical concept	Prompts used and results	Text mnemonic	Visual and text mnemonic	Observations and limitations
Antibiotics targeting cell wall	First prompt: "Make a mnemonic for antibiotics that target the cell wall, you can group the antibiotics by their mechanism and make it memorable." Second prompt: "Using the mnemonic, make a memorable photo." Result: photo was not memorable. Third prompt: "Retry this time make a funny mnemonic." Result: the cat image.	Mnemonic: "very big purple cats bake happy eggs." • V: vancomycin • B: beta-lactams • P: penicillins • C: cephalosporins • B: bacitracin • H: harbapenems		Creative and memorable representation, but incorrect text
Types of leukocytes	Prompt: "Develop a mnemonic to remember the different types of leukocytes. Also, create a funny and cartoonish visual that represents this mnemonic in a memorable way. The illustration should effectively depict the mnemonic."	Mnemonic (for leukocytes): "never let monkeys eat bananas." • N: neutrophils • L: lymphocytes • M: monocytes • E: eosinophils • B: basophils		Engaging visualization, but incorrect text
Life cycle of malaria	Prompt: "Create a mnemonic to help remember the malaria life cycle, and design a humorous, cartoon-style visual to represent it in a memorable way. The illustration should clearly depict the mnemonic for easy recall."	Mnemonic (each word stands for a stage of the malaria parasite's life cycle): "salty mice bite liver, chilling red blood cells." • S: sporozoites (transmitted via mosquito bite) • M: migrate to the liver • B: burst out of the liver as merozoites • L: liver stages • C: chills and fevers (as the parasites enter red blood cells) • Red blood cells: parasites invade and replicate in red blood cells		The AI was occasionally unable to fully adhere to detailed prompts in image generation. Additionally, the text included in the image was incorrect.
Renin-angiotensin-aldosterone system (RAAS)	First prompt used: "Generate a funny mnemonic for Renin-Angiotensin-Aldosterone System (RAAS) but make it simple and easy to remember." Second prompt: "Create simple and memorable image of this mnemonic 'Keen Elephants Always Raise Blood.' Use less texts, clear and correct spelling. Place the mnemonic as a title."	Mnemonic: "keen elephants always raise blood." • K: kidneys release renin when blood pressure or sodium levels are low. • E: enzyme (renin) converts angiotensinogen to angiotensin I. • A: ACE (angiotensin-converting enzyme) converts angiotensin I to angiotensin II. • R: raises blood pressure by vasoconstriction (angiotensin II constricts blood vessels). • B: blood volume increases as aldosterone causes sodium and water retention.		This mnemonic emphasizes the kidney's keen response to blood pressure regulation. Text is not clear.

Medical concept	Prompts used and results	Text mnemonic	Visual and text mnemonic	Observations and limitations
Non-selective COX inhibitors	Prompt used: Make a funny memorable picture mnemonic for me to remember the *Non-Selective COX Inhibitors*. They include: Salicylates: Aspirin; Pyrazalone derivatives; Propionic acid derivatives: Ibuprofen, Naproxen; Indole Derivatives: Indomethacin; Anthranilic acid derivative; Aryl acetic acid derivative: Diclofenac; Oxicam derivative; Pyrrole derivatives."	Mnemonic: "a perfect brew is delightfully aromatic, outstandingly pleasant." • A: aspirin • P: pyrazalone derivatives • B: ibuprofen • I: indole derivatives • D: diclofenac • A: anthranilic acid derivative • O: oxicam derivative • P: pyrrole derivatives		The coffee-themed elements like cups, beans, and mugs may be too abstract and unrelated to the actual topic. The picture lacks clarity and is not memorable.
Naeglaria fowleri	First prompt used: "Make an image to remember naeglaria fowleri, brain eating heat loving free living with a mneumonic for its major facts." Second prompt: "Make it funny: >" Response: "I couldn't generate the image because the content did not align with the guidelines for image creation. If you'd like, we can adjust the concept or explore a different approach. Let me know how you'd like to proceed!" Prompt: "Try again" Response: "The guidelines for image creation restrict certain content related to how medical or potentially dangerous organisms are portrayed, especially if humor or exaggerated characteristics could be seen as trivializing the topic. Creating a funny depiction of a 'brain-eating' amoeba might fall under those restrictions."	—[a]		The AI refused to generate the content, highlighting challenges in discerning educational needs from potentially inappropriate content, emphasizing the need for human oversight and refinement.

[a]Not applicable.

Generic Templates for Prompt Engineering

For text mnemonic generation (with ChatGPT), the following generic prompt template was developed: "Create a memorable sentence mnemonic for [medical concept]. The mnemonic should be [characteristic 1: funny/simple/easy to remember] and [characteristic 2: relevant to clinical practice/focused on key steps/highlight main components]. Each word or part of the sentence should represent a key aspect of the concept. If possible, incorporate [optional element: wordplay/alliteration/vivid imagery]. Make it relatable to [personal preference: a specific scenario/everyday objects/animals]."

For creation of the visual mnemonic (with DALL-E 3), the following generic prompt template was used: "Generate a [style: cartoon/funny/medical illustration] depicting the mnemonic '[text mnemonic]' for [medical concept]. The image should be [characteristic 1: visually engaging/humorous/clear] and [characteristic 2: memorable/related to the mnemonic words]. Incorporate [specific visual elements: anthropomorphized objects/exaggerated features/relevant symbols]. Ensure any text is minimal, clear, and correctly spelled. Place the mnemonic sentence as a title."

These templates were iteratively refined based on the quality and relevance of the AI-generated outputs. Examples of specific prompts based on these templates are in Table 1. These templates and examples provide a framework for creating diverse and engaging sentence mnemonics while allowing for customization based on the specific medical concept and desired learning outcomes.

Implementation Challenges and Refinement Strategies

Three key challenges emerged during implementation, leading to the development of targeted refinement strategies. The first

challenge was medical accuracy. Maintaining medical accuracy necessitated continuous verification against established medical resources. Initial outputs occasionally exhibited terminology errors or incomplete conceptual coverage. These issues were addressed by incorporating specific medical terminology in the prompts and implementing a systematic review process involving medical experts.

Second, achieving consistent visual clarity and anatomical accuracy in the AI-generated images presented challenges. Some images lacked clarity or contained inconsistencies between textual and visual elements. We improved visual quality through prompt refinement, including more precise anatomical descriptions and requests for simplified representations of complex concepts.

The third challenge was in content integration. Ensuring seamless integration between the text mnemonic and visual representation required careful prompt design and quality control. A structured review process was implemented to verify that both components effectively reinforced the target medical concept and functioned synergistically to enhance learning.

These findings offer practical observations for educators considering the use of AI-assisted mnemonic generation. While the PMM approach holds promise for personalized learning, our results underscore the essential role of human oversight, domain expertise, and iterative refinement in ensuring accuracy, clarity, and educational value.

Discussion

Principal Findings and Implications

This tutorial demonstrates a practical approach to generating PMMs using readily available AI tools. Our findings highlight the feasibility of creating customized mnemonics within a reasonable timeframe (2-5 minutes per concept, with 1-3 iterative attempts). The combination of text and visual elements aligns with dual-coding theory [3,17], potentially enhancing learning and recall. However, challenges related to medical accuracy, visual clarity, and content integration underscore the crucial role of human oversight and domain expertise. The “harbipenems” error, for example, emphasizes the need for medical professionals to validate AI-generated content. These findings suggest that AI-assisted PMM generation can be a valuable tool for personalized learning, but careful attention to quality control and prompt refinement is essential.

Comparison to the Literature

This tutorial’s approach aligns with the growing interest in applying AI for personalized learning in medical education. While much of the current research focuses on AI for tasks like data analysis [10,18], this tutorial explores the relatively novel application of AI for generating personalized learning content. Our emphasis on multimodal learning resonates with the principles of dual-coding theory [3], which suggests that combining visual and textual representations can enhance learning and memory. Furthermore, the challenges we encountered regarding accuracy and clarity in AI-generated content echo broader concerns in the literature about the need for human oversight in AI-driven educational applications [8,19].

Strengths and Limitations

This tutorial provides a practical, step-by-step guide for generating PMMs using AI, offering readily adaptable prompt templates and illustrative examples. The student-centered perspective offers valuable insights into the practical challenges and potential benefits of this approach.

This tutorial has several limitations. First, the AI models used may exhibit biases, potentially limiting the diversity and novelty of generated PMMs. Second, inaccuracies in visual representations, such as misspellings or mismatches with the text mnemonic, require careful review and correction. Third, current AI models may refuse to generate content for sensitive medical topics, necessitating alternative strategies or manual content creation. Finally, the lack of a formal evaluation with medical students limits the generalizability of our findings and prevents definitive conclusions about the effectiveness of PMMs on learning outcomes.

Future Directions

Future research should investigate the effectiveness of PMMs on learning outcomes through controlled studies comparing PMMs to traditional learning methods. Such studies should use objective measures of learning, such as recall accuracy, learning efficiency, and student satisfaction. Further research should also explore the long-term impact of PMMs on knowledge retention and application. The scalability and adaptability of the PMM approach across diverse medical subjects and educational settings warrant investigation. Additionally, future work should address the ethical considerations surrounding AI-generated educational content, including data privacy, bias, and overreliance on technology [8]. Developing guidelines for the ethical and effective use of AI in mnemonic creation and medical education more broadly will be crucial as this field evolves [19].

Conclusion

This tutorial presents a practical approach to generating PMMs for medical education using the AI tools ChatGPT and DALL-E 3. This approach emphasizes AI as a tool to enhance, rather than replace, traditional learning methods. Originating from medical students seeking to improve their own learning, this tutorial describes a step-by-step process involving prompt engineering, iterative refinement, and quality assessment, illustrated with examples for 6 medical concepts. The personalized nature of the mnemonics, coupled with the multimodal approach, demonstrates potential for enhancing student engagement and facilitating the retention of complex medical concepts. We also highlight key challenges related to medical accuracy, visual clarity, and content integration, underscoring the importance of human oversight and domain expertise in refining AI-generated content. This student-led exploration offers practical guidance and a valuable starting point for educators and students alike interested in leveraging AI for personalized learning in medical education.

Abstract

Faculty development is a cornerstone of academic medicine, supporting personal growth, professional advancement, and departmental effectiveness across all stages of a faculty member's career. Among the tools available, faculty retreats have increasingly emerged as a high-impact strategy to foster collaboration, advance strategic planning, and address individual and collective goals in a structured, reflective setting. While retreats are widely used in other sectors, practical guidance tailored to the academic medicine context remains limited. This tutorial offers a comprehensive, step-by-step framework for planning and implementing faculty retreats within academic departments. Key elements of effective retreat design are outlined, including (1) conducting a preretreat needs assessment to align goals with faculty priorities, (2) selecting an appropriate format (eg, in-person or hybrid), (3) fostering psychological safety to enhance participation, and (4) using facilitation techniques that promote inclusive dialogue and actionable outcomes. The tutorial also emphasizes logistical considerations, such as agenda design, timing, and participant engagement strategies, alongside mechanisms to ensure follow-up and accountability after the retreat. In addition to highlighting common barriers, such as resource limitations, scheduling constraints, and engagement disparities, the tutorial provides practical solutions drawn from real-world examples in academic medicine. By integrating thoughtful planning, evidence-informed facilitation, and postretreat follow-through, faculty retreats can serve as transformative experiences that support both individual development and departmental cohesion. This resource aims to fill a gap in the literature by equipping leaders in academic medicine with a structured approach to designing, executing, and sustaining the benefits of faculty retreats.

KEYWORDS

faculty development; faculty retreat; academic medicine; organizational leadership; medical education

Introduction and Background

As faculty development in academic medicine has evolved, it now emphasizes career-long growth and attention to both individual and departmental dynamics [1,2]. Faculty retreats have emerged as a valuable tool to enhance performance and institutional effectiveness by bringing faculty together outside routine settings for collaboration, strategic planning, and professional development. Retreats also offer a structured space to address challenges, build consensus, resolve conflicts, and foster collegiality (Textbox 1; [3-12]).

Textbox 1. Benefits of faculty development retreats.

Skill enhancement

Retreats provide dedicated time for faculty to engage in specific professional development activities [4,5].

Improved collaboration and networking

Retreats foster interdisciplinary collaboration and networking among faculty, leading to new research partnerships, coteaching opportunities, and the sharing of best practices [5,6].

Reflection and constructive feedback

Faculty retreats can offer time for reflection on teaching, research, and administrative responsibilities. Structured feedback from peers during retreats helps faculty identify areas for improvement and develop actionable plans to enhance their performance [7].

Burnout prevention and well-being

Retreats provide a break from the daily pressures of academic and clinical life, allowing faculty to focus on self-care and stress management. This can lead to improved well-being, reduced burnout, and increased job satisfaction, which positively affect performance [8].

Strengthened culture and community

There is a strong correlation between team building and company or department culture. The mutual collaboration that happens over the course of team-building exercises fosters a sense of community. This, in turn, helps department culture to develop and evolve smoothly and in a way that is true to the departmental vision [9].

Innovation and development

Faculty retreats often serve as spaces for brainstorming and developing innovative teaching strategies, curricular changes, new research, or quality improvement ideas [10].

While retreats have long been common in the business world, their broader use in academic medicine is more recent [13]. However, practical guidance for planning and implementing faculty retreats remains limited and fragmented. This tutorial offers a comprehensive overview of the purpose, value, and implementation of faculty retreats within academic departments, highlighting current trends and best practices.

Solution

Faculty Retreat Implementation Strategies

Preretreat Preparation: Needs Assessment

Conducting a needs assessment prior to the faculty retreat ensures that the most pressing issues are addressed, the goals of the intended group are aligned, and the participants are engaged effectively [14]. It is important to communicate the objectives of the needs assessment to the faculty prior to response solicitation by clarifying the purpose. It should be explained clearly that the data are intended to be used to direct faculty development objectives, including retreat planning. The needs assessment should gather information to achieve these goals. Further, the scope of the needs assessment should be carefully considered, whether it will focus on individual faculty members, a whole department, or the institution as a whole. This helps target the assessment appropriately.

It is important to ensure all faculty members who will be the intended participants of the retreat have an opportunity to contribute to the needs assessment. This increases buy-in and ensures the retreat meets their expectations. If the retreat involves interdisciplinary work or collaborations with external partners, gather input from relevant stakeholders to understand their expectations and needs as well. Finally, the needs assessment participants may constitute a larger group than those subsequently engaged in a future retreat, as the data may be used more broadly for additional faculty development efforts.

Consider the use of multiple methods for needs assessment data collection [15]. A combination of qualitative and quantitative methods provides a more robust picture of faculty needs by gathering diverse perspectives. This can include surveys and questionnaires (eg, Google Forms, SurveyMonkey (SurveyMonkey Inc), Qualtrics (Qualtrics International Inc), etc, for easy distribution and analysis). Use a mix of open-ended and multiple-choice questions to cover various areas (Textbox 2). Finally, ensure that survey responses are anonymous or use anonymous identifiers to provide distinction between responders, if needed.

Textbox 2. Example of preretreat needs assessment questions.

- What are the main challenges you face in your teaching or research?
- What are your goals for the upcoming academic year?
- What topics would you like to see covered at the retreat (eg, leadership development, team building, teaching strategies, and research collaboration)?
- How do you feel about the current team dynamics within the department/faculty?
- How can the retreat best support your professional development?
- Ranked Priorities: Ask faculty to rank the importance of potential retreat topics, such as:
- Well-being and self-care/self-compassion
- Mentorship and sponsorship
- Negotiating effectively
- Effective communication
- Strategic planning
- Team building
- Increasing scholarly activity (eg, research productivity)
- Leadership and management
- Promotion and tenure

Needs assessment data collection may also involve interviews or focus groups [16]. One-on-one in-depth interviews with leadership, faculty leaders, and administration can obtain deeper insights into institutional or departmental strategic priorities. This ensures that the retreat is aligned with larger institutional and departmental goals. Ask about specific challenges within departments, faculty development gaps, and potential solutions. Use these interviews to uncover nuanced issues that might not emerge in a survey. Organize small focus groups to encourage open discussion among faculty members. This is particularly useful for gathering collaborative input on broader issues, like curriculum design or faculty culture. Consider having a neutral facilitator to ensure open, honest dialogue.

In addition to solicited participant input, also consider reviewing objective institutional or departmental data. This can include performance data, such as performance metrics, teaching evaluations, faculty publication records, and other key indicators. This data can help identify key areas where faculty need support, such as improving student engagement or increasing research output. Review any existing data from faculty climate surveys or teaching evaluations to identify patterns or concerns that need to be addressed during the retreat. Finally, if available, analyze feedback from previous retreats or faculty development initiatives to identify ongoing or unresolved issues.

Once the needs assessment is obtained, identify key themes and prioritize needs [17]. Organize the feedback into categories, such as personal development needs, leadership skills, work-life balance, mentoring, etc. Before the retreat, share a summary of the needs assessment findings with faculty. This transparency builds trust and helps participants understand how their input has shaped the retreat agenda. Once developed, provide a draft of the retreat agenda, highlighting how it addresses the needs and priorities gathered from the assessment.

Finally, consider the needs assessment timeline. It should be conducted well enough in advance of the anticipated retreat to provide ample time for analysis and planning but not so far ahead of time that the data obtained and reviewed are no longer timely or pertinent. By conducting a thorough needs assessment, the faculty retreat can be tailored to the specific needs of the group, which will increase engagement, relevance, and the overall success of the retreat.

Preretreat Preparation: Setting Retreat Goals and Objectives

A comprehensive consideration of needs assessment data (see above) should identify and prioritize specific objectives. By addressing common areas of interest and import, clear and meaningful goals and objectives can be set to guide the retreat's agenda and outcomes [18]. In addition, early engagement of key participants, including faculty leaders and key stakeholders, will ensure that the retreat's objectives align with the broader mission and vision of the institution or department. Consider that retreat funders may impart influence on a retreat's scope and attempt to align an instructed scope with identified needs assessment priorities to improve the effectiveness of the retreat.

Finally, create SMART (Specific, Measurable, Achievable, Relevant, and Time-bound) goals to provide a clear roadmap for retreat planning and postretreat follow-up [19]. These goals help ensure that retreat objectives are not only aspirational but also operational. For example, instead of a vague aim, such as "foster collaboration," a SMART goal would be: "Improve cross-departmental collaboration by initiating at least three joint research proposals within the next academic year." Using SMART goals helps organizers and participants align around shared expectations and provides a framework for evaluating success. Specific goals target a defined area for improvement; Measurable goals allow for tracking progress; Achievable goals ensure feasibility given available resources; relevant goals align

with broader institutional priorities; and Time-bound goals set a clear deadline. During planning, facilitators should work with stakeholders to codevelop 2-3 SMART goals that reflect the most pressing needs and strategic aims of the department or institution. These goals can then guide session design, inform postretreat evaluation metrics, and promote accountability by linking retreat outcomes to tangible follow-up actions.

Prioritization of objectives will be required if the needs assessment identified several themes or areas of interest. Differentiate between objectives that can be addressed during the retreat versus those that require ongoing effort. Retreat goals can include long-term objectives, but given time constraints, the retreat may only be a start or a contributing component to that objective. Aligning the retreat content with long-term objectives can be effective from a strategic planning perspective. Finally, focus on a manageable number of objectives to avoid overwhelming participants; consider what is feasible in the retreat time allotted.

Preretreat Preparation: Resource Allocation

Determining resource allocation for a faculty retreat involves careful planning to ensure that funds, time, and human resources are used efficiently to meet the retreat's objectives [20]. One of the most important first steps is to set the budget, considering which elements are critical (resources essential to the success of the retreat) versus optional. Review the available budget from the department, institution, or external grants. Be sure to account for all funding sources and restrictions (Textbox 3).

Textbox 3. Potential retreat costs for budget consideration.

Venue costs

Space rental for meetings, workshops, and team activities

Meals and refreshments

Catering for meals, snacks, and coffee breaks

Accommodation (if overnight)

Lodging for multiday retreats

Travel expenses

Transportation costs (eg, shuttles, mileage reimbursement, train, or flight tickets)

Facilitator or speaker fees

Costs for external facilitators, speakers, or consultants

Workshop materials

Supplies for activities (eg, printed materials, flipcharts, and projectors)

Recreational activities

Funding for team-building exercises, social activities, or outings

Miscellaneous

Any additional costs (eg, technology support, insurance, and contingency funds for unexpected expenses)

Plan for contingencies

Buffer for unexpected costs. Set aside a portion (typically 5%-10%) of the overall budget as a contingency fund for unforeseen expenses, such as last-minute speaker fees, additional supplies, or travel delays

In addition to financial costs, consider human resources allocation, including the creation of a retreat organizing committee. Identify staff or faculty members who will be responsible for planning, logistics, and facilitating the retreat. Ensure these roles are clearly defined, including responsibilities for agenda setting, coordinating logistics with the venue and vendors, and managing participant communication. If the retreat requires significant logistical support, allocate part of the budget to administrative staff, event planners, or student assistants to assist with setup, note-taking, or technical support during the event.

Preretreat Preparation: Selecting Participants and Faculty

Selecting participants for a faculty retreat involves careful consideration to ensure that the right mix of individuals is involved, based on the retreat's purpose and goals (see above) [21]. Based on retreat objectives, consider prioritizing a balanced representation. This can involve fostering diversity in experience by engaging faculty across the career spectrum, from early-career to senior members, to enrich perspectives and strike a balance between tradition and innovation. This can also include cultural diversity to ensure background and social diversity to promote inclusive discussions and a wide range of viewpoints. Finally, tailor role-specific involvement to the retreat's focus by including teaching and education faculty for curriculum development, research-active faculty and grant managers for research goals, and both faculty and professional staff for career growth discussions.

When appropriate, encourage voluntary participation. Identify motivated participants by soliciting a call for interest. Send an open call to faculty and allow those with an interest in the retreat's objectives to self-nominate. However, a more selective

invitation process may be required in some cases to ensure that the right people are present, especially for leadership-focused retreats.

Keep the group size manageable, typically between 15 and 25 participants, depending on the format. On some occasions, an even smaller cohort may be preferred, no more than a dozen, to ensure all voices are heard and universal participation is feasible. Smaller groups are more conducive to intimate, productive discussions, while larger groups can handle broader, more diverse topics. For larger retreats, plan for breakout sessions that enable smaller, focused discussions among participants. If relevant, consider inviting external facilitators or industry experts who can offer outside perspectives and guide discussions more effectively. Finally, account for logistical and financial constraints incurred by the number of retreat participants, including travel, budget constraints, and scheduling availability.

Preretreat Preparation: Choosing Location and Setting

Choosing a location for a faculty retreat involves several key considerations to ensure that the setting supports the retreat's goals and fosters collaboration, relaxation, and productivity [22]. For example, if the focus is academic, such as strategic planning, curriculum development, or research collaboration, a location with quiet meeting spaces and minimal distractions might be best. If the focus is team building or bonding, consider locations that offer outdoor activities or team-building opportunities, such as nature resorts or retreat centers. Proximity and accessibility should be considered. Consider a central location within a reasonable distance easily accessible by car, train, or public transport, especially if it is a 1- or 2-day event or if participants are coming from multiple campuses. If it is remote, ensure there are clear directions and transport options with ample parking for faculty members that are driving.

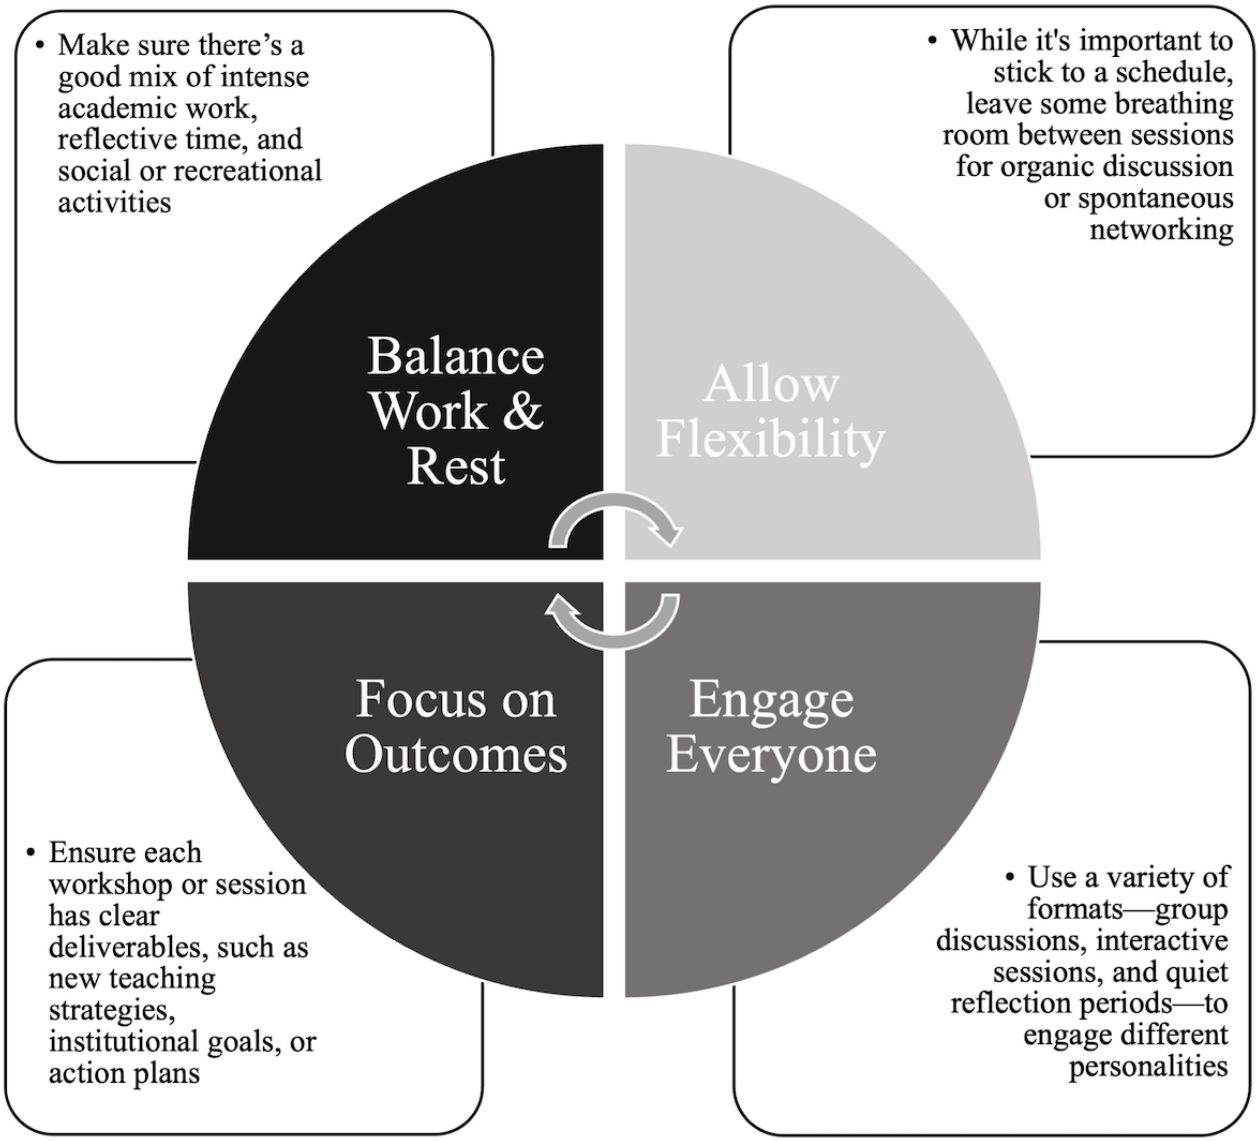
Regarding the actual meeting space and facilities, again consider the size of the group. The venue should have meeting rooms that accommodate the entire group comfortably. Look for spaces with flexible seating arrangements, good acoustics, and appropriate lighting. Also, consider technology needs and ensure that the facility can support presentations or workshops with the necessary audiovisual equipment (eg, projectors, screens, microphones, and Wi-Fi). If smaller group discussions or breakout sessions are planned, look for venues with multiple meeting rooms or areas conducive to group work. If it is a multiday retreat requiring an overnight stay, ensure the location offers comfortable amenities and accommodations for faculty. Confirm dining options available at the facility, including considerations for dietary restrictions. If incorporating relaxation or leisure time, look for venues that offer recreational amenities, such as hiking trails, swimming pools, or wellness facilities. Finally, consider the cost; a venue must fit the budget without compromising on essential needs. Consider that some universities or institutions have partnerships with certain venues or offer discounts for academic groups.

When choosing a location, group dynamics, inclusivity, and environment should also be considered. Consider accessibility for faculty members with mobility issues, and ensure that spaces accommodate various needs (eg, lactation room). If you have a diverse group, make sure the venue respects cultural differences, including dietary needs, religious observances, and inclusive spaces. Make sure the location is available for your preferred dates by planning early as popular retreat centers and venues often book up months in advance. Finally, ambience and environment are important elements to also consider for enhancing faculty engagement and collaboration. Consider seasonal considerations, as outdoor activities might be less enjoyable during rainy or cold seasons, and ensure the venue is prepared for inclement weather. Many faculty retreats benefit from being in scenic or natural settings (eg, mountains, lakesides, or parks) as they promote relaxation and creativity. Some institutions may prefer locations with cultural or academic significance, such as university-affiliated retreat centers, historical sites, or museums.

Preretreat Preparation: Structuring the Agenda and Activities

Before creating the agenda, establish the key objectives (see above). The agenda should be designed explicitly to meet these goals and reflected in any workshops, seminars, or team-building exercises (Figure 1; [23,24]). Allowing the identified key objectives to guide and define retreat content creates a clear path for a more meaningful faculty experience. While noncomprehensive, a list of potential retreat content has been provided in Textbox 4 along with an example retreat agenda (one and a half-day; Table 1).

Figure 1. Key agenda design tips.



Textbox 4. Agenda content ideas.

Professional development workshops

- Effective mentorship across career stages: Techniques for becoming or finding a mentor; case-based discussions.
- Navigating promotion and tenure: Department-specific guidance on academic advancement pathways.
- Time management for academic clinicians: Focused strategies on balancing clinical, teaching, and research responsibilities.
- Grant writing and funding strategies: Tips for National Institutes of Health/Health Resources and Services Administration (NIH/HRSA) submissions, developing specific aims, or finding pilot funds.
- Leadership skills for faculty: Training on conflict resolution, delegation, and leading teams.
- Work-life integration and wellness in academic medicine: Interactive session focused on reducing burnout and enhancing resilience.

Culture-focused sessions

- Implicit bias in clinical and academic settings: Facilitated discussion with activities for self-reflection and behavioral change.
- Building an inclusive department culture: Group exercises around shared values, microaggressions, and allyship.
- Health equity in research and education: Incorporating equity principles in curriculum, research, or patient care.

Strategic planning and innovation

- SWOT (strengths, weaknesses, opportunities, and threats) analysis breakout groups: Analyze departmental strengths, weaknesses, opportunities, and threats.
- Visioning and goal-setting workshops: Define shared goals for the next 1 - 3 years using techniques like appreciative inquiry.
- Innovation challenge or hackathon: Small groups generate and pitch new ideas (eg, curriculum and QI; quality improvement projects).
- Artificial intelligence (AI) in academic medicine (opportunities and risks): A future-facing panel or demo of tools for teaching, research, or clinical decision-making.

Team-building activities

- “Mission Possible” challenge: Groups solve department-relevant scenarios collaboratively (eg, resource allocation or onboarding plans).
- Human bingo or speed networking: Fast-paced way to connect across faculty and discover shared interests.
- Story circles or narrative medicine exercise: Faculty share brief, structured stories on meaningful clinical or academic experiences.
- Escape room or puzzle challenge (in person or virtual): Promotes collaboration and informal interaction.
- Personality type-based communication exercise (eg, MBTI; Myers-Briggs Type Indicator, StrengthsFinder, and DISC; Dominance, Influence, Steadiness, and Conscientiousness) to explore working styles and improve collaboration.

Webinars or prerecorded content

- “Academic Medicine in 2030 and Beyond” (invited guest speaker): Shown at the retreat or asynchronously, followed by discussion groups.
- NIH/funding agency updates: Presented by the internal grants office or invited program officers.
- Faculty wellness microlearning modules: Paired with breakout reflections or personal wellness planning.

Reflection and closure activities

- Commitment cards: Participants write one commitment they will take forward, which is collected and mailed to them months later.
- Gallery walk: Groups post ideas/goals on flip charts around the room and rotate to add or comment.
- Shared success board: Space to acknowledge team wins and individual accomplishments over the past year.

Table . Example retreat agenda (one and a half days).

Day, theme, and time	Session	Description
Day 1: faculty retreat (full day); theme: Advancing Together: Strategy, Scholarship, and Community		
8-8:30 AM	Arrival and Breakfast	• Light breakfast and coffee • Informal networking
8:30-9 AM	Welcome and Overview	• Opening remarks by the Chair or Vice Chair • Goals for the retreat
9-10:15 AM	Strategic Visioning Workshop	• Facilitated SWOT[a] analysis and goal-setting exercise in breakout groups
10:15-10:30 AM	Break	—[b]
10:30 AM-12 PM	Faculty Development Breakouts	• Choice of concurrent sessions • Grant writing tips and resources • Promotion pathways and CV[c] building • Burnout prevention and work-life integration
12-1:00 PM	Lunch (working or social)	• Optional discussion tables (eg, “Mentorship in Medicine” and “DEI[d] in Action”)
1-2:30 PM	Team Challenge: Mission Possible	• Small-group scenario activity focused on real departmental challenges (eg, onboarding, DEI, and teaching loads)
2:30-2:45 PM	Break	—
2:45-4 PM	Psychological Safety and Inclusive Culture Workshop	• Facilitated session with case examples and strategies for fostering trust and belonging
4-4:30 PM	Gallery Walk: Big Ideas Board	• Faculty rotate among flipcharts capturing ideas from earlier sessions and add input
4:30-5 PM	Day 1 Wrap-Up and Preview	• Recap of themes, reflection exercise, and preview of day 2
5-6:30 PM	Optional Social Hour	• Informal reception or outdoor gathering (may include dinner or group activity)
Day 2: Faculty retreat (half day); theme: From Ideas to Action		
8-8:30 AM	Breakfast and Networking	• Casual start with time for reflection
8:30-9:45 AM	Lightning Rounds: Faculty Innovations	• 5-minute presentations by faculty on projects, teaching methods, or QI[e] work
9:45-10:30 AM	Small Group Action Planning	• Based on day 1 priorities (eg, mentorship, wellness, and diversity), groups draft next steps
10:30-10:45 AM	Break	—
10:45-11:30 AM	Department Town Hall	• Leadership addresses submitted questions, strategic updates, and resource planning
11:30 AM-12 PM	Closing Reflections and Commitment Cards	• Faculty write one goal or takeaway • Cards mailed to them in 3-6 months
12 PM	Adjourn	• Optional lunch or grab-and-go meal

[a]SWOT: Strengths, Weaknesses, Opportunities, Threats.

[b]Not applicable.

[c]CV: curriculum vitae.

[d]DEI: diversity, equity, and inclusion.

[e]QI: quality improvement.

Conducting the Retreat

When it comes to conducting the retreat, several elements can ensure that things run smoothly. Primarily, identify a retreat coordinator, typically someone on the planning committee involved in the retreat planning process and familiar with all the retreat elements and plans. These individuals, a faculty or staff member, will be responsible for monitoring the retreat agenda, timekeeping, and serving as a day-of contact for any outside speakers, moderators, or vendors. In addition, these individuals should have the capacity or resources to troubleshoot any potential hiccups, technology-related or otherwise. Depending on the size and scope of the retreat, delegation of specific roles to additional individuals may be required. Clear responsibilities, set ahead of time, allow for smooth session delivery and a more effective retreat.

Another element to consider while conducting the retreat is ongoing assessment of active engagement. Even with careful preretreat needs assessment analysis and planning, engagement can wax and wane during any retreat. As mentioned previously, incorporating a mixture of interactive sessions, small-group discussions, and hands-on workshops to maintain energy and involvement can make engagement drop-off less likely. Depending on retreat length, ample break time and access to refreshments can also assist with energy levels.

Finally, for sessions that might be more interpersonal, it can be important to recognize and acknowledge participant vulnerability and to normalize all responses and emotions. Creating a psychologically safe environment—where individuals feel comfortable expressing themselves without fear of embarrassment, rejection, or retribution—is foundational to fostering trust and vulnerability in retreat settings [25]. Psychological safety has been shown to improve team learning, engagement, and innovation in both health care and academic environments [26,27]. Faculty are more likely to share honest perspectives, disclose challenges, and collaboratively problem-solve when they perceive the environment as respectful, nonjudgmental, and supportive [28-33].

To cultivate psychological safety, facilitators should cocreate ground rules with participants, such as “assume good intent,” “confidentiality is expected,” and “all voices matter.” Setting norms early helps frame the retreat as a shared, inclusive space [34]. Facilitators can further normalize openness by modeling vulnerability themselves, sharing personal experiences or acknowledging areas of uncertainty, which signals that it is safe to take interpersonal risks.

Evidence-based facilitation techniques also enhance psychological safety. These include structured turn-taking (eg, round-robin formats), the use of anonymous input tools (eg, polling apps or sticky-note activities), and small group breakouts that lower the stakes for participation [35]. Active facilitation, such as naming group dynamics, gently redirecting dominant voices, and explicitly inviting quieter participants to share, further supports inclusion. Attending to emotional cues, validating contributions, and pacing sessions to allow reflection all contribute to a respectful tone and a sense of collective care.

By embedding these practices into the retreat design, organizers can create the conditions for open dialogue, team cohesion, and shared commitment to change. Further, anticipating common retreat challenges and potential solutions in advance can prove invaluable for both planners and participants (Textbox 5).

Textbox 5. Common retreat challenges and solutions.

Budget constraints

- Consider solicitation of either institutional or departmental support [28]. This funding source typically requires early engagement of high-level leadership and stakeholders along with well-defined anticipated outcomes. In the absence of a leadership-led retreat, this strategy may take initiative on the part of other faculty members.
- Self-funding or donation funding can be considered. Creation of a "Faculty Well-Being Fund" or "Development Fund" with voluntary donations can be a strategy option. While potentially effective, this approach could result in participation bias, with self-selected faculty or donors more likely to engage [29].
- Focus on local resources and simple activities, which do not require extensive budgets. Similarly, consider if a virtual retreat might be a sufficient option.
- Finally, consider holding the retreat at work during the workweek. While this limits the impact of an external environment, it might allow any existing budget to be nonetheless maximized [30].

Schedule conflicts

- Tagged, protected time can be considered. This is an often-used strategy for trainees, typically resident, retreats. This might be more challenging for academicians with 24-hour call or service schedules.
- Careful, extreme advanced planning and faculty notification, to avoid busy times of the year, whether seasonal or department-specific busier times, may help with turnout and engagement [33].
- Limiting the length of a retreat, generally recommended not to extend beyond 2 days, can also limit schedule conflicts [30].

Participant engagement

- When budget and logistics allow, consider separating the retreat site from work, as this may prevent work-related distractions and allow the group to stay on point [32].
- If the retreat is held at a destination or vacation location and families attend as well, consider limiting attendance at the actual retreat to faculty only, again to discourage distractions and promote focus. Family engagement may be appropriate at associated retreat social events at the organizers' discretion.
- If occurring outside of usual work hours or expectations, consider whether provision of additional compensation may be possible. A notable limitation to consider here includes budget and introduction of participant bias.
- If the agenda allows, incorporation of social events is heavily encouraged. Scheduled social events can make it feel like an actual "retreat" from work. These events will also foster faculty camaraderie [30].
- Make sure there's interest. Consider a preretreat needs assessment to gauge. Careful assessment of responses can avoid the subsequent expenditures of unnecessary efforts.

Hybrid model considerations

- To avoid participant inequity, adopt a "remote-first" mindset when planning content and facilitation strategies. Ensure all materials are digital and accessible in real time. Design activities that are inclusive for all participants, not just those in the room.
- Designate a cofacilitator or team member to advocate for and monitor remote participant inclusion.
- Intentionally structure breakout groups to mix in-person and virtual participants or keep them separate but equally resourced.
- Create informal spaces and scheduled time for social interaction across modalities.
- Include shared virtual coffee breaks, games, or team-building sessions where all participants engage in a similar experience, ideally via a single platform.
- Document key discussions and decisions in real time on shared platforms.

Agenda Pitfalls

- Avoid overpacking an agenda. If time is limited, concentrate on a singular objective directed by the needs assessment prioritization [33].
- Steer clear of a dull agenda. Avoid didactic-like structure [30].
- Postretreat neglect.
- Designate a "retreat secretary" to keep and distribute minutes. Establish an action item list, with deadlines, for identified postretreat interventions [33].
- Conduct a postretreat assessment; solicit feedback.

Postretreat Considerations

The conclusion of the retreat marks not the end, but the continuation of the organizers' and leaders' responsibilities. To be most effective, a good retreat involves solicitation and consideration of participant feedback. During the planning process, retreat objectives and outcomes should have been defined to outline how success will be measured. Tailor subsequent postretreat feedback instruments so that reviews can be considered in the context of the stated retreat goals and objectives. For instance, if team building is a goal, consider postretreat surveys to gauge improved collaboration. Feedback instruments can be survey-based and/or involve focus groups, like the process used for preretreat needs assessment data gathering. Consider both quantitative and qualitative feedback content. In addition, organizers should capitalize on the groundwork laid or the momentum gained by the retreat and seek future opportunities to weave positive retreat outcomes into continuous improvement and ongoing development (Multimedia Appendix 1).

To ensure that momentum continues beyond the retreat, organizers should establish structured follow-up mechanisms that translate insights into action. Begin by forming small working groups around priority areas identified during the retreat. These groups should be assigned clear deliverables and timelines and report progress during faculty meetings or through a shared digital platform. Designating retreat "champions" or coleads within each group can help maintain accountability and enthusiasm. Within 1 month post retreat, schedule a follow-up meeting to review early progress, reinforce shared goals, and recalibrate as needed. In addition, consider incorporating retreat themes into existing faculty development programs or launching targeted initiatives—such as peer mentoring circles, writing groups, or leadership development cohorts—aligned with retreat goals. Finally, build in evaluation checkpoints at 3, 6, and 12 months to assess progress, solicit feedback, and celebrate milestones. These actions foster sustained engagement and embed retreat outcomes into the academic fabric of the department.

Timeline Considerations

Although mentioned above, it deserves reiterating, as a final note in the planning process, that implementation of any retreat takes significant time, from organizing and conducting preretreat needs assessment through to evaluating and considering postretreat feedback and impact. When possible, at the onset, retreat planners should attempt to develop a "retreat timeline" (Textbox 6) that considers each aspect of the retreat development and implementation process. This timeline, which can doubly serve as a retreat checklist, should be retreat-specific and will be highly dependent on the anticipated breadth and expanse of the retreat. Dynamic timeline adjustments may need to be made pending results of preretreat assessments or other variables, including desired venue availability, participant work schedule, etc.

Textbox 6. Example retreat timeline.

6 months (or more) in advance

- Announcement of Faculty Retreat Intentions
- Open Invitation to Self-Nominate Organizing Committee

4-6 months before

- Preretreat needs assessment and analysis

3-4 months before

- Agenda creation
- Save-the-date creation to participants
- Speaker/moderator invitation
- Location and accommodation reservations

1-2 months before

- Agenda confirmation
- Formal faculty invitation and RSVP (répondez s'il vous plaît [French])

1 week after

- Immediate postretreat feedback solicitation and consideration

1-3 months after

- Feedback follow-up
- Action items follow-up

Case Studies and Examples

Reviewing examples of prior faculty retreats in academic medicine can be particularly valuable and can demonstrate both areas of success and lessons learned. In 2022, Lee et al [36] published about their experience with the Abdominal Radiology Division at Harvard Medical School, Brigham and Women's Hospital. Held in 2021, this retreat aimed to specifically address division stressors and challenges experienced during the COVID-19 pandemic. Twenty-eight faculty participated in a 2 and a half-hour virtual retreat via Zoom (Zoom Communications). A preretreat survey was used to establish discussion topics as well as determine current faculty satisfaction. A postretreat survey assessed retreat effectiveness and faculty satisfaction regarding stated objectives. With regard to limitations, it was suggested that the size of the larger group (N=28) may have caused hesitancy in discussion responders, and the authors also noted that the retreat was relatively short in duration. However, the authors ultimately concluded that the retreat was successful with regards to several outcomes, including promoting group camaraderie, provisioning ideas to improve the work environment (eg, adjusting shift times or coverage), and identifying specific faculty academic needs (eg, mentorship and sponsorship).

Birx et al [37] published their experience with a retreat held for nursing faculty at Radford University. Specifically designed within a positive psychology framework, the stated retreat goal was to build faculty relationships to create a cohesive team and to accomplish institutional goals. Held at a nature conservatory owned by the university and involving 29 nursing faculty, the daylong team-building event used challenge course activities, described as "an experiential adventure program…involving mental, physical, and emotional risk taking." The authors used a mixed method evaluation, both pre- and post retreat, considering qualitative and quantitative data. They also incorporated an extended postevaluation, which was completed at the end of the semester to consider potential longer-term effects of the retreat. The authors concluded that the retreat offered an immediate positive effect on their targeted outcomes; however, these were not necessarily sustained throughout the semester, suggesting that a one-time intervention may not be sufficient to impart continued impact. This experience highlights the importance of building on the momentum achieved at a retreat and using it as a foundation for ongoing development.

While previously unpublished, the authors of this tutorial also recently planned and implemented a faculty retreat. Of note, a paucity of available free "how to" content to guide the authors was the impetus for this tutorial paper as well as a specific scholarly objective of the held retreat. The inaugural EmpowerED Faculty Retreat for women in the University of Alabama at Birmingham (UAB) Department of Emergency Medicine was held September 4 - 6, 2024, at a resort and outdoor leisure destination. Designed to foster leadership development, professional growth, wellness, and team building among faculty, the retreat featured didactic sessions, small group discussions, and wellness activities in a reflective, off-campus setting. A postretreat survey, completed by 11 of the 12 participants, revealed high levels of satisfaction and strong support for continuing this initiative. All respondents agreed that the retreat met or exceeded their expectations, citing a well-balanced agenda that integrated learning, networking, and self-care. The workshops—Dare to Dialogue: Navigating Difficult Conversations and Microskills for Professional Success—were particularly well received. Nearly 3 quarters of attendees reported applying retreat content within 1 month, including strategies for communication, time management, and relationship-building. Participants praised the retreat location and logistics, noting that the peaceful setting supported creativity and deeper connection. However, several suggested that centralized lodging would have enhanced informal interaction, particularly in the mornings and between sessions. Feedback also highlighted a desire for more small group engagement, 1:1 mentoring opportunities, and dedicated time to discuss department-specific topics. Looking ahead, faculty expressed strong interest in future retreats, identifying topics, such as negotiating, attaining promotion, and mentorship as high priorities. The most favored strategies for sustaining the work of the retreat included annual offsite gatherings, quarterly check-ins, and peer mentoring. Overall, the EmpowerED retreat was viewed as a transformative and affirming experience, supporting both individual development and a stronger sense of community within the department.

Future Directions and Emerging Trends

As models of faculty development, including retreat incorporation, continue to expand and evolve, several recent trends have been noted. These trends align with the current state of medicine, reflecting key developments, such as the emphasis on clinician well-being and integrating the growth of advanced technologies in both clinical practice and academic settings.

The COVID-19 pandemic was associated with a record-high physician burnout rate. While the American Medical Association (AMA) reports that these numbers have improved more recently, percentage rates remain astonishingly high, over 50% for some subspecialties [38]. There has been a noted emphasis on integrating wellness, mindfulness, resiliency training, and structured time for reflection into today's faculty and trainee retreats [32,39].

Considering advanced technology, faculty development can both use and integrate content specific to emerging technology, particularly artificial intelligence (AI), data analytics, and virtual platforms, which offer new opportunities to enhance the planning, delivery, and impact of faculty retreats. AI-driven tools may be used to streamline various aspects of retreat implementation. For example, natural language processing tools can analyze preretreat survey responses to identify common themes and tailor agendas to faculty needs. AI scheduling assistants can coordinate availability across large faculty groups, reducing the administrative burden on organizers. During the retreat itself, AI-powered collaboration platforms (eg, Miro with AI clustering features or Microsoft Copilot) can help synthesize live input from participants, identify emerging priorities, and generate summaries in real time. In the realm of personalized learning, AI-enabled learning management systems can recommend postretreat faculty development resources aligned

with individual career goals, teaching portfolios, or scholarly interests. These platforms may also track progress and provide nudges for continued engagement, thereby extending the retreat's value over time.

Virtual and hybrid retreat models, initially born out of necessity, now offer sustainable and scalable solutions for faculty development—particularly in geographically dispersed departments. With the integration of AI-enhanced virtual facilitators, breakout room optimization, and sentiment analysis, retreat organizers can gain immediate feedback and adjust facilitation strategies accordingly. When appropriate, a hybrid approach to a retreat (combining in-person and virtual participation) might allow for greater flexibility, particularly when inviting outside speakers. Virtual or hybrid models may also have the added benefit of decreasing overall budget. When considering the incorporation of virtual components, it is important to ensure that the audiovisual technology is high-functioning, and a moderator (in person, if hybrid) should facilitate virtual speakers [40]. As these technologies continue to mature, their thoughtful application will be critical to ensuring that innovation complements, rather than replaces, the relational and reflective core of faculty retreats. Further, a careful consideration of outcome comparisons in virtual versus hybrid versus in-person retreats should be a consideration for future analysis.

Conclusion

In conclusion, professional development for academic medicine faculty is a goal-directed, continuous effort pursued over one's entire career span and is vital to improve and hone skills. Faculty retreats, an increasingly popular form of professional development, can lead to improved faculty performance, effectiveness, and wellness. Initial retreat planning should include a needs assessment from the targeted audience, the results of which should be used to define retreat objectives. Then, SMART goals should be set to guide the retreat's agenda and outcomes. In order to meet retreat objectives, other important considerations include resource allocation (including personnel coordination and oversight) and participant selection, as well as location and setting choice. Following the event, solicited postretreat feedback can translate positive retreat outcomes into ongoing faculty improvement and development. Faculty retreats can represent a diverse, expansive, and valuable development tool for academic medicine. Careful planning consideration and subsequent implementation can help ensure their success.

Acknowledgments

We wish to thank Professor Resa E Lewiss for conceptualizing this work. Their intellectual contribution and guidance in shaping the research direction were invaluable to this project.

Abstract

Artificial intelligence (AI) is rapidly reshaping medical education, offering new opportunities to personalize learning, enhance research, and streamline administration. The aim of this study is to provide 12 practical, evidence-informed tips by drawing on current literature and real-world examples to guide the integration of AI into medical education, supporting educators across teaching, research, administration, and ethical domains. Key strategies include using adaptive learning platforms to tailor educational content, using AI tools to provide timely feedback, and incorporating AI-generated clinical scenarios in case-based learning. The importance of fostering AI literacy among students is emphasized, as well as utilizing AI-powered tools for efficient literature reviews, data analysis, and manuscript preparation. Administrative applications such as automating routine tasks, supporting strategic planning through data analysis, and enhancing faculty development with AI-driven platforms are also discussed. Ethical considerations are highlighted, with a focus on ensuring transparency, fairness, and accountability in all AI applications. By following these 12 tips, medical educators can leverage the benefits of AI to improve educational outcomes, increase efficiency, and prepare future clinicians for a technology-driven health care environment.

(JMIR Med Educ 2025;11:e81297) doi:10.2196/81297

KEYWORDS

artificial intelligence; ethics; educational innovation; AI literacy; medical education; educational technology

Introduction

Artificial intelligence (AI) is rapidly transforming medical education. It presents new opportunities for personalized learning, enhanced feedback, and streamlined administrative processes. Its impact is clear across multiple areas in medical schools, including medical student teaching, research, administrative governance, leadership paradigms, and ethical considerations.

In teaching, AI facilitates adaptive educational tools, intelligent clinical simulators, and automated assessment platforms. These technologies allow greater personalization of learning, helping students acquire clinical competencies in realistic simulated environments. Illustrative examples include intelligent tutoring systems and virtual patient simulators, which permit students to engage in risk-free clinical decision-making. Nevertheless, the integration of these tools into established curricula and the requisite faculty training present notable pedagogical challenges [1,2].

In the research field, AI serves as a catalytic agent in research by expediting the analysis of extensive biomedical datasets, accelerating the discovery of novel therapeutic interventions, and advancing personalized medicine. University researchers employ machine learning algorithms to discern intricate correlations within genomic, clinical, and imaging data. AI also automates labor-intensive tasks such as literature reviews and cohort selection, thereby allocating more time for critical analysis and experimental design. These advancements are substantiated by extensive work from institutions like Inserm (French National Institute of Health and Medical Research) and in research pertaining to health data integration [3,4].

On the administrative and leadership front, AI is redefining governance practices within medical education institutions. Its applications include optimizing human resource management, scheduling academic timetables, forecasting training requirements, and supporting strategic decision-making. Academic leaders are thus compelled to cultivate enhanced digital literacy to effectively oversee the ethical and efficient implementation of these technologies. The Quebec AI in Health Master Plan provides a pertinent example, outlining a strategic roadmap for AI integration across health and educational entities [5,6].

Finally, ethical considerations assume a central role in the integration of AI within medical education. Key issues encompass algorithmic transparency, the safeguarding of personal data for students and simulated patients, and the mitigation of potential biases within evaluation or diagnostic systems. These concerns underscore the critical need for reinforced ethical training for aspiring physicians, ensuring their responsible utilization of AI tools. Recent scholarship has identified over 70 ethical challenges associated with AI in education—many directly relevant to medical training [7,8]. Despite the substantial opportunities and expansive potential afforded by AI across these 4 sectors of medical education, a significant impediment persists: a considerable number of medical educators lack adequate training and resources for effective AI integration into their pedagogical practices. This deficiency is characterized by low digital literacy, a limited understanding of algorithmic principles, and a hesitancy to adopt tools perceived as complex or ethically ambiguous [7]. Furthermore, empirical studies indicate a pervasive sense of disempowerment among educators, attributable to the absence of specialized training and clear guidelines [2]. This paper will therefore delineate 12 practical recommendations designed to facilitate the integration of AI for the advancement of student instruction, research endeavors, administrative and leadership functions, and ethical considerations within medical education. Each recommendation appears to be informed by contemporary literature and best practices.

Teaching

Tip 1: Use AI to Personalize Learning Paths

Adaptive learning platforms powered by AI can tailor educational content to individual student needs, addressing unique learning requirements and competency rates. Sharma et al [9] highlight that adaptive learning is the “final piece of technology-enhanced learning” in medical education, demonstrating significant improvements in understanding and engagement. Commercial implementations such as Elsevier’s Cerego and McGraw Hill Education’s partnership exemplify the practical benefits of AI-driven personalization. Kellman’s [10] research on adaptive learning further supports this, showing educational improvements through repeated knowledge delivery and mastery criteria, with clinical trials in dermatology histopathology at University of California, Los Angeles, reporting significant pretest and posttest score improvements (P<.001).

Tip 2: Enhance Feedback With AI Tools

Building on this personalization, AI can also strengthen another essential component of learning: feedback. AI tools provide timely, formative feedback during clinical simulations, fostering clinical judgment and reflective practice. Howell’s [11] study on AI-enhanced debriefing demonstrates that AI can generate real-time, personalized feedback and Socratic questions, leading to improved learner outcomes and knowledge retention. Practical applications such as Western Technical College’s AI chatbot Jennifer West loaded with open education resources and health care simulation standards illustrate how AI can support consistent, high-quality debrief sessions. Facilitators benefit by focusing on student interaction, while students report enhanced self-reflection and peer feedback.

Tip 3: Integrate AI Into Case-Based Learning

Expanding on the role of AI in enhancing feedback, the next tip explores how AI can be integrated into case-based learning to further enrich clinical education. AI-generated clinical scenarios and virtual patients enrich problem-based learning by creating interactive, adaptive environments. The Diagnostic Reasoning and Its Development Group, Inc Group’s (2025) [12] research shows that AI-driven virtual patients can simulate real emotions, symptoms, and conditions, responding dynamically to student actions. This approach enhances clinical decision-making and interview skills in a safe, controlled setting. AI-powered tools prompt critical self-reflection such as asking, “What was your rationale for the administration of metoprolol?” or “How could holding the metoprolol change the patient’s outcome?”

Tip 4: Train Students in AI Literacy

As AI becomes increasingly embedded in clinical education, it is equally important to ensure that students are equipped to use these tools responsibly. The next tip focuses on developing AI literacy to prepare learners for ethical and effective engagement with emerging technologies. Preparing students to critically evaluate and use AI tools is essential. The American Medical Association (2023) [13] emphasizes the importance of AI literacy in medical education, advocating for curricula that teach students to assess AI applications ethically and effectively. Although specific studies on AI literacy training are limited, the broader literature recognizes its critical role in preparing future clinicians for technology-driven health care environments.

Research

Tip 5: Accelerate Literature Reviews With AI

AI-powered summarization and search tools streamline systematic reviews by processing vast amounts of literature efficiently. Sharma et al [9] note that technology-enhanced learning has risen due to easy internet access, supporting the logical extension of AI tools for research. AI-powered platforms such as Perplexity.ai can quickly retrieve, summarize, and synthesize academic papers, accelerating the research process and helping summarize and synthesize relevant academic sources.

Tip 6: Employ AI in Data Analysis

Beyond literature reviews, AI contributes to research through powerful tools for data analysis. Machine learning algorithms can analyze complex educational datasets, predict learner performance, and optimize content delivery [14]. The success of adaptive learning platforms in analyzing educational data patterns suggests similar benefits for research datasets in medical education [15].

Tip 7: Collaborate With AI for Writing and Publishing

After supporting data analysis, AI can also help researchers with writing and publishing by assisting in drafting, editing, and formatting manuscripts. AI tools assist in drafting, editing, and formatting manuscripts, improving academic writing efficiency. Akbar's [16] mixed methods study on doctoral students' use of AI tools provides foundational evidence for AI's role in academic research and writing processes. Researchers can use AI to brainstorm ideas, draft initial versions, and improve formatting but should ensure their final manuscript reflects their own critical thinking and contributions.

Administration and Leadership

Tip 8: Automate Routine Administrative Tasks

AI can automate scheduling, email management, and documentation, freeing faculty and staff for higher-value activities [17]. Although specific research on administrative automation in medical education is limited, the broader technology-enhanced learning literature supports its potential for efficiency gains [18].

Tip 9: Use AI for Strategic Planning

Alongside simplifying daily administrative tasks, AI can guide strategic planning. By analyzing institutional data, it supports better decisions for curriculum design and resource use. AI can analyze institutional data to inform curriculum development and resource allocation. Bixler and Ceballos's [19] conceptual model explores how AI supports educational leadership and decision-making, demonstrating its utility for strategic planning in medical education.

Tip 10: Enhance Faculty Development With AI

In addition to guiding strategic planning, AI can also play a key role in supporting educators themselves. Through adaptive tools, it provides personalized learning and feedback to strengthen faculty development. AI-driven platforms can provide personalized learning and feedback for faculty, mirroring the benefits seen in student learning. The principles of adaptive learning apply equally to faculty professional development, enabling customized experiences and ongoing support [20].

Ethical Considerations

Tip 11: Uphold Ethical Use of AI

Transparency, fairness, and accountability must guide all AI applications in medical education. Weidener and Fischer's [21] scoping review of AI ethics teaching in medical education highlights the importance of ethical instruction and practice. The American Medical Association (2023) [13] further reinforces the need for ethical standards, advocating for the responsible integration of AI. Additionally, educators should consider nuanced challenges such as the impact of AI-generated assessments or content creation on student autonomy and academic integrity, ensuring that AI supports rather than replaces critical thinking and professional development.

Future

Tip 12: Stay Informed and Adaptive

Maintaining ethical standards goes hand in hand with staying up-to-date on AI's rapid developments. By continuously learning, educators can adapt responsibly and uphold best practices in medical education. The rapid evolution of AI in medical education necessitates continuous learning and adaptation. Sharma et al [9] emphasize that ongoing attention to emerging developments is essential, as the field is likely to change significantly over time.

Practical Tips for Integrating AI Into Medical Education

Table 1 outlines 12 actionable strategies (Multimedia Appendix 1) for effectively integrating AI into medical education, with suggested tools and expected outcomes.

Table 1. Twelve practical tips for integrating AI[a] into medical education.

Tip title	Description	Example tools/platforms	Key outcomes
Tip 1: Use AI to personalize learning paths	Adaptive platforms tailor content to individual student needs, improving engagement and mastery	• Cerego • Smart • Sparrow • McGraw Hill ALEKS	• Improved learner engagement • Personalized progression
Tip 2: Enhance feedback with AI tools	AI delivers immediate, personalized feedback in clinical simulations, promoting reflective learning	• Jennifer West (AI chatbot) • SimConverse • FeedbackFruits	• Accelerated skill development • Deeper reflection
Tip 3: Integrate AI into case-based learning	AI generates dynamic clinical scenarios and virtual standardized patients for realistic decision-making practice	• Diagnostic Reasoning and Its Development Group, Inc Clinician • Body Interact • Open-Source Clinical Application Resource	• Improved diagnostic reasoning • Clinical readiness
Tip 4: Train students in AI literacy	Teaching AI literacy prepares students to evaluate, interpret, and use AI tools ethically and effectively	• Artificial Intelligence for Health (AI4HealthEd) • American Medical Association AI Curriculum • Google • Teachable Machine	• Greater digital competency • Ethical awareness
Tip 5: Use AI to accelerate literature reviews	AI simplifies literature searches and synthesis, saving time and broadening evidence coverage	• Perplexity.ai • Elicit • ResearchRabbit	• Faster research preparation • Improved evidence integration
Tip 6: Use AI for data analysis	AI analyzes complex datasets to predict performance and optimize learning strategies	• RapidMiner • Orange • IBM SPSS Modeler	• Data-driven decision-making • Targeted interventions
Tip 7: Collaborate with AI for writing and publishing	AI assists in drafting, editing, and formatting manuscripts while ensuring responsible authorship and academic integrity	• Grammarly • ChatGPT • Writefull	• Enhanced writing quality • Efficient publishing workflow
Tip 8: Automate routine administrative tasks	AI manages scheduling, email correspondence, and documentation to free educators' time for strategic work	• Explainable Artificial Intelligence (x.ai) • Clara • Google Duplex	• Increased faculty productivity • Streamlined operations
Tip 9: Use AI for strategic planning	AI analyzes institutional data to inform curriculum design, forecasting, and resource allocation	• Tableau • IBM Watson • Power Business Intelligence	• Informed planning • Optimized resource management
Tip 10: Enhance faculty development with AI	AI platforms deliver adaptive learning and feedback for continuous professional growth	• LinkedIn Learning • Coursera AI Tracks • Education Application (EdApp)	• Ongoing educator improvement • Personalized learning
Tip 11: Uphold ethical use of AI	Implement transparent, fair, and accountable AI practices in all academic and clinical settings	• Ethics guidelines (American Medical Association, United Nations Educational, Scientific and Cultural Organization) • Explainable AI tools	• Trustworthy AI adoption • Regulatory compliance
Tip 12: Stay informed and adaptive	Continuous learning helps educators keep pace with AI advancements and emerging best practices	• AI newsletters • PubMed alerts • arXiv.org	• Sustained innovation • Up-to-date knowledge

[a]AI: artificial intelligence.

Limitations

Although all 12 tips are grounded in published literature, they have not yet undergone external evaluation or been tested in educational practice. The paper synthesizes existing evidence but does not include longitudinal outcome data. Future studies could assess the practical impact and effectiveness of these recommendations in real-world settings.

Conclusion

The integration of AI into medical education is supported by robust evidence, particularly in teaching applications, with emerging support in research, administrative, and ethical domains. AI enhances personalized learning, improves feedback quality, enriches case-based instruction, and supports institutional decision-making. However, maintaining human-centered approaches, ensuring ethical implementation, and continuously updating knowledge are critical. Future research should focus on long-term outcomes, comparative effectiveness, and expanded investigation of AI applications in administrative and research functions.

Acknowledgments

The authors acknowledge that generative AI tools were used only for language and idea refinement (not idea generation) and for table formatting during manuscript preparation, under full human supervision. Tools used were Copilot Pro and ChatGPT. The responsibility for all content rests entirely with the authors. AI tools are not listed as authors and bear no responsibility for the manuscript.

Abstract

Background: Project Extension for Community Healthcare Outcomes (ECHO) is an innovative model to increase capacity to treat patients in their community. Despite a growing body of evidence supporting its effectiveness, little is known about the implementation processes of multiple ECHO programs within an institution from the perspective of executives and institutional leaders.

Objective: The study objective was to explore from an institutional and organizational standpoint the systemic characteristics that influence the implementation of Project ECHO programs, their growth within an ecosystem, and their sustainability.

Methods: Focus groups and individual interviews were carried out with executives and leaders from an institution that implemented 3 Project ECHO programs, and verbatim were analyzed based on organizational readiness and implementation tools for Project ECHO.

Results: This study highlighted the rarely reported perspectives of executives and institutional partners, shedding light on the organizational components that are essential to the deployment and sustainability of Project ECHO. Results reflect the intricate balance between institutional resources and its broader mission within a provincial, public health care system. In terms of acceptability, the fit between the projects and the institution's values of innovation, contribution to the broader community, and improving patient trajectory was central from the organizational leaders' standpoint. The structure of the projects and their rapid growth within the institution confirmed the adequacy with the institution. The projects benefited from temporary funds initially, and the lack of performance indicators that were easily measurable and the lack of recognition for invested time from clinicians were barriers to moving toward sustainability. Organizational characteristics, including a decentralized management structure and ministerial support for innovative educational practices, increased the perceived feasibility of implementing and maintaining these programs.

Conclusions: This qualitative study of institution leaders and directors highlighted the challenges and facilitators to the deployment of an innovative continuous education model aimed at building capacity in the community for the management of various health conditions. Despite limitations, such as temporary initial funding, challenges in collecting performance indicators, most valued, and rigidity of the projects' structure, results also show many characteristics (innovative model, alignment with the institution's mission, and simplicity of its deployment) that helped move these projects toward sustainability within the institution. Results offer learning experiences that will be relevant to other settings evolving within a similar public health care system, wanting to implement this model.

Extension for Community Healthcare Outcomes; ECHO; qualitative; implementation; hepatitis C; chronic pain; concomitant disorders; sustainability; barriers; facilitators

Introduction

Wait times to access specialized care in Canada are 242% longer than they were in 1993, now at about 12.6 weeks [1]. Rates of referrals to specialized care are influenced by many factors, ranging from practitioners' degree of comfort and patient-doctor relationship to the occurrence of a global health crisis impacting referral pathways and delays, as demonstrated with the COVID-19 pandemic [2-5]. Given the rapidly evolving knowledge across the various fields of medicine and considering the limited capacity of specialized centers to absorb all of the patient referrals, it is essential to increase the capacity and comfort levels of primary care providers to manage increasingly complex cases.

Several innovative continuous education models have emerged, among which one is Project Extension for Community Healthcare Outcomes (ECHO) [6-8]. This continuous telementoring model aims to empower community-based health care professionals to provide care to individuals with specific conditions within their community. The model relies on videoconferencing meetings between hub experts and spokes (participants from the community) where there is a case discussion and didactic presentation. Four principles guide fidelity of the model when applied to new settings and new conditions: using technology to leverage scarce resources, using best practices to reduce disparity, using a case-based learning approach to better understand the complexity of patient presentation, and monitoring outcomes [9]. The benefits for health care providers of participating in such telementoring offerings in terms of knowledge, confidence, self-efficacy, and care delivery are well-established [6,10-15]. The model has been replicated and deployed in 202 countries (2813 programs) to address common and complex diseases [16]. Yet, there are known barriers to implementation and participation, including conflicting priorities and competing demands, issues of inclusiveness, time constraints, technology requirements, and a low degree of endorsement from the clinic leadership [17-23].

Beyond the characteristics of the intervention, from an organizational perspective, many inner and outer setting parameters, such as structural characteristics, population needs, local context, sources of funding, and external incentives, can influence the successful implementation of Project ECHO [24]. Little is known about systemic factors that must be considered when planning and implementing such a program and monitoring its growth within the institution, and how it might benefit more broadly the local health care ecosystem. Most implementation studies explored the postimplementation perspectives of health care professionals, whether participants (spokes) or hub experts, with little attention to date given to the perspectives of institutional leaders and managers.

In addition, many institutions harbor several ECHO programs within a single center [16]. However, data on the implementation processes of multiple programs within a single site are scarce. Agley and colleagues [25] explored the implementation of 5 programs within 1 site and found that Project ECHO is associated with change in practice and knowledge and reduced isolation of practitioners, but that rigorous studies of such a model are warranted.

The Consolidated Framework for Implementation Research (CFIR), created by Damschroder, comprising a set of 39 constructs spread across 5 domains, successfully guided the implementation of several projects across various health domains [26]. An adapted CFIR was developed by an ECHO implementation team to create ECHO-specific tools to help organizations assess their readiness and capacity to support an ECHO project and provide a checklist to support a successful implementation process [24].

The study objective was to explore, from an institutional and organizational standpoint, the systemic characteristics that influence the implementation of Project ECHO, their growth within an ecosystem, and their sustainability. Results will help guide other teams to successfully identify optimal implementation conditions for multiple programs within the same institution.

Methods

Study Setting

This study is part of a larger project aiming at evaluating the implementation of 3 Project ECHO programs (Hepatitis C, chronic pain, and concurrent mental health and substance use disorder) within a tertiary care, university-affiliated hospital center [27]. The pilot Project ECHO Centre hospitalier de l'Université de Montréal (CHUM) Hepatitis C program was launched in April 2017 to enable health care professionals to increase the rate of Hepatitis C screening, assessment, and treatment in Quebec remote areas. Shortly thereafter, the Project ECHO CHUM *Douleur Chronique* was launched in September 2017. Its goal is to foster knowledge regarding best practices in chronic pain management and enable collaboration between health care professionals of different degrees of specialization. Finally, a third program, Project ECHO CHUM Troubles Concomitants (concurrent mental health and substance use disorder), began in September 2018 to help health care professionals from different backgrounds gain knowledge in assessment, treatment, and referral of patients with concomitant mental health and substance use disorders.

Study Design

This is a qualitative study comprised of focus groups and individual interviews conducted between November 2020 and April 2021 with stakeholders, directors, health care managers, project coordinators, and medical program leads within the hospital or the university network, and Project ECHO medical leads.

Ethical Considerations

The study was approved by the research ethics committee of the CHUM (19.281). Written informed consent was obtained from all participants, and they could opt out from the study at any time. Data were deidentified prior to analyses. Participants did not receive a compensation for taking part in this study. The description of the study methods followed the Consolidated

Criteria for Reporting Qualitative Research (COREQ) guidelines [28].

Participants

Potential participants were targeted by the research team based on their role within and outside of the institution, to cover all relevant directions that were involved with the project, including (1) medical leads, coordinators, and managers involved directly or indirectly with the implementation and delivery of Project ECHO; (2) directors and health care managers of various hospital services and programs involved with Project ECHO (communication services, professional services, etc); and (3) stakeholders within the larger university network (Réseau universitaire intégré de santé et de services sociaux de l'Université de Montréal). A total of 30 potential participants were thus approached. Of the total, 13 participants were excluded because they refused to participate (n=5) or did not respond to our invitation (n=8). The 17 study participants included are presented in Table 1, which illustrates the roles and responsibilities of each participant within Project ECHO. Project ECHO spokes and experts were interviewed separately, and these data have been presented elsewhere [27]. Descriptions of participants' characteristics are presented in Table 1.

Table . Characteristics of study participants.

Participants' characteristics	Frequency, n (%)
Role	
ECHO[a] medical leads	3 (18)
Project ECHO coordinators	4 (23)
Health care managers	2 (12)
Directors (teaching, academics, communication, and operations) and stakeholders	8 (47)
Gender	
Women	13 (77)
Men	4 (23)
Age (y)	
25 - 34	1 (6)
35 - 44	5 (29)
45 - 54	3 (18)
55 - 64	7 (41)
65+	1 (6)
Number of years involved in Project ECHO	
1	3 (18)
2	2 (12)
3	12 (70)
Employer	
Centre hospitalier de l'Université de Montréal	13 (77)
Réseau universitaire intégré de santé et de services sociaux de l'Université de Montréal (Integrated University Network for Health and Social Services at Université de Montréal)	4 (23)

[a]ECHO: Extension for Community Healthcare Outcomes.

Recruitment

Potential participants were identified by the study investigators and those involved in the deployment of each of the 3 studied Project ECHO programs. Potential participants received an email inviting them to participate in a focus group. They were asked to express their interest by replying to the email, after which a research assistant explained the study procedure to them and scheduled the focus group. Those interested but unable to take part in a focus group because of scheduling conflicts were invited to participate in an individual interview. They were informed of the study's objectives, namely to understand the barriers and facilitators to the deployment of ECHO programs and their sustainability, but they were not informed of the interviewers' reasons or interests in the research topic.

Procedure

Before the scheduled interview, participants received a link through email to complete an online consent form and a brief sociodemographic questionnaire. In total, 3 semistructured focus groups (2 with medical leads, project coordinators, and health care managers and 1 with directors and stakeholders) and 4

semistructured individual interviews were conducted online using the secured videoconferencing platform Zoom (Zoom Communications) by 1 of 2 women research team members (MGP [PhD] or ÉD [MSc]) trained and experienced (5+ y) in qualitative methods and were audio-recorded. Both interviewers had been working at the institution where the study was conducted for more than 5 years and knew many of the study participants in the context of other research projects or collaborations. Semistructured interview guides were built with open-ended questions aimed to explore topics such as barriers and facilitators to program implementation, interest toward this program, program fit within the larger institution and provincial health care ecosystem, and sustainability (Multimedia Appendix 1). Audio recordings were transcribed verbatim (transcripts were not returned to participants for comments due to time constraints). Field notes were taken during the interviews and used to supplement the data analysis. Focus groups lasted between 55 and 59 minutes (median 58 min) and varied in size between 3 and 6 participants, while individual interviews lasted between 18 and 28 minutes (median 24 min). Interviews were carried out in French, and the selected quotes were translated into English using a forward-backward translation process.

Data Analysis

A qualitative content analysis with both deductive and inductive coding was used [29,30]. A deductive approach was used as a theoretical lens through which the data were interpreted [31], with initial domains mapping onto the Organizational Readiness and Implementation Tools for Project ECHO [24] (an adaptation of the CFIR [26]). These domains represented an initial starting point to understand the data, but other domains could be added to the framework as needed. More specifically, 1 analyst (MGP) read the transcripts many times and identified units of meaning that mapped into the participants' perceptions of implementation barriers and facilitators of the projects within the institution. A coding sheet identifying the dimensions of the CFIR framework that fit the project's context (acceptability, appropriateness, cost and trialability, and feasibility) was collaboratively identified with team members (ÉD and CW-B). Within each of these dimensions, inductive coding was used to identify subcategories and units of meaning. This step was performed by GP with frequent meetings with other analysts (ÉD and CW-B). When disagreements arose regarding data interpretation, we examined whether they stemmed from differences in backgrounds and sought to integrate these viewpoints to enrich the analysis. Memos were written throughout the analysis process. NVivo software (Lumivero) [32] was used to conduct the analyses. Participants' feedback on the study results was not solicited.

Reflexivity Statement
